Alexander Grothendieck

Les Dérivateurs

an integrated reader, with commentary

The text is Alexander Grothendieck's, from the edition of *Les Dérivateurs* by M. Künzer, J. Malgoire and G. Maltsiniotis (Universités de Montpellier II et Paris VII), https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/Derivateurs.html. The LaTeX transcription of that edition is AI-transcribed (Claude Opus 5.5, Anthropic). The commentary, the register of claims and the corrections are AI-produced by GPT-6 Astra (OpenAI, ChatGPT Pro mode), checked and integrated by Claude (Anthropic). Eight commentary blocks in parts II-a, III-V and XIIb-a, seven paragraphs of other blocks there, nineteen entries of the register of claims and three bibliography entries are AI-produced by Claude Fable 5.2 (Anthropic), from answers of GPT-6 Astra that it reviewed.

Dérivateurs

1. Préliminaires sur les foncteurs images inverses des préfaisceaux sur des catégories d'indices, et leurs adjoints multiples.

A "catégorie de coefficients",
I "catégorie d'indices",
$A(I) = \underline{\mathsf{Hom}}(I^\circ, A)$ préfaisceaux sur I à valeurs dans A.

Si $f : I \to J$, on en déduit :

$$f^* : A(J) \to A(I) \quad ,$$

et on s'intéresse à l'existence des foncteurs adjoints successifs à gauche et à droite. Notation provisoire :

$$f^? \; f_! \; f^* \; f_* \; f^! \quad .$$

Voici les faits principaux :

Commentary · Exposition [ms. 1]

Variance and the two Kan extensions

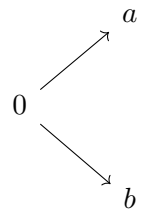
The elementary presheaf calculation fixes the conventions for everything that follows. Throughout these pages an I-diagram has arrows in the direction of I^{op}. Thus a diagram on $0 \to 1$ is an arrow $F_1 \to F_0$. We retain this convention in the commentary. If $f : I \to J$, the adjunctions are

$$f_! \dashv f^* \dashv f_*.$$

They are adjunctions of ordinary categories at this stage. Their pointwise formulas, whenever the indicated limits exist, are

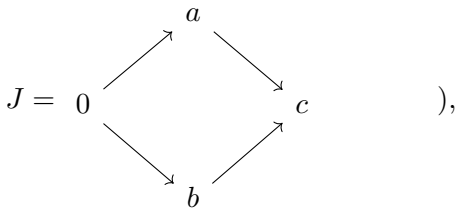
$$(f_*F)_j = \lim_{(f/j)^{\mathrm{op}}} F \circ \mathrm{pr}, \qquad (f_!F)_j = \operatorname*{colim}_{(j/f)^{\mathrm{op}}} F \circ \mathrm{pr}\,.$$

Here f/j has objects $(i, f(i) \to j)$, whereas j/f has objects $(i, j \to f(i))$. The opposite signs are essential: forgetting one exchanges the two formulas. These are the usual pointwise Kan formulas applied to f^{op}; see Riehl (n.d., §6.2).



For completeness, a map $G \to f_*F$ consists, at j, of a compatible family of maps $G_j \to F_i$, one for every $f(i) \to j$. A map $f^*G \to F$ supplies this family by composing $G_j \to G_{f(i)} \to F_i$. Conversely, the members indexed by identities recover the original map. The two constructions are inverse and natural. The left adjunction follows by reversing all arrows. This proves the existence assertion without any adjoint functor theorem; for finite categories the comma categories are finite, so finite limits or colimits suffice.

The word "immersion" here denotes the inclusion of a full subcategory, with "open" meaning a sieve and "closed" a cosieve. A sieve is closed under taking the source of an arrow whose target belongs to it; a cosieve is closed under taking the target. In a poset these are, respectively, downward and upward closed subsets. This agrees with the conventions forced by the displayed examples. For a fully faithful f, the identity at i is terminal in $f/f(i)$ and initial in $f(i)/f$. The formulas therefore give $f^*f_*F \cong F \cong f^*f_!F$. Both Kan extensions are fully faithful. Calling f^* a localization expresses these adjunction identities, not a claim that restriction itself is fully faithful.



a) Sous réserve de l'existence des $\varprojlim$ (resp. $\varinjlim$) pertinentes, f_* (resp. $f_!$) existe. Par exemple s'il existe `[des]` $\varprojlim$ (resp. $\varinjlim$) *finies*, alors f_* (resp. $f_!$) existe si I, J sont des catégories finies.

b) Même si A est une catégorie abélienne, avec $\varprojlim$ et $\varinjlim$ (par exemple Ab), les *biadjoints* n'existent pas toujours. Par exemple, dans le cas particulier où $J = e$ est la catégorie ponctuelle,

et I l'ensemble ordonné

(dans le cas de $f^!$), ou l'ensemble ordonné opposé (dans le cas de $f^?$). Même si f est une immersion ouverte, $f^!$ n'existe pas forcément (par exemple elle n'existe pas si I est comme `[ci-]`dessus, et

et si f est une immersion fermée, $f^?$ n'existe pas forcément.

Commentary · Examples [ms. 1]

Why the next adjoint can fail

The first counterexample is already a calculation with abelian groups. On the fork $0 \to a, 0 \to b$, a presheaf is a cospan $A \to C \leftarrow B$, and its limit is $A \times_C B$. Consider the componentwise surjection of cospans

$$(\mathbb{Z} \xrightarrow{2} \mathbb{Z} \leftarrow 0) \longrightarrow (\mathbb{Z}/2 \xrightarrow{0} \mathbb{Z}/2 \leftarrow 0),$$

whose nonzero components are reduction modulo 2. The induced map on limits is $0 \to \mathbb{Z}/2$, which is not surjective. A functor having a right adjoint is a left adjoint and hence preserves cokernels; in this abelian diagram category it would preserve epimorphisms. The limit functor therefore has no right adjoint. This verifies precisely the failure of $f^!$ asserted in (b).

For the opposite fork the colimit is a pushout. The componentwise injection from the span $\mathbb{Z} \xrightarrow{2} \mathbb{Z}, \mathbb{Z} \to 0$, to the analogous span with $\mathbb{Q}$ in place of $\mathbb{Z}$ induces $\mathbb{Z}/2 \to 0$ on pushouts. It fails to preserve a monomorphism and cannot be a right adjoint. Thus its left adjoint $f^?$ does not exist. These examples use neither an absence of ordinary limits nor a failure of abelian structure.

The open-immersion example is the same obstruction localized at the new vertex c. For the inclusion of the fork into the diamond, $(f_*F)_c$ is the preceding pullback. Evaluation at c preserves colimits, so a right adjoint to f_* would force this pullback functor to preserve cokernels. The same surjection disproves that possibility. The dual argument treats a closed immersion and $f^?$. The point of the examples is that iterated adjunction is a property of a particular functor, not a consequence of the ambient categories having all limits and colimits.

c) Si f est une *immersion fermée*, et A est *ponctuée* (*i.e.* admet un objet à la fois initial et final), alors $f^!$ existe. Si f est une immersion ouverte, $f^?$ existe. (Toujours sous réserve de p. 2
l'existence dans A des limites pertinentes). Si f est une immersion, f_* et $f_!$ `[sont]` pleinement fidèles *i.e.* f^* `[est]` un foncteur de localisation.

d) Supposons seulement l'existence de l'objet final e dans A (plus au besoin certaines $\varprojlim$ finies). Si

[page 2]

$$i : Y \hookrightarrow S$$

est une immersion fermée, de complémentaire U

$$Y \xhookrightarrow{i} S \xhookleftarrow{j} U$$

de sorte que j soit une immersion ouverte, alors $A(Y)$ s'identifie par le foncteur i_* à la sous-catégorie pleine de $A(S)$ formée des $F \in \mathsf{Ob}\ A(S)$ tels que $F|U \simeq e_U$ (préfaisceau final). De même, si l'objet initial $\emptyset$ existe dans A, et les $\varinjlim$ pertinentes, alors $A(U)$ s'identifie par $j_!$ à la sous-catégorie pleine de $A(S)$ formée des F tels que $F|Y = \emptyset_Y$ (préfaisceau initial, prenant partout la valeur $\emptyset$).

Si A est même *ponctuée* ($e = \emptyset$), alors on a, pour tout $F \in \mathsf{Ob}\ A(S)$, un carré à la fois cartésien et cocartésien, fonctoriel en F

(1)
$$\begin{array}{ccccc} & & F & & \\ & \overset{\text{adj}}{\nearrow} & & \overset{\text{adj}}{\searrow} & \\ j_!j^*F & & & & i_*i^*F \\ & \searrow & & \nearrow & \\ & & e & & \end{array} \quad .$$

Dans le cas A abélienne, ce diagramme prend la forme d'une suite exacte

$$0 \longrightarrow j_!j^*F \longrightarrow F \longrightarrow i_*i^*F \longrightarrow 0 \quad .$$

e) Mêmes conditions pour i et j. On suppose que A a les $\varprojlim$ pertinentes, dont objet final. On a alors un carré cartésien fonctoriel en $F \in \mathsf{Ob}\ A(S)$ `[il faut supposer la catégorie` A `ponctuée]`

(2)
$$\begin{array}{ccc} F & \longleftarrow & i_*i^!F \\ {\scriptstyle\text{adj}}\downarrow & & \downarrow \\ j_*j^*F & \longleftarrow & e \end{array}$$

i.e. $i^!F$ s'identifie par le foncteur pleinement fidèle i_* au *noyau* de $F \to j_*j^*F$. Dans le cas abélien, cela prend la forme d'une suite exacte

$$0 \longrightarrow i_*i^!F \longrightarrow F \longrightarrow j_*j^*F \quad .$$

Commentary · Exposition [ms. 2]

Support, zero extension, and the exceptional inverse image

Let $U \subset S$ be a sieve and $Y = S \setminus U$ its complementary cosieve. A presheaf on Y extends by the terminal object on U under i_*. Indeed, Y/u is empty for $u \in U$, whereas restriction to Y recovers the original presheaf. Conversely, if $F|_U$ is terminal, the unit $F \to i_*i^*F$ is an isomorphism at every object. This proves the description of the essential image in (d). Dually, $j_!$ extends a presheaf on U by the initial object on Y.

Assume now that A has a zero object and the required limits. Form

$$K = F \times_{j_*j^*F} 0.$$

Its restriction to U is zero, so $K = i_*G$ for a unique G up to the canonical equivalence above. For $H \in A(Y)$, the maps $i_*H \to j_*j^*F$ are in bijection with maps $j^*i_*H = 0 \to j^*F$, hence form a singleton. The universal property of the pullback gives

$$\mathrm{Hom}(H, G) \cong \mathrm{Hom}(i_*H, K) \cong \mathrm{Hom}(i_*H, F).$$

Thus $G = i^!F$, proving both the extra adjunction and square (2). This argument explains the editors' pointedness correction: a terminal object alone supplies no canonical map from it to j_*j^*F. For $A = \mathsf{Set}$ and $S = [1]$, the closed inclusion of 1 has $i_*B = (B \to *)$. It does not preserve the initial object, so cannot have a right adjoint.

The dual construction uses

$$Q = F \amalg_{i_!i^*F} 0.$$

Now $Q|_Y = 0$, hence $Q = j_! j^? F$, and the same universal-property argument proves $j^? \dashv j_!$. The first square of (d) is bicartesian for a different, simpler reason: at each point it is a square with an identity on one side and a zero object on the other. Checking at points proves both universal properties. No stability hypothesis is needed for this particular square. In an abelian category its associated short exact sequence need not split as a sequence of diagrams, even though every component is split. For $S = [1]$ and $F = (\mathbb{Z} \xrightarrow{1} \mathbb{Z})$, the sequence is

$$0 \longrightarrow (0 \to \mathbb{Z}) \longrightarrow (\mathbb{Z} \xrightarrow{1} \mathbb{Z}) \longrightarrow (\mathbb{Z} \to 0) \longrightarrow 0.$$

A splitting would require the identity map on the first copy of $\mathbb{Z}$ to have zero composite with the displayed identity arrow, which is impossible.

Je me dispense d'écrire le carré cocartésien dual, quand A a les $\varinjlim$ pertinentes, y compris objet initial. Il semble qu'elle n'ait pas servi en pratique. Les foncteurs adjoints et biadjoints classiquement utiles sont inclus ci-dessous (où les "pas utiles" sont entre crochets) p. 3 [page 3]

$$[i_!]\ i^*\ i_*\ i^!$$
$$[j^?]\ j_!\ j^*\ j_*$$

i.e. les foncteurs $i_!$ et $j^?$ n'ont pas servi classiquement.

f) Cas des catégories $\mathbf{\Delta}_i$ (simplexes type, $i \in \mathbb{N}$), et des foncteurs entre ceux-ci (applications semi-simpliciales). Il semblerait que pour une telle f, si A est ponctuée, il y ait les *bi-adjoints* à la fois à gauche et à droite. De plus, pour $\mathbf{\Delta}_i$ et $\mathbf{\Delta}_j$ fixés quand on regarde toutes les $f : \mathbf{\Delta}_i \to \mathbf{\Delta}_j$ et toutes les $g : \mathbf{\Delta}_j \to \mathbf{\Delta}_i$, que les suites totales de foncteurs multi-adjoints pour chacun des f^*, g^* correspondants sont toutes les mêmes `[ce n'est pas vrai]`. Ça a l'air vrai du moins si $j = i + 1$ (et je l'ai vérifié pour $i = 0$, $i = 1$), on doit trouver une "suite d'adjonctions" de longueur $2i + 7 = (i + 1) + (i + 2) + 2 + 2$. De façon précise, la suite comporte quatre termes "extrêmes" (les deux premiers, les deux derniers) et les $(i + 1) + (i + 2)$ termes intermédiaires correspondant aux foncteurs de la forme f^* ou g^*, où $f : \mathbf{\Delta}_{i+1} \to \mathbf{\Delta}_i$ est une des $(i + 1)$ applications de dégénérescence, et $g : \mathbf{\Delta}_i \to \mathbf{\Delta}_{i+1}$ une des $i + 2$ applications bord `[ce n'est pas tout à fait vrai; il faut se limiter aux applications qui sont injectives ou surjectives]`.

Commentary · Examples [ms. 3] p. 4 [page 4]

The simplex adjunctions, with their endpoints

Write $C_n = A^{[n]^{\mathrm{op}}}$, so its objects are strings $X_n \to \cdots \to X_0$. Let $\delta^k : [n] \to [n+1]$ omit k, and let $\sigma^k : [n+1] \to [n]$ identify k and $k+1$. The inequalities in the finite ordinals give

$$\delta^{k+1} \dashv \sigma^k \dashv \delta^k.$$

Applying contravariant presheaves reverses both arrows and natural transformations; consequently the restrictions form the adjunction chain

$$(\delta^{n+1})^* \dashv (\sigma^n)^* \dashv (\delta^n)^* \dashv \cdots \dashv (\sigma^0)^* \dashv (\delta^0)^*.$$

One can also check each bijection of Hom sets by writing down the compatible component maps. There are $2n + 3$ terms here.

If A is pointed with finite limits and colimits, two more terms occur at either end. On the left, let $L : C_n \to C_{n+1}$ prepend zero at the high end: $L(X) = (0 \to X_n \to \cdots \to X_0)$. Then $L \dashv (\delta^{n+1})^*$. Define $Q : C_{n+1} \to C_n$ by

$$(QX)_r = X_r \amalg_{X_{n+1}} 0 \qquad (0 \le r \le n).$$

A map $X \to LY$ is exactly a compatible family $X_r \to Y_r$ killing X_{n+1}, so $Q \dashv L$. At the right end let $R(X) = (X_n \to \cdots \to X_0 \to 0)$. Then $(\delta^0)^* \dashv R$. Its right adjoint is the string $K(X)_r = X_{r+1} \times_{X_0} 0$, since a map $RY \to X$ is exactly a family of maps to those fibers. The full chain has $2n + 7$ terms, as suggested in the manuscript.

For $n = 0$ it is particularly transparent:

$$\mathrm{coker} \dashv (0 \to -) \dashv \mathrm{ev}_0 \dashv \mathrm{const} \dashv \mathrm{ev}_1 \dashv (- \to 0) \dashv \ker.$$

Here kernel and cokernel mean fiber and cofiber over the zero object, so abelian structure is unnecessary. This also proves the first conjecture in (f): every monotone map of finite ordinals factors into elementary faces and degeneracies, each restriction occurring far enough inside one of these chains to have two adjoints on both sides. Composing the corresponding adjunctions supplies $f^?$ and $f^!$.

The stronger statement about one common chain for *all* maps between two fixed ordinals is false. Already for [1] and itself, the identity restriction has only identity adjoints up to isomorphism, whereas the restriction along a constant map is not the identity on C_1, for example when $A = \mathsf{Ab}$. Between $[n]$ and $[n+1]$, the central chain displayed above contains exactly the injective faces and surjective degeneracies. Other monotone maps are composites, not additional entries in that chain. The editors' qualifications should therefore be retained; the nearby count is a correct statement about the specified chain, not a classification of every restriction functor.

2. Préliminaires heuristiques sur les dérivateurs.

On se donne une sous-catégorie pleine Dia (comme "diagrammes") de $\mathcal{C}at$. Ça peut être tout $\mathcal{C}at$, ou plus petit. Mais on supposera le plus souvent que Dia contient au moins les "catégories ordonnées" (correspondant aux ensembles ordonnés, *i.e.* telles que *a*) tout morphisme est un mono et *b*) tout iso est une identité `[ce n'est pas vrai : la catégorie réduite à une double flèche satisfait à ces conditions, mais n'est pas un ensemble ordonné]`). Par abus de langage, on identifie un ensemble ordonné avec la catégorie correspondante (et une catégorie au topos qu'elle définit?). On considère Dia comme une 2-*catégorie.* [1]

Commentary · Context [ms. 4]

From derived coefficients to diagram categories

The opening calculations make the geometric language of supports available before any homotopy theory is introduced. There is a documented reason for this starting point. In *Pursuing Stacks*, §69, Grothendieck traces his concern to the inadequacy of a single derived category for the trace and determinant formulas arising around SGA 5. The proposed replacement assigns a derived category to every diagram shape; filtered complexes and diagrams of triangles are instances of this larger construction. The demand that the same structure reappear at every shape already anticipates the shifted derivators of manuscript p. 18 (Grothendieck, 1983, §69, pp. 1–3 of the edited extract).

His letter to Thomason of 2 April 1991 returns to the same question: which intrinsic structure survives passage from models to categories of coefficients? That letter explicitly connects the renewed work to the 1983 notes and discusses both derivators and the role of small categories as homotopy models (Grothendieck, 1991a, pp. 2–4 of the edited letter). These are statements by Grothendieck about his program; they do not establish a retrospective priority claim for every later theorem. Heller's independently formulated homotopy theories already organized homotopy categories of diagrams, homotopy Kan extensions, and pointed operations in a related axiomatic framework (Heller, 1988, Chs. II–III).

The terminology on the next pages must be read provisionally. The superscript $\circ$ on Dia reverses both functors and transformations. A transformation $\alpha : f \Rightarrow g$ induces $\alpha^* : g^* \Rightarrow f^*$ because a presheaf sends $\alpha_i : f(i) \to g(i)$ to $F(g(i)) \to F(f(i))$. In modern notation the input 2-category would therefore be $\mathsf{Dia}^{\mathrm{coop}}$. A common modern convention uses covariant diagrams and writes $\mathscr{D} : \mathsf{Cat}^{\mathrm{op}} \to \mathsf{CAT}$, reversing functors but retaining the direction of 2-cells. The translation is $\mathscr{D}(I) = \mathbb{D}(I^{\mathrm{op}})$. A left derivator in this manuscript has right Kan extensions; this is the terminology of left exactness, not that of a left adjoint. The preliminary labels Der_1, Der_2, and Der_3 will also be reassigned when the systematic axioms begin.

The small correction about posets is substantive but completely local. A category is a poset precisely when it is thin and skeletal: each Hom set has at most one member, and isomorphic objects are equal. Having only monomorphisms and no nonidentity isomorphisms does not imply thinness. The parallel-pair category printed in the editors' note is a counterexample, since every composable arrow that could test cancellation is an identity. No later construction depends on the incorrect characterization.

Un *dérivateur* $\mathbb{D}$ (sur Dia, comme "*domaine*" du dérivateur) est un 2-foncteur contravariant de Dia dans $\mathcal{C}at$, satisfaisant certaines conditions. Donc

$$\mathbb{D} : \mathsf{Dia}^{\circ} \longrightarrow \mathcal{C}at \quad .$$

Si $I \in \mathsf{Ob}_0\mathsf{Dia}$ est une catégorie (ou un "type de diagramme") du domaine de $\mathbb{D}$, on doit donc avoir une catégorie $\mathbb{D}(I)$. Les objets de $\mathbb{D}(I)$ s'appelleront les *objets-coefficients* (ou *coefficients*) de type $\mathbb{D}$, au dessus de I. Pour

$$f : I \longrightarrow J$$

1. N.B. Il faut des conditions de stabilité pour Dia, au moins la stabilité par $I \times J$ et $I \amalg J$, en fait, nettement plus …

une 1-flèche de Dia, on doit avoir un foncteur

$$f^*_{\mathbb{D}} \text{ ou } f^* : \mathbb{D}(J) \longrightarrow \mathbb{D}(I) \quad ,$$

dit *"foncteur image inverse"*. Si F est un coefficient de type $\mathbb{D}$ sur J son "*image inverse*" est donc un coefficient de type $\mathbb{D}$ sur I. On suppose (pour simplifier!) que le 2-foncteur $\mathbb{D}$ est *strict*, donc qu'on a transitivité stricte

$$(gf)^* = f^* g^* \ , \qquad \text{si} \qquad I \xrightarrow{f} J \xrightarrow{g} K \qquad \text{dans Dia} \ .$$

De plus, si on a deux foncteurs $f, g : I \rightrightarrows J$, et un morphisme entre eux [page 5]

$$I \underset{g}{\overset{f}{\underset{\downarrow u}{\overset{\downarrow u}{\rightrightarrows}}}} J \quad ,$$

on se donne un morphisme $u^*_{\mathbb{D}}$ ou u^* entre les foncteurs g^* et f^*, d'où

$$\mathbb{D}(I) \underset{g^*}{\overset{f^*}{\underset{\uparrow u^*}{\overset{\uparrow u^*}{\leftrightarrows}}}} \mathbb{D}(J) \quad .$$

On doit encore avoir transitivité pour une composition de morphismes de foncteurs : p. 5

$$I \underset{h}{\overset{f}{\underset{g \downarrow v}{\overset{\downarrow u}{\rightrightarrows}}}} J$$

doit donner

$$(vu)^* = u^* v^*$$

donc

$$\mathbb{D}(I) \underset{h^*}{\overset{f^*}{\underset{g^* \uparrow v^*}{\overset{\uparrow u^*}{\leftrightarrows}}}} \mathbb{D}(J) \quad .$$

De plus, si f est une identité, f^* aussi

$$(\mathsf{id}_I)^* = \mathsf{id}_{\mathbb{D}(I)} \quad ,$$

et de même si u est une identité

$$(\mathsf{id}_f)^* = \mathsf{id}_{f^*} \quad .$$

J'indique tout de suite l'axiome le plus important sur un dérivateur (au-delà de la donnée [page 6]
d'un 2-contra foncteur strict) :

Der$_1$: Si $f : I \to J$ dans Dia, alors $f^*_{\mathbb{D}} = f^* : \mathbb{D}(J) \to \mathbb{D}(I)$ a un adjoint à droite et un adjoint à gauche.

Ces foncteurs seront notés (du moins provisoirement) $f^{\mathbb{D}}_*$ ou f_* , et $f^{\mathbb{D}}_!$ ou $f_!$, soit

$$f_! \, , \ f_* : \mathbb{D}(I) \rightrightarrows \mathbb{D}(J) \quad ,$$

de sorte qu'on trouve une suite de *trois* foncteurs adjoints entre $\mathbb{D}(I)$ et $\mathbb{D}(J)$

$$f_! \, , \ f^* , \ f_* \quad .$$

N.B. Pour la plupart des développements on n'aura pas besoin de l'existence à la fois des $f_!$ et des f_* . Un *dérivateur à gauche* ne suppose que les f_* (adjoints à droite des f^*), et [page 7]
l'existence de $f_!$ seulement quand f est une *immersion ouverte*. Dualement, un *dérivateur à* p. 6

droite ne suppose que les $f_!$ (adjoints à gauche des f^*), et f_* seulement si f est une *immersion fermée*. Ce sont sans doute les dérivateurs à gauche qui sont les plus importants.

Der$_2$: Si $f : I \to J$ est dans Dia, si c'est une immersion *fermée*, le biadjoint à droite $f^!_{\mathbb{D}}$ ou $f^!$ de f^* existe. Si c'est une immersion ouverte, le biadjoint à gauche $f^?$ existe. [2] Dans les deux cas, on veut que f^* soit un foncteur de localisation, ce qui équivaut à dire que f_* est pleinement fidèle, ou que $f_!$ est pleinement fidèle. [3]

N.B. Dans le cas d'un dérivateur à gauche, on suppose seulement l'existence de $f^!$ si f est une immersion fermée. Donc pour résumer, pour un tel dérivateur, on suppose l'existence de

$$\begin{cases} f_* \text{ quel que soit } f : I \to J \text{ dans Dia} \\ f_! \text{ si } f \text{ est une immersion ouverte} \\ f^! \text{ si } f \text{ est une immersion fermée (cas ponctué seulement).} \end{cases}$$

Dualement, pour un dérivateur à droite, on suppose l'existence de

$$\begin{cases} f_! \text{ quel que soit } f : I \to J \text{ dans Dia} \\ f_* \text{ si } f \text{ est une immersion fermée} \\ f^? \text{ si } f \text{ est une immersion ouverte (cas ponctué seulement).} \end{cases}$$

Je voudrais formuler des axiomes astucieux, pour le cas d'un couple

$$Y \overset{i}{\hookrightarrow} I \overset{j}{\hookleftarrow} U$$

d'une immersion ouverte j et d'une immersion fermée i dans Dia, complémentaires l'une de l'autre. D'abord une formulation si on suppose $\mathbb{D}$ "*ponctué*", *i.e.* les catégories $\mathbb{D}(I)$ ponctuées, et les foncteurs f^* compatibles avec les ponctuations. On veut "interpréter" le carré (1) page 2 :

[page 8]

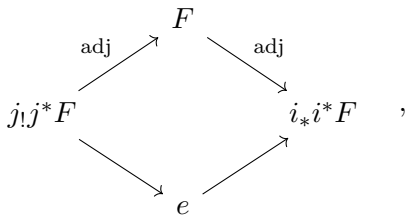
Commentary · Exposition [ms. 7]

Coherent squares and what the axioms remember

The passage from a square in $\mathbb{D}(I)$ to an object of $\mathbb{D}(I \times [1] \times [1])$ is the first genuinely homotopical issue. The underlying-diagram functor discards part of the data. A commutative square in a homotopy category records equality of two homotopy classes; a coherent square also records the homotopy implementing that equality, together with whatever compatibility is required in a larger diagram. It is therefore the coherent object to which a homotopy pullback or pushout operation applies.

Put $\square = [1] \times [1]$ and let W be the full subcategory obtained by deleting $(1, 1)$. For presheaves, W^{op} is a cospan. A coherent square $X \in \mathbb{D}(I \times \square)$ is cartesian if it is in the essential image of right Kan extension along $I \times W \hookrightarrow I \times \square$. Equivalently, its unit comparison with that right Kan extension is an isomorphism. The opposite corner and left Kan extension define cocartesian squares. These definitions use the universal property of an adjoint inside the whole family of diagram categories, rather than an ordinary pullback in $\mathbb{D}(I)$. In the represented derivator of a complete category they reduce to ordinary cartesian and cocartesian squares.

The desire to lift diagrams does not say that every diagram in $\mathbb{D}(I)$ has a preferred lift. A frequently imposed additional axiom, strongness, asks that the underlying arrow functor $\mathbb{D}(I \times [1]) \to \mathbb{D}(I)^{[1]^{\mathrm{op}}}$ be full and essentially surjective. Even that says neither that the lift is unique nor that the functor is faithful. The special support squares have more structure: they arise from restrictions, adjunction units or counits, and zero extensions. Those operations give the coherent constructions that an arbitrary incoherent square lacks.



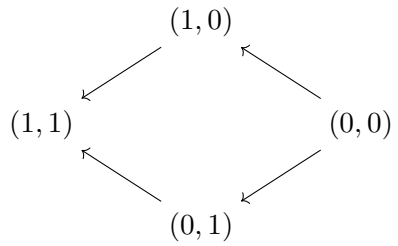
In the modern full derivator axioms, pointedness can be required only at $\mathbb{D}(e)$. It then propagates to all diagram categories, and the exceptional adjoints required here follow; this is proved in Groth

2. Il n'y a lieu d'exiger les biadjoints que pour un dérivateur ponctué. HOT n'y satisfait pas.

3. Il faut de plus caractériser l'image de f_* si f est une immersion fermée (les F tels que $g^*F \xrightarrow{\sim} e_{\mathbb{D}(U)}$) et celle de $f_!$ si c'est une immersion ouverte (les F tels que $g^*F \simeq \emptyset_{\mathbb{D}(Y)}$), où g est l'immersion complémentaire.

(2013, Proposition 3.2 and Corollary 3.8). Thus the manuscript's extra-adjoint requirement was a useful way to expose the intended geometry, but is not an additional independent condition on an already pointed derivator. This does not justify imposing exceptional adjoints on the unpointed derivator of spaces: the initial and terminal spaces differ. The qualification in footnote 2 is necessary.

(1)



,

Der′$_2$: Pour tous $I, J \in \mathsf{Dia}$, on a

$$\mathbb{D}(I \amalg J) \xrightarrow[(\alpha^*,\beta^*)]{\sim} \mathbb{D}(I) \times \mathbb{D}(J) \quad ,$$

où α, β sont les injections canoniques de I et J dans $I \amalg J$.

carré à la fois cartésien et cocartésien. On cherche donc un carré dans $\mathbb{D}(I)$, mais mieux que ça. Soit $J = \mathbf{\Delta}_1 \times \mathbf{\Delta}_1$ le carré standard p. 7

et considérons la catégorie $I \times J$. On a

$$\begin{aligned} J &\longrightarrow \underline{\mathsf{Hom}}(I, I \times J) \\ j &\longmapsto \big(i \longmapsto (i, j)\big) \end{aligned}$$

D'autre part, par $\mathbb{D}$

$$\underline{\mathsf{Hom}}(I, I \times J)^\circ \longrightarrow \underline{\mathsf{Hom}}(\mathbb{D}(I \times J), \mathbb{D}(I))$$

d'où un composé

$$J^\circ \longrightarrow \underline{\mathsf{Hom}}(\mathbb{D}(I \times J), \mathbb{D}(I))$$

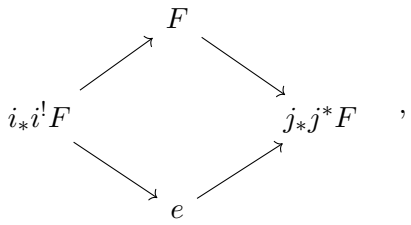
ou encore

$$\mathbb{D}(I \times J) \longrightarrow \underline{\mathsf{Hom}}(J^\circ, \mathbb{D}(I)) \quad .$$

Ceci vaut pour tout $J \in \mathsf{Ob}\,\mathsf{Dia}$. On peut donc dire que la donnée d'un "coefficient" Φ sur une catégorie produit $I \times J$ donne naissance à un diagramme de type J° dans la catégorie $\mathbb{D}(I)$ des coefficients sur I. La philosophie des dérivateurs consiste en grande partie, inversement, chaque fois qu'on a un diagramme dans une catégorie de coefficients $\mathbb{D}(I)$ (sur un diagramme I), disons diagramme de type $K : K \to \mathbb{D}(I)$, de se demander s'il ne provient pas "canoniquement" d'un objet de $\mathbb{D}(I \times K^\circ)$ *i.e.* d'un coefficient sur $I \times K^\circ$. [page 9]

Ainsi pour le carré p. 8. On voudrait qu'il provienne de $\mathbb{D}(I \times J)$, où $J = \mathbf{\Delta}_1 \times \mathbf{\Delta}_1$, et ceci fonctoriellement, donc on désire un foncteur "canonique"

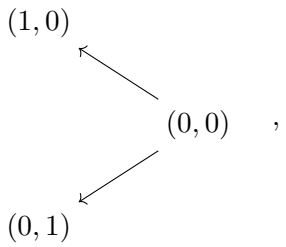
$$\mathbb{D}(I) \longrightarrow \mathbb{D}(I \times \mathbf{\Delta}_1 \times \mathbf{\Delta}_1)$$



p. 8

qui en composant avec

$$\mathbb{D}(I \times \mathbf{\Delta}_1 \times \mathbf{\Delta}_1) \longrightarrow \underline{\mathsf{Hom}}((\mathbf{\Delta}_1 \times \mathbf{\Delta}_1)^\circ, \mathbb{D}(I))$$

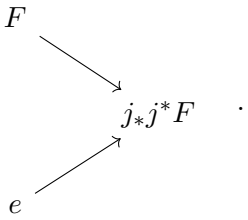


donne le foncteur décrit par le carré (1). De plus, il faut exprimer dans le contexte présent la condition "bicartésienne" du carré (1), dans le contexte de la page 7. Question analogue pour le carré (2) de la page 2 :

(2)

,

où il faut de plus interpréter la condition cartésienne. On va définir en fait un coefficient sur la sous-catégorie ouverte W suivante de $\mathbf{\Delta}_1 \times \mathbf{\Delta}_1$

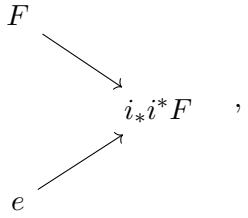


,

plus exactement sur $W \times I$, et si α

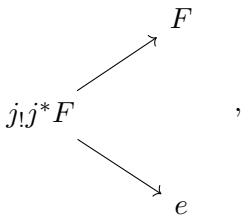
[page 10]

$$\alpha : W \times I \longrightarrow \mathbf{\Delta}_1 \times \mathbf{\Delta}_1 \times I$$



est l'inclusion canonique, on définira le carré "cartésien" comme l'image par α_* de ce coefficient. Ceci nous ramène donc au problème de "globaliser" d'abord le diagramme partiel

.



Et de même pour le carré (1) sauf qu'on est embarrassé si on choisit de le regarder surtout comme cartésien (ce qui suggère à procéder comme tantôt) ou comme <u>co</u>cartésien (ce qui suggère de procéder de façon duale). Mais les deux coefficients qu'on trouvera par ces deux procédés, produits soit de

p. 9

,

soit de

,

devraient être *canoniquement* isomorphes.
Si $\mathbb{D}$ est un dérivateur, la catégorie [page 11]

$$\mathcal{A} = A_{\mathbb{D}} = \mathbb{D}(e)$$

joue un rôle important. On l'appelle la *catégorie de base,* ou *la catégorie fondamentale*, du dérivateur, ces objets sont les *coefficients fondamentaux.* Pour I quelconque dans Dia, on a donc pour $F \in \mathbb{D}(I)$, coefficient sur I

$$I^\circ \longrightarrow \mathcal{A} \quad , \qquad i \longmapsto F_i$$

un diagramme de type I° dans $\mathcal{A}$, fonctoriellement, *i.e.*

$$\mathbb{D}(I) \longrightarrow \underline{\mathsf{Hom}}(I^\circ, \underset{\mathbb{D}(e)}{\mathcal{A}})$$

(*cf.* page 8).
Der$_3$: Pour tout $I \in \mathsf{Dia}$, ce foncteur est *conservatif,*[4] *i.e.* pour que

$$F \longrightarrow G$$

dans $\mathbb{D}(I)$ soit [un] isomorphisme, il faut et il suffit que pour tout $i \in I$, p. 10

$$F_i \longrightarrow G_i$$

le soit.
Corollaire. *Le foncteur canonique (pour I, $J \in \mathsf{Dia}$)*

$$\mathbb{D}(I \times J) \xrightarrow{\theta} \underline{\mathsf{Hom}}(J^\circ, \mathbb{D}(I))$$

est conservatif.

En effet, si F est dans $\mathbb{D}(I \times J)$, on a pour $(i, j) \in I \times J$

$$F_{i,j} \simeq \theta(F)(j)_i \quad .$$

Intuitivement, on regarde un dérivateur $\mathbb{D}$ comme "étant" la catégorie fondamentale $\mathcal{A}$, avec une "structure" supplémentaire, [à] savoir la donnée des "extensions" de $\mathcal{A}$ (comme catégorie [page 12] des coefficients ponctuels) aux diagrammes $I \in \mathsf{Dia}$, de façon contravariante en I. Un coefficient F dans $\mathbb{D}(I) \overset{\text{déf}}{=} \mathcal{A}_I$ est regardé comme "étant" le diagramme $(F_i)_{i \in I}$ correspondant d'objets fondamentaux, avec une donnée supplémentaire de "globalisation". Les F_i, ou "fibres" de F en les $i \in I$, sont les caractéristiques locaux, du coefficient "global sur I" F.

Commentary · Examples [ms. 11]
Conservative is not faithful

The conservativity axiom detects whether a *given coherent morphism* is invertible. It does not reconstruct that morphism from its components. A small derived example makes the distinction exact. In the abelian category of arrows $X_1 \to X_0$, put

$$P = (\mathbb{Z} \to 0), \qquad Q = (0 \to \mathbb{Z}), \qquad E = (\mathbb{Z} \xrightarrow{1} \mathbb{Z}).$$

The nonsplit sequence

$$0 \longrightarrow Q \longrightarrow E \longrightarrow P \longrightarrow 0$$

defines a nonzero element of $\mathrm{Ext}^1(P, Q)$, and hence a nonzero morphism $P \to Q[1]$ in the derived category of arrows. Its two evaluated components are $\mathbb{Z} \to 0[1]$ and $0 \to \mathbb{Z}[1]$, both zero. This is

4. N.B. Mais ce foncteur n'a aucune envie d'être *fidèle.*

the same nonsplitting calculated in the support example, now viewed as a morphism in a derived category. It exhibits exactly the information lost by

$$D(\mathsf{Ab}^{[1]^{\mathrm{op}}}) \longrightarrow D(\mathsf{Ab})^{[1]^{\mathrm{op}}}.$$

There is no contradiction with conservativity. The nonzero extension class is not a morphism all of whose components are isomorphisms.

The corollary for partial underlying diagrams is proved in the text, not left as a gap. If a coherent morphism over $I \times J$ becomes an isomorphism at every j in $\mathbb{D}(I)$, evaluating again at every i gives an isomorphism at each (i, j). The original conservativity axiom on $I \times J$ now applies. In particular, a shifted family retains the same test for invertibility. This short argument does not need strongness, full faithfulness, a model structure, or a choice of representatives.

Tous les dérivateurs connus sont obtenus de la façon standard suivante. On part d'une "catégorie de modèles"

$$\mathcal{M} \quad , \quad \Sigma$$

munie d'un ensemble de flèches, appelées "équivalences", et satisfaisant aux axiomes pertinents pour le passage à une catégorie des fractions

$$\mathcal{A} = \mathcal{M}\Sigma^{-1}$$

qui sera la "catégorie fondamentale". On définit pour tout I dans Dia

$$\begin{aligned} \mathcal{M}_I &= \underline{\mathsf{Hom}}(I^\circ, \mathcal{M}) \\ \Sigma_I &= \{u \in \mathsf{Fl}(\mathcal{M}_I) \mid \forall i \in I, u_i \in \Sigma\} \\ \mathcal{A}_I &= \mathcal{M}_I \Sigma_I^{-1} \end{aligned}$$

Il est clair que $\mathcal{A}_I \overset{\text{déf}}{=} \mathbb{D}_{\mathcal{M},\Sigma}(I)$ dépend de I de façon fonctorielle contravariante, et même de façon 2-fonctorielle. [page 13]

Bien entendu, pour avoir vraiment un dérivateur, il faut vérifier les axiomes. Le plus fort est l'existence des $f_!$, f_*. Elle est prouvée par Thomason lorsque $(\mathcal{M}, \Sigma)$ provient d'une "catégorie de modèles" au sens de Quillen. Ce n'est pas clair pour moi qu'alors $(\mathcal{M}_I, \Sigma_I)$ provienne également d'une catégorie de modèles (dont par exemple les fibrations et les cofibrations seraient définies à partir de ces données dans $\mathcal{M}$, comme tantôt pour les équivalences). p. 11

Quand on prend pour $(\mathcal{M}, \Sigma)$ une catégorie de modèles pour Hot (par exemple les ensembles semi-simpliciaux $\mathcal{M} = \underline{\mathsf{Hom}}(\mathbf{\Delta}^\circ, \mathcal{E}ns)$, d'où $\mathcal{M}_I \simeq \underline{\mathsf{Hom}}(\mathbf{\Delta}^\circ \times I^\circ, \mathcal{E}ns) \simeq \underline{\mathsf{Hom}}(\mathbf{\Delta}^\circ, \underbrace{\underline{\mathsf{Hom}}(I^\circ, \mathcal{E}ns)}_{\widehat{I}})$, catégorie des objets semi-simpliciaux dans le topos $\widehat{I}$, on trouve une description d'un dérivateur (non additif), qui jouera un rôle particulièrement important. Je le désigne par

$$\mathsf{HOT} \quad ,$$

sa catégorie des coefficients fondamentaux est Hot, la catégorie homotopique standard.

Commentary · Later developments [ms. 13]

Localizing diagrams and deriving their Kan extensions

For a relative category $(\mathcal{M}, W)$, objectwise weak equivalences are preserved by every restriction. Thus localization supplies the displayed prederivator, subject to the usual size convention ensuring that its Hom classes are sets. Naturality of the localized transformations follows from the universal property of localization. One may use a functorial localization construction to keep restriction strictly functorial. Arbitrary independent choices of localized categories instead give canonically equivalent data with coherence isomorphisms.

The difficult assertion is the existence and pointwise behavior of the derived Kan extensions. Grothendieck attributes the model-category case to Thomason here, without specifying a publication.

We have not identified a published Thomason theorem with exactly the generality of this attribution. A precise later source is Cisinski (2003, Theorem 6.11): a Quillen model category admitting small limits gives a left derivator in the presheaf convention. Applying the result to the opposite model category gives the dual assertion when small colimits exist. The proof also establishes local smallness of the diagram localizations. This settles the mathematical existence question without requiring an ordinary Quillen model structure on every diagram category.

For a combinatorial model category there is a familiar more direct route. The projective diagram model structure has objectwise fibrations and weak equivalences; the injective structure has objectwise cofibrations and weak equivalences. Their homotopy categories are the same localization, although their replacements differ. Projective replacements derive left Kan extension, while injective replacements derive right Kan extension. In general one cannot declare *both* fibrations and cofibrations objectwise and expect the lifting axioms. The passage from models to presheaves is treated in a more flexible formalism by Cisinski (2010, Theorem 6.22 and Corollary 6.24).

For the indicated model of spaces, the exponential law gives

$$(\mathsf{sSet})^{I^{\mathrm{op}}} \cong \mathsf{Set}^{\Delta^{\mathrm{op}} \times I^{\mathrm{op}}} \cong (\mathsf{Set}^{I^{\mathrm{op}}})^{\Delta^{\mathrm{op}}}.$$

The weak equivalences in this construction are evaluated at each i. They are not a newly imposed local weak-equivalence relation for an arbitrary Grothendieck topology. Also, "semi-simplicial" is historical terminology here: the displayed Δ includes degeneracies and gives what is now called a simplicial set. Replacing it silently by the category of injective order maps would change the model category under discussion.

La notion de "morphisme de Dérivateurs" est claire, c'est un morphisme entre deux 2-foncteurs stricts [page 14]

$$\mathsf{Dia}^{\circ} \longrightarrow \mathcal{C}at$$

Donc

$$u : \mathbb{D} \longrightarrow \mathbb{D}'$$

est défini par la donnée, pour tout $I \in \mathsf{Dia}$, de

$$u_I : \mathbb{D}(I) \longrightarrow \mathbb{D}'(I)$$

avec commutativité (stricte?) pour $f : I \to J$

$$\begin{array}{ccc} \mathbb{D}(J) & \xrightarrow{f^*_{\mathbb{D}}} & \mathbb{D}(I) \\ {\scriptstyle u_J}\downarrow & & \downarrow{\scriptstyle u_I} \\ \mathbb{D}'(J) & \xrightarrow{f^*_{\mathbb{D}'}} & \mathbb{D}'(I) \end{array} \quad . \tag{1}$$

On a

$$\begin{array}{ccc} \underline{\mathsf{Hom}}(I,J)^{\circ} & \xrightarrow{\mathbb{D}_{I,J}} & \underline{\mathsf{Hom}}(\mathbb{D}(J),\mathbb{D}(I)) \\ {\scriptstyle \mathbb{D}'_{I,J}}\downarrow & & \downarrow{\scriptstyle \phi \mapsto u_I \circ \phi} \\ \underline{\mathsf{Hom}}(\mathbb{D}'(J),\mathbb{D}'(I)) & \xrightarrow[\psi \mapsto \psi \circ u_J]{} & \underline{\mathsf{Hom}}(\mathbb{D}(J),\mathbb{D}'(I)) \end{array} \tag{2}$$

et la commutativité de (1) signifie la commutativité de (2) *pour les objets*. Mais bien sûr on la veut aussi pour les flèches, *i.e.* on veut la commutativité du diagramme (2). [5]

Sans doute on veut un peu plus sur les morphismes de dérivateurs - on veut une commutation aux f_* et (?) aux $f_!$ (cette fois seulement à isomorphisme canonique près) ... [6]

5. Donner l'exemple de morphisme de dérivateurs défini par un foncteur de catégories de modèles $(\mathcal{M}, \Sigma) \to (\mathcal{M}', \Sigma')$.

6. Commutation à f_* (resp. $f_!$) morphisme *exact à gauche* (resp. *exact à droite*). Les morphismes *exacts* sont ceux à la fois exacts à gauche et à droite.

Commentary · Exposition [ms. 14]

Morphisms and their comparison maps

A morphism between the entire families of coefficient categories must respect restriction, including its dependence on natural transformations of indexing functors. The square (2) is the condition that is lost if one checks only the individual functors in square (1). In modern treatments one normally allows coherent invertible comparison maps

$$\gamma_f : f^*_{\mathbb{D}'} u_J \xrightarrow{\sim} u_I f^*_{\mathbb{D}}$$

rather than demanding strict equality. The coherence conditions concern identity functors, composites, and natural transformations. Modifications between such pseudonatural morphisms provide the 2-cells. A functor of relative categories preserving weak equivalences gives an example by applying it at every component and then localizing; no preservation of Kan extensions follows merely from this construction.

Adjunction does give canonical comparison maps, with precisely the orientations on manuscript pp. 15–16. For the right Kan extension the map is the composite

$$\begin{aligned} u_J f_*^{\mathbb{D}} &\longrightarrow f_*^{\mathbb{D}'} f^*_{\mathbb{D}'} u_J f_*^{\mathbb{D}} \\ &\xrightarrow{f_*^{\mathbb{D}'} \gamma_f f_*^{\mathbb{D}}} f_*^{\mathbb{D}'} u_I f^*_{\mathbb{D}} f_*^{\mathbb{D}} \longrightarrow f_*^{\mathbb{D}'} u_I . \end{aligned}$$

The outer arrows are the unit in $\mathbb{D}'$ and the counit in $\mathbb{D}$. The left Kan comparison $f_!^{\mathbb{D}'} u_I \to u_J f_!^{\mathbb{D}}$ is the adjoint of

$$u_I \longrightarrow u_I f^*_{\mathbb{D}} f_!^{\mathbb{D}} \xrightarrow{\gamma_f^{-1}} f^*_{\mathbb{D}'} u_J f_!^{\mathbb{D}} .$$

An invertible restriction comparison need not have an invertible mate. Preservation of limits or colimits is the additional assertion that the corresponding mates are invertible. These definitions also explain which comparison is meant; an unspecified isomorphism of the two functors is not sufficient.

In the manuscript, left and right exactness at this point mean preservation of all the relevant right and left Kan extensions. Modern "exact morphism of stable derivators" usually refers to finite homotopy limits and colimits. Stability makes the two finite notions coincide; it does not equate preservation of arbitrary products and coproducts. For example, derived tensor product with $\mathbb{Q}$ is exact on $D(\mathbb{Z})$ and preserves coproducts. The map

$$\mathbb{Q} \otimes \prod_{n \geq 1} \mathbb{Z} \longrightarrow \prod_{n \geq 1} \mathbb{Q}$$

is not surjective: an element on the left has a common denominator, whereas $(1/n!)_{n \geq 1}$ does not. The footnote about triangulated categories is correct in its finite setting and should not be promoted to an assertion about arbitrary Kan extensions. For model categories, a right Quillen adjoint yields a derived morphism preserving homotopy limits, with the dual statement for a left Quillen adjoint; Cisinski (2003, Proposition 6.12 and its dual) provide the relevant construction.

p. 12
[page 15]

Par exemple, considérons le dérivateur

$$\mathsf{HOTAB}$$

dont la catégorie fondamentale est Hotab, la sous-catégorie pleine de la catégorie dérivée $\mathsf{Der}(\mathsf{Ab})$ de Ab, formée des complexes à cohomologie nulle en degré > 0. On peut décrire HOTAB par la catégorie de modèles $\underline{\mathsf{Hom}}(\mathbf{\Delta}^\circ, \mathsf{Ab})$ des groupes abéliens semi-simpliciaux, avec comme équivalences les quasi-isomorphismes au sens habituel. Le "foncteur abélianisation" canonique

$$\mathsf{Hot} \longrightarrow \mathsf{Hotab}$$

se prolonge en un morphisme de dérivateurs

$$\mathsf{HOT} \longrightarrow \mathsf{HOTAB} \quad .$$

La question de sa compatibilité aux f_* ne semble pas tautologique. Elle impliquerait, par exemple, que si

$$\begin{array}{ccc} X & \xleftarrow{g} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow[j]{} & Y' \end{array}$$

est un diagramme cartésien dans $\mathcal{M} = \underline{\mathsf{Hom}}(\mathbf{\Delta}^\circ, \mathcal{E}ns)$ avec f une fibration (de Thom dans le cadre des espaces topologiques, avec f par exemple fibration localement triviale) alors le diagramme de Hotab

$$\begin{array}{ccc} \mathbb{R}\Gamma_!(X) & \longleftarrow & \mathbb{R}\Gamma_!(X') \\ \downarrow & & \downarrow \\ \mathbb{R}\Gamma_!(Y) & \longleftarrow & \mathbb{R}\Gamma_!(Y') \end{array}$$

est hot-cartésien[7]. Et de même pour une hot-somme amalgamée (carrée hot-cocartésien dans Hot).
Si c'est vrai, et pas connu de plus, ce serait quand même scandaleux! [page 16]

Commentary · Examples [ms. 15]

Abelianization preserves homotopy colimits

The model for HOTAB is simplicial abelian groups. Normalization identifies these with nonnegative chain complexes, or equivalently cochain complexes in nonpositive degrees; see The Stacks Project Authors (2026c, Theorem 14.24.3, Tag 019D). Its homotopy category is $D^{\leq 0}(\mathsf{Ab})$. This is an additive, pointed theory, but it is not stable: suspension need not be invertible inside the connective category. Consequently one must not infer preservation of homotopy limits from an additive appearance.

The morphism from spaces is induced by the degreewise free abelian group functor $\mathbb{Z}[-]$. It is left adjoint to the forgetful functor on simplicial objects. The latter preserves fibrations and trivial fibrations in the standard model structures, so this is a Quillen adjunction. Its derived left adjoint preserves homotopy colimits, including the homotopy pushouts in the last sentence of manuscript p. 15. That sentence therefore has a positive answer, although the preceding pullback assertion does not. Under normalization, this is the usual chain construction, with its coherent diagram version.

A finite discrete counterexample makes the failure of the pullback assertion explicit. Let $X = Y' = \{0, 1\}$ and $Y = *$, so $X' = X \times Y'$ has four points. All objects are Kan complexes and the maps to the point are fibrations. After abelianization the square has upper left and lower right terms $\mathbb{Z}^2$, lower left term $\mathbb{Z}$, and upper right term $\mathbb{Z}^4$. Each map $\mathbb{Z}^2 \to \mathbb{Z}$ is augmentation. Since these maps are surjective, their ordinary pullback computes their homotopy pullback in simplicial abelian groups, and it is

$$\{(a_0, a_1, b_0, b_1) \in \mathbb{Z}^4 : a_0 + a_1 = b_0 + b_1\} \cong \mathbb{Z}^3.$$

The comparison from the chains of X' sends the basis vector e_{ij} to (e_i, e_j). Its kernel is generated by

$$e_{00} - e_{01} - e_{10} + e_{11}.$$

It is therefore not an isomorphism. This proves the correction in footnote 7 while keeping separate the valid colimit statement. Already the terminal-object test would rule out continuity, since $\mathbb{Z}[*] = \mathbb{Z}$ and the terminal simplicial abelian group is zero, but the displayed example addresses exactly the nonempty square that Grothendieck is discussing.

En procédant comme pour les morphismes de changements de base pour les Rf_*, on trouve en tout cas un morphisme canonique, pour $f : I \to J$

$$u_J f_*^{\mathbb{D}} \longrightarrow f_*^{\mathbb{D}'} u_I$$

7. C'est faux déjà si Y est l'espace ponctuel : trivialement le $\mathbb{R}\Gamma_!$ ne transforme pas produits en sommes! Ce foncteur est sûrement [pas] "exact à gauche" (comme morphisme de dérivateurs).

et de même p. 13

$$f_!^{\mathbb{D}'} u_I \longrightarrow u_J f_!^{\mathbb{D}} \quad ,$$

et la question est de savoir si c'est des isomorphismes. Questions analogues pour les $f^!$, pour f immersion fermée (ou pour $f^?$, pour f immersion ouverte). Comme la notion de morphisme de dérivateurs devrait quand même "coller" à la notion bien connue de morphisme (triangulé) de catégories triangulées [8], donc être exact en un sens convenable, cela montre bien que l'on doit exiger la commutation d'un morphisme de dérivateurs aux f_* et aux $f_!$. [9] Je devrais demander à Thomason s'il a regardé, pour un morphisme

$$\mathcal{M} \longrightarrow \mathcal{M}'$$

entre catégories de modèles, qui soit disons *exact à gauche*, et "compatible" avec les équivalences, fibrations (et cofibrations (???)).

Notation : DER pour la 2-catégorie des *dérivateurs.*

Dualité. Si $\mathbb{D}$ est un dérivateur, on va définir un dérivateur *dual* $\mathbb{D}^\circ$ par [page 17]

$$\mathbb{D}^\circ(I) \overset{\text{déf}}{=} \mathbb{D}(I^\circ)^\circ \quad .$$

Les coefficients sur I de type $\mathbb{D}^\circ$ sont les coefficient sur la catégorie opposée I° à I de type $\mathbb{D}$, et en tant que catégorie c'est la catégorie *opposée* de celle des coefficients de type $\mathbb{D}$ sur I°. Pour définir la loi 2-fonctorielle, on note que pour I, J dans Dia on a

$$\begin{array}{ccc} \underline{\mathsf{Hom}}(I,J)^\circ & \xrightarrow{\mathbb{D}_{I,J}} & \underline{\mathsf{Hom}}(\mathbb{D}(J),\mathbb{D}(I)) \\ \wr\downarrow \text{dualité} & & \wr\downarrow \text{dualité} \\ \underline{\mathsf{Hom}}(I^\circ,J^\circ) & \xrightarrow{\theta} & \underline{\mathsf{Hom}}(\mathbb{D}(J)^\circ,\mathbb{D}(I)^\circ)^\circ \end{array} \quad ,$$

où θ est l'unique foncteur rendant le diagramme commutatif. Alors θ°est un foncteur

$$\underline{\mathsf{Hom}}(I^\circ,J^\circ)^\circ \longrightarrow \underline{\mathsf{Hom}}(\mathbb{D}(J)^\circ,\mathbb{D}(I)^\circ) \quad ,$$

c'est ça par définition $\mathbb{D}^\circ_{I,J}$ [plutôt $\mathbb{D}^\circ_{I^\circ,J^\circ}$].

Si $\mathbb{D}$ est défini par $(\mathcal{M},\Sigma)$, alors $\mathbb{D}^\circ$ par $(\mathcal{M}^\circ,\Sigma^\circ)$, puisque

$$(\mathcal{M}^\circ)_I \overset{\text{déf}}{=} \underline{\mathsf{Hom}}(I^\circ,\mathcal{M}^\circ) \simeq \underline{\mathsf{Hom}}(I,\mathcal{M})^\circ \simeq (\mathcal{M}_{I^\circ})^\circ$$

et $\Sigma^\circ{}_I$ est déduit de Σ_{I°, d'où p. 14

$$(\mathcal{M}^\circ)_I(\Sigma^\circ{}_I)^{-1} \simeq (\mathcal{M}_{I^\circ}\Sigma_{I^\circ}^{-1})^\circ = \mathbb{D}(I^\circ)^\circ \quad .$$

[page 18]

Commentary · Later developments [ms. 17]

What the whole diagram theory remembers

A modern comparison makes precise the extra information carried by the variable I. For an ∞-category $\mathcal{C}$, define, in the convention of this manuscript,

$$\mathbb{D}_{\mathcal{C}}(I) = h\,\mathrm{Fun}(N(I)^{\mathrm{op}},\mathcal{C}).$$

Here N is the nerve and h takes the homotopy category. One first forms coherent diagrams and then passes to homotopy; reversing these operations would give $\mathrm{Fun}(I^{\mathrm{op}},h\mathcal{C})$, which is generally different. Restriction and its natural transformations supply the prederivator structure. If $\mathcal{C}$ has all small

8. Non! Le cas des catégories triangulées est "misleading", car pour celles-ci l'exactitude à gauche et à droite revient au même.

9. N.B. On conçoit qu'un foncteur entre dérivateurs puisse être exact à gauche ou exact à droite ou les deux.

limits and colimits, its pointwise Kan extensions supply the two adjoints and the comma-square formula. Riehl and Verity (2017, §5.3, especially Proposition 5.3.9 and Remark 5.3.10) explain this passage using the homotopy 2-category of an ∞-cosmos. Their convention uses covariant diagrams; replacing I by I^{op} yields the formula above.

The formula also clarifies the philosophical remark on manuscript page 18. Passing to $\mathbb{D}(e) = h\mathcal{C}$ discards most of the indexing variable. Retaining the entire prederivator can retain much more. Arlin (2020, Theorem 19 and Corollary 20) proves a fully faithful embedding using strict transformations and the specified simplicial enrichment. With pseudonatural transformations, his Theorem 29 gives a bicategorically fully faithful embedding for *small* quasicategories when the domain contains all small categories. The size hypothesis, the domain, and the kind of transformation belong to the theorem; none can be silently omitted. In the model-category setting, Renaudin (2009, Theorems 3.3.2 and 3.4.4) obtains the corresponding local equivalence, and then a biequivalence with derivators of small presentation, from left proper combinatorial model categories localized at Quillen equivalences, with adjunctions as morphisms.

These results concern the entire diagram theory. They do not assert that every functor $h\mathcal{C} \to h\mathcal{E}$ admits a coherent lift, or that a lift is determined by its value at e. Nor does an objectwise description of a prederivator by localized diagram categories dispense with the proof of its Kan-extension axioms. The comparison is useful precisely because it keeps three questions separate: existence of coherent diagrams, existence of homotopy Kan extensions, and reconstruction of an enhanced category from all its diagram categories. Grothendieck's successive shifts $\mathbb{D}_I$ belong to this richer level of information.

Philosophie. Chaque fois qu'on a un foncteur

$$\mathcal{A} \xrightarrow{u_0} \mathcal{A}'$$

entre deux catégories qui peuvent s'interpréter naturellement comme les catégories fondamentales de deux dérivateurs $\mathbb{D}$, $\mathbb{D}'$, il se pose la question d'interpréter u_0 comme provenant d'un morphisme de dérivateurs

$$\mathbb{D} \xrightarrow{u} \mathbb{D}' \quad .$$

Celui-ci est, en pratique, toujours déterminé canoniquement, à isomorphisme canonique près. (Mais je doute pourtant que le foncteur restriction aux catégories fondamentales

$$\underline{\mathsf{Hom}}(\mathbb{D}, \mathbb{D}') \longrightarrow \underline{\mathsf{Hom}}(\mathcal{A}, \mathcal{A}')$$

soit pleinement fidèle …)

Commentary · Examples [ms. 18]

A negative answer to the evaluation question

For unrestricted morphisms of derivators, the doubt about full faithfulness can be answered within the elementary examples already at hand. Let $A = [1]$ and let $\mathscr{R}(I) = \mathrm{Fun}(I^{\mathrm{op}}, A)$. Since the two-element ordered set has all small meets and joins, this represented prederivator is a derivator: its Kan extensions are the ordinary pointwise ones. The represented construction is standard; compare Groth (2013, Examples 1.2(1) and 1.6).

For any prederivator $\mathscr{E}$ in our convention and any $X \in \mathscr{E}(A^{\mathrm{op}})$, define a morphism $U_X : \mathscr{R} \to \mathscr{E}$ as follows. An object $F \in \mathscr{R}(I)$ is a functor $F : I^{\mathrm{op}} \to A$, so $F^{\mathrm{op}} : I \to A^{\mathrm{op}}$, and we set

$$(U_X)_I(F) = (F^{\mathrm{op}})^* X.$$

If $F \Rightarrow G$ is a natural transformation, taking opposites gives $G^{\mathrm{op}} \Rightarrow F^{\mathrm{op}}$; the reversal of 2-cells by $\mathscr{E}$ gives the required map $(U_X)_I(F) \to (U_X)_I(G)$. The composition and restriction laws follow directly from those of $\mathscr{E}$. A map $m : X \to Y$ likewise induces a modification $U_m : U_X \Rightarrow U_Y$ with component $(F^{\mathrm{op}})^* m$ at F.

Now take $\mathscr{E}$ to be the unbounded derived derivator of abelian groups. Its category $\mathscr{E}(A^{\mathrm{op}})$ is the derived category of arrows $0 \to 1$. As in the preceding nonfaithfulness example, the extension

$$0 \to (0 \to \mathbb{Z}) \to (\mathbb{Z} \xrightarrow{1} \mathbb{Z}) \to (\mathbb{Z} \to 0) \to 0$$

yields a nonzero map $m : (\mathbb{Z} \to 0) \to (0 \to \mathbb{Z})[1]$ with both evaluated components zero. Therefore $(U_m)_e$ is the zero natural transformation between the base-category functors. Nevertheless U_m itself is nonzero: at $I = A^{\mathrm{op}}$ and $F = \mathrm{id}_A$, its value is exactly m. Evaluation at e is thus not faithful, and consequently not fully faithful.

This settles the question for the usual category of all pseudonatural morphisms, and already for the strictly natural morphisms just constructed. It does not assert the same counterexample for a subcategory in which every morphism must preserve all left or right Kan extensions. The manuscript is still negotiating that convention. The proof identifies the precise obstruction in the unrestricted case: an entire coherent arrow can carry a morphism which vanishes at each of its two endpoints.

On va appliquer cette philosophie aux foncteurs f^*, $f_!$, f_* (et éventuellement $f^!$, $f^?$), pour $f : I \to J$, donc pour les foncteurs entre $\mathbb{D}(I)$ et $\mathbb{D}(J)$. Cela nous amène donc à regarder $\mathbb{D}(I)$ et $\mathbb{D}(J)$ comme des catégories fondamentales de dérivateurs convenables.

Dérivateur induit par un dérivateur $\mathbb{D}$, sur une catégorie d'indices $I \in \mathsf{Dia}$. C'est un dérivateur $\mathbb{D}_I$ défini par

$$\mathbb{D}_I(J) = \mathbb{D}(I \times J) \quad .$$

Le foncteur associé à $\mathbb{D}_I$, pour deux catégories J, $J' \in \mathsf{Dia}$ [page 19]

$$\underline{\mathsf{Hom}}(J, J')^\circ \xrightarrow{(\mathbb{D}_I)_{J,J'}} \underline{\mathsf{Hom}}(\mathbb{D}_I(J'), \mathbb{D}_I(J)) = \underline{\mathsf{Hom}}(\mathbb{D}(I \times J'), \mathbb{D}(I \times J))$$

est le composé

$$\underline{\mathsf{Hom}}(J, J')^\circ \longrightarrow \underline{\mathsf{Hom}}(I \times J, I \times J')^\circ \xrightarrow{\mathbb{D}_{I\times J, I\times J'}} \underline{\mathsf{Hom}}(\mathbb{D}(I \times J'), \mathbb{D}(I \times J)) \quad ,$$

où la première flèche est le foncteur

$$f \longmapsto \mathsf{id}_I \times f \quad .$$

En d'autres termes, $\mathbb{D}_I$ est le composé

$$\begin{aligned} &\mathsf{Dia}^\circ \longrightarrow \mathsf{Dia}^\circ \xrightarrow{\mathbb{D}} \mathcal{C}at \\ &J \longmapsto I \times J \qquad . \end{aligned}$$

On a

$$f^*_{\mathbb{D}_I} = (\mathsf{id} \times f)^*_{\mathbb{D}} \quad .$$

Si les f_* (resp. les $f_!$) existent pour $\mathbb{D}$, ils existent pour $\mathbb{D}_I$. (De même pour toute espèce de multiadjoints.) Comme $J \mapsto I \times J$ transforme immersion fermée (resp. ouverte) en itou, l'axiome $\mathbf{Der}_2$ (plus précisément, chacun de ces ingrédients, *cf.* annotations marginales p. 7) est stable par passage de $\mathbb{D}$ à $\mathbb{D}_I$. De même pour $\mathbf{Der}_3$. (Pour chaque nouvel axiome qu'on dégagera, il faudra vérifier la stabilité.)

Commentary · Exposition [ms. 19]

Duality and the change of coefficient category

The two opposites in $\mathbb{D}^{\mathrm{op}}(I) = \mathbb{D}(I^{\mathrm{op}})^{\mathrm{op}}$ have distinct roles. The first reverses the direction of the indexing arrows; the second reverses arrows between coefficient objects. Both are needed to obtain another prederivator with the same variance convention. In a model presentation this is the canonical identification

$$\mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M}^{\mathrm{op}}) \cong \mathrm{Fun}(I, \mathcal{M})^{\mathrm{op}},$$

followed by localization. Localization commutes with taking opposites by its universal property: a functor inverting the selected arrows on either side is exactly the opposite of such a functor on the other side. Thus the dual model statement is proved by the displayed argument. The incorrect indices in the definition of the dual action on Hom categories are already corrected by the editors.

The shift $\mathbb{D}_I(J) = \mathbb{D}(I \times J)$ changes which objects count as coefficients. An entire coherent I-diagram now becomes a single coefficient, and a coherent J-diagram of such coefficients is an object over $I \times J$. At the level of a relative category this is the elementary exponential law

$$(\mathcal{M}^{I^{\mathrm{op}}})^{J^{\mathrm{op}}} \cong \mathcal{M}^{(I\times J)^{\mathrm{op}}},$$

with exactly the same objectwise weak equivalences. This is why the shift is intrinsic to the proposed language: it permits an argument about one coefficient to be reapplied to a family with parameters.

The preliminary stability checks on p. 19 are valid for the axioms already written. Products preserve sieves and cosieves. Adjoints to $(\mathrm{id}_I \times f)^*$ are supplied by the corresponding adjoints in $\mathbb{D}$, and the conservativity argument uses evaluation at each (i, j). The full pointwise Kan-extension axiom still needs a separate verification. In the completed theory this is the shift theorem, Groth (2013, Theorem 1.25); it is not an unproved additional assumption about an arbitrary family.

Likewise the candidate components $(f \times \mathrm{id}_J)_!$ and $(f \times \mathrm{id}_J)_*$ on p. 20 do not constitute a morphism of derivators merely by being written down. One must show that their comparison maps for changes of J are invertible and satisfy coherence. The product base-change squares supply this, and the coherence follows from the calculus of mates. Restriction is strictly natural before choices of identifications, whereas adjoint extensions are naturally pseudonatural. The following pages are devoted to precisely these exchange maps. It is appropriate to call the present construction a sketch awaiting those checks, not an error in the definition of the shift.

Soit

$$f : I \longrightarrow I' \quad .$$

Considérons entre $\mathbb{D}(I)$, $\mathbb{D}(I')$ les foncteurs

$$\mathbb{D}(I) \;\underset{\xrightarrow[f_*]{}}{\overset{\xrightarrow{f_!}}{\xleftarrow{f^*}}}\; \mathbb{D}(I')$$

(sous réserve d'existence des f_* resp. $f_!$). Peut on les interpréter en termes de morphismes de dérivateurs

$$\mathbb{D}_I \;\underset{\xrightarrow[\overline{f_*}]{}}{\overset{\xrightarrow{\overline{f_!}}}{\xleftarrow{\overline{f^*}}}}\; \mathbb{D}_{I'} \qquad ?$$

Donc il faut définir, pour J dans Dia, des foncteurs correspondants entre $\mathbb{D}_I(J)$ et $\mathbb{D}_{I'}(J)$, *i.e.* entre $\mathbb{D}(I \times J)$ et $\mathbb{D}(I' \times J)$. Or on a bien

$$f \times \mathsf{id}_J : I \times J \longrightarrow I' \times J$$

et on posera (sous réserve d'existence des deux derniers)

$$\begin{cases} \overline{f^*}(J) = (f \times \mathsf{id}_J)^*_{\mathbb{D}} \\ \overline{f_!}(J) = (f \times \mathsf{id}_J)^{\mathbb{D}}_! \\ \overline{f_*}(J) = (f \times \mathsf{id}_J)^{\mathbb{D}}_* \quad . \end{cases}$$

Autrement dit, on peut considérer

[page 21]

$$\mathsf{Dia} \ni I \longmapsto \mathbb{D}_I \quad , \qquad \mathbb{D} \in \mathsf{DER} \quad ,$$

comme fonctoriel en I de trois façons (une contravariante, les deux autres covariantes), suivant qu'on utilise les f^*, les $f_!$ (s'ils existent) ou les f_* (s'ils existent). On désignera par

$$f^{\mathbb{D}}_! \quad , \qquad f^*_{\mathbb{D}} \quad , \qquad f^{\mathbb{D}}_*$$

indifféremment les foncteurs entre $\mathbb{D}(I)$ et $\mathbb{D}(I')$ ou (de façon plus fine) entre $\mathbb{D}_I$ et $\mathbb{D}_{I'}$, dont les précédents se déduisent en passant aux catégories fondamentales correspondantes. De même pour $f^!$ ou pour $f^?$ sous réserve d'existence. Par exemple, si on suppose que les $f^!$ existent pour $\mathbb{D}$, quel que soit f immersion fermée, alors on trouve pour un tel f un morphisme de dérivateurs

$$\mathbb{D}_I \xleftarrow{f^!_{\mathbb{D}}} \mathbb{D}_{I'} \quad .$$

Il s'impose de regarder si tous ces morphismes de dérivateurs sont exacts, *i.e.* si pour

$$g : J \longrightarrow J'$$

dans Dia, ils commutent à $g_!$, g_*.

Pour expliciter cette question, on est amenés à regarder le diagramme de catégories

p. 16
[page 22 vide]
[page 23]

$$\begin{array}{ccc} I \times J & \xrightarrow{G=\mathsf{id}_I \times g} & I \times J' \\ {\scriptstyle F=f\times \mathsf{id}_J}\downarrow & & \downarrow{\scriptstyle F'=f\times \mathsf{id}_{J'}} \\ I' \times J & \xrightarrow{G'=\mathsf{id}_{I'}\times g} & I' \times J' \end{array} \quad ,$$

qui est d'ailleurs un carré cartésien dans $\mathcal{C}at$. La commutativité de $f^*_{\mathbb{D}}$ aux g_* s'explicite alors par la commutativité dans

$$\begin{array}{ccc} \mathbb{D}(I \times J) & \xrightarrow{G_*} & \mathbb{D}(I \times J') \\ {\scriptstyle F^*}\uparrow & \overset{\text{iso?}}{\nwarrow} & \uparrow{\scriptstyle F'^*} \\ \mathbb{D}(I' \times J) & \xrightarrow{G'_*} & \mathbb{D}(I' \times J') \end{array} \quad .$$

Cette commutativité sera assurée par des axiomes ultérieures sur les dérivateurs. (cf. plus bas page 59). Ainsi, $f^*_{\mathbb{D}}$ est exact à droite `[plutôt à gauche]`, et dualement, il doit être aussi exact à gauche `[plutôt à droite]`. Donc $f^*_D : \mathbb{D}_{I'} \to \mathbb{D}_I$ est *exact*. Considérons $f^{\mathbb{D}}_*$, cette fois c'est la commutativité de

$$\begin{array}{ccc} \mathbb{D}(I \times J) & \xrightarrow{G_*} & \mathbb{D}(I \times J') \\ {\scriptstyle F_*}\downarrow & & \downarrow{\scriptstyle F'_*} \\ \mathbb{D}(I' \times J) & \xrightarrow{G'_*} & \mathbb{D}(I' \times J') \end{array} \quad ,$$

c'est trivial (à isomorphisme canonique près). Ainsi, on trouve que $f^{\mathbb{D}}_* : \mathbb{D}_I \to \mathbb{D}_{I'}$ est *exact à gauche*, et dualement $f^{\mathbb{D}}_!$ est *exact à droite.* Mais est-ce que $f^{\mathbb{D}}_*$ est aussi exact à *droite*? Cela signifie donc commutativité de [page 24]

$$\begin{array}{ccc} \mathbb{D}(I \times J) & \xrightarrow{G_!} & \mathbb{D}(I \times J') \\ {\scriptstyle F_*}\downarrow & & \downarrow{\scriptstyle F'_*} \\ \mathbb{D}(I' \times J) & \xrightarrow[G'_!]{} & \mathbb{D}(I' \times J') \end{array} \quad .$$

Commentary · Exposition [ms. 23]

Three different interchange questions

The extra variable in a shifted derivator is a parameter. An object of $\mathbb{D}(I \times J)$ is therefore a coherent I-family of coherent J-diagrams; it is not, in general, merely a functor from I° to $\mathbb{D}(J)$. Keeping the two variables coherent makes the question on these pages well posed. There are three operations to compare: restriction in one variable with a Kan extension in the other; two right, or two left, Kan extensions; and a right Kan extension with a left Kan extension. Only the last comparison introduces a new exactness condition.

Here is the pointwise mechanism for the first comparison. For a projection in the J-direction, the slice occurring in its right Kan formula at (i, j') has the form

$$(I/i) \times (g/j').$$

The first factor has terminal object $(i, 1_i)$. Since our diagrams are contravariant, taking cohomology in that factor amounts to evaluating at this terminal object. Consequently the value is the right Kan formula in the J-variable applied to the i-th fibre. The same calculation with i replaced by $f(i)$ gives the restriction comparison. Der 2 promotes these pointwise isomorphisms to an isomorphism of coherent diagrams. The dual argument treats left Kan extensions. This is the content of Groth (2013, Proposition 2.5), in the convention of covariant diagrams.

For the second comparison, no pointwise calculation is necessary. Restriction around the product square agrees in either order. The two composites of right adjoints are therefore right adjoint to the same functor, and uniqueness of an adjoint gives their canonical isomorphism. The left-adjoint assertion is identical. These are the derivator forms of Fubini's rule for limits and for colimits.

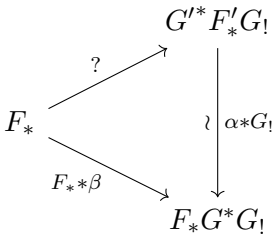
For the mixed comparison there is still a canonical map, in the direction

$$G'_! F_* \longrightarrow F'_* G_!,$$

but no formal argument makes it invertible. Its construction uses a unit, the already established restriction comparison, and an adjunction. The asymmetry of its direction is meaningful: it is the familiar comparison from a colimit of limits to a limit of colimits. The source's provisional word *exact* means preservation of all the Kan extensions available in the chosen domain. This is stronger than the finite exactness used in modern treatments of stable derivators. The distinction is needed before reading the subsequent appeal to triangulated categories.

On arrive bien à définir p. 17

$$G'_! F_* \xrightarrow{?} F'_* G_!$$



ou ce qui revient au même par adjonction

$$F_* \xrightarrow{?} G'^* F'_* G_!$$

en utilisant le morphisme de changement de base

$$G'^* F'_* \xrightarrow{\alpha}_{\sim} F_* G^*$$

qui est [un] *isomorphisme* (on l'a vu), d'où

où $\beta : \mathsf{id} \to G^* G_!$ est le morphisme d'adjonction, d'où le morphisme voulu. (On peut aussi chercher $F'^*(G'_! F_*) \to G_!$, et utiliser la commutation $G_! F^* \xrightarrow{\sim} F'^* G'_!$, *i.e.* l'exactitude à *droite* de $f^*_{\mathbb{D}}$.) [page 25]

Mais ce morphisme est-il un isomorphisme? Je pense que dans le cas additif ça peut être raisonnable, mais dans le cas non additif ça n'a aucune raison d'être vrai. On voit en tout cas que si pour tout $f : I \to I'$ dans Dia, $f_*^{\mathbb{D}} : \mathbb{D}_I \to \mathbb{D}_{I'}$ est (non seulement exact à gauche mais aussi) exact à droite, alors pour tout $g : J \to J'$ dans Dia, $g_!^{\mathbb{D}}$ est (non seulement exact à droite mais même) exacte à gauche.

Prenons le dérivateur des préfaisceaux d'ensembles sur des I variables, sa catégorie fondamentale est $\mathcal{E}ns$. C'est un dérivateur non ponctué. Considérons $I \to I'$ une immersion fermée non surjective, $f_* : \mathbb{D}(I) \to \mathbb{D}(I')$. Si $f_*^{\mathbb{D}}$ était exact à droite f_* devrait transformer objet initial de $\mathbb{D}(I)$ en objet initial de $\mathbb{D}(I')$, sauf erreur (*cf.* plus bas). Or il n'en est rien, puisque pour tout $F \in \mathsf{Im}\big(f_*^{\mathbb{D}} : \mathbb{D}(I) \to \mathbb{D}(I')\big)$ la restriction de F à $I' \setminus I$ est le faisceau final $e_U = (i \mapsto e)$, et non le faisceau initial $\emptyset_U = (i \mapsto \emptyset)$.

On va prouver ceci :

Proposition. *Si $\mathbb{D}$ est un dérivateur à gauche (à droite), alors les produits finis (sommes finies) existent dans les $\mathbb{D}(I)$. Tout morphisme $\varphi : \mathbb{D} \to \mathbb{D}'$ de dérivateurs qui est exact à gauche (à droite) commute aux dits produits (sommes), chaque I donnant $\varphi(I) : \mathbb{D}(I) \to \mathbb{D}'(I)$. En particulier, il transforme objet final (initial) en itou.*

p. 18
[page 26]

Commentary · Examples [ms. 25]

The empty shape and finite products

The simplest test for a claim about preservation of all homotopy colimits is the empty diagram. If $i : Y \hookrightarrow X$ is a proper closed inclusion of index categories, then in the represented derivator of sets i_* extends a presheaf by the terminal set outside Y. Thus $(i_*\varnothing_Y)_x = \{*\}$ for $x \notin Y$, whereas $(\varnothing_X)_x = \varnothing$. A right adjoint can preserve every limit and still fail this first colimit test.

The finite-product proposition uses a different feature of derivators: discrete coherent diagrams carry no hidden coherence. For a finite set S, Der 1 identifies

$$\mathbb{D}(I \times S) \simeq \prod_{s \in S} \mathbb{D}(I).$$

Restriction along $\pi : I \times S \to I$ becomes the diagonal. Its right adjoint π_* is therefore the ordinary product in the category $\mathbb{D}(I)$: for (F_s) and E the adjunction reads

$$\mathrm{Hom}(E, \pi_*(F_s)) \cong \prod_{s \in S} \mathrm{Hom}(E, F_s).$$

This proves the assertion including $S = \varnothing$, when the right-hand set is a singleton. The left-adjoint calculation gives coproducts. A morphism preserving the corresponding Kan extensions preserves these ordinary products or coproducts because it identifies their representing adjunctions. This argument explains exactly why the empty-diagram test is available. The phrase "adjoint à gauche" at the beginning of manuscript page 26 is an edition-preserved slip: for products it must be a right adjoint, as the same paragraph subsequently says.

Dire que les produits finis indexés par l'ensemble fini I existent dans la catégorie $\mathcal{A} = \mathbb{D}(e)$ (disons) équivaut à dire que le foncteur diagonal

$$\mathcal{A} \xrightarrow{\Delta} \mathcal{A}^I$$

admet un adjoint à gauche. Or si

$$f : I \to e$$

est la projection de I (considéré comme ensemble ordonné discret) sur l'ensemble ordonné ponctuel e, le foncteur Δ s'identifie à $f^* : \mathbb{D}(e) \to \mathbb{D}(I)$ (grâce à l'axiome $\mathbf{Der}_2$ sur le comportement du dérivateur pour une somme discrète de catégories d'indices). Donc l'existence du produit revient à celle de l'adjoint à droite f_* de f^*, OK pour dérivateur à gauche. Et un homomorphisme exact à gauche de dérivateurs à gauche, comme il commute aux f_*, commute aux produits finis. Itou pour les sommes finies, et les dérivateurs à droite.

L'exemple précédent utilise le fait que le dérivateur envisagé n'est pas ponctué. Mais même pour un dérivateur ponctué $\mathbb{D}$, un morphisme $f_*^{\mathbb{D}} : \mathbb{D}_I \to \mathbb{D}_{I'}$ n'est pas forcément exact à droite. Si on prend le dérivateur associé à une catégorie $\mathcal{M}$ quelconque (avec $\Sigma = \emptyset$),

$$\mathbb{D}_{\mathcal{M}}(I) = \underline{\mathsf{Hom}}(I^\circ, \mathcal{M}) \overset{\text{déf}}{=} \mathcal{M}(I)$$

alors le dérivateur induit

$$(\mathbb{D}_{\mathcal{M}})_I = \{J \mapsto \mathbb{D}_{\mathcal{M}}(I \times J) = \underline{\mathsf{Hom}}((I \times J)^\circ, \mathcal{M}) \simeq \underline{\mathsf{Hom}}(J^\circ, \underline{\mathsf{Hom}}(I^\circ, \mathcal{M}))\}$$

s'identifie à [page 27]

$$\mathbb{D}_{\underline{\mathsf{Hom}}(I^\circ, \mathcal{M})} = \mathbb{D}_{\mathcal{M}(I)}$$

i.e.

$$(\mathbb{D}_{\mathcal{M}})_I = \mathbb{D}_{\mathcal{M}(I)}$$

N.B. Ici $\mathcal{M}$ et $\mathbb{D}_{\mathcal{M}}$ se déterminent mutuellement et le foncteur

$$\mathcal{M} \longmapsto \mathbb{D}_{\mathcal{M}}$$

$$\mathcal{C}at \longrightarrow \mathsf{DER}$$

est 2-fidèle, *i.e.* si $\mathcal{M}$, $\mathcal{M}'$ sont deux catégories

$$\underline{\mathsf{Hom}}(\mathcal{M}, \mathcal{M}') \xrightarrow{\simeq} \mathsf{Hom}(\mathbb{D}_{\mathcal{M}}, \mathbb{D}_{\mathcal{M}'})$$

est une équivalence de catégories. D'autre part, on vérifie tout de suite que $u : \mathcal{M} \to \mathcal{M}'$ est exact à gauche (ou à droite) si et seulement si $\mathbb{D}_u : \mathbb{D}_{\mathcal{M}} \to \mathbb{D}_{\mathcal{M}'}$ l'est.

Ainsi, pour voir si un morphisme de dérivateurs de la forme

$$f_*^{\mathbb{D}} : \quad \begin{array}{ccc} (\mathbb{D}_{\mathcal{M}})_I & \longrightarrow & (\mathbb{D}_{\mathcal{M}})_{I'} \\ \| & & \| \\ \mathbb{D}_{\mathcal{M}(I)} & & \mathbb{D}_{\mathcal{M}(I')} \end{array}$$

est exact à *droite,* il revient au même de dire

que le foncteur pour les catégories fondamentales associées [p. 19] [page 28]

$$\mathcal{M}(I) \xrightarrow{f_*^{\mathcal{M}}} \mathcal{M}(I')$$

est exact à droite. Or ici c'est un foncteur image directe de préfaisceaux ordinaires, et ce foncteur n'a aucune envie d'être exact à *droite.* (Même si $\mathcal{M}$ est *abélienne*, d'ailleurs!) Prenons par exemple pour $f : I \hookrightarrow I'$ une immersion ouverte avec $I' = \mathbf{\Delta}_1 \times \mathbf{\Delta}_1$, $I = I' - \{c\}$, c objet final de I'

$$I' = \begin{array}{ccc} c & \longleftarrow & b \\ \uparrow & & \uparrow \\ a & \longleftarrow & 0 \end{array} \qquad I = \begin{array}{ccc} & & b \\ & & \uparrow \\ a & \longleftarrow & 0 \end{array}$$

Le foncteur f_* est celui qui associe à un diagramme

$$F = \left\{ \begin{array}{ccc} & & F_b \\ & & \downarrow \\ F_a & \longrightarrow & F_0 \end{array} \right\}$$

le carré cartésien complété

$$\overline{F} = \left\{ \begin{array}{ccc} F_a \times_{F_0} F_b & \longrightarrow & F_b \\ \downarrow & & \downarrow \beta \\ F_a & \xrightarrow{\alpha} & F_0 \end{array} \right\}$$

Or si $F \mapsto \overline{F}$ était exact à droite, $F \mapsto F_a \times_{F_0} F_b$ le serait aussi. Or $F_a \times_{F_0} F_b = K(F) = \mathsf{Ker}(F_a \times F_b \xrightarrow{\alpha pr_1 - \beta pr_2} F_0)$, en tant que foncteur additif en F, n'est pas exact à droite, par exemple il ne transforme pas nécessairement épimorphisme en épimorphisme. Prenons par exemple

$$F' = \left\{ \begin{array}{ccc} & & F_b \\ & & \downarrow \\ F_a & \longrightarrow & 0 \end{array} \right\}$$

et l'homomorphisme évident $F \to F'$ qui est l'identité sur F_a et sur F_b. C'est un épimorphisme et l'homomorphisme correspondant $\overline{F} \to \overline{F'}$ est l'inclusion [page 29]

$$F_a \times_{F_0} F_b \longrightarrow F_a \times F_b$$

qui n'est un épimorphisme que si $\alpha = \beta = 0$.

Commentary · Exposition [ms. 27]

What represented prederivators remember

For a category $\mathcal{M}$, the assignment $\mathbb{D}_{\mathcal{M}}(I) = \mathrm{Fun}(I^\circ, \mathcal{M})$ is always a prederivator. The existence of the limits or colimits demanded by the diagram domain is needed before calling it a derivator. Its shift is represented by another ordinary category because currying gives

$$\mathrm{Fun}((I \times J)^\circ, \mathcal{M}) \cong \mathrm{Fun}(J^\circ, \mathrm{Fun}(I^\circ, \mathcal{M})).$$

Both sides carry the same objects, maps and composition laws after currying; the identification commutes with restriction in J and hence identifies the prederivators, rather than only their separate values.

The fully faithful assertion about categories and represented prederivators can also be made explicit. A functor $u : \mathcal{M} \to \mathcal{M}'$ acts by postcomposition at every shape. Conversely, let $\Phi : \mathbb{D}_{\mathcal{M}} \to \mathbb{D}_{\mathcal{M}'}$ be a pseudonatural morphism and put $u = \Phi_e$. Its pseudonaturality at $i : e \to I$ identifies the i-th value of $\Phi_I(F)$ with $u(F_i)$. For an arrow $i \to j$, the corresponding natural transformation between these point functors makes these identifications commute with the presheaf arrow $F_j \to F_i$. They therefore form a natural isomorphism $\Phi_I(F) \cong uF$. Naturality in F and in changes of shape follows from the coherence conditions for Φ. A modification between two such morphisms is determined, by the same evaluation argument, by its component at e, and every natural transformation $u \Rightarrow v$ extends by postcomposition. This proves the asserted equivalence of hom-categories. With strict morphisms one uses strict naturality instead.

There is a useful qualification to the next assertion. Preservation of *all relevant* limits by u implies preservation of right Kan extensions because these are calculated pointwise by those limits. The converse follows by taking Kan extensions to the point. If the domain contains infinite categories, ordinary finite left exactness of u is not enough. The same qualification applies dually to colimits. Thus the represented example detects a genuine obstruction to the manuscript's strong exactness condition; it does not show that homotopical exactness has failed to remember an elementary property of $\mathcal{M}$.

Perplexité : On devrait pouvoir définir une notion de dérivateur (additif) "*triangulé*" (qui correspondrait à l'intuition des catégories triangulées; c'est un dérivateur satisfaisant à des axiomes assez forts), de sorte que pour les morphismes entre ceux-ci l'exactitude à gauche et l'exactitude à droite soient *équivalentes.* p. 20

"Théorème de changement de base" pour dérivateurs. Soit $\mathbb{D}$ dérivateur à gauche (existence de f_*) et considérons

$$f : I \longrightarrow J \qquad \text{dans } \mathsf{Dia} \quad ,$$

soit $j_0 \in \mathsf{Ob}\ J$, on se propose de "calculer" le foncteur

$$F \mapsto f_*(F)_{j_0} = \alpha_{j_0}^*(f_*(F)) \quad ,$$

où

$$\alpha_{j_0} : e \longrightarrow J$$

est l'inclusion de la catégorie ponctuelle e dans J, de valeur j_0.

Considérons le diagramme [page 30]

$$(1) \qquad \begin{array}{ccc} I/j_0 & \xrightarrow{q} & I \\ {\scriptstyle f'}\downarrow & \swarrow{\scriptstyle \gamma} & \downarrow{\scriptstyle f} \\ e & \xrightarrow[p=\alpha_{j_0}]{} & J \end{array} \quad ,$$

où I/j_0 est la catégorie $I \times_J J/j_0$ des couples

$$\{(i, \varphi) \mid i \in \mathsf{Ob}\ I,\ \varphi : f(i) \to j_0\}$$

et q est le foncteur $(i, \varphi) \mapsto i$. Ce diagramme n'est pas commutatif, mais il y a un foncteur `[plutôt morphisme de foncteurs]` canonique

$$fq \xrightarrow{\gamma} pf' \quad ,$$

où fq est le foncteur $(i, \varphi) \mapsto f(i)$ et pf' le foncteur constant $(i, \varphi) \mapsto j_0$ et où $\gamma(i, \varphi) : f(i) \to j_0$ est défini par $\gamma(i, \varphi) = \varphi$.

Commentary · Examples [ms. 29]

The pullback obstruction, and the finite stable repair

The abelian counterexample can be made numerical. Let the coefficient category be abelian groups and choose

$$F_a = F_0 = \mathbb{Z}, \qquad F_b = 0, \qquad \alpha = 1_{\mathbb{Z}}, \quad \beta = 0.$$

Then $K(F) = \mathbb{Z} \times_{\mathbb{Z}} 0 = 0$. Replace the central value F_0 by zero to obtain F'. The map $F \to F'$ is an epimorphism at each object of the indexing cospan, but $K(F') = \mathbb{Z}$, and the induced map of missing corners is $0 \to \mathbb{Z}$. Hence the right Kan extension fails to preserve epimorphisms and cannot be right exact even in the ordinary finite abelian sense. Every group and every map in this example is visible in the original three-object shape.

The ensuing "Perplexité" points toward stability, with a necessary change in the meaning of exactness. A pointed derivator is stable when its coherent cartesian and cocartesian squares coincide. Between stable derivators a morphism preserving zero objects and cartesian squares therefore preserves cocartesian squares as well, and conversely. This settles the finite version of the question; see Groth (2013, Definition 3.15 and Corollary 4.17). Additivity alone cannot imply stability. In a represented pointed derivator the pushout of $0 \leftarrow A \rightarrow 0$ is always zero, so its suspension functor is zero. If that derivator were stable, suspension would be an equivalence, forcing every object to be zero.

Even stability does not make arbitrary limits commute with arbitrary colimits. Work in the derivator of complexes over a nonzero field k, and regard vector spaces as complexes in degree zero. On the discrete shape $\mathbb{N} \times \mathbb{N}$ put

$$X_{nm} = \begin{cases} k, & n = m, \\ 0, & n \neq m. \end{cases}$$

Products and coproducts of vector spaces are exact, so here their derived values are their ordinary values. The mixed comparison is

$$\bigoplus_m \prod_n X_{nm} = k^{(\mathbb{N})} \longrightarrow \prod_n \bigoplus_m X_{nm} = k^{\mathbb{N}}.$$

It is the inclusion of finitely supported sequences; the sequence $(1, 1, 1, \ldots)$ is absent from its image. This disproves the unrestricted interpretation of the anticipated stable exactness theorem.

The precise positive result is stronger than merely commuting a finite product with a finite sum: in a stable derivator homotopy finite limits commute with arbitrary homotopy colimits, and dually. A homotopy finite category is equivalent to a finite skeletal category with no nonidentity endomorphisms; finiteness of the underlying set of arrows alone is insufficient. The equivalence of this commutation property with stability is proved in Groth and Shulman (2017, Theorem 2.14). It identifies the exact boundary between the true stable intuition and the stronger interchange asked for on these pages.

Plus généralement, considérons un diagramme dans Dia

(2)
$$\begin{array}{ccc} I' & \xrightarrow{q} & I \\ {\scriptstyle f'}\downarrow & \swarrow{\scriptstyle \gamma} & \downarrow{\scriptstyle f} \\ J' & \xrightarrow[p]{} & J \end{array} \quad ,$$

avec $\gamma : fq \to pf'$. On définit alors un *morphisme de changement de base pour les images directes* relatif à ce diagramme p. 21

$$p^* f_* \xrightarrow{c_\gamma} f'_* q^*$$

de deux façons, qui donnent le même résultat (histoire générale de foncteurs adjoints à expliciter une bonne fois, en termes d'un diagramme de foncteurs [page 31]

$$\begin{array}{ccc} X' & \xleftarrow{q^*} & X \\ {\scriptstyle f'^*}\uparrow & \nearrow & \uparrow{\scriptstyle f^*} \\ Y' & \xleftarrow[p^*]{} & Y \end{array}$$

en supposant que les foncteurs adjoints à gauche f'_*, f_* des deux foncteurs verticaux existent). Un cas intéressant est celui où

$$pf' = fq \quad , \qquad \gamma = \mathsf{id}_{fq}$$

et où on pose $c_\gamma = c$.

Ici

$$p^* f_* \xrightarrow{?} f'_* q^*$$

revient à

$$f_* \xrightarrow{?} p_* f'_* q^* \simeq \qquad \begin{array}{c} (pf')_* q^* \\ \uparrow{\scriptstyle \gamma_* * q^*} \\ (fq)_* q^* \simeq (f_* q_*) q^* = f_*(q_* q^*) \end{array} \quad .$$

Or on a

$$\mathsf{id} \xrightarrow{\alpha} q_* q^* \qquad \text{(adjonction)} \quad ,$$

d'où

$$f_* \xrightarrow{f_* * \alpha} f_*(q_* q^*)$$

et en composant avec $\gamma * q^*$, on trouve ce qu'on veut. Et on peut au lieu de ceci chercher

$$\begin{array}{ccc} f'^*(p^*f_*) & \xrightarrow{\ ?\ } & q^* \\ \| & & \\ (pf')^*f_* & & \\ \downarrow{\scriptstyle \gamma^**f_*} & & \\ (fq)^*f_* \simeq q^*(f^*f_*) & \xrightarrow{q^**\gamma'} & q^* \end{array} ,$$

où $\gamma' : f^*f_* \to \mathsf{id}$ est l'adjonction.

Der$_4$: Le morphisme de changement de base pour images directes f_* associé à un diagramme (1) est toujours un isomorphisme (dérivateurs à gauche). Condition duale pour dérivateurs à droite et le changement de base pour images directes $f_!$, pour le diagramme

p. 22 [page 32]

$$(1') \qquad \begin{array}{ccc} j_0\backslash I & \longrightarrow & I \\ \downarrow & \overset{\gamma}{\nearrow} & \downarrow{\scriptstyle f} \\ e & \xrightarrow[p=\alpha_{j_0}]{} & J \end{array}$$

associé à $f : I \to J$ dans Dia, et $j_0 \in \mathsf{Ob}\ J$.

Commentary · Context [ms. 31]

The base-change map as a mate

The requested general adjunction calculation belongs to the calculus of mates. Its two-categorical setting was already available in Kelly and Street (1974); a derivator-oriented account is Groth et al. (2014a, Appendix A). Here we spell out the map in the manuscript's variance, since reversing a single arrow changes the statement.

Suppose $\gamma : fq \Rightarrow pf'$ is given. Contravariance on 2-cells gives $\gamma^* : f'^*p^* \Rightarrow q^*f^*$. Write η' for the unit of $f'^* \dashv f'_*$ and ε for the counit of $f^* \dashv f_*$. The canonical transformation is the composite

$$\begin{aligned} p^*f_* &\xrightarrow{\eta'\, p^*f_*} f'_*f'^*p^*f_* \\ &\xrightarrow{f'_*\gamma^*f_*} f'_*q^*f^*f_* \xrightarrow{f'_*q^*\varepsilon} f'_*q^*. \end{aligned}$$

In particular, this construction needs only the adjoints f_* and f'_*; adjoints to p^* and q^* are convenient for the alternative calculation, but are not part of its minimal input.

The equality of the two calculations is an equality of natural transformations. Under the adjunction bijection

$$\mathrm{Nat}(p^*f_*, f'_*q^*) \cong \mathrm{Nat}(f'^*p^*f_*, q^*)$$

the displayed composite is sent to $q^*\varepsilon \circ (\gamma^*f_*)$, by the triangular identity for $f'^* \dashv f'_*$. In the alternative construction, transpose first across $p^* \dashv p_*$; replace $(pf')_*$ and $(fq)_*$ by the composites of right adjoints; then transpose back across $f'^* \dashv f'_*$. Naturality of the units moves them past γ^*, and the unit–counit pair for $q^* \dashv q_*$ cancels by its triangular identity. The resulting transformation is exactly $q^*\varepsilon \circ (\gamma^*f_*)$. Since the adjunction bijection is injective, the original two transformations agree.

A strictly commuting square supplies $\gamma = 1$, but does not supply invertibility of its mate. The role of Der 4 is to assert invertibility for the particular comma squares that compute fibres. More general base-change theorems will require conditions on the square. The words "adjoints à gauche" on this page are another source slip: the functors bearing a subscript $*$ in this calculation are right adjoints.

Der$_5$ [10] : Soit $f : I \to J$ une *hot-équivalence stricte, i.e.* $\forall j_0 \in \mathsf{Ob}\ J$, I/j_0 est contractile. Alors f^* est pleinement fidèle, *i.e.* le morphisme d'adjonction

$$\mathsf{id}_{\mathbb{D}(J)} \longrightarrow f_*f^*$$

10. Totalement canulé, devient raisonnable que pour coefficients constants sur F.

est un isomorphisme ($\mathbb{D}$ dérivateur à gauche). Dualement, si f est une équivalence co-stricte, *i.e.* $f^\circ : I^\circ \to J^\circ$ est une équivalence stricte, *i.e.* $\forall j_0 \in \mathsf{Ob}\ J$, $j_0\backslash I$ est contractile, alors (si $\mathbb{D}$ est un dérivateur à droite) le foncteur f^* est pleinement fidèle, *i.e.* le morphisme d'adjonction

$$f_! f^* \longrightarrow \mathsf{id}_{\mathbb{D}(J)}$$

est un isomorphisme.

N.B. Donc les foncteurs f_* (resp. $f_!$) sont des foncteurs de localisation.

N.B. Les pages 33 à 40 ont été suprimées, car canulées.

Je vais reprendre la terminologie et les axiomes relatifs aux dérivateurs. [page 41]

Commentary · Examples [ms. 32]

The cancelled axiom and the walking arrow

The cancellation is mathematically necessary and should remain visible. Let $Y = [1] = (0 \to 1)$ and let $f : e \to Y$ select 0. Each slice f/y has one object and one arrow, so f satisfies the stated strict hot-equivalence condition. In the represented derivator of abelian groups a coefficient on Y is a map $F_1 \to F_0$. The restriction f^* remembers F_0, and its right adjoint sends A to the constant map $A \xrightarrow{1} A$. Consequently the unit is

$$(F_1 \longrightarrow F_0) \longrightarrow (F_0 \xrightarrow{1} F_0),$$

whose component at 1 is the original structure map. With $F_1 = 0$ and $F_0 = \mathbb{Z}$ it is not invertible. Contractibility of the slice controls a constant coefficient system on that slice; it does not turn the restriction of an arbitrary F into such a system.

The failure can also be read directly as failure of full faithfulness. The distinct endomorphisms of the diagram $\mathbb{Z} \to 0$ obtained from the identity and zero on $\mathbb{Z}$ have the same restriction to the object 0. Thus f^* is not faithful. The dual example, using the final endpoint and left Kan extension, disproves the dual part of the cancelled axiom.

There is a valid constant-coefficient conclusion. If $F = p_Y^* M$, the pointwise right Kan formula gives

$$(f_* f^* p_Y^* M)_y \simeq \Gamma_{\mathbb{D}}(f/y, p_{f/y}^* M).$$

Under the valid contractibility theorem the right-hand side is M, and the isomorphism is precisely the component of the unit. Der 2 then shows that the unit on $p_Y^* M$ is an isomorphism. This is the repair anticipated in footnote 10. Full faithfulness of restriction on all coherent diagrams is a stronger condition, usually called a homotopical epimorphism. It must not be substituted for either orientation of cofinality without an additional argument.

Un *prédérivateur* est un 2-foncteur

$$\mathsf{Dia}^\circ \xrightarrow{\mathbb{D}} \mathcal{C}at \quad ,$$

où Dia est une 2-sous-catégorie pleine de $\mathcal{C}at$.[11] On suppose tout au moins que Dia contient les *ensembles ordonnés finis,* que Dia est stable par $\varprojlim$ finies, par sommes finies. Qu'avec toute catégorie C et toute sous-catégorie strictement pleine ouverte (resp. fermée) elle contienne la sous-catégorie complémentaire.[12]

On définit le prédérivateur $\mathbb{D}_{\mathcal{M},\Sigma}$ associé à un système p. 23 [page 42]

$$(\mathcal{M}, \Sigma) \qquad \mathcal{M} \text{ Catégorie}, \quad \Sigma \subset \mathsf{Fl}(\mathcal{M}) \quad .$$

Si $\Sigma = \emptyset$, on écrit $\mathbb{D}_{\mathcal{M}}$.

11. Dia *domaine* du dérivateur. Les objets sont les *catégories d'indices* pour $\mathbb{D}$. Les $\mathbb{D}(I)$ sont les catégories de coefficients pour $\mathbb{D}$, les objets de $\mathbb{D}(I)$ les "coeficients de type $\mathbb{D}$ sur I".

12. Notation f^* : image inverse des coefficients.

Commentary · Exposition [ms. 41]

Restarting the axioms without changing variance

The return to definitions is a revision of the theory, not an additional list to be imposed on top of the cancelled axioms. We keep $\mathbb{D}(I)$ for contravariant coherent diagrams. In fully explicit modern notation its source is $\mathsf{Dia}^{\mathrm{coop}}$, with both 1-cells and 2-cells reversed. Equivalently one can work with the covariant-diagram convention by setting $\mathbb{D}_{\mathrm{cov}}(A) = \mathbb{D}(A^\circ)$. This translation explains why modern formulas often use the opposite comma category; compare Groth et al. (2014a, Warning 2.2).

The diagram domain is part of the hypotheses. The operations used below require products, coproducts, opposites, and the relevant comma categories. The stated finite-limit and complement closures do not explicitly include all these operations. Taking all small categories in a fixed universe makes the present formulas unambiguous; when using a smaller domain, one must require the corresponding closure conditions before writing the dual prederivator or the pointwise Kan formulas. No assertion about a shape outside the domain follows formally from an axiom restricted to that domain.

For a relative category $(\mathcal{M}, \Sigma)$ the diagram localization exists as a prederivator once the chosen universes allow the required localizations. Saturating the weak equivalences does not by itself prove the derivator axioms. On the other hand, the shift identity does not demand a new homotopical theorem. The exponential law identifies $\mathcal{M}^{(I\times J)^\circ}$ with $(\mathcal{M}^{I^\circ})^{J^\circ}$, and identifies the two classes of pointwise weak equivalences before localization. Localizing therefore gives the claimed equivalence of shifted prederivators. Functoriality in relative functors and in natural transformations is descended through the same universal property. This is a useful place to separate what follows from localization alone from the homotopy Kan extension properties that require additional assumptions.

Les prédérivateurs forment une 2- catégorie PREDER, et

$$(\mathcal{M}, \Sigma) \longmapsto \mathbb{D}_{\mathcal{M},\Sigma}$$

est un 2-foncteur

$$\mathsf{PREMOD}\begin{pmatrix}\text{“Catégorie des catégories}\\ \text{de modèles” (faibles)}\end{pmatrix} \longrightarrow \mathsf{PREDER} \quad .$$

Pour $\mathbb{D}$ donné, on définit le dérivateur induit ($I \in \mathsf{Dia}$)

$$\mathbb{D}_I = \big(J \longmapsto \mathbb{D}(I \times J)\big) \quad ,$$

dépendant de I de façon contravariante, d'où un 2-foncteur

$$\begin{aligned}\mathsf{Dia}^\circ &\longrightarrow \mathsf{PREDER}\\ I &\longmapsto \mathbb{D}_I\end{aligned}$$

ou encore un bi-2-foncteur

$$\begin{aligned}\mathsf{PREDER}\times\mathsf{Dia}^\circ &\longrightarrow \mathsf{PREDER}\\ (\mathbb{D}, I) &\longmapsto \mathbb{D}_I \quad .\end{aligned}$$

Si $\mathbb{D}$ est défini par $(\mathcal{M}, \Sigma)$, alors $\mathbb{D}_I$ est défini par $(\mathcal{M}(I), \Sigma(I))$:

$$(\mathbb{D}_{\mathcal{M},\Sigma})_I \simeq \mathbb{D}_{\mathcal{M}(I),\Sigma(I)} \quad ,$$

où $\mathcal{M}(I) = \underline{\mathsf{Hom}}(I^\circ, \mathcal{M})$ (préfaisceaux sur I à valeurs dans $\mathcal{M}$), et $\Sigma(I) \subset \mathsf{Fl}\,\mathcal{M}(I)$ est déduit de Σ en regardant fibre par fibre (supposant maintenant Σ saturé). [page 43]

Pour tous axiomes qu'on dégagera pour certains prédérivateurs, il faudra vérifier qu'il sont stables par passage aux prédérivateurs induits $\mathbb{D}_I$, et aussi comment ils se comportent par dualité (passage de $\mathbb{D}$ à $\mathbb{D}^\circ$).

Définition du prédérivateur dual $\mathbb{D}^\circ$

$$\mathbb{D}^\circ(I) \overset{\text{déf}}{=} \mathbb{D}(I^\circ)^\circ \qquad\qquad \textit{etc.}$$

Der 1 (Premier axiome de localisation) : *a*) Si I, $J \in \mathsf{Dia}$, alors

$$\mathbb{D}(I \amalg J) \longrightarrow \mathbb{D}(I) \times \mathbb{D}(J)$$

est une équivalence de catégories.

b) $\mathbb{D}(\emptyset)$ est la catégorie finale.

Stable par passage aux prédérivateurs induits, et passage au dual.

Corollaire. *Soit* $(I_\alpha)_{\alpha \in A}$ [une] *famille finie de catégories de* Dia, $I = \coprod_{\alpha \in A} I_\alpha$. *Alors*

$$\mathbb{D}(I) \longrightarrow \prod_{\alpha \in A} \mathbb{D}(I_\alpha)$$

est une équivalence de catégories.

Der 2 (Deuxième axiome de localisation) : Pour tout $I \in \mathsf{Dia}$, le foncteur canonique p. 24

$$\mathbb{D}(I) \longrightarrow \underline{\mathsf{Hom}}(I^\circ, \mathcal{A}_\mathbb{D}) \quad ,$$

$\mathcal{A}_\mathbb{D} = \mathbb{D}(e)$ catégorie fondamentale pour le dérivateur $\mathbb{D}$, est conservatif.

Stable par induction, et par dualité.

[page 44]

[page 44]

Commentary · Exposition [ms. 43]

What the localization axioms do and do not say

Der 1 decomposes coefficients over disconnected indexing categories. By induction on the number of summands, its binary and empty cases give the displayed assertion for every finite family. It survives a shift because $I \times (J \amalg K)$ is canonically $(I \times J) \amalg (I \times K)$ and $I \times \varnothing = \varnothing$. It survives duality because taking opposites commutes with products of categories and with the corresponding indexing coproducts.

Der 2 is a detection statement for morphisms already present in $\mathbb{D}(I)$. If such a morphism becomes invertible at every object of I, it was invertible. This gives neither a lifting of every incoherent diagram nor a lifting of every map between incoherent diagrams. The later strongness axiom addresses a different issue and must not be read into this one. To check Der 2 after shifting by J, apply it first to the J-valued fibres and then to the pairs of objects of $I \times J$. The converse direction follows because every functor preserves isomorphisms. Duality preserves the same criterion.

The next axiom names f_*F relative cohomology. Its transitivity is an adjunction calculation: both g_*f_* and $(gf)_*$ are right adjoint to $f^*g^* = (gf)^*$. This gives a specified canonical comparison, compatible with further composition. The existence of finite products again follows by applying this axiom to finite discrete projections. A right adjoint f_* preserves them automatically. Preservation by restriction f^* in a one-sided derivator uses the independent-variable base-change assertion discussed at manuscript page 23; the final pointwise axiom supplies the missing justification. The corresponding homological statements follow by duality.

Un prédérivateur est appelé un *dérivateur à gauche* s'il satisfait **Der 1** et **Der 2**, et de plus les axiomes suivants (dont voici le premier).

Der 3 (g) (Existence des images directes) : Pour tout $f : I \to J$ dans Dia, le foncteur $f^* : \mathbb{D}(J) \to \mathbb{D}(I)$ admet un *adjoint à droite* f_*.

Stable par induction.

On appelle f_* le foncteur image directe (cohomologique) pour f. L'objet $f_*(F) \in \mathbb{D}(J)$ (pour $F \in \mathbb{D}(I)$) s'appelle aussi l'objet de "*cohomologie relative*" de I sur J (par f), à coefficients dans F. On a des isomorphismes canoniques

$$(gf)_* \simeq g_*f_* \quad .$$

Corollaire. *Les catégories* $\mathbb{D}(I)$ *ont des produits finis, les foncteurs* f^* *et* f_* *y commutent.*

Utilise **Der 1** pour $I = \emptyset$ et $I = e \amalg e$, et **Der 3** pour $I \xrightarrow{f} e$.

On a un axiome dual :
Der 3 (d) : existence des adjoints à gauche $f_!$ des f^*, le foncteur $f_!$ s'appelle "image directe homologique" par f, et on a une notion d'*homologie relative* de I sur J (pour f), à coefficients dans F.

Par la suite, la mention (g) ou (d) à coté de la désignation **Der** n d'un axiome, signifie qu'il s'applique aux dérivateurs à gauche, respectivement à droite. De même pour les énoncés, définitions *etc.*
[page 45] [page 45]

Der 4$_0$ (g) [13] : Soit $U \overset{j}{\hookrightarrow} X \overset{i}{\hookleftarrow} Y$ dans Dia, immersions ouverte et fermée complémentaires l'une de l'autre. Alors le morphisme d'adjonction dans $\mathbb{D}(Y)$

$$i^* i_*(F_Y) \longrightarrow F_Y$$

est un isomorphisme, donc

$$i_* : \mathbb{D}(Y) \longrightarrow \mathbb{D}(X)$$

est pleinement fidèle, et $i^* : \mathbb{D}(X) \to \mathbb{D}(Y)$ est un foncteur de localisation. L'image essentielle de i_* est formée des objets F de $\mathbb{D}(X)$ tels que $j^*(F)$ soit l'objet final de $\mathbb{D}(U)$.
Der 4$_0$ (d) : Avec les notations précédentes pour i, j, le morphisme d'adjonction dans $\mathbb{D}(U)$ p. 25

$$F_U \longrightarrow j^* j_! F_U$$

est un isomorphisme, - $j_!$ est pleinement fidèle, j^* un foncteur de localisation. L'image essentielle de $j_!$ est la sous-catégorie pleine de $\mathbb{D}(X)$ formée des F tels que $i^*(F)$ soit objet initial de $\mathbb{D}(Y)$.

Il y a les deux carrés de la page 8 et 9, mais pour interpréter la condition cartésienne ou cocartésienne c'est prématuré ici.
[page 46] [page 46]

Commentary · Exposition [ms. 45]

Extension by an empty fibre

The proposed additional axiom Der 4_0 is a consequence of the pointwise Kan formula. This is a useful calculation because it distinguishes the special behaviour of an immersion from the false full-faithfulness statement for arbitrary cofinal functors.

In the manuscript's convention a closed full inclusion $i : Y \hookrightarrow X$ is a cosieve: an arrow whose source lies in Y has target in Y. For $y \in Y$, the comma category $(i/i(y))$ has terminal object $(y, 1)$. Since the diagram is contravariant, its cohomology is the value at that terminal object. Thus $(i_*E)_{i(y)} \cong E_y$, and these are the components of the counit $i^* i_* E \to E$. Der 2 makes the counit invertible, proving full faithfulness of i_*.

For $x \notin Y$, the comma category (i/x) is empty: an arrow $i(y) \to x$ would contradict the cosieve condition. Hence $(i_*E)_x$ is terminal, the right Kan extension over an empty category. Conversely let $F \in \mathbb{D}(X)$ have terminal fibres on the complement. In the unit $F \to i_* i^* F$, the components on Y are isomorphisms by the preceding calculation, and the components off Y are maps between terminal objects. Der 2 makes the whole unit invertible, so F belongs to the essential image. This proves both assertions of Der $4_0(g)$.

For an open inclusion $j : U \hookrightarrow X$, which is a sieve, the left Kan formula uses (x/j). Outside U this is empty, and inside U its initial object becomes terminal after taking the opposite indexing category for the colimit. Therefore $j_!$ is fully faithful and extends by initial objects. This proves the dual assertion. The calculation is recorded in modern covariant notation in Groth (2013, Proposition 1.23). Only the empty and pointwise Kan formulas are doing work here; no separate extension-by-zero axiom is needed. Pointedness later identifies the terminal and initial extensions with extension by the same zero object.

13. Inutile comme axiome, va devenir un théorème (résulte des autres axiomes).

Axiomes de changement de base.
Der 4 (g) (Fibres d'une image directe) : Soient $f : X \to Y$ dans Dia, $y \in Y$, considérons le diagramme connu

$$\begin{array}{ccc} X/y & \xrightarrow{q} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ e & \xrightarrow[p=\alpha_y]{} & Y \end{array}$$

et le morphisme de changement de base correspondant

$$f_*(F)_y \overset{\text{déf}}{=} p^* f_*(F) \longrightarrow f'_*(q^*(F)) (\overset{\text{déf}}{=} \Gamma_{\mathbb{D}}(X/y, q^*(F))) \quad .$$

C'est toujours un isomorphisme.
[page 47]
Der 5 (g) (Axiome de cofinalité pour la cohomologie)[14] : Soit $\alpha : X' \to X$ dans Dia "cohomologiquement cofinal" *i.e.* les $x\backslash X'$ sont contractiles ($x \in X$) *i.e.* $\alpha^\circ : X'^\circ \to X^\circ$ est une hot-équivalence "localement sur X°". Alors $\forall F \in \mathbb{D}(X)$, l'homomorphisme [page 47]

$$\Gamma_{\mathbb{D}}(X, F) \longrightarrow \Gamma_{\mathbb{D}}(X', \alpha^* F)$$

est un isomorphisme (dans $\mathcal{A} = \mathbb{D}(e)$).
N.B. Si $f : X \to e$, on pose $\Gamma_{\mathbb{D}}(X, F) = f_*(F)$ (cohomologie "absolue" de X, à coefficients dans F).
Même chose[15] si α est "homologiquement cofinal", i.e. les X'/x sont contractiles [phrase barrée].
Remarque. On devrait pouvoir renforcer considérablement cet axiome, en exigeant que p. 26

$$\alpha_!(\varepsilon_{X'}) \xrightarrow{\sim} \varepsilon_X \qquad \text{dans} \quad \mathsf{HOT}(X) \quad ,$$

où $\varepsilon_{X'}$, ε_X [sont] les objets finaux de $\mathsf{HOT}(X')$, $\mathsf{HOT}(X)$, et où $\alpha_!(\varepsilon_{X'}) \to \varepsilon_X$ est l'homomorphisme d'adjonction, compte tenu que $\varepsilon_{X'} \simeq \alpha^*(\varepsilon_X)$. On dit que X' est *homotopiquement trivial sur* X. (Et si la condition duale est satisfaite dans $\mathsf{HOT}(X^\circ)$, on dit que X' est cohomotopiquement trivial sur X.) Cette condition n'est sans doute pas autoduale. Elle est vérifiée aussi bien si α est cohomologiquement cofinal, que s'il est homologiquement cofinal (hot-équivalence costricte ou stricte).
N.B. Pour $f : X \to e$, dire que f est cohomologiquement cofinal, homologiquement cofinal, ou que X est contractile, est équivalent.
Corollaire 1 (g) (Théorème d'asphéricité pour les coefficients constants en cohomologie). *Soit $f : X \to e$ dans* Dia*, X contractile, $M \in \mathbb{D}(e)$. Alors l'homomorphisme d'adjonction*

$$M \xrightarrow{\sim} f_* f^*(M) \quad (\overset{\text{déf}}{=} \Gamma(X, f^*(M)))$$

est un isomorphisme.
Corollaire 2 (g)[16] *Soit $f : X \to Y$* [une] *hot-équivalence stricte (i.e. $\forall y \in Y$, X/y contractile). Alors pour $F \in \mathsf{Ob}\,\mathbb{D}(Y)$*

$$F \overset{\text{adj}}{\xrightarrow{\sim}} f_* f^* F$$

[est un] *isomorphisme.* [Ce corollaire est barré, mais pas sa démonstration.]
[page 48]

[page 48]

14. Il est conséquence d'énoncés plus faibles.
15. Faux!
16. Faux, sauf pour coefficients constants.

Commentary · Present state [ms. 47]

Cofinality retains an orientation

The valid cohomological cofinality condition is contractibility of (x/α), whose objects are arrows $x \to \alpha(x')$. For contravariant coefficients it preserves the homotopy limit. Contractibility of (α/x) is the opposite condition and preserves the homotopy colimit. These conditions become equivalent for a map to the point, but not for a general map. The cofinality theorem is part of the established derivator calculus; in covariant notation see Groth et al. (2014a, Corollary 3.13 and Remark 3.14). The theorem's derivation for all small categories does not remove the need to check domain hypotheses in a restricted theory.

The walking-arrow example in the commentary at manuscript page 32 settles the crossed-out sentence. For the inclusion of 0 in $Y = [1]$, every (α/y) is a point, but $\Gamma(Y, F) = F_1$ while $\Gamma(e, \alpha^* F) = F_0$. The comparison is the given structure map $F_1 \to F_0$, which may be $0 \to \mathbb{Z}$. Homotopy invariance with arbitrary varying coefficients cannot ignore its direction.

The proposed condition involving the terminal object of HOT can be calculated completely. In the homotopy theory of presheaves of spaces, the pointwise left Kan formula yields

$$(\alpha_! \varepsilon_{X'})_x \simeq \operatorname*{hocolim}_{(x/\alpha)^\circ} * \simeq B(x/\alpha).$$

For the second identification, the simplicial replacement of the constant point has one simplex for each composable string of arrows in the indexing category; its realization is the nerve realization. Passing to the opposite category reverses these strings and gives the same homotopy type. The counit in the remark has component the augmentation $B(x/\alpha) \to *$. Der 2 therefore identifies its invertibility with weak contractibility of every (x/α). Thus this condition is a reformulation of the valid cohomological cofinality hypothesis, not a substantial strengthening of it.

It also refutes the assertion that either orientation suffices. For the same initial-endpoint inclusion, $(1/\alpha)$ is empty, so the component of $\alpha_! \varepsilon$ at 1 is the empty space and its map to the point is not a weak equivalence. The opposite-endpoint inclusion supplies the dual discrepancy. The remark's prediction that the condition is not self-dual is correct, while its claimed implication from both cofinality conditions is false.

The constant-coefficient corollary has no such problem. If $p : X \to e$ and NX is weakly contractible, the valid cohomological cofinality theorem applied to M gives $M \cong p_* p^* M$. This is exactly the unit, rather than an unspecified isomorphism. What fails in the following cancelled corollary is the replacement of a genuinely varying restriction of F by a constant coefficient system on a contractible slice.

On applique **Der 2**, **Der 4** (g), pour se ramener à regarder, pour $y_0 \in Y$, l'homomorphisme α du diagramme (commutatif!) suivant :

$$\begin{array}{ccc} \Gamma(\{y_0\}, F_{y_0}) = F_{y_0} & \xrightarrow{\quad\alpha\quad} & \Gamma_{\mathbb{D}}(X/y_0, f^*(F)) \\ \varphi\wr \uparrow & \nearrow_{\alpha'} & \\ \Gamma(Y/y_0, F) & & \end{array} ,$$

où α' est déduit du foncteur induit par f

$$X/y_0 \longrightarrow Y/y_0$$

et où φ est déduit du foncteur

$$\{y_0\} \longrightarrow Y/y_0 \qquad \text{(objet final)}\,.$$

Donc φ est un isomorphisme par **Der 5** (g) [17] (N.B. Si $z \in Z$, d'où $\{z\} \to Z$, ce foncteur est cohomologiquement cofinal si et seulement si z est objet final, homologiquement final `[plutôt cofinal]` si et seulement si z est objet initial). Donc la conclusion du corollaire équivaut à p. 27

17. *cf.* corollaire 3, page 50, qu'on devrait remonter ici.

dire que α' est un isomorphisme. Mais $X/y_0 \to Y/y_0$ est aussi homologiquement cofinal, car si $u : y_1 \to y_0$ est dans Y/y_0, on a un isomorphisme canonique

$$(X/y_0)/(y_1, u) \simeq X/y_1$$

qui est contractile. Donc par la deuxième partie de **Der 5** (g),[18] on gagne.
[page 49]

[page 49]

Commentary · Exposition [ms. 48]

Locating the failed inference in the surviving proof

Most of the surviving proof is correct. The category Y/y_0 has terminal object $(y_0, 1)$, and cohomology of a contravariant diagram therefore evaluates to F_{y_0}. The inclusion of that terminal object is cohomologically cofinal: its comma category over an object is the one-element set consisting of the unique map to the terminal object. More generally, for $z \in Z$ the comma category $(x/\{z\})$ is the discrete set $Z(x, z)$. Its nerve is contractible exactly when that set has one element. Hence the singleton inclusion is cohomologically cofinal precisely when z is terminal; the dual assertion characterizes initial objects.

The displayed slice identification is also exact. An object of $(X/y_0)/(y_1, u)$ consists of $x \in X$, a map $v : f(x) \to y_0$, and a map $w : f(x) \to y_1$ with $uw = v$. Forgetting v, which is determined by w, identifies this category with X/y_1, on morphisms as well as objects. This proves the *homological* cofinality of $X/y_0 \to Y/y_0$ under the stated hypothesis. It does not prove cohomological cofinality. The final sentence invokes exactly the opposite-orientation clause that was crossed out on manuscript page 47. No additional fault in the slice calculation is needed to account for the failure. The author and editors explicitly mark the false premise; a modern repair retains the calculation and changes the coefficient hypothesis or the cofinality hypothesis, as in the preceding commentary.

Corollaire 4 (g) (critère de changement de base pour images directes cohomologiques). *Soit*

$$\begin{array}{ccc} X' & \xrightarrow{q} & X \\ {\scriptstyle f'}\downarrow & \overset{\gamma}{\swarrow} & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[p]{} & Y \end{array}$$

dans Dia (*cf.* page 30), *d'où l'homomorphisme de changement de base*

$$p^* f_*(F) \longrightarrow f'_* q^*(F) \qquad (F \in \mathsf{Ob}\, \mathbb{D}(X)) \quad .$$

Pour que ce soit un isomorphisme pour tous F, il suffit que pour tout $y' \in \mathsf{Ob}\, Y'$, le foncteur induit par (p. 9)

$$X'/y' \longrightarrow X/p(y')$$

soit une hot-équivalence stricte (ou costricte);[19] *cela signifie aussi (dans le cas strict) que pour*

$$y'_0 \in \mathsf{Ob}\, Y' , \quad x_0 \in \mathsf{Ob}\, X , \quad u_0 : f(x_0) \longrightarrow p(y'_0)$$

la catégorie $K(y'_0, x_0, u_0)$ des objets de la forme

$$(x', v', u) \mid x' \in \mathsf{Ob}\, X', \quad v' : f'(x') \to y'_0, \quad u : q(x') \overset{\leftarrow\!-\!-}{\longrightarrow} x_0$$

rendant commutatif le carré dans Y'

(∗)

$$\begin{array}{ccc} f(q(x')) & \xrightarrow{\gamma(x')} & p(f'(x')) \\ {\scriptstyle f(u)}\downarrow\uparrow & \text{cas de hot-équivalence} \leftarrow \text{costricte} & \downarrow{\scriptstyle p(v')} \\ f(x_0) & \xrightarrow[u_0]{} & p(y'_0) \end{array}$$

18. (qui est fausse)
19. Faux pour "stricte", ne marche que pour "costricte".

est contractile.
N.B. Dans le cas de la hot équivalence costricte, c'est la même description de p. 28

$$K = (x_0, u_0)\backslash(X'/y'_0) \quad ,$$

sauf que la flèche u est en sens inverse $x_0 \to q(x')$ et itou dans le diagramme commutatif $(*)$.
On applique **Der 2**, **Der 4** (g) et corollaire 1 `[plutôt` **Der 5** (g)`]`.

Commentary · Exposition [ms. 49]

The factorization category controls base change

The base-change criterion is a statement about the square, including its specified natural transformation. It does not assert that every cartesian square is exact, and it does not require the square to be cartesian. To see what it tests, fix $y' \in Y'$, put $y = p(y')$, and write

$$h_{y'} : X'/y' \longrightarrow X/y, \qquad (x', v : f'(x') \to y') \longmapsto (q(x'), p(v)\gamma_{x'}).$$

The pointwise formula for right Kan extension identifies the value of the Beck–Chevalley map at y' with restriction of cohomology along $h_{y'}$. Since the coefficients are contravariant, the appropriate cofinality test uses arrows *from* an object of X/y *to* the image of $h_{y'}$. This is precisely the orientation retained in footnote 19. The discarded orientation is the mistake already isolated in the commentary at manuscript p. 32, "The cancelled axiom and the walking arrow."

For clarity, the category attached to $x \in X$ and $\alpha : f(x) \to p(y')$ has objects

$$(x', u : x \to q(x'), v : f'(x') \to y'), \qquad p(v)\gamma_{x'} f(u) = \alpha.$$

A morphism to (x'', u', v') is an arrow $t : x' \to x''$ such that $q(t)u = u'$ and $v' f'(t) = v$. Thus this is the comma category $(x, \alpha)\backslash h_{y'}$, with all compatibility conditions retained. Weak contractibility of every such category implies that restriction along $h_{y'}$ preserves homotopy limits of the contravariant diagrams in question. Applying this at every y', and then using **Der 2**, proves the criterion. The words "dans Y'" before the displayed square are a slip in the edition: the square is in Y.

The resulting invariant is now called a *homotopy exact square*. In modern covariant notation its factorization categories are those of Groth et al. (2014a, Definition 3.7 and Theorem 3.8); passage to opposite indexing categories recovers exactly the arrows above. Their Theorem 3.16 also gives the converse when exactness is required for every derivator. The useful content of this later formulation is that the elementary categories of factorizations, rather than any particular presentation by model categories, determine the universal base-change property.

Corollaire 5 (g). *Soit $f : X \to Y$ pleinement fidèle dans* Dia*, et $F \in \mathbb{D}(X)$. Alors l'homomorphisme d'adjonction*

$$f^* f_*(F) \longrightarrow F$$

est un isomorphisme.

En efffet, il suffit de le vérifier fibre par fibre (**Der 2**). Soit $x \in X$, $y = f(x) \in Y$, alors

$$f^* f_*(F)_x \simeq f_*(F)_y \simeq \Gamma_{\mathbb{D}}(X/y, F)$$

or à cause de la pleine fidélité $X/y \simeq X/x$.

Corollaire 3 (remonter page 48).[20] *Soit $Z \in$ Dia, supposons que Z a un objet final e_Z. Soit $p : e \to Z$ le foncteur correspondant. Alors l'homomorphisme canonique (pour F dans $\mathbb{D}(Z)$)*

$$\begin{array}{ccc} Z & & \\ \uparrow p & \Big\downarrow f & \\ e & & \end{array} \qquad\qquad f_*(F) \longrightarrow p^*(F)$$

20. Va résulter de **Der 6** (g) plus fort ci-dessous.

est un isomorphisme. [21]

Cet homomorphisme est [un] cas particulier de celui-ci, pour

$$\begin{array}{ccc} Z' & \xrightarrow{\quad p \quad} & Z \\ & {\scriptstyle f'}\searrow \quad \swarrow{\scriptstyle f} & \\ & S & \end{array}$$

(en faisant $Z' = S = e$, $f' = \mathsf{id}_e$),

$$f_*(F) \longrightarrow f'_*(p^*(F)) \quad , \qquad (\, F \in \mathsf{Ob}\, \mathbb{D}(Z)\,) \quad ,$$

et c'est un cas particulier [22] des morphismes de changement de base pour

$$\begin{array}{ccc} Z' & \xrightarrow{\ p\ } & Z \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ S & \xrightarrow{\ \mathsf{id}\ } & S \end{array} \quad .$$

p. 29
[page 51]

Commentary · Exposition [ms. 50]

Fully faithful direct image and extension by a terminal object

There are two separate assertions behind the next localization calculation. First, a fully faithful inclusion retains all coefficients on its image. If $f : X \to Y$ is fully faithful, the map

$$X/x \longrightarrow X/f(x), \qquad (x', a : x' \to x) \longmapsto (x', f(a)),$$

is an isomorphism of categories. The right member here is the comma category formed with f. Fullness and faithfulness give, respectively, existence and uniqueness of the inverse on objects and arrows. Since X/x has terminal object $(x, 1_x)$, the pointwise formula gives

$$(f^* f_* F)_x \simeq \Gamma_{\mathbb{D}}(X/x, F) \simeq F_x.$$

The map so obtained is the counit, not merely an unspecified isomorphism between its source and target. Conservativity therefore proves that f_* is fully faithful.

Second, for a cosieve $i : Y \hookrightarrow X$, right extension in the presheaf convention fills the complementary sieve U with terminal objects. If $u \in U$, there can be no arrow from an object of Y to u, so Y/u is empty. The pointwise formula consequently makes $(i_* F)_u$ terminal. Conversely, let $E \in \mathbb{D}(X)$ be terminal on U. On Y, the unit $E \to i_* i^* E$ is invertible by the first assertion. On U, it is a map between terminal objects and is again invertible. The two parts cover all objects of X, so **Der 2** finishes the proof. This argument uses no zero object. In a pointed theory the terminal values happen also to be initial, which explains the later terminology "extension by zero."

These computations also explain why the argument survives the loss of ordinary diagrammatic information. We do not recover an arbitrary coherent diagram from a list of its values. We construct a specific morphism, the unit or counit, and show that this morphism is invertible at every object. That is exactly what conservativity permits. The corresponding modern statement is Groth (2013, Proposition 1.23), with sieve and cosieve interchanged when changing the variance convention.

Remarque : On retrouve le fait que $i^* i_*(F_Y) \xrightarrow{\sim} F_Y$ est [un] isomorphisme, pour i une immersion fermée. De plus, avec les notations de **Der 4** (g), $j^*(i_*(F_Y))$ se calcule par le théorème de changement de base (corollaire 2 [plutôt 4] ci-dessus), qui s'applique dans toute situation commutative

$$\begin{array}{ccc} X' & \xrightarrow{\ q\ } & X \\ {\scriptstyle f'}\downarrow & \text{cart} & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{\ p\ } & Y \end{array}$$

21. Axiome de la catégorie d'indices à objet final (coefficient quelconque).
22. déjà envisagé dans cor. 2, p. 47

quand p est une immersion ouverte (et $\gamma = \mathsf{id}$) (alors $X'/y' \to X/p(y')$ est même un isomorphisme!), et on trouve, revenant aux notations de **Der 4** (g),

$$\begin{array}{ccc} \emptyset & \xrightarrow{q} & Y \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle i} \\ U & \xrightarrow[j]{} & X \end{array}$$

i.e. $j^*(i_*(F_Y)) \simeq f'_*(\varphi)$, où $\varphi = q^*(F_Y)$ est l'unique élément de la catégorie (équivalente à une catégorie ponctuelle, par **Der 1**) $\mathbb{D}(\emptyset)$. D'autre part, f'_* transforme objet final en objet final, d'où $j^*i_*(F_Y)$ est objet final.

Inversement, soit F dans $\mathbb{D}(X)$, tel que $j^*(F) = e_{\mathbb{D}(U)}$. Considérons

$$F \xrightarrow{u} i_*i^*F \qquad \text{(adjonction)}\,;$$

je dis que c'est un isomorphisme. En effet, par l'axiome de localisation **Der 2**, il suffit de prouver que $i^*(u)$ et $j^*(u)$ sont `[des]` isomorphismes. Pour $i^*(u)$ cela résulte du fait que i^* soit foncteur de localisation, et pour j^* du fait que $j^*(F)$ et $j^*(i_*i^*(F))$ sont des objets finaux dans $\mathbb{D}(U)$. [page 52]

p. 30
[page 53]

Commentary · Exposition [ms. 52]

Properness as a condition on all lifts

The geometric terminology begins with a computational requirement. A right direct image over y is initially computed on the comma category X/y. To compute it on the strict fibre X_y instead, the inclusion $X_y \to X/y$ must be cofinal in the orientation appropriate to contravariant coefficients. Properness asserts this simultaneously for every y.

There is a concrete way to express the requirement without derived functors. For $x \in X$ and $\alpha : f(x) \to y$, let $L_f(x,\alpha)$ be the category whose objects are arrows

$$v : x \longrightarrow x_1, \qquad f(v) = \alpha,$$

and whose morphisms from v to v' are arrows $t : x_1 \to x'_1$ with $tv = v'$ and $f(t) = 1_y$. This is a category of lifts of one fixed base arrow, with a fixed source upstairs. There is a canonical isomorphism

$$L_f(x,\alpha) \cong (x,\alpha)\backslash X_y.$$

Indeed, a morphism $(x,\alpha) \to (x_1, 1_y)$ in X/y is exactly such a lift v, and a morphism between two of them is exactly the triangle defining t. Thus f is proper precisely when every $L_f(x,\alpha)$ has weakly contractible nerve. In particular, a lift must exist, all choices must be connected, and their higher homotopy must vanish. Mere existence of lifts is insufficient.

For smoothness one fixes the *target* upstairs instead. Given $x \in X$ and $\beta : y \to f(x)$, the incoming lift category consists of $v : x_0 \to x$ over β and triangles over 1_y. Smoothness says that these categories are weakly contractible. The first display on manuscript p. 54 should consequently have target $y\backslash X$, not $y\backslash Y$; the latter is what the edition actually prints. The error is typographical, since the succeeding characterization by fibres of $X/x \to Y/f(x)$ has the correct meaning. In the modern literature this elementary equivalence is stated in Maltsiniotis (2020, Definition 3.2.1 and Proposition 3.2.3); Maltsiniotis (2005, Theorem 1.2) gives its formulation by base change.

The stability under strict pullback can now be proved without any cohomology. In a pullback $X' = X \times_Y Y'$, choose $x' = (x, y')$ and an arrow $\alpha' : y' \to z'$ in Y'. A lift of α' out of x' is exactly a lift of $p(\alpha')$ out of x, its second component already being prescribed. The same correspondence identifies every morphism between lifts. The lift categories are therefore isomorphic. Reversing all arrows proves the smooth case.

Several small consequences deserve to be read literally. A cosieve inclusion is proper because every allowed outgoing arrow has one lift; a sieve inclusion is smooth by the dual argument. If f is proper, nonemptiness of $L_f(x,\alpha)$ shows that every arrow out of an object of its image is itself in the image. Thus the strict image is a full cosieve. Finally, $X \to e$ is both proper and smooth: the lift categories are $x\backslash X$ and X/x, which have initial and terminal objects. Product projections inherit both properties by strict pullback.

Morphismes homotopiquement propres, homotopiquement lisses.

Soit $f : X \to Y$ [un] morphisme de catégories, considérons $y_0 \in \mathsf{Ob}\, Y$, et le foncteur canonique

$$X_{y_0} \xrightarrow{\varphi} X/y_0 \qquad \varphi(x) = (x, \mathsf{id}_{f(x)}) \tag{1}$$

(X_{y_0} fibre de X en y_0). Soit $(x_0, u_0) \in \mathsf{Ob}\, X/y_0$ donc $x_0 \in \mathsf{Ob}\, X$, $u_0 : f(x_0) \to y_0$. Considérons la catégorie coinduite par φ sur (x_0, u_0)

$$(x_0, u_0)\backslash(X_{y_0}) \quad ,$$

pour tester si φ est une hot-équivalence costricte *i.e.* homologiquement [plutôt cohomologiquement] cofinal. On va l'interpréter via le foncteur induit par f

$$x_0\backslash X \xrightarrow{\psi} f(x_0)\backslash Y$$

allant de la catégorie des spécialisations de x_0 dans X vers celle des spécialisations de $f(x_0)$ dans Y. On trouve alors un isomorphisme canonique de la catégorie coinduite $(x_0, u_0)\backslash X_{y_0}$ par X_{y_0} au dessus de l'objet (x_0, u_0) de X/y_0 et de la catégorie fibre $(x_0\backslash X)_{u_0}$ de $x_0\backslash X$ au dessus de $f(x_0)\backslash Y$ en u_0. Donc

Proposition. *Pour que les foncteurs $\varphi : X_{y_0} \to X/y_0$ ($y_0 \in \mathsf{Ob}\, Y$) soient des hot-équivalences costrictes, il faut et il suffit que les fibres des foncteurs $x_0\backslash X \to f(x_0)\backslash Y$ induits par f soient contractiles.*

On dit alors que f est *homotopiquement propre.* La notion duale s'exprime, soit par la condition que les foncteurs induits par f [page 54]

$$X_{y_0} \longrightarrow y_0\backslash Y$$

soient des hot-équivalences strictes *i.e.* qu'ils soient cohomologiquement [plutôt homologiquement] cofinaux, soit que les fibres des morphismes induits sur les "catégories localisées" (catégories des générisations)

$$X/x_0 \longrightarrow Y/f(x_0)$$

soient contractiles. (N.B. On utilise ici qu'une catégorie Z est contractile si et seulement si Z° l'est.) On dit alors que f est *homotopiquement lisse.*

Proposition. *La notion de foncteur propre (resp. lisse) est stable par changement de base, par composition. Les isomorphismes, et plus généralement, les immersions fermées sont propres. L'image d'un morphisme propre est une sous-catégorie fermée.* [23]

N.B. Le foncteur $X \to e$ est toujours propre et lisse, car les catégories $x_0\backslash X$ et X/x_0 sont contractiles (ayant objet initial ou objet final). Donc tout foncteur de projection $X \times Y \xrightarrow{pr_2} Y$ est à la fois propre et lisse.

DÉMONSTRATION. Stabilité par changement de base : p. 31 [page 55]

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & \text{cart} & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow[p]{} & Y' \end{array} \quad ,$$

d'où pour $x' \in \mathsf{Ob}\, X'$

$$\begin{array}{ccc} X/x & \longleftarrow & X'/x' \\ \downarrow & & \downarrow \\ Y/y & \longleftarrow & Y'/y' \end{array} \quad ,$$

23. Attention, une équivalence de catégories n'est pas propre! Si $X' \hookrightarrow X$ [est] une inclusion d'une sous-catégorie de X, elle n'est propre que si c'est une immersion fermée.

où x, y', y sont les images de x' dans X, Y', Y. On vérifie que ce diagramme est *cartésien*, donc les fibres de $X'/x' \longrightarrow Y'/y'$ sont isomorphes à des fibres de $X/x \longrightarrow Y/y$, donc contractiles si celles-ci le sont.

Commentary · Examples [ms. 54]

Why an equivalence can fail properness

Let J be the groupoid with two objects $0, 1$ and exactly one morphism between each ordered pair, and let $i : e \to J$ select 0. The functor i is fully faithful and essentially surjective, hence an equivalence. Nevertheless, for the unique isomorphism $\alpha : 0 \to 1$, the outgoing lift category $L_i(*, \alpha)$ is empty. There is no object of the strict domain lying over 1. The incoming lift category for the inverse isomorphism is empty for the same reason, so i is neither proper nor smooth.

This failure is visible directly in base change. Pull i back along $j : e \to J$ selecting 1. The strict pullback is empty. For an ordinary set M, or a space M, the right Kan extension i_*M has value M at 1: the comma category $e/1$ has a single object. The right direct image from the empty pullback is terminal. Hence the comparison at 1 is

$$M \longrightarrow *,$$

which fails to be invertible, for example when M is a discrete two-point space. This example verifies the caution in footnote 23 and shows exactly where the strictness matters. Replacing the strict pullback by an equivalence-invariant pullback would change the problem under discussion.

For an equivalence $f : X \to Y$, the preceding argument gives a more precise criterion: f is proper if and only if it is surjective on objects, and the same criterion characterizes smoothness. Necessity follows because every object of Y is isomorphic to one in the image and properness supplies a lift of that isomorphism. For sufficiency, fix $\alpha : f(x) \to y$ and choose x_1 with $f(x_1) = y$. Full faithfulness gives a unique lift $x \to x_1$ of α. Any two lift objects have a unique morphism between them over 1_y, again by full faithfulness. Their lift category is therefore nonempty and equivalent to a point. The incoming version is identical. This is the criterion recorded in Maltsiniotis (2020, Remark 3.2.5).

Dans un cas $X \xrightarrow{f} Y$ on vérifie que pour un foncteur bilocalisé de f

$$X/x \xrightarrow{\varphi = f/x} Y/y \quad ,$$

tout “bilocalisé”

$$(X/x)/\xi \longrightarrow (Y/y)/\eta \qquad\qquad (\xi : x' \to x\,, \quad \eta : y' \to y)$$

de φ s’identifie encore à un bilocalisé de f

$$X/x' \longrightarrow Y/y' \quad .$$

Donc si f est lisse, les bilocalisés f/x ($x \in \mathsf{Ob}\, X$) le sont aussi. Notons d’autre part.

Proposition.[24] *Tout morphisme propre (ou dualement lisse) à fibres contractiles est une hot-équivalence.*

Cela provient du fait que pour un tel foncteur propre, si F est un préfaisceau, ou complexe de préfaisceaux abéliens sur X, la formation des $Rf_*(F)$ commute au passage aux fibres, et de même pour $R^1f_*(F)$ si F est un préfaisceau en groupes (pas même abéliens). [page 56]

Commentary · Exposition [ms. 55]

Contractible fibres and the missing steps in composition

The assertion about contractible fibres does not need a separate theorem detecting weak equivalences by abelian and nonabelian cohomology. Suppose first that f is proper and every X_y is weakly contractible. By definition $X_y \to X/y$ is coaspherical, hence a weak equivalence on nerves by Quillen’s Theorem A. Therefore every X/y is weakly contractible. A second application of

24. *cf.* amélioration dans cor. 2, page suivante.

Theorem A, now to f, proves that Nf is a weak equivalence. Opposite categories give the smooth case. This is a completion of the proof sketched here, using Quillen (1973, §1, Theorem A), rather than a correction of the theorem.

The same argument proves the stronger assertion on manuscript p. 56. Base change along $Y/y \to Y$ and $y\backslash Y \to Y$ preserves properness or smoothness and preserves the contractibility of strict fibres. Each base has contractible nerve, since it has a terminal or an initial object. The total categories are X/y and $y\backslash X$, respectively, and the fibre theorem makes each of them contractible. Thus f is both aspherical and coaspherical.

Here is also a full proof of the composition assertion. Let $f : X \to Y$ and $g : Y \to Z$ be proper, fix $x \in X$, and fix $\alpha : gf(x) \to z$. There is a functor

$$L_{gf}(x, \alpha) \longrightarrow L_g(f(x), \alpha), \qquad (v : x \to x_1) \longmapsto f(v).$$

The undercategory functor $x\backslash X \to f(x)\backslash Y$ is proper: after fixing an object $v : x \to x_1$, its outgoing lift categories identify with the corresponding outgoing lift categories of f at x_1. Its strict fibres are contractible by the definition of properness of f. The displayed functor is its strict pullback along $L_g(f(x), \alpha) \to f(x)\backslash Y$. It is consequently proper with contractible fibres, so the preceding theorem makes it a weak equivalence. Its target is contractible because g is proper. Its source is therefore contractible, and this is the required condition for gf. Duality proves composition for smooth functors. The argument is the elementary mechanism behind Maltsiniotis (2020, Propositions 3.2.6 and 3.2.10).

There is no cancellation theorem with the other two positions in a composite. The functors $[1] \to e$ and $e \to e$ are proper, but their factor $e \to [1]$ selecting 0 is not: the arrow $0 \to 1$ has no lift. The statement about sections in the text has precisely this content. It should not be read as a defect of the proof of composition.

Corollaire 1. *Si $f : X \to Y$ est cohomologiquement propre à fibres contractiles, alors Y est contractile si et seulement si X l'est.*

Grâce à ceci, on trouve que le composé de deux foncteurs propres (lisses) est propre (lisse). N.B. Contrairement à ce qui a lieu en topologie pour la notion de propreté, si gf est propre et g propre, f ne l'est pas nécessairement, *i.e.* un S-morphisme de S-catégories X, Y propres sur S n'est pas nécessairement propre. Ainsi une section de X/S, pour X propre sur S, n'est pas nécessairement propre, *i.e.* n'est pas nécessairement une immersion fermée. C'est déjà faux si $S = e$ (auquel cas $f : X \to e$ est toujours propre). p. 32

Corollaire 2. *Un morphisme propre ou lisse, à fibres contractiles est à la fois une hot-équivalence stricte et costricte.*

En effet, on applique le corollaire 1 à $X/y \to Y/y$ ou $y\backslash X \to y\backslash Y$.

Théorème (g) *Soit une situation de changement de base dans* Dia

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & \text{cart} & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow[p]{} & Y' \end{array} \qquad , \qquad p^* f_*(F) \xrightarrow{c} f'_* q^*(F)$$

($F \in \mathbb{D}(X)$), $\mathbb{D}$ dérivateur exact à gauche. Si f est (homotopiquement) propre ou p homotopiquement lisse, alors c est un isomorphisme.

La question c'est si pour tout $y' \in Y'$, posant $y = p(y')$ et considérant le foncteur induit par q [page 57]

$$X/y \longleftarrow X'/y'$$

le morphisme correspondant

$$\Gamma_{\mathbb{D}}(X/y, F) \longrightarrow \Gamma_{\mathbb{D}}(X'/y', q^* F)$$

est [un] isomorphisme. Dans le cas f propre, on considère

$$\begin{array}{ccc} X_y & \xleftarrow{\sim} & X_{y'} \\ {\scriptstyle\sim}\ \text{costricte}\downarrow & & \downarrow{\scriptstyle\sim}\ \text{costricte} \\ X/y & \longleftarrow & X'/y' \end{array}$$

d'où la conclusion, puisque par **Der 5** (g), dans

$$\begin{array}{ccc} \Gamma(X_y) & \longrightarrow & \Gamma(X_{y'}) \\ \uparrow & & \uparrow \\ \Gamma(X/y) & \longrightarrow & \Gamma(X'/y') \end{array}$$

les flèches verticales et l'horizontale supérieure sont [des] isomorphismes, donc aussi l'horizontale inférieure.

Dans le cas p lisse, considérons du coté Y, Y' le carré de changement de base p. 33

$$\begin{array}{ccc} Y & \longleftarrow & Y' \\ \uparrow & & \uparrow \\ Y/y & \longleftarrow & Y'/y' \end{array}$$

d'où le diagramme contigu [page 58]

$$\begin{array}{ccccc} X & \longleftarrow & X' & & \\ & \nwarrow & \downarrow & \nwarrow & \\ & X/y & \xleftarrow[\kappa]{} & X'/y' & \\ \downarrow & & \downarrow & & \downarrow \\ Y & \longleftarrow & Y' & & \\ & \nwarrow & & \nwarrow & \\ & Y/y & \xleftarrow[\pi]{} & Y'/y' & \end{array} ,$$

où les carrés latéraux (verticaux) sont cartésiens. On note que π est lisse et à fibres contractiles (car p est lisse) donc κ aussi. Donc κ est une hot-équivalence costricte, donc $\Gamma(X/y) \xrightarrow{\sim} \Gamma(X'/y')$, on gagne encore.

N.B. Sauf erreur, on a une réciproque du théorème, [à] savoir : Si $f : X \to Y$ est tel que le théorème de changement de base pour $f_*(F)$ est vrai pour *tout* dérivateur (il suffit sans doute de HOTAB et HOT) et pour tout $Y' \to Y$, alors f est homotopiquement propre. D'autre part, si $g : Y' \to Y$ est tel que le théorème de changement de base pour g est vrai pout tout $X \to Y$ et tout $F \in \mathbb{D}(X)$ ($\mathbb{D}$ dérivateur exact à droite quelconque), alors g est homotopiquement lisse.

Du côté homologique les foncteurs lisses f sont exactement ceux pour lesquels $f_!$ commute à tout changement de base. Les foncteurs propres g sont exactement ceux pour lesquels le changement de base par g commute à $f_!$, pour tout $f : X \to Y$ et tout $\mathbb{D}$ dérivateur exact à gauche.

Ainsi, les foncteurs propres $f : X \to Y$ se caractérisent de *quatre* façons remarquables [page 59]

a) f_* commute à tout changement de base ($\forall$ dérivateur $\mathbb{D}$ exact à gauche);

b) le changement de base f^* commute à tout $g_!$ ($g : Y' \to Y$, $\mathbb{D}$ dérivateur exact à droite);

c) $\forall y \in \mathsf{Ob}\, Y$, $X_y \to X/y$ est une hot-équivalence costricte *i.e.* est un foncteur homologiquement [plutôt cohomologiquement] cofinal;

d) $\forall x \in \mathsf{Ob}\, X$ le foncteur induit sur les colocalisés

$$x\backslash X \longrightarrow f(x)\backslash Y$$

Commentary · Present state [ms. 58]

The converse, and why spaces suffice

The conjectural converse is proved in the subsequent theory. Its exact scope is universal base change: for a fixed $f : X \to Y$, one considers every strict pullback square and every coefficient in the indicated derivator. The class of homotopy exact squares is already detected by the derivator of spaces; Groth et al. (2014a, Theorem 3.16) equate this test with exactness for all derivators and with weak contractibility of the factorization categories. Thus the proposed pair HOTAB and HOT can be reduced to HOT alone. The proper/smooth theory is developed systematically by Maltsiniotis (2020, §3.2). We spell out the small tests that detect the two converse assertions, because they explain why the conjecture has the stated strength.

Fix $y \in Y$ and form the fibre square, with $j : X_y \to X$ and $s : X_y \to e$. In the derivator of spaces its right comparison

$$y^* f_* \longrightarrow s_* j^*$$

is invertible if and only if its left-adjoint mate

$$j_! s^* \longrightarrow f^* y_!$$

is invertible. This is taking the adjoint of a transformation between right adjoints, so invertibility is preserved in both directions. Apply the left mate to the terminal space $*$. At $x \in X$ its target is the discrete space $\mathrm{Hom}_Y(f(x), y)$, because $y_! *$ is the representable presheaf $\mathrm{Hom}_Y(-, y)$. Its source is

$$(j_! *)_x \simeq \coprod_{\alpha : f(x) \to y} |NL_f(x, \alpha)|.$$

Indeed, the left pointwise formula is the homotopy colimit of the point over $x\backslash X_y$ (with the opposite convention making no difference to its realization), and this category is the disjoint union of the lift categories indexed by α. The mate collapses each summand to its indexing point. It is an equivalence precisely when every summand is weakly contractible. This proves properness from universal right base change, and even shows that the fibre squares alone suffice for this converse.

For the smooth converse, fix $p : Y' \to Y$ and assume that base change along p commutes with every right direct image in the derivator of spaces. Choose $f : e \to Y$ selecting any y_0, and evaluate at $y' \in Y'$. For every space M, the comparison becomes

$$\mathrm{Map}(S, M) \longrightarrow \mathrm{Map}(|N(Y'_{y_0}/y')|, M), \qquad S = \mathrm{Hom}_Y(y_0, p(y')),$$

where S is discrete. The map underlying this comparison sends an arrow $z \to y'$ with $p(z) = y_0$ to its image in Y. If the displayed map is an equivalence for every M, Yoneda in the homotopy category of spaces says that this underlying map to S is an equivalence. Its fibre over $\beta : y_0 \to p(y')$ is the nerve of the incoming lift category at y'. All these categories are therefore weakly contractible, which is smoothness.

The converse statements thus require no conjectural detection principle left over from these pages. There is, however, a notational qualification in the printed paragraph: a comparison involving f_* requires right Kan extensions, which the manuscript calls a derivator "à gauche." The subsequent sentence concerning $f_!$ requires left Kan extensions. Where the edition switches these adjectives, the adjunctions identify the intended assertion without ambiguity. Passing to the left-adjoint mate also explains condition (b) on manuscript p. 59: for a pullback square, properness of the right vertical functor controls

$$q_! f'^* \longrightarrow f^* p_!,$$

just as it controls $p^* f_* \to f'_* q^*$. These are two adjoint forms of one exactness statement.

est à fibres contractiles.

Autre situation standard où le changement de base marche (mais où les foncteurs qui interviennent n'ont aucune raison d'être propres ou lisses).

Soient

$$f : I \longrightarrow I' \quad , \qquad g : J \longrightarrow J'$$

dans Dia, d'où le diagramme (comparer page 23)

$$\begin{array}{ccc} X' = I \times J & \xrightarrow{G'} & I \times J' = X \\ {\scriptstyle F'}\downarrow & & \downarrow{\scriptstyle F} \\ Y' = I' \times J & \xrightarrow{G} & I' \times J' = Y \end{array} \quad .$$

Ce diagramme est tel que pour tout dérivateur à gauche

[page 60]

Commentary · Exposition [ms. 59]

Independent changes of the two variables

The product square illustrates exactness that does not arise from properness of either original functor. Its proof is worth expanding because it also checks the correction in brackets on manuscript p. 60. Fix

$$x_0 = (i_0, j_0'), \quad y_0' = (i_0', j_0), \quad \alpha = (u_0' : f(i_0) \to i_0',\ v_0' : j_0' \to g(j_0)).$$

An object of the factorization category is specified by $i \in I$, $j \in J$ and arrows

$$a : i_0 \to i, \quad r : f(i) \to i_0', \quad b : j_0' \to g(j), \quad s : j \to j_0$$

with $rf(a) = u_0'$ and $g(s)b = v_0'$. The first equation and the second are independent. The same separation holds for morphisms, giving the isomorphism

$$K \cong (i_0, u_0')\backslash(I/i_0') \ \times \ (j_0'\backslash J)/(j_0, v_0').$$

The first factor has initial object $((i_0, u_0'), 1)$; the second has terminal object $((j_0, v_0'), 1)$. Their nerves are therefore contractible, as is the product. This proves the desired base-change isomorphism. The product need not itself have an initial object, which is why the second part of the edition's bracketed correction is necessary as well as the corrected formula.

The result says that a homotopy Kan extension in one variable can be performed while retaining the other variable as a parameter. Restriction in that other variable commutes with the extension. It is one reason that shifted derivators $\mathbb{D}^J(I) = \mathbb{D}(I \times J)$ provide an efficient language for parametrized constructions. It does not say that an arbitrary homotopy limit commutes with an arbitrary homotopy colimit. The latter exchange is the stronger question raised earlier in the chapter and requires additional hypotheses.

on a le changement de base

$$G^* F_* \simeq F'_* G'^* \quad ,$$

la raison ici étant que les foncteurs induits

$$X'/y' \longrightarrow X/y$$

sont des hot-équivalences costrictes, *i.e.* que les catégories K (page 49) sont contractiles. En effet, si $x_0 = (i_0, j_0') \in \mathsf{Ob}X$, $y_0' = (i_0', j_0) \in \mathsf{Ob}Y'$, $u_0 = (u_0', v_0') : F(x_0) \to G(y_0')$, où $u_0' : f(i_0) \to i_0'$, $v_0' : j_0' \to g(j_0)$ sont donnés, on vérifie que la catégorie K cherchée est isomorphe simplement à $(i_0, u_0')\backslash(I/i_0') \times (j_0, v_0')\backslash(J/j_0')$ qui est contractile ayant un objet initial `[plutôt` $(i_0, u_0')\backslash(I/i_0') \times (j_0'\backslash J)/(j_0, v_0')$ `qui est contractile étant produit d'une catégorie ayant un objet initial et d'une catégorie ayant un objet final]`. Ouf!

Je m'aperçois d'un très gros canular. Je croyais me rappeler que pour $f : X \to Y$ qui est une hot-équivalence stricte, on avait pour tout $F \in \mathbb{D}(Y)$, $F \xrightarrow{\sim} f_* f^* F$ (par exemple pour $\mathbb{D} = \mathsf{Der}(Ab)$, ou $\mathbb{D} = \mathsf{Hot}$), *i.e.* f^* pleinement fidèle, d'où aussi que $\Gamma_{\mathbb{D}}(Y, F) \to \Gamma_{\mathbb{D}}(X, f^* F)$ est `[un]` isomorphisme. Mais ce n'est vrai que si F est un coefficient *constant* sur Y, *i.e.* de la forme $q^*(M)$ ($q : Y \to e$, $M \in \mathbb{D}(e) = \mathcal{A}_{\mathbb{D}}$). C'est faux, pour F général, déjà dans le cas de l'immersion $f : \{\varphi\} \to Y$, où φ est un objet initial. Alors, f est toujours une hot-équivalence stricte, mais l'homomorphisme $\Gamma(Y, F) \to \Gamma(X, f^* F)$ n'est en général pas un isomorphisme.

Commentary · Development (commentators') [ms. 60]

A cone construction exposing the homotopy obstruction

The lifting criterion allows an entire space of obstructions to be placed into a functor over the walking arrow. The criterion itself is established mathematics. We did not find the following explicit organization, including its universal ordinary base-change test, in the passages checked in Maltsiniotis (2005, §1 and §4) and Groth et al. (2014a, §3). We record the construction and its proof as a development of the present discussion, without a claim of priority.

Proposition (the cone test). [ours] All categories are small relative to the fixed indexing universe, and completeness below refers to its small limits. Let K be a small category and let $X = K^{\triangleleft}$ be obtained by freely adjoining an initial object o. Define

$$f : X \longrightarrow [1], \qquad f(o) = 0, \quad f(k) = 1 \quad (k \in K).$$

Then f is smooth and a weak equivalence on nerves. It is proper if and only if NK is weakly contractible. If K is nonempty and connected, every strict base-change square for f satisfies right Beck–Chevalley for ordinary diagrams in every complete category. If in addition NK is not weakly contractible, the fibre square at 1 fails right Beck–Chevalley for the derivator of spaces.

Proof. For an incoming arrow into o, the only relevant base arrow is 1_0, and its lift category is a point. For a target $k \in K$ and base arrow $0 \to 1$, the unique lift is $o \to k$, so again the lift category is a point. For base arrow 1_1, the incoming lift category is K/k, with terminal object 1_k. This proves smoothness. Both X and $[1]$ have initial objects; their nerves are contractible, and every functor between them is a weak equivalence on nerves.

The outgoing lift categories are equally explicit. At o over 1_0 the lift category is a point; at $k \in K$ over 1_1 it is $k\backslash K$, with initial object 1_k. The remaining lift category, at o over $0 \to 1$, is exactly K. Thus properness is equivalent to weak contractibility of NK.

For the assertion about ordinary base change, let $p : Y' \to [1]$ be arbitrary and let $X' = X \times_{[1]} Y'$. Fix $y' \in Y'$ and consider

$$h : X'/y' \longrightarrow X/p(y').$$

If $p(y') = 0$, its target is the one-object category consisting of o, and its source is Y'/y', since every arrow into y' must lie over 1_0. The source has a terminal object. If $p(y') = 1$, identify $X/1$ with X. For $k \in K$ there is an isomorphism

$$k\backslash h \cong (k\backslash K) \times (Y'_1/y'),$$

where Y'_1 is the full subcategory of objects sent to 1. Both factors are nonempty and connected: the first has an initial object, the second a terminal object. For the remaining object o, the comma category $o\backslash h$ is X'/y' itself. It contains the full subcategory $K \times \{y'\}$, which is connected. Every object $(a, z \to y')$ maps to this subcategory: if $a \in K$, use (a, y'); if $a = o$, choose any $k \in K$ and use $o \to k$. Hence $o\backslash h$ is nonempty and connected as well.

For completeness, this connectedness criterion preserves ordinary limits of contravariant diagrams for the following direct reason. Given a cone with vertex T over Fh, define its component at a by choosing $(b, a \to h(b))$ in $a\backslash h$ and composing $T \to F(h(b)) \to F(a)$. Morphisms in the comma category give equal composites, and connectedness makes the choice irrelevant. Applying this to an arrow $a \to a'$ proves compatibility of the constructed components. It is the unique cone over F inducing the given cone. Thus restriction induces a bijection on cones with every vertex T, proving the limit comparison isomorphism and consequently ordinary right base change.

Finally take $p : e \to [1]$ to select 1. For a constant space coefficient M, the comparison is

$$M \simeq \mathrm{Map}(|NX|, M) \longrightarrow \mathrm{Map}(|NK|, M).$$

If this were an equivalence for every M, the map $|NK| \to *$ would be an isomorphism in the homotopy category by Yoneda, contradicting the hypothesis. This proves the last assertion. □

A finite example makes the failure explicit. Take K to have four objects a_0, a_1, b_0, b_1, with the four nonidentity arrows $a_i \to b_j$ and no others. Its nerve has four vertices, four edges, and no nondegenerate higher simplices; its realization is a circle. The category X has five objects. All the

ordinary base-change comparisons in the proposition are invertible. In the derivator of spaces, take $M = S^1$. The comparison for the fibre at 1 is

$$S^1 \longrightarrow \mathrm{Map}(S^1, S^1),$$

sending a point to the constant map. The source has one connected component, whereas the target has components indexed by the integer degree. The map lands in degree zero and is not surjective on components. Here the distinction between connected lift categories and contractible lift categories accounts for the entire obstruction.

Notions de $\mathbb{D}$-équivalence et de $\mathbb{D}$-contractibilité.

On va donc reprendre les questions d'acyclicité et de changement de base.

Définition 1. Soit $\mathbb{D}$ un prédérivateur, et soit

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & e & \end{array}$$

dans Dia. On dit que f est une $\mathbb{D}$-*équivalence* si le foncteur

$$F \longmapsto f^*F \quad , \qquad \mathbb{D}(Y) \longrightarrow \mathbb{D}(X)$$

induit un foncteur pleinement fidèle sur la sous-catégorie de $\mathbb{D}(Y)$ formée des $\mathbb{D}$-coefficients *constants*, *i.e.* si pour tous $M, N \in \mathsf{Ob}\mathcal{A} = \mathbb{D}(e)$ ("coefficients absolus"), on a

$$\mathsf{Hom}(q^*M, q^*N) \xrightarrow{\sim} \mathsf{Hom}(p^*M, p^*N) \quad . \tag{1}$$

Supposons que p_* et q_* existent. On posera, pour un faisceau F sur X

$$H^*_{\mathbb{D}}(X, F) \overset{\text{déf}}{=} p_*(F) \qquad (\text{et de même } \ H^{\mathbb{D}}_*(X, F) = p_!(F)\ ).$$

N.B. Et si $F = p^*M$, $M \in \mathcal{A}$, on note simplement $H^*_{\mathbb{D}}(X, M)$, $H^{\mathbb{D}}_*(X, M)$.
L'homomorphisme (1) s'interprète par adjonction comme

$$\begin{array}{ccc} \mathsf{Hom}(M, q_*q^*N) & \longrightarrow & \mathsf{Hom}(M, p_*p^*N) \\ \| & & \| \\ \mathsf{Hom}(M, H^*_{\mathbb{D}}(Y, q^*N)) & \longrightarrow & \mathsf{Hom}(M, H^*_{\mathbb{D}}(X, p^*N)) \end{array}$$

déduit de l'homomorphisme

$$q_*q^*N \longrightarrow p_*p^*N \quad , \qquad i.e. \quad H^*_{\mathbb{D}}(Y, N) \longrightarrow H^*_{\mathbb{D}}(X, N) \quad . \tag{2}$$

Donc dire que (1) est un isomorphisme pour tous M, N signifie que (2) est un isomorphisme pour tout N. De même, si $p_!$, $q_!$ existent cela équivaut à dire que

$$p_!p^*N \longrightarrow q_!q^*N \quad , \qquad i.e. \quad H^{\mathbb{D}}_*(X, N) \longrightarrow H^{\mathbb{D}}_*(Y, N) \tag{2'}$$

est un isomorphisme dans $\mathcal{A}$ pour tout $N \in \mathcal{A}$.

p. 36
[page 62]

Commentary · Exposition [ms. 61]

Equivalence measured by constant coefficients

The definition of $\mathbb{D}$-equivalence deliberately retains less information than an equivalence $\mathbb{D}(Y) \simeq \mathbb{D}(X)$. It compares only the full subcategories formed by constant coefficients, while retaining every morphism between them in the coherent diagram categories. Such morphisms can contain cohomological information not visible in the values of the constant diagrams themselves.

Write $p : X \to e$ and $q : Y \to e$, with $p = qf$. If the required right adjoints exist, adjunction gives

$$\mathrm{Hom}_{\mathbb{D}(Y)}(q^*M, q^*N) \cong \mathrm{Hom}_{\mathbb{D}(e)}(M, q_*q^*N).$$

The analogous formula for X identifies the restriction map with the map represented by $q_*q^*N \to p_*p^*N$. It is bijective for every M exactly when this representing map is invertible. This is ordinary Yoneda in $\mathbb{D}(e)$; it does not require an enrichment. With left adjoints one instead writes

$$\mathrm{Hom}_{\mathbb{D}(Y)}(q^*M, q^*N) \cong \mathrm{Hom}_{\mathbb{D}(e)}(q_!q^*M, N)$$

and uses contravariant Yoneda while varying N. This proves both characterizations on manuscript p. 62, including the weaker existence hypothesis that only the representing objects for constant coefficients are needed.

The elementary formal properties also hold already for prederivators. A natural transformation $f \Rightarrow g$ induces the identity on the restrictions of constant coefficients, because its composite with $Y \to e$ is the identity transformation. The maps on their Hom sets therefore agree; a zigzag of transformations has the same consequence. For composable functors, the maps on these sets compose. Two-out-of-three for bijections proves two-out-of-three for $\mathbb{D}$-equivalences. Taking the terminal category as target then gives the characterization of $\mathbb{D}$-contractibility by full faithfulness of the constant-diagram functor.

For $\mathbb{D} = \mathsf{HOT}$ the representing objects have familiar meanings:

$$H^*_{\mathsf{HOT}}(X, M) \simeq \mathrm{Map}(|NX|, M), \qquad H_*^{\mathsf{HOT}}(X, M) \simeq |NX| \times M.$$

The first expression is the derived *mapping space*, considered as an object of the homotopy category. It is not the ordinary Hom set of that category: taking only its connected components would lose higher information. This is the intended reading of the printed $\mathrm{Hom}_{\mathcal{A}}$ in the example. The second formula follows because the homotopy colimit of a constant space is its tensor with the classifying space of the indexing category. These two constructions are adjoint: products with $|NX|$ are left adjoint to mapping spaces out of $|NX|$. Setting $M = *$ in the homological formula proves that a HOT-equivalence is precisely a weak equivalence of nerves; the converse follows by taking products with arbitrary M. The coefficient-sensitive definition thus recovers the ordinary homotopy type for this particular derivator, without asserting that every coefficient theory detects the same class of functors.

En résumé :

Proposition 1. *Si p_* et q_* existent, i.e. si $H^*_{\mathbb{D}}(X, \bullet)$ et $H^*_{\mathbb{D}}(Y, \bullet)$ existent (il suffit même que ça existe pour des coefficients constants), alors f est une $\mathbb{D}$-équivalence si et seulement si f induit un isomorphisme pour les $\mathbb{D}$-cohomologies à coefficients constants de X et Y. Si $p_!$ et $q_!$ existent, i.e. si $H^{\mathbb{D}}_*(X, \bullet)$ et $H^{\mathbb{D}}_*(Y, \bullet)$ existent, f est une $\mathbb{D}$-équivalence si et seulement si f induit un isomorphisme pour les $\mathbb{D}$-homologies à coefficients constants de X et Y.*

Remarque 1. Pour que f soit `[une]` $\mathbb{D}$-équivalence, il *suffit* que pour tout F *constant* sur Y le morphisme d'adjonction $F \to f_*f^*F$ soit `[un]` isomorphisme.

Remarque 2. Si f, $f' : X \to Y$ sont dans une même composante connexe de $\underline{\mathsf{Hom}}(X, Y)$, alors f est $\mathbb{D}$-équivalence $\Leftrightarrow$ f' $\mathbb{D}$-équivalence.

Proposition 2. *Les isomorphismes sont des $\mathbb{D}$-équivalences. Si $X \xrightarrow{f} Y \xrightarrow{g} Z$, si deux parmis f, g, gf sont des $\mathbb{D}$-équivalences, le troisième aussi.*

Définition 2. On dit que X dans Dia est $\mathbb{D}$-*asphérique* (ou $\mathbb{D}$-*contractile*, ou $\mathbb{D}$-*trivial*) si $X \xrightarrow{p} e$ est une $\mathbb{D}$-équivalence, *i.e.* si p^* est pleinement fidèle.

Si p_* existe, cela signifie donc que pour $M \in \mathsf{Ob}(\mathcal{A})$

$$M \xrightarrow[\sim]{\text{adj}} p_* p^* M \quad , \qquad i.e. \quad M \xrightarrow{\sim} H^*_{\mathbb{D}}(X, M) \quad ,$$

et si $p_!$ existe, cela signifie que pour tout M

$$p_! p^* M \xrightarrow[\sim]{\text{adj}} M \quad , \qquad i.e. \quad H^{\mathbb{D}}_*(X, M) \xrightarrow{\sim} M \quad .$$

Corollaire. *Si Y* (resp. X) *est contractile, alors $f : X \to Y$ est une $\mathbb{D}$-équivalence si et seulement si X* (resp. Y) *est contractile.*

Exemple. Prenons $\mathbb{D} = \mathsf{HOT}$. (On peut prendre Dia = catégorie des petites catégories). Alors, pour $M \in \mathcal{A} = \mathsf{Hot}$ et X petite catégorie, on a

$$H^*_{\mathsf{HOT}}(X, M) \simeq \mathsf{Hom}_{\mathcal{A}}(\mathsf{hot}(X), M) \quad ,$$

où

$$\mathsf{hot} : \mathcal{C}at \longrightarrow \mathcal{A} = \mathsf{Hot}$$

est le foncteur canonique qui associe à tout X son "type d'homotopie". On a

$$H^{\mathsf{HOT}}_*(X, M) = \mathsf{hot}(X) \times M \quad .$$

Commentary · Examples [ms. 62]

How much constant coefficients can detect

The definition of $\mathbb{D}$-equivalence invites a small calculation which makes the dependence on the coefficient theory completely explicit. This calculation concerns represented *prederivators*; no existence of Kan extensions is required. We use $\pi_0 I$ for the set of equivalence classes of objects under zigzags of arrows, equivalently the connected components of NI.

Proposition (coefficient sensitivity of a represented theory). Let A be a locally small category and let $\mathbb{D}_A(I) = \mathrm{Fun}(I^{\mathrm{op}}, A)$. For a functor $f : X \to Y$, precisely the following alternatives occur.

(i) If some set $\mathrm{Hom}_A(M, N)$ contains two different elements, then f is a $\mathbb{D}_A$-equivalence if and only if $\pi_0 f : \pi_0 X \to \pi_0 Y$ is a bijection.

(ii) If every hom-set has at most one element and at least one hom-set is empty, then f is a $\mathbb{D}_A$-equivalence if and only if X is empty exactly when Y is empty.

(iii) If A is empty, or if every hom-set of the nonempty category A is a singleton, then every functor is a $\mathbb{D}_A$-equivalence. In the latter case A is equivalent to the terminal category.

Proof. A natural transformation between constant A-valued diagrams with values M and N consists of arrows $a_i : M \to N$. Naturality along any arrow of I says that the two corresponding arrows a_i are equal. Thus, canonically,

$$\mathrm{Hom}_{\mathbb{D}_A(I)}(M_I, N_I) \cong \mathrm{Hom}_A(M, N)^{\pi_0 I}.$$

Restriction along f is precomposition with $u = \pi_0 f$. If u is a bijection, all these restriction maps are bijections. Conversely, suppose a hom-set H contains distinct elements a, b. If u is not surjective, choose a component of Y outside its image. The constant a-valued function on $\pi_0 Y$ and the function which takes value b only at that component have the same restriction. If u is not injective, choose different components x_1, x_2 with the same image. The function on $\pi_0 X$ taking value b at x_2 and a elsewhere cannot be a restriction. Hence bijectivity on H-valued functions forces u to be a bijection, proving (i).

For (ii), every hom-set is either a singleton or the empty set. Singleton-valued functions never impose a condition. For an empty hom-set, its power by a set S is a singleton when S is empty and is empty otherwise. Therefore the induced map is bijective exactly when $\pi_0 X$ and $\pi_0 Y$ have the

same emptiness status. The hypothesis that an empty hom-set exists makes this condition necessary. For (iii), there are either no pairs (M, N) to test, or each tested set of transformations is a singleton. Finally, if all hom-sets in a nonempty A are singletons, the unique arrows between any two objects are inverse, since the only endomorphism is the identity. This proves the stated equivalence with the terminal category. □

For $A = \mathsf{Set}$, or $A = \mathsf{Ab}$, alternative (i) applies. For the two-element ordered category $0 < 1$, alternative (ii) applies: all functors between nonempty indexing categories are equivalences for this coefficient test. More strikingly, if G is a nontrivial group, the functor $BG \to e$ is a $\mathbb{D}_A$-equivalence for *every* represented prederivator. Both categories have one connected component, so the displayed formula proves the assertion without assumptions on A. To see directly why spaces distinguish it, write $B = |N(BG)|$ and take the constant coefficients $M = *$ and $N = B$. The tested map identifies with

$$[*, B] \longrightarrow [B, B].$$

Its image consists of the homotopy class of constant maps. The identity of B is not in this image: it induces the identity on the nontrivial fundamental group G, whereas a constant map induces the trivial homomorphism. The identification follows from the constant-coefficient homotopy-limit formula $\operatorname{holim}_{(BG)^{\mathrm{op}}} B \simeq \mathrm{Map}(B, B)$ explained in the preceding source discussion. Thus this functor is not a HOT-equivalence, and constant coefficients in an ordinary functor category and constant coefficients in the localized theory of spaces have quite different detecting power.

The hom-set calculation is the elementary naturality condition for constant functors; compare Riehl (n.d., §§1.4 and 1.7). The connected-component test in the first case is standard. We have written out the thin and empty cases as well, so that no nondegeneracy assumption on the coefficient category is hidden. This is an elementary worked consequence of naturality, not an additional axiom on a derivator.

On en déduit que $f : X \to Y$ est une HOT-équivalence (au sens de la définition 1) si et seulement si c'est une hot-équivalence (ou "équivalence faible") *i.e.* si et seulement si

$$\mathsf{hot}(f) : \mathsf{hot}(X) \xrightarrow{\sim} \mathsf{hot}(Y)$$

est un isomorphisme.

Proposition 2. *Soit $f : X \to Y$. Conditions équivalentes (si $\mathbb{D}$ `[est un]` dérivateur à gauche).* p. 37

a) *f est une $\mathbb{D}$-équivalence, et le reste après tout changement de base $Y' \to Y$ qui est un isomorphisme local (par exemple pour $Y/F \to Y$, $F \in \mathsf{Ob}\widehat{Y}$).*

b) *Pour tout $y \in \mathsf{Ob}Y$, le foncteur induit $X/y \to Y/y$ est une $\mathbb{D}$-équivalence.*

c) *Pour tout $y \in \mathsf{Ob}Y$, X/y est $\mathbb{D}$-contractile.*[25]

N.B. On dit que $g : Z \to Y$ est un *isomorphisme local* si pour tout $z \in \mathsf{Ob}Z$, posons $y = g(z)$, le morphisme induit sur les catégories localisées en z et y

$$Z/z \xrightarrow{\sim} Y/y$$

est un isomorphisme. Par exemple toute immersion ouverte, tout foncteur induit $Y/y \to Y$ (foncteur de localisation) sont des isomorphismes locaux.

Il en résulte a) ⇒ b) trivialement.

b) ⇔ c). Résulte du corollaire de la page précédente, si l'on sait que Y/y est $\mathbb{D}$-contractile[26]. Cela résultera de **Der 5** ci-dessous.

c) ⇒ a) "Passage du local au global". Comme l'hypothèse c) est stable par changement de base par immersion ouverte, il suffit de prouver que c) implique que f est une $\mathbb{D}$-équivalence, *i.e.* que pour tout $F = M_Y$ ($M \in \mathsf{Ob}\mathcal{A}$), coefficient constant sur Y, l'homomorphisme d'adjonction [page 64]

$$M_Y \longrightarrow f_* f^* M_Y = f_* M_X$$

25. Autres conditions équivalentes :
d) *Pour tout faisceau constant M_Y sur Y, on a $M_Y \xrightarrow{\sim} f_* f^* M_Y$.*
d′) *Comme* d) *avec faisceau localement constant.*

26. Cf. cor. 1 de **Der 5** (g)

est [un] isomorphisme. Il suffit de prouver que c'est un isomorphisme fibre par fibre (**Der 2**), donc que pour tout $y \in Y$,

$$M_y \longrightarrow f_*(M_X)_y$$

est un isomorphisme. Par **Der 4** (g), on a

$$f_*(M_X)_y \xrightarrow{\sim} \Gamma(X/y, M) \quad ,$$

et l'hypothèse que X/y est $\mathbb{D}$-contractile donne ce qu'on veut.

Proposition 2′. *Dualement, si $\mathbb{D}$ est un dérivateur à gauche* [plutôt à droite]*, conditions équivalentes sur $f : X \to Y$:*

a) *f $\mathbb{D}$-équivalence,* [et] *le reste par tout changement de base $g : Y' \to Y$ qui est un "isomorphisme colocal" (i.e. pour tout $y' \in \mathsf{Ob}Y'$, le foncteur induit sur les catégories "colocalisées" $y'\backslash Y' \xrightarrow{\sim} y\backslash Y$ (où $y = g(y')$)* [est un isomorphisme]*).*

b) *Pour tout $y \in Y$, le foncteur induit $y\backslash X \to y\backslash Y$ est une $\mathbb{D}$-équivalence.*

c) *Pour tout $y \in Y$, $y\backslash Y$ est $\mathbb{D}$-contractile.*

Pour le prouver, on doit utiliser que les $y\backslash Y$ sont $\mathbb{D}$-contractiles (cf. cor. 1 de **Der 5** (d)).

Commentary · Exposition [ms. 64]

Local isomorphisms and local constancy

A local isomorphism in this text is a discrete fibration of categories. Indeed, the requirement that $Z/z \to Y/g(z)$ be an isomorphism says that every arrow $y_0 \to g(z)$ has exactly one lift with target z. Conversely, unique lifts give the required inverse on slice categories, including their morphisms. A category of elements of a presheaf has this property: lifting an arrow into an element means taking its restriction. The projection $Y/y \to Y$ is the representable case.

This description supplies a small omitted step in the implication (c)⇒(a). The text mentions stability under open immersions, while (a) quantifies over all local isomorphisms. If $g : Y' \to Y$ is a discrete fibration and $X' = X \times_Y Y'$, then for every $y' \in Y'$ there is a canonical isomorphism

$$X'/y' \cong X/g(y').$$

To recover the left-hand object from $(x, \alpha : f(x) \to g(y'))$, lift α uniquely with target y'. Its source y'_0 satisfies $g(y'_0) = f(x)$ and gives the required pair (x, y'_0). Unique lifting also identifies all arrows. Hence condition (c) is stable under every base change in (a), not merely the sieve inclusions mentioned in the proof. The remainder of the argument is complete: the unit on a constant coefficient, evaluated at y, is

$$M \longrightarrow \Gamma_{\mathbb{D}}(X/y, M),$$

which is invertible by $\mathbb{D}$-contractibility, and **Der 2** makes the unit invertible globally.

The locally constant strengthening in footnote 25 has a similarly short proof. Let $F \in \mathbb{D}(Y)$ have invertible structure maps. On Y/y, the natural transformation from the projection to the constant functor at y induces, in the presheaf convention, a morphism from the constant coefficient with value F_y to the restriction of F. Every component is invertible. By **Der 2** this is an isomorphism of coherent coefficients. Its pullback to X/y is therefore constant as well, so the preceding argument applies. Conversely, a statement for every locally constant coefficient includes every constant coefficient. This proves the equivalence claimed in the footnote, rather than requiring local constancy to be an additional axiom.

In Proposition $2'$ the displayed condition (c) must read $y\backslash X$, as duality and condition (b) require. The edition prints $y\backslash Y$. Read literally, that condition holds automatically because $y\backslash Y$ has an initial object, and cannot characterize f. For example, $\emptyset \to e$ fails to be an equivalence for the derivator represented by sets although the printed (c) holds. The following sentence about the contractibility of $y\backslash Y$ is correct: that is the *base* category used to pass between (b) and the repaired (c).

The closure assertions on manuscript p. 65 now have transparent proofs. Pullback preserves discrete fibrations. After a local base change over Z, a composite of strict $\mathbb{D}$-equivalences remains a composite of $\mathbb{D}$-equivalences. The same argument and two-out-of-three prove cancellation when f and gf are strict. For a categorical equivalence f, the pullback along a discrete fibration is again an equivalence: full faithfulness follows by uniquely lifting the arrow upstairs through f, and essential surjectivity follows by lifting an isomorphism with prescribed target through the discrete fibration. Any prederivator preserves categorical equivalences. The assertion about equivalences therefore needs no stronger hypothesis at this point.

Définition 3. Soit $\mathbb{D}$ un prédérivateur (peut-être même un dérivateur à gauche ou à droite). On dit que f est une $\mathbb{D}$-équivalence *stricte* si f satisfait la condition a) de `[la]` proposition 2. On dit que c'est une $\mathbb{D}$-équivalence *costricte* si f satisfait celle de `[la]` proposition $2'$; on dit aussi parfois que f est $\mathbb{D}$-cofinal. (La condition duale, *i.e.* $\mathbb{D}$-équivalence stricte, s'appelerait co-$\mathbb{D}$-cofinal!) [27]

Proposition 3. *Soit $X \xrightarrow{f} Y \xrightarrow{g} Z$. Si f, g sont des $\mathbb{D}$-équivalences strictes, alors gf aussi. Si gf et f sont des $\mathbb{D}$-équivalences strictes, alors g aussi. Si $\mathbb{D}$* `[est un]` *dérivateur à gauche ou à droite, toute équivalence* `[de catégories]` *est une $\mathbb{D}$-équivalence stricte.* (Car elle a un adjoint à droite.)

27. Meilleure terminologie : f est $\mathbb{D}$-*asphérique* ($\mathbb{D}$-équivalence stricte), $\mathbb{D}$-*coasphérique* ($\mathbb{D}$-équivalence costricte).

On utilise le fait que la notion d'isomorphisme local est stable par changement de base.

[page 66]

Proposition 4. *Soient $\mathbb{D}$ un dérivateur à droite, $f : X \to Y$ un foncteur dans* Dia*, tel que pour $y \in Y$, $y\backslash X$ soit $\mathbb{D}$-contractile (donc f une $\mathbb{D}$-équivalence costricte, sous réserve que $\mathbb{D}$ soit un dérivateur à droite …). Alors pour tout F dans $\mathbb{D}(Y)$ (pas nécessairement à coefficients constant) on a*

$$H^*_{\mathbb{D}}(Y, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(X, f^*(F))$$

est un isomorphisme. Réciproquement, si la condition est vraie pour tout F, alors les $y\backslash X$ sont $\mathbb{D}$-contractiles.

Démonstration. Il revient au même de dire que pour tout $M \in \mathsf{Ob}\mathcal{A} = \mathbb{D}(e)$, on a

$$\mathsf{Hom}(M, H^*_{\mathbb{D}}(Y, F)) \xrightarrow{\text{iso}} \mathsf{Hom}(M, H^*_{\mathbb{D}}(X, f^*(F))) \ .$$

Mais par adjonction, cette flèche s'interprète comme

$$(*) \qquad \mathsf{Hom}(M_Y, F) \longrightarrow \mathsf{Hom}(M_X, f^*F)$$

D'autre part, si $f_!$ existe, on a

$$\mathsf{Hom}(M_X, f^*F) = \mathsf{Hom}(f_!(M_X), F) \ ,$$

et l'homomorphisme $(*)$ est déduit de l'homomorphisme d'adjonction

$$(**) \qquad f_!(M_X) = f_!(f^*(M_Y)) \longrightarrow M_Y \ ,$$

en prenant les Hom dans F. Donc la condition équivaut à dire que cet homomorphisme est [un] isomorphisme, quel que soit le coefficient constant M_Y sur Y. Pour voir si c'est un isomorphisme, on regarde fibre par fibre (**Der 2**), or les fibres s'interprètent comme $H^{\mathbb{D}}_*(y\backslash X, M_X)$ (par **Der 4** (d)) et comme M.

Commentary · Exposition [ms. 66]

Cofinality and the final Yoneda argument

The final proposition explains why coasphericity controls arbitrary coefficients although $\mathbb{D}$-equivalence was defined using constant ones. Its proof varies the *target* coefficient while keeping the source constant. That change in the Yoneda argument is what strengthens the conclusion.

There is one existence qualification. A derivator "à droite" in the terminology of these pages supplies $f_!$, not the absolute right Kan extensions used to define $H^*_{\mathbb{D}}$. The cohomological statement consequently also requires the existence of p_* and q_*, where $p : X \to e$ and $q : Y \to e$. Without them the Hom-set formulation in the proof remains meaningful and gives the correct one-sided statement. We prove that formulation first.

Suppose left Kan extensions and their pointwise formulas exist. For $M \in \mathbb{D}(e)$, abbreviate p^*M and q^*M to M_X and M_Y. Adjunction identifies the map

$$\mathrm{Hom}_{\mathbb{D}(Y)}(M_Y, F) \longrightarrow \mathrm{Hom}_{\mathbb{D}(X)}(M_X, f^*F)$$

with precomposition by the counit

$$\varepsilon_M : f_!M_X \longrightarrow M_Y.$$

For fixed M, this is a bijection for every F if and only if ε_M is invertible, by Yoneda in $\mathbb{D}(Y)$. By conservativity and the left pointwise formula, that happens for every M if and only if

$$H^{\mathbb{D}}_*(y\backslash X, M) \longrightarrow M$$

is invertible for every y and M. By the definition and characterization of $\mathbb{D}$-contractibility, this is precisely the requirement that every $y\backslash X$ be $\mathbb{D}$-contractible. Thus the forward implication and the converse in the Hom-set statement are both proved using only the left Kan extensions.

Now assume in addition that p_* and q_* exist. Adjunction identifies the same Hom comparison with

$$\mathrm{Hom}_{\mathbb{D}(e)}(M, q_*F) \longrightarrow \mathrm{Hom}_{\mathbb{D}(e)}(M, p_*f^*F).$$

Varying M and applying Yoneda once more makes its bijectivity equivalent to invertibility of $q_*F \to p_*f^*F$. This proves the cohomological statement exactly as intended, with its existence hypothesis made explicit. No additional repair of the algebraic proof is needed. In modern terminology this is the cofinality criterion for the relevant homotopy limits, with the comma orientation dictated throughout by the presheaf convention.

Overview · I-a

Chapter I, first part: from presheaf operations to homotopical base change

These pages construct a language in which a homotopy theory can carry its own diagram categories. The point of departure is elementary: a functor of indexing categories gives restriction of presheaves, restriction has Kan-extension adjoints when the required limits exist, and special inclusions admit further adjoints when the coefficient category is pointed. What changes in passing to homotopy theory is the meaning of a diagram. A diagram in a homotopy category records only the images of objects and arrows after localization. Localizing a category of diagrams retains additional morphisms and coherence. Grothendieck proposes to organize all these localized categories together, so that a universal construction can be performed on a coherent diagram and remain compatible with further parameters.

The historical motivation is stated explicitly in *Pursuing Stacks*, §69: a single derived category does not provide an adequate setting for the trace and determinant identities encountered around SGA 5 (Grothendieck, 1983, §69). Categories of filtered complexes and diagrams of complexes supply more information, but they too must be organized into a structure stable under introducing new diagram shapes. The letter to Thomason of 2 April 1991 describes the renewed investigation of this intrinsic structure (Grothendieck, 1991a, pp. 2–4). Heller's homotopy theories form a closely related independent axiomatic development (Heller, 1988). The present opening chapter is exploratory: proposed axioms are changed, conclusions are withdrawn, and the final definitions are reached through computations that reveal which hypotheses are actually needed.

The convention that governs the calculations. We work in a fixed universe of small indexing categories; a restricted domain must contain every opposite, product, coproduct, and comma category used in a particular assertion. The manuscript uses presheaves,

$$\mathbb{D}_A(I) = \mathrm{Fun}(I^{\mathrm{op}}, A), \qquad f_! \dashv f^* \dashv f_*.$$

Thus an object over $[1] = (0 \to 1)$ has an underlying arrow $F_1 \to F_0$. Restriction reverses both functors and natural transformations, so the explicit modern source is $\mathsf{Dia}^{\mathrm{coop}}$. The manuscript calls a theory with right Kan extensions a derivator *à gauche*, because these are the operations of left exactness. A theory with left Kan extensions is called *à droite*. The systematic axioms starting at manuscript p. 41 replace the earlier provisional numbering. These changes of convention are substantive reading instructions: a remembered modern formula with the opposite variance can reverse the cofinality condition.

The ordinary pointwise formulas already display the relevant slices:

$$(f_*F)_y = \lim_{(f/y)^{\mathrm{op}}} F, \qquad (f_!F)_y = \operatorname*{colim}_{(y/f)^{\mathrm{op}}} F.$$

For derivators these are homotopy Kan formulas, expressed by invertibility of specified base-change maps. The map, not merely an isomorphism between its source and target, is part of the assertion. This explains the care devoted to adjunction units, counits, and the two equivalent constructions of the base-change mate.

Supports, coherent squares, and shifts. Open inclusions are sieves and closed inclusions are cosieves. In the presheaf convention a closed inclusion extends by terminal objects under i_*; an open inclusion extends by initial objects under $j_!$. Pointedness identifies the two values with zero and permits the exceptional adjoints $i^!$ and $j^?$. The commentary proves these assertions from their universal properties and works out the nonsplit short exact sequence of arrow diagrams underlying the support decomposition. It also gives the finite-ordinal adjunction chain, including its four exceptional endpoints, while retaining the edition's correction of the stronger claim about every monotone map.

The same nonsplit extension exhibits a nonzero morphism between coherent derived diagrams whose components are all zero. Consequently the underlying-diagram functor is conservative without being faithful. This is precisely the distinction the localization axiom requires. Homotopy cartesian squares are coherent squares obtained by right Kan extension from a missing-corner diagram; they need not be ordinary pullbacks in the base homotopy category. Strongness, when imposed, addresses lifting arrows and morphisms of arrows. It is a separate condition from conservativity.

The shift $\mathbb{D}_I(J) = \mathbb{D}(I \times J)$ turns an entire coherent I-diagram into one coefficient. Its elementary formal properties explain the repeated demand that each new axiom survive shifting. The completed shift theorem and product base change establish the proposed morphisms induced by f^*, $f_!$, and f_*. At manuscript p. 18 the question whether evaluation at the base category is fully faithful also has a concrete negative answer for unrestricted morphisms: the invisible extension class yields a nonzero modification between morphisms out of the represented derivator of [1] whose component at the point is zero. The example does not impose continuity on these morphisms.

For a Quillen model category, existence of the homotopy Kan extensions is a theorem rather than a formal property of localization. Cisinski supplies a precise general treatment (Cisinski, 2003, Theorem 6.11). In the ∞-categorical formulation one takes

$$\mathbb{D}_{\mathcal{C}}(I) = h\,\mathrm{Fun}(N(I)^{\mathrm{op}}, \mathcal{C});$$

the pointwise extensions of a complete and cocomplete ∞-category give the derivator operations (Riehl and Verity, 2017, §5.3). Reconstruction results for the whole prederivator retain their hypotheses on size and morphisms. Renaudin's comparison concerns combinatorial model theories and adjunctions (Renaudin, 2009, Theorems 3.3.2 and 3.4.4), while Arlin distinguishes strict transformations from pseudonatural ones (Arlin, 2020, Theorems 19 and 29). These are stronger invariants than the base category alone.

The exactness question has a finiteness boundary. The connective derived theory HOTAB is additive and pointed but is not stable. Its abelianization morphism from spaces preserves homotopy colimits. It fails to preserve homotopy pullbacks: for two discrete two-point spaces over a point, the comparison is a map from $\mathbb{Z}^4$ to $\mathbb{Z}^3$ with an explicitly displayed rank-one kernel. This separates the true pushout assertion from the false pullback assertion in the same passage.

Stability answers the later "Perplexité" after the scope of exactness is fixed. Between stable derivators, preservation of zero objects and cartesian squares is equivalent to preservation of zero objects and cocartesian squares (Groth, 2013, Corollary 4.17). Homotopy finite limits commute with homotopy colimits in the corresponding precise stable theorem (Groth and Shulman, 2017, Theorem 2.14). Arbitrary products and coproducts still need not commute. The diagonal array of copies of a field gives the comparison $k^{(\mathbb{N})} \to k^{\mathbb{N}}$, which omits every sequence with infinite support. The modern finite theorem therefore does not validate an unrestricted preservation claim for all Kan extensions.

Cofinality and universal base change. The decisive correction in the chapter concerns the coefficient system. Contractibility of every f/y does not make restriction fully faithful on all coefficients. For the inclusion of the initial endpoint into [1], every such comma category is a point, but the unit on $F_1 \to F_0$ contains the original structure map. The example $0 \to \mathbb{Z}$ disproves the proposed axiom. The surviving proof of the later cancelled corollary contains a valid slice identification; its last inference uses exactly the false, opposite-orientation cofinality clause. The audit identifies this inference without inventing an additional gap in the calculation.

For right direct image in the manuscript's convention, the correct cofinality test uses arrows from an object of the target to the image of the functor. Applied pointwise to a square,

it produces categories of factorizations of a fixed base arrow. Their weak contractibility is the universal homotopy-exactness criterion. Properness specializes it to the comparison between a strict fibre and a comma category; smoothness is the dual incoming-lift condition. The commentary completes the composition proof by identifying the relevant lift-category functor as a strict pullback and applying Quillen's Theorem A (Quillen, 1973, §1).

The conjectured converse is established: spaces alone detect universal homotopy exactness, so the proposed simultaneous use of HOT and HOTAB is unnecessary (Groth et al., 2014a, Theorem 3.16). Proper and smooth functors are treated systematically by Maltsiniotis (Maltsiniotis, 2005, Theorem 1.2). Strict pullbacks matter here. An equivalence of categories that misses an object can fail both properness and smoothness, as the two-object groupoid example shows.

The commentators' marked cone construction makes the strength of the homotopical test explicit. Adjoin an initial object to a small category K, send that object to 0, and send K to 1. The resulting functor to [1] is always smooth and a weak equivalence of nerves; it is proper exactly when NK is weakly contractible. If K is nonempty and connected, all its strict base-change squares pass the right Kan test for every complete ordinary coefficient category. A four-object crown gives $|NK| \simeq S^1$ and a failure for space coefficients, detected by the degree components of $\mathrm{Map}(S^1, S^1)$. The construction, including its universal ordinary-coefficient assertion, is proved in full and carries no claim of priority.

The final definition and its scope. The corrected notion of $\mathbb{D}$-equivalence compares every morphism between constant coherent coefficients. By Yoneda it is equivalent, when the representing objects exist, to invariance of constant-coefficient homology or cohomology. Its two-out-of-three property is therefore already formal at the prederivator level. The local versions distinguish discrete fibrations from discrete opfibrations and lead to asphericity and coasphericity. The omitted stability check under all local isomorphisms is supplied by an explicit isomorphism of comma categories. Locally constant coefficients are handled by a canonical morphism on a slice and conservativity.

The last proposition turns this constant-coefficient test into a criterion for arbitrary coefficients by varying the target in a Yoneda argument. Its Hom-set formulation needs left Kan extensions only; its cohomological formulation additionally needs the absolute right Kan extensions that define H^*. This is an existence qualification, not a failure of the argument. The questions treated here consequently have precise answers once variance, coefficient class, finiteness, and existence of adjoints are stated. The attribution to Thomason, which the text leaves unspecified, remains a documentary uncertainty.

Donc la flèche envisagée (∗∗) s'interprète comme ed. 39

[page 67]

$$H_*^{\mathbb{D}}(y\backslash X, M_X) \longrightarrow M$$

$$f_!(M_X) = f_!(f^*(M_Y)) \xrightarrow{\sim} M_Y \ .$$

Commentary · Exposition [ms. 67]

The conclusion reached on manuscript page 67

Manuscript pages 60–66 are commented with the first part of the chapter; its blocks "Equivalence measured by constant coefficients", "How much constant coefficients can detect", "Local isomorphisms and local constancy", and "Cofinality and the final Yoneda argument" give the definitions and the argument now being completed. The distinction needed below is quite exact. A $\mathbb{D}$-equivalence preserves the morphisms between constant objects; a coaspherical functor preserves cohomology with *every* coefficient object on its target. Neither assertion, by itself, says that inverse image is fully faithful on the entire coefficient category.

For the theorem on manuscript page 67, the relevant test is the counit

$$f_! p^* M \longrightarrow q^* M, \qquad p = qf.$$

Applying $\mathrm{Hom}(-, F)$ and then the two adjunctions identifies this test with cohomological invariance for all F. Evaluation at y identifies it instead with the augmentation of homology of $(y\backslash f)$ with constant value M. These are two readings of the *same natural transformation*. This observation explains the appearance of homology in a theorem about cohomology; it also prevents a spurious gap from being introduced into an otherwise complete Yoneda argument. The theorem explicitly supplies the right adjoints to the terminal projections, whose existence was less explicit in the proposition on page 66.

Je vais renuméroter les axiomes sur le prédérivateurs.
Der 1, **Der 2** comme avant (p. 45).

Der 3 [28] : Soit X dans Dia, $p : X \to e$. Supposons X contractile. [29] Alors

$$p^* : M \longmapsto M_X \quad , \qquad p^* : \mathcal{A} = \mathbb{D}(e) \longrightarrow \mathbb{D}(X)$$

est pleinement fidèle.
Der 4 (g) : existence des f_*.
Der 4 (d) : existence des $f_!$.
Der 5 (g) Calcul des fibres de $f_*(F)$.
Der 5 (d) Calcul des fibres de $f_!(F)$.
L'ancien axiome **Der 5** (g) résulte de **Der 2**, **Der 3**, **Der 4** (g,d), **Der 5** (d), grâce au théorème précédent.

Commentary · Exposition [ms. 68]

Keeping the axiom numbers separate

Grothendieck is reorganising the assumptions after the failure diagnosed on manuscript page 60. The new numbering must be kept separate from both the preceding pages and present-day derivator terminology. Here **Der 3** asserts that a contractible indexing category has fully faithful constant-diagram functor. The two parts of **Der 4** assert existence of right and left Kan extensions; the two parts of **Der 5** give their pointwise comma-category formulas. In the now common numbering, existence is usually (Der3), and the pointwise formulas are (Der4); compare Groth (2013, Definition 1.5). The extra strongness axiom used to lift incoherent arrows is a different matter and is not being imposed by this renumbering.

Throughout these comments we retain the manuscript's presheaf convention: a coefficient object over X has underlying diagram $X^{\mathrm{op}} \to \mathbb{D}(e)$. Thus

$$(f_*F)_y \simeq H^*_{\mathbb{D}}(X/y, F), \qquad (f_!F)_y \simeq H^{\mathbb{D}}_*(y\backslash X, F).$$

A modern reference using covariant diagrams reverses the comma categories. The right adjoint is still the right adjoint; the difference comes from replacing every indexing category by its opposite.

The new contractibility axiom is not an assertion that the whole category $\mathbb{D}(X)$ collapses to $\mathbb{D}(e)$. It concerns only constant objects and their morphisms. For example, over the walking arrow a coefficient is a coherent arrow, and its two values need not be isomorphic even though the walking arrow has contractible nerve. What the axiom guarantees is that taking a constant object over this shape introduces no new endomorphisms. This is precisely the amount of invariance used when the lifting categories in the following theorem are contractible.

The comment that both homological and cohomological axioms seem indispensable should consequently be read as a description of this proof strategy, not as a proved independence theorem. Modern treatments may begin with a one-sided derivator and formulate the corresponding one-sided conclusions. The argument here deliberately uses the opposite adjoint to make a universal-coefficient test accessible to pointwise calculation.

Un aspect intéressant du théorème précédent, si on l'envisage comme énonçant l'équivalence de a) et b), c'est que cet énoncé ne fait pas appel à des notions homologiques, mais que sa démonstration y fait appel, sous une forme relativement forte (calcul des fibres de $f_!(F)$). Pour les théorèmes de changement de base pour la $\mathbb{D}$-cohomologie relative, *i.e.* pour les $f^{\mathbb{D}}_*$, on a besoin aussi constamment du calcul des fibres des $f_*(F)$. Donc il semble qu'on ne peut se passer d'aucun des axiomes précédents, y compris **Der 4** (d) et **Der 5** (d), même si on ne veut s'intéresser qu'au formalisme des f^*, f_* (aspect cohomologique). Par la suite, on va donc supposer ces axiomes satisfaits.

28. Axiome des catégories d'indices asphériques, *cf.* variantes **Der 3** a) b) c) page 97, et surtout pages 111-112.
29. N.B. Il suffit de supposer que X a un objet final. Mais ce n'est pas un axiome autodual.

Commentary · Exposition [ms. 68]

The category of lifts behind properness

There is a useful concrete form of the first two conditions of Theorem 2. Given $x \in X$ and $\alpha : f(x) \to y$, let $L_f(x,\alpha)$ have objects

$$h : x \longrightarrow z, \qquad f(z) = y, \qquad f(h) = \alpha.$$

A morphism from h to h' is a map $k : z \to z'$ with $f(k) = 1_y$ and $kh = h'$. These are strict lifting data; replacing equality by an unspecified isomorphism would change the condition. The theorem says that f is $\mathbb{D}$-proper precisely when every $L_f(x,\alpha)$ is $\mathbb{D}$-contractible.

Indeed, if $i_y : X_y \to X/y$ is the canonical inclusion, an object of X/y is exactly a pair (x,α) as above, and

$$((x,\alpha)\backslash i_y) \cong L_f(x,\alpha).$$

Condition (a), applied to the definition of coasphericity, is therefore condition (b). This also proves its stability under arbitrary strict base change. For a pullback $f' : X \times_Y Y' \to Y'$, the lift of an arrow $\alpha' : y'_0 \to y'_1$ from (x, y'_0) is the lift of its image in Y, together with the already fixed second coordinate y'_1. The resulting lifting categories are isomorphic.

The significance of these categories is stronger than the existence of lifts. An opfibration gives a preferred cocartesian lift, which is an initial object of $L_f(x,\alpha)$. Properness permits a whole category of choices, requiring only that constant coefficients cannot distinguish its homotopy from a point. In particular, requiring merely that each strict fibre X_y be contractible misses the lifting condition altogether.

To obtain the base-change statement, first replace Y by any $Y' \to Y$. At an object y', the right Kan extension is calculated over X'/y'. By coasphericity of $X'_{y'} \to X'/y'$ and Theorem 1, restriction induces

$$H^*_{\mathbb{D}}(X'/y', F) \xrightarrow{\sim} H^*_{\mathbb{D}}(X'_{y'}, F|_{X'_{y'}})$$

for *every* coefficient object F on X'/y'. Consequently right direct image is calculated by the actual fibres. After a further base change, the actual fibre is unchanged. The two evaluations of the Beck–Chevalley comparison are therefore identified by their canonical restriction maps; **Der 2** makes the comparison an isomorphism.

Conversely, suppose the fibre formula holds after localisation $Y/y \to Y$. The category Y/y has terminal object 1_y, so evaluating the right direct image there identifies its global cohomology with that of X/y. The asserted fibre formula then states that restriction along i_y preserves cohomology for every object of $\mathbb{D}(X/y)$. Theorem 1 gives the coasphericity of i_y. This completes the equivalence of (a), (b), (c), (c′), and (c″), without substituting constant coefficients where the argument needs arbitrary ones.

Théorème 2. *Soit $f : X \to Y$ dans* Dia. *Conditions équivalentes :*

a) *Pour tout $y_0 \in \mathsf{Ob}\, Y$, le foncteur canonique*

$$X_{y_0} \xrightarrow{\varphi} X/y_0 \quad (\simeq X \times_Y Y/y_0)\ ,$$

où X_{y_0} désigne la fibre en y_0, est une $\mathbb{D}$-équivalence co-stricte.

b) *Pour tout $x_0 \in \mathsf{Ob}\, X$, le foncteur induit sur les catégories colocalisées en x_0 et en $y_0 = f(x_0)$*

$$x_0\backslash X \longrightarrow y_0\backslash Y$$

est à fibres $\mathbb{D}$-contractiles.

c) *La formation des f_*F (F dans $\mathbb{D}(X)$) commute à tout changement de base $Y' \to Y$, et ça reste vrai après tout changement de base – i.e. si on a $Y'' \to Y' \to Y$, d'où* [page 69]

$$\begin{array}{ccccc} X'' & \longrightarrow & X' & \longrightarrow & X \\ {\scriptstyle f''}\downarrow & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y'' & \xrightarrow[p']{} & Y' & \xrightarrow[p]{} & Y \end{array}$$

le "théorème de changement de base" est vrai pour f'_* et p'^*.

c′) *La formation des $f_*(F)$ ($F \in \mathsf{Ob}\,\mathbb{D}(X)$) commute au passage aux fibres et ceci reste vrai après tout changement de base $p : Y' \to Y$.*

c″) *Comme* c′) *avec $Y' \to Y$ un morphisme de localisation $Y/y \to Y$.*

d) *Si $Y'' \xrightarrow{p} Y' \to Y$, avec p coasphérique, alors $q : X'' = X \times_Y Y'' \to X' = X \times_Y Y'$ est coasphérique.*

d′) *Comme* d) *avec $Y'' = e$* (donc Y' est catégorie avec objet final e). ed. 41

d″) *Comme* d) *avec $Y'' = \{1\}$, $Y' = \mathbf{\Delta}_1$.*

.

Démonstration. a) ⇔ b) cf. proposition page 53. Montrons que ces conditions impliquent c). Comme elles sont stables par changement de base (*cf.* démonstration immédiate page 55) donc par **Der 2** on est ramené à prouver que $H^*_{\mathbb{D}}(X/y, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(Y_y, F)$ ($F \in \mathsf{Ob}\,\mathbb{D}(Y)$), ce qui résulte du théorème 1.[30] (Cf. démonstration du théorème page 56, qui marche avec des hypothèses plus générales.)

On a c) ⇔ c′) ⇒ c″) (l'équivalence c) ⇔ c′) par **Der 2**).

Prouvons c″) ⇒ a).

Considérons le diagramme à carrés cartésiens

[page 70]

$$\begin{array}{ccccc} X_{y_0} & \xrightarrow{q} & X/y_0 & \longrightarrow & X \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle f_0} & & \downarrow{\scriptstyle f} \\ \{y_0\} & \longrightarrow & Y/y_0 & \longrightarrow & Y \end{array} \quad .$$

L'hypothèse c″) prouve que pour tout F dans $\mathbb{D}(X/y_0)$, on a $H^*_{\mathbb{D}}(X/y_0, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(X_{y_0}, F)$. Par le théorème 1, ceci implique que f est un $\mathbb{D}$-équivalence co-stricte.

Commentary · Exposition [ms. 70]

Completing the tests in the proper base-change theorem

The three conditions labelled (d) are not proved in the displayed argument. They have a short verification which also explains why a single walking arrow is a sufficient test. Write a pullback square as

$$\begin{array}{ccc} X'' & \xrightarrow{q} & X' \\ {\scriptstyle f''}\downarrow & & \downarrow{\scriptstyle f'} \\ Y'' & \xrightarrow[p]{} & Y'. \end{array}$$

If f' is proper, the isomorphism $p^* f'_* \simeq f''_* q^*$ has, on passing to its left adjoint, the canonical isomorphism

$$q_! f''^* \simeq f'^* p_!.$$

Here we take the left adjoints of the two *composite functors*; no general assertion that every mate of every invertible cell is invertible is needed. If p is coaspherical, its counit is an isomorphism on constants by Theorem 1. Applying the displayed comparison to a constant object on Y'' identifies the counit $q_! M_{X''} \to M_{X'}$ with its pullback. Theorem 1 now makes q coaspherical. This proves (c)⇒(d).

Condition (d) implies its tests on inclusions of terminal objects, and these imply the test $\{1\} \to [1]$. Conversely, pull f back along the functor $[1] \to Y$ determined by $\alpha : f(x) \to y$. Apply (d″) to the terminal-object inclusion $\{1\} \to [1]$. In the resulting coaspherical functor $X_y \to X \times_Y [1]$, the comma category under $(x, 0)$ is exactly $L_f(x, \alpha)$. Thus (d″) implies (b). All the asserted conditions are now accounted for.

The parenthesis in (d′), "donc Y' est catégorie avec objet final e", should be understood as specifying the terminal-object tests. A $\mathbb{D}$-coaspherical functor from the point need not literally select a terminal object for every possible coefficient theory. For example, take the represented derivator of the complete lattice $\{0 < 1\}$. Every nonempty discrete category is $\mathbb{D}$-contractible, since its diagonal

30. Donc on utilise **Der 5** (d).

constant-diagram functor is fully faithful. The inclusion $e \to BC_2$ is then $\mathbb{D}$-coaspherical: its only comma category is the discrete two-element set C_2. The unique object of BC_2 is not terminal. Reading (d′) as the restricted terminal-object test avoids attributing this false converse to the proof.

Several other slips here are already in the edition. The proof on page 69 requires X_y, not Y_y, and a coefficient on X, not on Y. At the end of the argument on page 70 the coaspherical functor is the displayed $q : X_{y_0} \to X/y_0$, not f. Definition 4 refers to Theorem 2, not Theorem 1. These corrections repair the typing and references; they do not alter the theorem.

Corollaire 1. Énoncé dual du théorème, pour les foncteurs $X_{y_0} \to y_0\backslash X$, $X/x_0 \to Y/y_0$, et le changement de base des $j_!(F)$ …

Définition 4. Sous les conditions équivalentes du théorème 1, on dit que f est $\mathbb{D}$-*propre.* La condition duale s'appelle f $\mathbb{D}$-*lisse.*

Corollaire 2. *Soit $f : X \to Y$ dans* Dia. *Si f est $\mathbb{D}$-propre ou $\mathbb{D}$-lisse, et à fibres $\mathbb{D}$-contractiles, alors f est une $\mathbb{D}$-équivalence stricte et costricte. Mieux, f est une $\mathbb{D}$-équivalence* universelle *i.e. est une $\mathbb{D}$-équivalence et le reste après tout changement de base.*[31]

Il suffit de prouver que f est une $\mathbb{D}$-équivalence. Supposons par exemple f $\mathbb{D}$-propre. Il suffit ed. 42
de prouver que si Y est $\mathbb{D}$-contractile, alors X l'est (quitte à l'appliquer aux Y/y_0 après [page 71]
changement de base, pour montrer que les X/y_0 sont contractiles). Pour ceci, il suffit de prouver que f est une $\mathbb{D}$-équivalence, et on sait que ceci est le cas si pour tout F *constant* sur Y, l'homomorphisme $F \xrightarrow{\text{adj}} f_*f^*F$ est `[un]` isomorphisme. En fait, c'est vrai pour *tout* F.

Corollaire 3. *Si $f : X \to Y$ est $\mathbb{D}$-propre ou $\mathbb{D}$-lisse, à fibres $\mathbb{D}$-contractiles, alors $f^* : \mathbb{D}(Y) \to \mathbb{D}(X)$ est pleinement fidèle, i.e. les homomorphismes d'adjonction*

$$F \longrightarrow f_*f^*F \quad , \qquad f_!f^*F \longrightarrow F$$

dans $\mathbb{D}(Y)$ sont des isomorphismes.

Il suffit de le voir pour f propre, et cela résulte du calcul des fibres de f_*f^*F …

Proposition 5. *La notion de foncteur $\mathbb{D}$-propre* (resp. $\mathbb{D}$-*lisse*) *est stable par changement de base,* (trivial), *et par composition* (utiliser `[le]` corollaire 2). *Toute immersion fermée est $\mathbb{D}$-propre, toute immersion ouverte $\mathbb{D}$-lisse. Plus généralement, tout isomorphisme local est $\mathbb{D}$-lisse, tout co-isomorphisme local est $\mathbb{D}$-propre.*

Proposition 6. *Soient X, Y sur S, $f : X \to Y$ un S-morphisme. Supposons X, Y propres sur S, ou X et Y lisses sur S, et que pour tout $s \in \mathsf{Ob}\, S$, $f_s : X_s \to Y_s$ soit une $\mathbb{D}$-équivalence, alors f aussi.*[32]

Commentary · Examples [ms. 71]

Properness does not require constant fibres

Let $A : [1] \to \mathcal{C}at$ send 0 to the point and 1 to the discrete category $\{a, b\}$, with the transition selecting a. Its Grothendieck construction X has three objects u, a, b, one nonidentity arrow $u \to a$, and projection $f : X \to [1]$ sending u to 0 and a, b to 1. The map $u \to a$ is a cocartesian lift of $0 \to 1$.

31. Se généralise : **Corollaire 2′.** *Soit*

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

avec X, Y, $\mathbb{D}$-propres sur S. Si f induit une $\mathbb{D}$-équivalence sur les fibres c'est une $\mathbb{D}$-équivalence. Itou dans le cas lisse.

C'est la proposition 6 ci-dessous.

32. Démonstration. On prouvera même que sur la sous-catégorie des coefficients sur Y qui proviennent de $\mathbb{D}(Y)$ `[plutôt de` $\mathbb{D}(S)$`]`, $f^* : \mathbb{D}(Y) \to \mathbb{D}(X)$ induit un foncteur pleinement fidèle. Si f `[est]` propre, je l'interprète comme $q_*q^*F \xrightarrow{\sim} p_*p^*F$ pour tout F, et cela résulte du calcul de p_*, q_* par passage aux fibres (propre), et de l'hypothèse sur les f_s. OK.

The corresponding lift category is a point; the lift categories over identities have their identity lifts as initial objects. Thus f is proper for every derivator under consideration.

For a contravariant coefficient diagram F on X, the right direct image is

$$(f_*F)_0 \simeq F_u, \qquad (f_*F)_1 \simeq F_a \times F_b,$$

and its transition is the composite $F_a \times F_b \to F_a \to F_u$. In the derivator of complexes, these are derived products, which for a finite pair agree with the ordinary finite product. For constant value M, the transition is the projection $M \times M \to M$. Taking $M = \mathbb{Q}$ in degree zero proves that it is not locally constant. The map is therefore proper but not a cohomological fibration in the definition about to be introduced.

This example separates two uses of a fibre calculation. Properness identifies a direct image with the cohomology of the fibres. A fibration condition additionally requires that these cohomologies be transported by isomorphisms along the base. There is no contradiction in a proper map having fibres with different homotopy types.

By contrast, if a proper map has $\mathbb{D}$-contractible fibres, then for every $F \in \mathbb{D}(Y)$ the component at y of its unit is

$$F_y \longrightarrow H^*_{\mathbb{D}}(X_y, (F_y)_{X_y}),$$

which is an isomorphism. Pointwise detection proves that f^* is fully faithful. Since f^* has both adjoints, this is equivalent both to invertibility of the unit of $f^* \dashv f_*$ and to invertibility of the counit of $f_! \dashv f^*$. This proves Corollary 3 and its smooth counterpart. It also gives universal $\mathbb{D}$-equivalence: properness and the fibres are preserved by base change. The claims of strict and costrict equivalence follow by applying that universal assertion to both kinds of local-isomorphism base changes.

Théorème 3. *Soit*

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow{p} & Y' \end{array}$$

[page 72]

cartésien dans Dia. *Alors le morphisme de changement de base*

$$p^* f_* \longrightarrow f'_* q^*$$

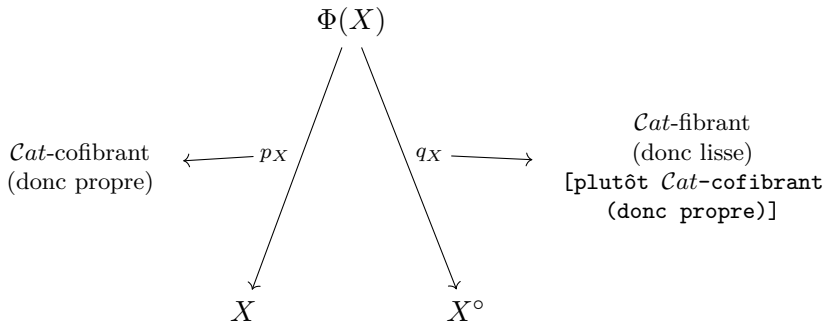
est un isomorphisme si f est $\mathbb{D}$-propre, ou p $\mathbb{D}$-lisse.
Le cas $\mathbb{D}$-propre déjà prouvé. Le cas $\mathbb{D}$-lisse : la démonstration p. 56 est OK.

Commentary · Context [ms. 72]

The geometric pattern and its categorical content

The vocabulary "proper" and "smooth" records a specific geometric analogy. In étale cohomology, proper direct image commutes with base change, and a smooth change of base gives a second base-change theorem under the appropriate torsion hypotheses. The comparison map has the same shape as the one displayed here. Maltsiniotis (2005, Introduction and Theorem 1.2) explicitly traces the categorical definitions to this pattern in *Pursuing Stacks* and identifies the corresponding SGA 4 exposés. His Theorems 4.13 and 5.4 develop the relation between lifting categories and base change in the framework of asphericity structures.

There is no implication here that a proper functor between categories is a proper morphism of spaces in the topological sense. The definition asks for a Beck–Chevalley isomorphism in a coefficient theory. The lifting categories supply its combinatorial content. The smooth half of Theorem 3 is obtained by applying that same calculation with the two adjunctions interchanged; it is not obtained merely by observing that the underlying square is a pullback. In the covariant-diagram convention, Groth (2013, Propositions 1.24 and 1.26) formulate the corresponding exactness of pullback squares for Grothendieck fibrations and opfibrations and of comma squares. Opposing all four indexing categories returns the convention of this manuscript.



For Proposition 6 one needs only to compare q_*q^*M and p_*p^*M over the common base S. Their components are constant-coefficient cohomologies of Y_s and X_s. The hypothesis identifies those components, and **Der 2** finishes the proof. The footnote's stronger statement for coefficients pulled

back from S follows by the same calculation with M replaced pointwise by F_s, followed by adjunction. This argument is valid without requiring the comparison map $X \to Y$ itself to be proper.

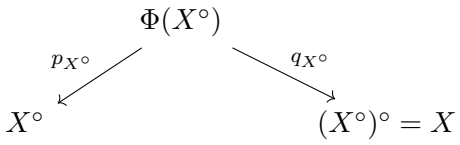
ed. 43

Comparaison de X et X°.

Soit X [une] catégorie, on définit une catégorie $\Phi(X)$ et des foncteurs

qui seront des hot-équivalences, et des $\mathbb{D}$-équivalences si $\mathbb{D}$ est un dérivateur dont le domaine contient X et $\Phi(X)$. On pose

$$\mathsf{Ob}\,\Phi(X) = \mathsf{Fl}(X) \quad ,$$



donc mêmes objets que $\mathcal{F}\ell(X) = \underline{\mathsf{Hom}}(\mathbf{\Delta}_1, X)$, mais les morphismes sont différents :

$$\begin{array}{ccc} Y_1 & \xrightarrow{u} & Y_0 \\ {\scriptstyle v_1}\uparrow & & \downarrow{\scriptstyle v_0} \\ Y_1' & \xrightarrow[u']{} & Y_0' \end{array}$$

[page 73]

un morphisme de u dans u' est un couple $v_0 : Y_0 \to Y_0'$, $v_1 : Y_1' \to Y_1$ tel que $v_0 u v_1 = u'$. Ainsi source et but $s(u)$ et $b(u)$ sont l'une contravariante, l'autre covariant en u. On prend pour q le foncteur source, pour p le foncteur but.

Si on applique ceci à X°, on trouve

On a $\mathsf{Ob}\,\Phi(X^\circ) = \mathsf{Fl}(X^\circ) \simeq \mathsf{Fl}(X)$

$$\begin{array}{ccc} Y_1 & \xrightarrow{u} & Y_0 \\ {\scriptstyle v_0}\uparrow & & \downarrow{\scriptstyle v_1} \\ Y_1' & \xrightarrow[u']{} & Y_0' \end{array} \qquad \begin{array}{l} \text{dans } X \\ \\ \text{dans } X \end{array}$$

et mêmes homomorphismes au sens de $\Phi(X)$ et au sens de $\Phi(X^\circ)$. Donc

$$\begin{cases} \Phi(X^\circ) = \Phi(X) \\ p_{X^\circ} = q_X \\ q_{X^\circ} = p_X \quad , \end{cases}$$

ed. 44

le passage de X à X° revient à échanger p_X et q_X. La fibre de $\Phi(X)$ en $x \in \mathsf{Ob}X$ est $\simeq (X/x)^\circ$, celle en $y^\circ \in \mathsf{Ob}X^\circ$ est $\simeq y\backslash X$

$$\begin{cases} p_X^{-1}(\{x\}) \simeq (X/x)^\circ \\ q_X^{-1}(\{y^\circ\}) \simeq y\backslash X \end{cases}$$

N.B. : p_X est W-lisse `[plutôt W-propre]` à fibres W-asphériques, donc dans W^u [W^u = `ensemble des morphismes qui sont dans` W `et le restent après tout changement de base`], q_X est W-propre à fibres W-asphériques, donc dans W^u.

Commentary · Exposition [ms. 73]

The twisted-arrow category and its two projections

The category $\Phi(X)$ is the twisted-arrow category, with the orientation explicitly fixed by the equation $u' = v_0 u v_1$. Keeping that equation in view avoids confusing it with the ordinary arrow category. An object $u : a \to b$ maps to b under p_X and to a, considered in X^{op}, under q_X. Composition is componentwise in the appropriate orders. Replacing u by u^{op} interchanges the two components of a twisted morphism and gives a canonical isomorphism

$$\Phi(X^{\mathrm{op}}) \cong \Phi(X),$$

not the opposite category on the right. The two projection formulas follow under this identification.

Both projections are opfibrations. For p_X, an arrow $\beta : b \to b'$ is lifted from u by the twisted arrow $u \to \beta u$, with source component 1_a and target component β. If a twisted arrow from u to $w : c \to d$ has target component $\gamma\beta$, it factors uniquely through this chosen lift, using target component γ and the same source component. This is the cocartesian universal property. For q_X, an arrow $a \to a'$ in X^{op} is an arrow $\alpha : a' \to a$ in X; its cocartesian lift is $u \to u\alpha$. The same factorisation argument applies.

The fibre of p_X over b is $(X/b)^{\mathrm{op}}$: its arrows are the reversed triangles between maps to b. Its object 1_b is initial. The fibre of q_X over a is $a\backslash X$, whose object 1_a is initial as well. Consequently both maps are proper with contractible fibres. The preceding corollaries prove directly that they are universal $\mathbb{D}$-equivalences and that inverse image along either is fully faithful. This gives a shorter proof of the assertion announced on page 74; it uses exactly the corrected "cofibrant, donc propre" label in the edition.

The displayed slice identities are also literal categorical isomorphisms, and not merely equivalences of homotopy types. An object of $\Phi(X)/x$ is a composable pair $a \xrightarrow{u} b \xrightarrow{h} x$. It determines the arrow $(a, hu) \to (b, h)$ in X/x, hence an object of $\Phi(X/x)$. A twisted morphism consists of $v_1 : a' \to a$, $v_0 : b \to b'$ with $u' = v_0 u v_1$ and $h' v_0 = h$. The remaining slice equation $h' u' = h u v_1$ then follows. These are precisely the morphisms in $\Phi(X/x)$. Reversing the construction is immediate. The second identity follows by applying this argument to X^{op} and interchanging the endpoints.

The last comma notation in the succeeding proof requires a correction. The strict-equivalence test for $q_Z : \Phi(Z) \to Z^{\mathrm{op}}$ uses $\Phi(Z)/z_0^{\mathrm{op}}$, whose additional arrow in Z is $z_0 \to s(u)$. It is this category that is isomorphic to $\Phi(z_0\backslash Z)$. The edition instead prints $z_0\backslash\Phi(Z)$; interpreted literally as a comma category under q_Z, that symbol would require $s(u) \to z_0$ in Z and reverse the intended arrow. With the intended comma category restored, the proof continues correctly. If Z has a terminal object, $z_0\backslash Z$ has both an initial and a terminal object. The unique arrow between these is terminal in its twisted-arrow category, exactly as Grothendieck observes.

On vérifie

$$\begin{cases} \Phi(X)/x \simeq \Phi(X/x) & x \in \mathsf{Ob}X \\ \Phi(X)/x^\circ \simeq \Phi(x\backslash X) & x^\circ \in \mathsf{Ob}X^\circ \end{cases}$$

[page 74]

Je dis que p_X, q_X sont des $\mathbb{D}$-*équivalences strictes* et *costrictes.* Par les formules précédentes, cela signifie que les $\Phi(X/x)$, $\Phi(x\backslash X)$ sont $\mathbb{D}$-contractiles. Donc que si Z a un objet final, $\Phi(Z)$ est $\mathbb{D}$-contractile. Mais considérons

$$\begin{array}{ccc} \Phi(Z) & & \\ & \searrow^{q_Z} & ; \\ & & Z^\circ \end{array}$$

il suffit de prouver que c'est une $\mathbb{D}$-équivalence stricte (puisque Z°, ayant un objet initial, est $\mathbb{D}$-contractil), donc que les $z_0\backslash\Phi(Z)$ sont $\mathbb{D}$-contractiles. On a par les formules précédentes

$$z_0\backslash\Phi(Z) \simeq \Phi(z_0\backslash Z) = \Phi(T) \quad ,$$

où cette fois T a un objet initial $\emptyset$ et un objet final e. Considérons alors l'objet

$$\emptyset \longrightarrow e$$

de $\Phi(T)$, c'est un objet final, car pour tout $x \to y$ dans $\Phi(T)$, il y a une unique flèche

$$\begin{array}{ccc} x & \longrightarrow & y \\ \uparrow & & \downarrow \\ \emptyset & \longrightarrow & e \end{array}$$

Commentary · Examples [ms. 74]

Intervals in a finite ordered set

For $X = [1]$, the twisted-arrow category has objects 1_0, $u : 0 \to 1$, and 1_1, with precisely the nonidentity arrows

$$1_0 \longrightarrow u \longleftarrow 1_1.$$

Thus u is terminal. Under the target projection, the fibre at 0 is the point 1_0, whereas the fibre at 1 is the arrow $1_1 \to u$. Under the source projection, the roles are reversed. Each fibre is contractible, although the projections are not isomorphisms of categories. Their nerves subdivide the interval into two edges.

For the chain $[n]$, objects are intervals (i, j) with $0 \le i \le j \le n$. There is exactly one morphism

$$(i, j) \longrightarrow (i', j') \quad \Longleftrightarrow \quad i' \le i \le j \le j'.$$

The largest interval $(0, n)$ is terminal. More generally this description works for comparable pairs in any poset, showing immediately that Φ preserves finite posets. This is the domain-closure observation at the end of manuscript page 75; it is not an assertion that every finite category is a finite poset.

The comparison with the opposite category is useful because it is natural. For a functor $f : X \to Y$, applying f to arrows and to both components gives $\Phi(f)$, and both endpoint squares commute. Since their vertical projections are $\mathbb{D}$-equivalences, two-out-of-three first gives

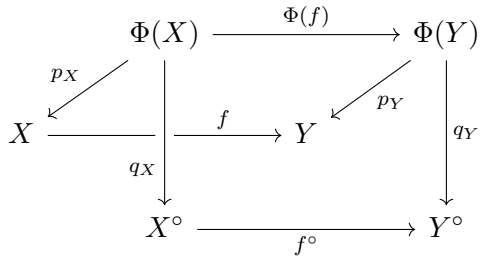
$$f \in W_{\mathbb{D}} \iff \Phi(f) \in W_{\mathbb{D}},$$

and then the corresponding equivalence with $f^{\mathrm{op}} \in W_{\mathbb{D}}$. One must have $X^{\mathrm{op}}, Y^{\mathrm{op}}, \Phi(X), \Phi(Y)$ in the domain. There is no claim that X and X^{op} are equivalent as ordinary categories. The natural span compares precisely the information detected by the chosen coefficient theory.

Pour résumer ed. 45

Proposition 1 : *p_X et q_X sont des* hot*-équivalences strictes,* i.e. Hot*-asphériques (donc aussi des $\mathbb{D}$-équivalences strictes si $\Phi(X)$ est dans le domaine de $\mathbb{D}$) à fibres les $(X/x)^\circ$ et $y\backslash X$ respectivement (donc à fibres contractiles).* [page 75]

Corollaire 1. *Pour que X soit $\mathbb{D}$-contractile, il faut et il suffit que X° le soit.*



Plus généralement :

Corollaire 2. *Soit $f : X \to Y$. Pour que f soit une $\mathbb{D}$-équivalence, il faut et il suffit que f° le soit.*

On utilisera que le diagramme

$$\begin{array}{ccccc} & & \Phi(X) & & \\ & \swarrow^{p_X} & & \searrow^{q_X} & \\ X & & & & X^\circ \end{array}$$

est fonctoriel en X. On a donc

les deux carrés commutatifs. Comme p_X et p_Y sont des $\mathbb{D}$-équivalences, f est une $\mathbb{D}$-équivalence si et seulement si $\Phi(f)$ l'est, et de même pour f°. Ces raisonnements supposent que si X est dans le domaine de $\mathbb{D}$, $\Phi(X)$ aussi. C'est le cas si Dia est formé des catégories ordonnées finies.

Commentary · Later developments [ms. 75]

Twisted arrows after the opposite-category comparison

The construction has become a standard indexing device for homotopy ends and coends. Riehl (2014, Example 7.2.9 and the footnote in Section 7.8) describe the twisted-arrow category and the identification of its nerve with edgewise subdivision. This supplies a simplicial interpretation of the span $X \leftarrow \Phi(X) \to X^{\mathrm{op}}$. Its realization compares the two classifying spaces without choosing an equivalence of categories.

For a derivator written with the covariant convention, Ponto and Shulman (2016, Section 5) use the same category to define the homotopy coend of $A \in \mathbb{V}(X^{\mathrm{op}} \times X)$ by

$$\int^X A = (\pi_{\Phi(X)^{\mathrm{op}}})_!(t^{\mathrm{op}}, s^{\mathrm{op}})^* A.$$

The opposite on the indexing category is essential in this formula. Ends use the other variance. The passage from this formula to composition of homotopy profunctors explains why the two endpoint projections occur together so persistently in later derivator calculus. Grothendieck uses them here for a narrower purpose: to show that the weak-equivalence class obtained from constant coefficients is unchanged by taking opposites. The later coend formalism extends the utility of the construction; it is not an extra assumption in his proof.

ed. 46

[page 76]

$\mathbb{D}$-fibrations

Proposition 1. *Soit $f : X \to Y$ dans* Dia*, conditions équivalentes :*

a) *Pour tout $y \in Y$, l'inclusion $X_y \to X/y$ est une $\mathbb{D}$-équivalence, et pour toute flèche $y_1 \to y_0$ de Y, $X/y_1 \to X/y_0$ est une $\mathbb{D}$-équivalence.*

b) *Pour tout coefficient* constant *F sur Y, $f_* f^* F$ est localement constant,*[33] *et "se calcule fibre par fibre"* i.e. *l'homomorphisme canonique*

$$f_* f^*(F)_y \xrightarrow{\sim} H^*_{\mathbb{D}}(X_y, F|X_y)$$

`[est un isomorphisme]`.

Ces conditions sont équivalentes, et impliquent les conditions de (b) pour tout F *localement* constant sur Y.

La première condition dans (a) signifie que pour tout $y \in Y$, et tout $M \in \mathsf{Ob}\mathcal{A}$,

$$H^*_{\mathbb{D}}(X/y, M) \longrightarrow H^*_{\mathbb{D}}(X_y, M)$$

33. Par là on entend que pour tout $u : y \to y'$ dans Y, $G_{y'} \to G_y$ est `[un]` isomorphisme. Sans axiomes supplémentaires sur $\mathbb{D}$, il n'est pas clair que cela implique que les "restrictions" de G aux Y/y ou $y\backslash Y$, soient isomorphes à des coefficients constants. Voir cependant l'axiome **Der 3** a′), page 97, qui assure que c'est pareil.

est un isomorphisme. Or cette flèche s'interprète comme

$$f_*(M_X)_y \longrightarrow H^*_{\mathbb{D}}(X_y, M)$$

est un isomorphisme, *i.e.* que $f_*(M_X)$ se calcule fibre par fibre. Comme $M_X \simeq f^*(M_Y)$, c'est la deuxième condition (b). La deuxième condition dans (a), pour $y_1 \to y_0$ signifie que pour M dans $\mathcal{A}$,

$$H^*_{\mathbb{D}}(X/y_0, M) \longrightarrow H^*_{\mathbb{D}}(X/y_1, M)$$

est [un] isomorphisme, or cette flèche s'interprète comme

$$f_*(M_X)_{y_0} \longrightarrow f_*(M_X)_{y_1} \quad ,$$

que ce soit toujours un isomorphisme, c'est la première condition (b). Que (b) soit valable aussi pour F localement constant sur Y est immédiat, car c'est une condition de nature locale par rapport à Y.

Commentary · Exposition [ms. 76]

Local constancy and the first fibration condition

The new fibration condition retains two separate tests. First, the canonical inclusion of an actual fibre into its comma category must be a $\mathbb{D}$-equivalence. Second, the transition functors between comma categories must be $\mathbb{D}$-equivalences. The first identifies the values of f_*M_X with fibre cohomology. The second says that their transport maps are isomorphisms. Since $\mathbb{D}$-equivalence tests all absolute coefficients M, this is an equivalence of conditions, not an inference from the cohomology of a single distinguished coefficient.

The extension from constant to locally constant coefficients is valid with the usual two-dimensional functoriality and pointwise detection axioms. There is a direct proof of the local issue raised in footnote 33. If a category A has terminal object a, the natural transformation $1_A \to ap$ induces, in the manuscript's presheaf convention, a morphism

$$p^*a^*F \longrightarrow F.$$

For arrowwise locally constant F, every component is an isomorphism; **Der 2** makes the whole morphism invertible. If A has an initial object, the corresponding natural transformation gives the comparison in the other direction, with the same conclusion. Applying these observations to Y/y and $y\backslash Y$ proves that restrictions of a locally constant object are constant there. This only uses categories possessing the indicated distinguished object. The stronger assertion for *every* weakly contractible category is the separate issue addressed by the later variants of **Der 3**.

Now fix an arrow $y_1 \to y_0$. Pull a locally constant F back to Y/y_0, where it is isomorphic to the constant object with value F_{y_0}. Pulling this isomorphism further to X/y_0, X/y_1, and the two fibres turns the desired comparison into the one already established for constant coefficients. The isomorphism $F_{y_0} \to F_{y_1}$ supplies the change of value at the other endpoint. This proves the statement for locally constant F, including the compatibility of transport, rather than relying only on the phrase "de nature locale".

For model-category derivators, a systematic treatment is Cisinski (2009, Theorem 1.3 and Section 3): weak equivalences of indexing nerves induce equivalences on the homotopy categories of locally constant diagrams. The distinction between constant and locally constant objects remains necessary when the base has nontrivial fundamental group. It is exactly this distinction that will invalidate the proposed implication on manuscript pages 80–81.

La proposition duale fait appel aux foncteurs

$$y_0\backslash X \longrightarrow y_1\backslash X \qquad \text{et} \qquad X_y \longrightarrow y\backslash X \quad , \qquad \text{[page 77]}$$

et aux faisceaux $f_!f^*M$, pour M constant, ou localement constant sur Y.

Définition 1. Si les conditions équivalentes de la proposition 1 sont satisfaites, on dit ed. 47
que f est une $\mathbb{D}$-*fibration cohomologique* (ou $\mathbb{D}$-*fibration gauche*). Si les conditions duales sont satisfaites, on dit que c'est une $\mathbb{D}$-*fibration homologique* (ou $\mathbb{D}$-*fibration droite*).

N.B. Les $\mathbb{D}$-fibrations cohomologiques sont stables par tout changement de base qui est un isomorphisme local. Les $\mathbb{D}$-fibrations homologiques par tout changement de base qui est un co-isomorphisme local. Mais ce ne sont pas des notions stables par *tout* changement de base[34]. Mais la notion de $\mathbb{D}$-fibration cohomologique est stable par changement de base $\mathbb{D}$-lisse, et celle de $\mathbb{D}$-fibration homologique par changement de base $\mathbb{D}$-propre.

Commentary · Development (commentators') [ms. 77]

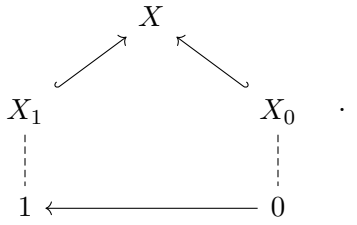
A two-object failure of arbitrary base change

The footnote asks for an example showing that the first fibration condition need not survive arbitrary base change. We can supply one before the more elaborate counterexamples later in the manuscript. We checked the treatments of smoothness and asphericity in Maltsiniotis (2005, Sections 1 and 4) and of locally constant diagrams in Cisinski (2009); we did not find this precise small example there. The construction below is an elementary verification for this commentary, without a claim of priority.

A non-universal cohomological fibration. [ours] Let J be the groupoid with two objects a, b and exactly one arrow between every ordered pair of objects. Let $f : [1] \to J$ send 0 to a, 1 to b, and the nonidentity arrow to the unique isomorphism $a \to b$. For the space derivator, f is both a cohomological and a homological fibration in Definition 1, but one strict base change of f has neither property.

Proof. Each strict fibre of f is a point. For either $y \in J$, an object of $[1]/y$ consists of $i \in [1]$ and an arrow $f(i) \to y$. The latter is unique. Projection therefore gives an isomorphism $[1]/y \cong [1]$. Under these isomorphisms every transition functor is the identity. The inclusion of either fibre is an endpoint inclusion $e \to [1]$, hence a weak equivalence of nerves. This proves the cohomological condition. The same argument with $y\backslash[1]$ proves the homological condition. More generally these tests succeed for any coefficient theory in which the point and the walking arrow have the usual constant-coefficient invariance.

Define $g : [1] \to J$ in the reverse order: $g(0) = b$, $g(1) = a$. Form the strict pullback



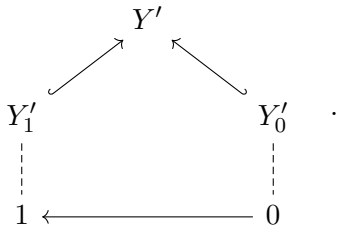
$$P = [1] \times_J [1] \xrightarrow{f'} [1],$$

with f on the first factor and g on the second. Its objects are exactly $(1, 0)$ and $(0, 1)$. There is no arrow from the first to the second, because there is no arrow $1 \to 0$ in the first factor. There is none in the reverse direction, because there is no arrow $1 \to 0$ in the second factor. Thus P is the discrete two-object category, with one object in each fibre of f'.

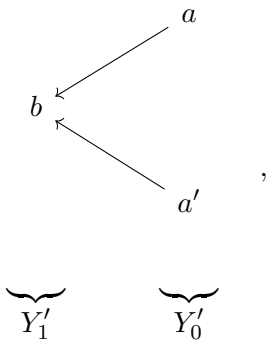
The comma category $P/1$ is discrete with two objects, whereas P_1 is a point. Hence $P_1 \to P/1$ is not a weak equivalence, and f' is not a cohomological fibration. Dually $0\backslash P$ is discrete with two objects while P_0 is a point, so the homological condition fails too. For complexes of rational vector spaces the same failure is visible in degree zero: the fibre comparison is $\mathbb{Q} \times \mathbb{Q} \to \mathbb{Q}$, a projection with nonzero kernel. □

Both [1] and J in the original pair of maps are contractible, and every original strict fibre is a point. The defect is the incompatible choice of direction for a strict lift of the base isomorphism. This example therefore isolates the need for a universal condition without invoking monodromy or a failure of constant coefficients to detect it. The later counterexamples address a different, stronger assertion: whether a universal fibration preserves all $\mathbb{D}$-equivalences under pullback.

Je vais essayer de construire un exemple où le changement de base canule, en posant $Y = \mathbf{\Delta}_1$. Se donner X sur $\mathbf{\Delta}_1$ revient à se donner une sous-catégorie ouverte X_0, et son complémentaire fermé X_1



34. ? donner exemple!



Dire que $X \to Y = \mathbf{\Delta}_1$ est une $\mathbb{D}$-fibration cohomologique signifie simplement que les restrictions [page 78]

$$X_0 \xrightarrow{j} X \quad , \qquad X_1 \xrightarrow{i} X$$

sont des $\mathbb{D}$-équivalences. Prenons un changement de base $Y' \to Y = \mathbf{\Delta}_1$, *i.e.* un Y' avec Y'_0, Y'_1

On voit que la condition Y' lisse sur $\mathbf{\Delta}_1$ signifie que pour tout $y'_1 \in \mathsf{Ob}Y'_1$, la catégorie Y'_0/y'_1 des objets y_0 de Y'_0 au dessus de y'_1 (*i.e.* munis de $y_0 \to y'_1$) est contractile. On voit que si $Y'_1 \neq \emptyset$ alors $Y'_0 \neq \emptyset$ – mais un exemple avec $Y'_0 = \emptyset$, où $Y'_1 = \emptyset$, n'est pas intéressant (car une projection $I \times J \to I$ est toujours une $\mathbb{D}$-fibration cohomologique). Prenons par exemple pour Y' ed. 48

somme amalgamée de deux copies de $Y = \mathbf{\Delta}_1$, donc $X' = X \times_Y Y'$ peut se voir comme somme amalgamée $X \amalg_{X_1} X$. Mais ça semble *pas* être un contre-exemple. Il faudrait que $X_1 \to X'$ ne soit *pas* une $\mathbb{D}$-équivalence.

Commentary · Examples [ms. 78]

Why the first doubled-arrow attempt does not work for spaces

The fork $a \to b \leftarrow a'$ is a useful test even though it does not provide the desired counterexample for the space derivator. A functor $X \to [1]$ decomposes X into a sieve X_0 and a cosieve X_1. Pullback along that fork is two copies of X identified along X_1:

$$X' = X \amalg_{X_1} X.$$

Every nonidentity chain in X' lies in one of the copies. Indeed, after it enters the common cosieve X_1, it cannot leave it to reach the other copy of X_0. Consequently the same pushout description holds degree by degree for nerves:

$$NX' = NX \amalg_{NX_1} NX.$$

The maps $NX_1 \to NX$ are inclusions of simplicial subsets. Their realizations are inclusions of CW subcomplexes. If $X \to [1]$ is a cohomological fibration for spaces, both $X_0 \to X$ and $X_1 \to X$ are weak homotopy equivalences. In particular the latter inclusion is a homotopy equivalence of CW complexes and a cofibration. Gluing a second copy along it preserves its homotopy type: the homotopy extension property, applied to an inverse and its homotopy, makes the inclusion of either copy in the pushout a homotopy equivalence. It follows that $|NX_1| \to |NX'|$ is a weak equivalence.

At a and a' the new fibre and comma category are copies of X_0. At b they are X_1 and X'; the preceding paragraph supplies their comparison. The transport from either of the first two comma categories to the last is a copy of $X_0 \to X \to X'$, hence a weak equivalence. Thus this particular base change is still a cohomological fibration. This establishes Grothendieck's expressed suspicion in the space case; it does not assert that arbitrary base changes work.

Proposition 2. *Soit $f : X \to Y$ dans* Dia. *Conditions équivalentes :*
a) *Pour tout $Y'' \xrightarrow{p} Y' \to Y$, d'où* [page 79]

$$\begin{array}{ccccc} X'' & \xrightarrow{q} & X' & \longrightarrow & X \\ \downarrow & \text{cart} & \downarrow & \text{cart} & \downarrow f \\ Y'' & \xrightarrow[p]{} & Y' & \longrightarrow & Y \end{array} ,$$

si p est une $\mathbb{D}$-équivalence, [alors] *q aussi.*[35]

b) *f est une $\mathbb{D}$-fibration cohomologique "universelle",* i.e. *est une fibration cohomologique, et le reste après tout changement de base.*

b′) *Condition duale de* (b) *: f est une $\mathbb{D}$-fibration homologique universelle.*[36]

a) ⇒ *b*) : Supposons *a*), soit $Y' \to Y$ changement de base, d'où

$$\begin{array}{ccc} X' & \longrightarrow & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \longrightarrow & Y \end{array} .$$

Pour prouver que f' est une $\mathbb{D}$-fibration cohomologique, on regarde au dessus de Y' les foncteurs de la forme $\{y'\} \to Y'/y'$ ($y' \in \mathsf{Ob}\, Y'$) et $Y'/y'_1 \to Y'/y'_0$ (si $u' : y'_1 \to y'_0$ flèche de Y'), et on voit que les flèches dans $\mathcal{C}at/Y'$ déduites de ceux-ci par le changement de base $X' \xrightarrow{f'} Y'$ restent des $\mathbb{D}$-équivalences ed. 49

$$\begin{array}{ccccccc} X'_1 & \xrightarrow{q} & X'_0 & \longrightarrow & X' & \longrightarrow & X \\ {\scriptstyle f'_1}\downarrow & \text{cart} & \downarrow{\scriptstyle f'_0} & \text{cart} & \downarrow{\scriptstyle f'} & \text{cart} & \downarrow{\scriptstyle f} \\ Y'_1 & \xrightarrow[p]{} & Y'_0 & \longrightarrow & Y' & \longrightarrow & Y \end{array} .$$ [page 80]

Comme p est une $\mathbb{D}$-équivalence, cela résulte bien de a).

b) ⇒ *a*) : Comme la condition *b*) est évidemment stable par changement de base, on est ramené à prouver que si f satisfait *b*), et si on a

(∗)
$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & \text{cart} & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow[p]{} & Y' \end{array}$$

si p est une $\mathbb{D}$-équivalence, alors q aussi, *i.e.*

$$\begin{array}{ccc} H^*_{\mathbb{D}}(X, M) & \xrightarrow{\sim} & H^*_{\mathbb{D}}(X', M) \\ \wr\downarrow & & \wr\downarrow \\ H^*_{\mathbb{D}}(Y, f_*(M_X)) & & H^*_{\mathbb{D}}(Y', f'_*(M_{X'})) \end{array}$$

35. Il faut supposer Y', Y'' Hot-asphériques, cf. page 96, et supposer vérifié l'axiome Der 3 a') de la page 97.

36. b) ⇒ a) canulée, *cf.* annotation marginale,[37] *cf.* contre-exemple page 89. Mais ça marche pour les dérivateurs $\mathbb{D}_i$ ($i \in \mathbb{N}$) associés aux "localisateurs fondamentaux" W_i, *i.e.* à la théorie des i-types d'homotopie.

37. L'implication b) ⇒ a) pas prouvée, seulement sous forme plus faible :

a′) si Y'', Y' sont $\mathbb{D}$-asphériques et 1-connexes, alors $X'' \to X'$ est une $\mathbb{D}$-équivalence. (Il suffit même de le supposer pour Y', Y'' ayant des objets finaux (pour impliquer b) ou ayant des objets initiaux (pour impliquer b′).)

pour tout M dans $\mathcal{A} = \mathbb{D}(e)$. Mais $F = f_*(M_X)$ est localement constant et se calcule "fibre par fibre", de même pour $F' = f'_*(M_{X'})$.

L'équivalence $a) \Leftrightarrow b')$ se déduit de $a) \Leftrightarrow b)$ par dualité (la condition $a)$ étant autoduale), ou en reprenant le même raisonnement pour $a) \Rightarrow b')$, et pour $b') \Rightarrow a)$ aussi (en remplaçant la cohomologie par l'homologie). [page 81]

Commentary · Exposition [ms. 81]

The coefficient lost in the attempted proof

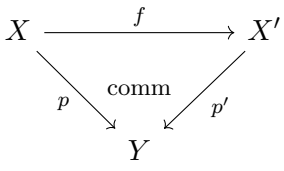
The proposition is an experiment whose unsuccessful part Grothendieck subsequently identifies himself. Its three conditions must therefore be read together with the marginal corrections. Condition (a) says that pullback along every base change of f preserves the entire class of $\mathbb{D}$-equivalences. Conditions (b) and (b′) say that constant coefficients have universally well-behaved cohomological or homological direct images. The first condition implies the other two. The converse requires information about coefficients which the first definition of a $\mathbb{D}$-equivalence does not provide.

Here is the precise point. In a pullback square with lower horizontal map $p : Y' \to Y$, universal fibrewise calculation gives an isomorphism

$$p^* f_* M_X \simeq f'_* M_{X'}.$$

To conclude that $q : X' \to X$ is a $\mathbb{D}$-equivalence, one must compare the cohomology of Y and Y' with coefficient $F = f_* M_X$. This coefficient is locally constant. It need not be constant. The assumption that p is a $\mathbb{D}$-equivalence compares cohomology only with constant coefficients. There is no applicable hypothesis at the last step of the displayed argument. This is the gap, and the examples on manuscript pages 87–95 make it an actual obstruction.

The surviving implication can be proved without this step. For an object y of a base category, the categories Y/y and $\{y\}$ have final objects. The functors between them, and the functors $Y/y_1 \to Y/y_0$ induced by arrows of Y, are $\mathbb{D}$-equivalences under the asphericity axiom. Pulling them back along f gives exactly the inclusions $X_y \to X/y$ and the transition functors between the comma categories. Condition (a), applied also after a preliminary base change, therefore implies (b). Using undercategories gives (b′). Nothing in this argument proves the converse.



The correction in footnote 35, restricting the test categories to weakly contractible categories, is adequate once locally constant objects on such categories are constant. The qualification is essential: replacing weak contractibility by $\mathbb{D}$-acyclicity is insufficient. Nor does connectedness of a base remove monodromy. We shall return below to a two-object covering that makes this visible with set-valued coefficients alone. Thus the sentence in footnote 36 about all truncated homotopy theories cannot be retained under the usual interpretation of $\mathbb{D}_i$; its case $i = 0$ already fails.

Définition 2. Si les conditions équivalentes de la proposition 2 sont satisfaites, on dit que f est une $\mathbb{D}$-*fibration*.

N.B. C'est une notion *à la fois* locale et "colocale" sur Y (alors que fibration gauche est locale, fibration droite colocale).

Proposition 3. a) *La notion de $\mathbb{D}$-fibration est stable par changement de base et par composition.*[38] ed. 50

b) *Soient*

avec p, p' des $\mathbb{D}$-fibrations (il suffit que p, p' soient des $\mathbb{D}$-fibrations cohomologiques, ou que ce soient des $\mathbb{D}$-fibrations homologiques, ou que p, p' soient propres, ou p, p' lisses). Si f induit des $\mathbb{D}$-équivalences dans les fibres, alors f est une $\mathbb{D}$-équivalence.[39]

38. La stabilité par composition *n'est* pas claire.

39. Peut se préciser considérablement dans le cas où p, p' sont des $\mathbb{D}$-fibrations, *cf.* prop. 6, page 84.

Démonstration. *a*) est immédiat sous la condition *a*) (prop. 2) de la notion de $\mathbb{D}$-fibration. Pour *b*), supposons que f induise des $\mathbb{D}$-équivalences sur les fibres. On veux prouver que

$$H^*_{\mathbb{D}}(X, M) \longrightarrow H^*_{\mathbb{D}}(X', M)$$

est un isomorphisme, pour tout M dans $\mathcal{A}$, mais cette flèche s'identifie à

$$H^*_{\mathbb{D}}(Y, p_*(M_X)) \longrightarrow H^*_{\mathbb{D}}(Y, p'_*(M_{X'}))$$

déduite de

$$p_*(M_X) \longrightarrow p'_*(M_{X'}) \qquad (\text{NB } \ M_X \simeq f^* M_{X'})$$

et il suffit de prouver que cette flèche est un isomorphisme. Pour ceci, on regarde fibre par fibre, et on utilise le fait que "les images directes se calculent fibre par fibre". [page 82]

Commentary · Exposition [ms. 82]

Fibration terminology during the revision

The notation temporarily conceals two different classes of functors. If "$\mathbb{D}$-fibration" means the pullback-preservation condition (a), closure under composition is immediate: a $\mathbb{D}$-equivalence is first pulled back along one factor and then along the other. Base change stability is immediate for the same reason. If the word instead means universal cohomological fibrewise calculation, that proof is unavailable. In a composite, the intermediate coefficient is a locally constant direct image, and the available comparison controls only direct images of coefficients pulled back from the base. The reservation in footnote 38 is consequently a substantive correction to the argument, rather than a doubt about the formal stability of condition (a).

The fibrewise comparison theorem in Proposition 3(b) survives. Write $f : X \to X'$ over Y, with projections p and p'. The natural cohomological comparison is

$$p'_* M_{X'} \longrightarrow p_* M_X,$$

obtained by applying p'_* to the unit $M_{X'} \to f_* f^* M_{X'}$. If both direct images are computed on strict fibres, its component at y is the cohomological map induced by $f_y : X_y \to X'_y$. A $\mathbb{D}$-equivalence on each fibre therefore makes this map invertible by the detection axiom, and applying the direct image $Y \to e$ proves the assertion. The three displayed cohomological arrows in the printed proof point in the reverse direction; the theorem does not depend on that slip. The homological proof uses the counit and has the covariant direction.

The lemma on manuscript page 85 strengthens the sufficient criterion. The property that f_y is a $\mathbb{D}$-equivalence propagates across every arrow of Y, by applying two-out-of-three to the square of comma categories. It is therefore enough to test one object in each connected component. The proposed converse, from the total-space equivalence to fibre equivalences, fails because taking global cohomology can annihilate a nonzero local system. This does not contradict pointwise detection in $\mathbb{D}(Y)$: the functor of global sections is generally not conservative.

Question. Soit $f : X \to Y$ une $\mathbb{D}$-fibration, et soit $F \in \mathbb{D}(Y)$. Alors $f_* f^* F$ se calcule-t-il par passage aux fibres? Même question pour $f_! f^* F$. Pour la première propriété, concernant f_*, on montre que cela marche si F est de la forme $p_*(M_Y)$, où $p : Y' \to Y$ est $\mathbb{D}$-*propre,* et $M \in \mathsf{Ob}\,\mathcal{A}$. D'autre part, la sous-catégorie pleine C de $\mathbb{D}(Y)$ formée des F pour lesquels ça marche est (sauf erreur) "stable par $\mathbb{D}$-hot-$\varprojlim$" en le sens suivant : si on a une catégorie I avec objet final e formant une sous-catégorie fermée (*i.e.* $e \to x \Rightarrow x = e$), et si on a $\mathcal{F} \in \mathbb{D}(Y \times I)$, d'où $I^\circ \to \mathbb{D}(Y)$, $i \mapsto \mathcal{F}_i$ (diagramme squelettique), si les $\mathcal{F}_i$ pour $i \neq e$ sont dans C, et si $\mathcal{F}$ est dans l'image essentielle de j_*, où $j : Y \times (I \setminus \{e\}) \hookrightarrow Y \times I$ est l'inclusion, alors $\mathcal{F}_e$ est aussi dans C.

Commentary · Exposition [ms. 82]

Two useful classes of coefficients

The question about arbitrary coefficients should be separated from the assertion actually needed in the preceding proof. A universally cohomological fibration already calculates f_*f^*F on strict fibres whenever F is locally constant, under the local constancy axiom. Two further operations on coefficients explain the tentative observations here.

Suppose $p : Y' \to Y$ is $\mathbb{D}$-proper, $M \in \mathbb{D}(e)$, and $F = p_*M_{Y'}$. Form $X' = X \times_Y Y'$, with maps $q : X' \to X$ and $f' : X' \to Y'$. Proper base change gives

$$f^*p_*M_{Y'} \simeq q_*M_{X'}, \qquad f_*f^*p_*M_{Y'} \simeq p_*f'_*M_{X'}.$$

The fibre formula for p_* turns evaluation at y into cohomology over Y'_y. Universal fibrewise calculation for f' identifies the restriction of $f'_*M_{X'}$ to Y'_y with the direct image along $X_y \times Y'_y \to Y'_y$. The resulting object is $H^*_{\mathbb{D}}(X_y \times Y'_y, M)$. On the other side, $F_y = H^*_{\mathbb{D}}(Y'_y, M)$, and the product interchange formula identifies $H^*_{\mathbb{D}}(X_y, (F_y)_{X_y})$ with the same object. All identifications are the canonical mates, so this proves the desired comparison, not merely an accidental isomorphism between its endpoints. The printed $p_*(M_Y)$ must here be understood as $p_*(M_{Y'})$.

There is also a formal closure argument. Fix y. The two sides of the fibre comparison, as functors of $F \in \mathbb{D}(Y)$, preserve coherent homotopy limits: restrictions preserve limits computed in the diagram variable, and right Kan extensions compose. Their comparison is a natural transformation between these continuous functors. If it is invertible on a coherent diagram of coefficients, it is invertible on its homotopy limit, by applying the two functors and then the canonical limit comparison. In particular this proves the punctured-cone assertion in the text, provided the indicated diagram shapes belong to Dia. No claim about arbitrary incoherent diagrams in the category $\mathbb{D}(Y)$ is required. This distinction matters because an arbitrary diagram in a homotopy category need not have a chosen coherent lift.

On peut cependant considérer que si on veux que $f : X \to Y$ satisfasse à toutes les propriétés cohomologiques et homologiques qui s'attachent à la notion d'une "fibration" ("localement triviale"), on devrait mettre dans les conditions que f est *lisse*, et *propre*, pour que les changements de base par f commutent aux foncteurs g_*, $g_!$.

Commentary · Development (commentators') [ms. 82]

The fibre formula for coefficients from the base

The question on this page has an affirmative answer for the universal notion of fibration retained on manuscript pages 117–118. The restriction on the coefficient is essential to the argument: it may vary arbitrarily on the base, but the coefficient on the total category is its inverse image. We give the argument because it also answers the question about trivial fibrations on page 84. Throughout this block the domain contains the comma categories, categories of factorizations, and their pullbacks used below. The usual domain of all small categories has this property; so does the domain of finite posets when the categories under consideration are finite posets.

Proposition (fibre calculation for inverse images). [ours] Suppose that $\mathbb{D}$ takes admissible disjoint unions to products, has both homotopy Kan extensions and their pointwise formulas, and detects isomorphisms pointwise. All disjoint unions indexed by the hom-sets below are assumed admissible. Let $f : X \to Y$ be a weak cohomological $\mathbb{D}$-fibration after every base change. Then, for every $F \in \mathbb{D}(Y)$ and $y \in Y$, the canonical comparison

$$(f_*f^*F)_y \longrightarrow H^*_{\mathbb{D}}(X_y, (F_y)_{X_y})$$

is an isomorphism. These comparisons also imply base change for f_*f^*F along an arbitrary functor into Y. The dual assertion holds for $f_!f^*F$ when f is universally a weak homological fibration.

Fix y and write $H = X/y$, $S = X_y$, $v : H \to Y$ for $(x, f(x) \to y) \mapsto f(x)$, and $s : H \to e$, $t : S \to e$ for the projections. The two functors in the comparison are the right adjoints

$$T = s_*v^*, \qquad R = t_*t^*y^* : \mathbb{D}(Y) \longrightarrow \mathbb{D}(e).$$

The pointwise formula identifies T with evaluation of f_*f^* at y. Their left adjoints are respectively $v_!s^*$ and $y_!t_!t^*$. It therefore suffices to prove that the left mate of the comparison,

$$y_!t_!t^* \longrightarrow v_!s^*,$$

is invertible. We can test this on $M \in \mathbb{D}(e)$ and then at each object $z \in Y$.

For an arrow $\gamma : z \to y$, let E_γ be the category of factorizations

$$z \xrightarrow{\beta} c \xrightarrow{\alpha} y, \qquad \alpha\beta = \gamma.$$

A morphism from (c, β, α) to (c', β', α') is $h : c \to c'$ with $h\beta = \beta'$ and $\alpha' h = \alpha$. This category has initial object $(z, 1_z, \gamma)$ and terminal object $(y, \gamma, 1_y)$. Put

$$K_\gamma = X \times_Y E_\gamma,$$

where $E_\gamma \to Y$ remembers the middle object. Thus an object of K_γ is a factorization $z \to f(x) \to y$ of γ, and its morphisms are arrows of X making the two triangles commute.

The pullback $K_\gamma \to E_\gamma$ is a weak cohomological fibration by hypothesis. Its strict fibre over the terminal factorization is X_y. Since slicing over a terminal object changes nothing, the first clause in the definition of a weak cohomological fibration says precisely that

$$X_y \longrightarrow K_\gamma, \qquad x \longmapsto (x, \gamma, 1_y),$$

is a $\mathbb{D}$-equivalence. Consequently it induces an isomorphism on homology with every constant coefficient M. Here we use the equivalence of the homological and cohomological tests for a $\mathbb{D}$-equivalence established on manuscript pages 61–62; no assertion about arbitrary local systems is being substituted for it.

Now $z\backslash v$ is the disjoint union of the K_γ over the discrete set $Y(z, y)$. Indeed, its objects give the two arrows $z \to f(x) \to y$, and every morphism preserves their composite. The pointwise formula for left Kan extension and the coproduct axiom identify the component of the mate at z with

$$\coprod_{\gamma \in Y(z,y)} H^{\mathbb{D}}_*(X_y, M) \longrightarrow \coprod_{\gamma \in Y(z,y)} H^{\mathbb{D}}_*(K_\gamma, M).$$

Each summand is induced by the displayed inclusion of X_y and is an isomorphism. Hence the mate is an isomorphism by pointwise detection, and so is the original comparison between right adjoints. This proves the fibre formula. For a base change $a : Y' \to Y$, both sides of the base-change map at $y' \in Y'$ identify with the same cohomology of $X_{a(y')}$ with value $F_{a(y')}$. Naturality of the comparisons gives the base-change assertion. Applying the argument with the opposite indexing categories and opposite coefficient categories gives the homological assertion. □

The mechanism is the relative form of the factorization-category proof of homotopy exactness in Groth et al. (2014a, Theorem 3.8). The full-faithfulness consequence in the next block has an all-derivator formulation in the homotopical epimorphism criterion of Groth and Štovíček (2016, Theorem 6.10). We have checked these references, as well as Maltsiniotis (2005) and Cisinski (2009); we did not locate this precise answer to the page-82 question in those texts. The label marks our application and proof here, not a claim of priority. Notice what the proof does not require: neither properness of f nor local constancy of F on Y.

Signalons : ed. 51

Proposition 4. *Soit $f : X \to Y$* propre. *Pour que f soit une $\mathbb{D}$-fibration, il faut et il suffit que pour tout $y_1 \to y_0$ dans Y, le foncteur $X/y_1 \to X/y_0$ induit soit une $\mathbb{D}$-équivalence* (i.e. *que f soit une $\mathbb{D}$-fibration* cohomologique). *Dualement, si f est $\mathbb{D}$-lisse, pour que ce soit une $\mathbb{D}$-fibration, il faut et il suffit que pour tout $y_1 \to y_0$ dans Y, $y_0\backslash X \to y_1\backslash X$ soit une $\mathbb{D}$-équivalence.* [page 83]

On pourrait appeler $\mathbb{D}$-fibrations *parfaites* les foncteurs à la fois propres et lisses qui sont des $\mathbb{D}$-fibrations cohomologiques (ou ce qui revient au même des $\mathbb{D}$-fibrations homologiques).

Corollaire. *Supposons f $\mathcal{C}at$-cofibration (donc propre). Pour que f soit une $\mathbb{D}$-fibration, il faut et il suffit que les foncteurs $X_{y_0} \to X_{y_1}$ (pour $y_0 \to u_1$ dans Y) soient des $\mathbb{D}$-équivalences. Duallement, pour $\mathcal{C}at$-fibration (donc lisse).*

Proposition 5. *Soit $f : X \to Y$ dans* Dia. *Conditions équivalentes :*

a) *f est une $\mathbb{D}$-équivalence, et le reste par tout changement de base ;*

b) *f est une $\mathbb{D}$-fibration à fibres $\mathbb{D}$-contractiles.*

Démonstration. *a*) ⇒ *b*) : Que *a*) implique que f soit une $\mathbb{D}$-fibration est immédiat sur la définition de celle-ci (condition *a*) de la proposition 2), et que les fibres sont contractiles est tautologique.

b) ⇒ *a*) : Il suffit de montrer que *b*) implique que f est une $\mathbb{D}$-équivalence. Mais c'est un cas particulier de la proposition 3 *b*) (en y prenant $X' = Y$).

Commentary · Exposition [ms. 83]

Properness separates the two tests

For a proper functor the first half of the cohomological-fibration condition is already supplied by proper base change: the inclusion $X_y \to X/y$ is coaspherical, hence a $\mathbb{D}$-equivalence, and right Kan extensions calculate on strict fibres. What remains is local constancy of f_*M_X for every M. This remaining condition is stable under arbitrary change of base. Indeed properness identifies the new direct image with the restriction of the old one, and restriction preserves local constancy. This proves the criterion of Proposition 4 in the universal cohomological sense. Its identification with the revised bilateral fibration notion uses the local-constancy hypotheses explained at manuscript pages 97–100.

For a Grothendieck opfibration, a choice of cocartesian lifts gives transition functors $\alpha_! : X_{y_0} \to X_{y_1}$ for arrows $\alpha : y_0 \to y_1$. They are defined up to canonical natural isomorphism. The map on constant-coefficient cohomology between the two strict fibres is the map induced by $\alpha_!$, with the cohomological direction reversed. Consequently local constancy says precisely that every transition functor is a $\mathbb{D}$-equivalence. The criterion is independent of the chosen cleavage. The dual statement uses cartesian transport in a Grothendieck fibration.

The later adjective "trivial" is also justified without the false converse of Proposition 2. A universal $\mathbb{D}$-equivalence has $\mathbb{D}$-contractible strict fibres by pulling back to points. Its further pullbacks are again universal equivalences. It has the cohomological and homological fibration tests because the relevant maps form triangles whose other two sides are these universal equivalences. Conversely, a universal cohomological fibration with $\mathbb{D}$-contractible fibres has $M_Y \to f_*M_X$ invertible at every point, hence invertible in $\mathbb{D}(Y)$. Taking global cohomology proves that it is a $\mathbb{D}$-equivalence, and the argument repeats after every base change. Thus Proposition 5 survives the revision. The stronger full-faithfulness question on page 84 requires the separate factorization-category argument given in its commentary.

Quand ces conditions sont satisfaites, on s'attend à ce que le foncteur

$$f^* : \mathbb{D}(Y) \longrightarrow \mathbb{D}(X)$$

[page 84]

soit pleinement fidèle, *i.e.* que les morphisme d'adjonction

$$F \longrightarrow f_*f^*F \quad , \qquad f_!f^* \longrightarrow F$$

dans $\mathbb{D}(Y)$ soient des isomorphismes. (C'est vrai si f est $\mathbb{D}$-propre ou $\mathbb{D}$-lisse, cf. cor. 3, p.71.) Cela revient encore à dire que les f_*f^*F se calculent par passage aux fibres, ou encore itou pour les $f_!f^*F$. Cela nous ramène à la question de la page 82.

Commentary · Development (commentators') [ms. 84]

Universal equivalences give fully faithful restriction

The expectation in the preceding paragraph follows from the fibre formula just proved. It is stronger than the assertion that f preserves cohomology of constant objects, because it controls all morphisms between arbitrary coefficients on Y.

Corollary (the question about trivial fibrations). [ours] Under the domain and derivator hypotheses of the preceding development, suppose that every pullback of $f : X \to Y$ is a $\mathbb{D}$-equivalence. Then

$$f^* : \mathbb{D}(Y) \longrightarrow \mathbb{D}(X)$$

is fully faithful. Both the unit $F \to f_*f^*F$ and the counit $f_!f^*F \to F$ are isomorphisms, for every $F \in \mathbb{D}(Y)$.

To prove this, first pull back over a point $y \to Y$. The hypothesis says that X_y is $\mathbb{D}$-aspherical. Pulling back over Y/y likewise shows that X/y is $\mathbb{D}$-aspherical, since Y/y has a terminal object. The inclusion $X_y \to X/y$ and all transition functors between these comma categories are therefore $\mathbb{D}$-equivalences by two-out-of-three. The same argument works after any base change. Thus f is universally a weak cohomological fibration. At y, compose the adjunction unit with the comparison proved in the preceding block:

$$F_y \longrightarrow (f_* f^* F)_y \longrightarrow H^*_{\mathbb{D}}(X_y, (F_y)_{X_y}).$$

The composite is the constant-coefficient unit for $X_y \to e$, which is invertible by asphericity. The second arrow is invertible by the proposition. The first arrow is therefore invertible, and pointwise detection proves that $F \to f_* f^* F$ is an isomorphism. This is equivalent to full faithfulness of f^*. Since f^* also has the left adjoint $f_!$, full faithfulness makes the other displayed adjunction counit invertible as well. □

There is also a useful direct connection with the modern criterion. For each arrow $\gamma : z \to y$, the category E_γ of its factorizations has an initial and a terminal object. Universality makes $K_\gamma = X \times_Y E_\gamma$ aspherical. These are exactly the factorization categories controlling full faithfulness. In the special case of weak equivalences of nerves, Groth and Ševčík (2016, Theorem 6.10) therefore supplies the same conclusion simultaneously for every derivator. The argument above gives the coefficient-relative conclusion asked for in the manuscript and explains why universality, rather than the single global equivalence $X \to Y$, is the relevant hypothesis.

Définition 3. On dit alors que f est une $\mathbb{D}$-fibration *triviale*.

Proposition 6 (précise prop. 3 page 81). *Considérons un triangle commutatif dans* Dia

$$\begin{array}{ccc} X & \xrightarrow{\ f\ } & X' \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle p'} & \\ & S & \end{array} \quad .$$

a) *Supposons que p et p' soient des $\mathbb{D}$-fibrations gauches, ou que p et p' soient des $\mathbb{D}$-fibrations droites. Soit S_0 une partie de S qui rencontre toute composante connexe de S. Pour que f soit une $\mathbb{D}$-équivalence, il* suffit *que pour tout $s_0 \in S_0$, f induise une $\mathbb{D}$-équivalence $X_{s_0} \to Y_{s_0}$.* ed. 52

b) *Cette condition est aussi nécessaire*[40] *si p et p' sont des $\mathbb{D}$-fibrations. Donc dans ce cas, f est une $\mathbb{D}$-équivalence si et seulement si f induit des $\mathbb{D}$-équivalences fibre par fibre.*

Démonstration. a) Il suffit, en vertu de la proposition 3, de montrer que l'hypothèse implique que pour *tout* $s \in S$, f induit une $\mathbb{D}$-équivalence $f_s : X_s \to X'_s$. Cela résulte aussitôt du lemme : [page 85]

Lemme. *Si p et p' sont toutes deux soit des $\mathbb{D}$-fibrations gauches, soit des $\mathbb{D}$-fibrations droites, et si $s_1 \to s_0$ est une flèche dans S, alors f_{s_1} est une $\mathbb{D}$-équivalence si et seulement si f_{s_0} l'est. (Donc l'ensemble $S' \subset \mathsf{Ob}\, S$ des $s \in S$ tels que f_s soit une $\mathbb{D}$-équivalence est une réunion de composantes connexes de S.)*

Supposons par exemple que p, p' soient des $\mathbb{D}$-fibrations gauches. Considérons, pour $s \in S$, le diagramme

$$\begin{array}{ccc} X_s & \xrightarrow{f_s} & X'_s \\ \downarrow & & \downarrow \\ X/s & \xrightarrow[f/s]{} & X'/s \end{array} \quad .$$

40. Pas prouvé![41] Même si $X' = S$, ce n'est pas clair, même si $\mathbb{D} = \mathsf{HOTAB}$, f propre et lisse. Mais OK si S est $\mathbb{D}$-contractile.

41. Faux, *cf.* contre-exemple, p. 87.

Les flèches verticales sont des $\mathbb{D}$-équivalences par l'hypothèse sur p, p', donc f_s est une $\mathbb{D}$-équivalence si et seulement si f/s l'est. Considérons maintenant

$$\begin{array}{ccc} X/s_1 & \xrightarrow{f/s_1} & X'/s_1 \\ \downarrow & & \downarrow \\ X/s_0 & \xrightarrow[f/s_0]{} & X'/s_0 \end{array} \quad .$$

Ici encore, l'hypothèse sur p, p' implique que les flèches verticales sont des $\mathbb{D}$-équivalences, donc f_{s_1} est une $\mathbb{D}$-équivalence si et seulement si f_{s_0} l'est.

Si $Y' = S$, l'énoncé (non prouvé) dit que si $f : X \to S$ est une $\mathbb{D}$-fibration et une $\mathbb{D}$-équivalence, alors les fibres sont $\mathbb{D}$-contractiles. Ce n'est pas sûr même pour une projection $X = T \times S \to S$. Si $\eta = hot_0(S)$, $\xi = hot_0(T)$, la question se réduit à celle-ci : Si pour tout M dans $\mathcal{A}$, on a : l'homomorphisme [page 86]

$$\alpha_M : \xi \times_{\mathbb{D}} M \longrightarrow M$$

satisfait ed. 53

$$\eta \times_{\mathbb{D}} \alpha_M : \eta \times_{\mathbb{D}} (\xi \times_{\mathbb{D}} M) \xrightarrow{\sim} \eta \times_{\mathbb{D}} M$$

est un isomorphisme, alors α_M est lui même un isomorphisme.

Commentary · Development (commentators') [ms. 86]

Why a product cannot supply the counterexample

The product case singled out on manuscript page 86 has a short resolution that does not use an additive coefficient theory. We give it to isolate the role of twisting in the counterexamples which follow. It is a formal retract argument; we claim no priority for it. The locally constant-coefficient results of Cisinski (2009) address the general homotopical framework, but we did not find this particular paragraph of the manuscript treated there.

Cancellation for a nonempty product base. [ours] Assume the action of indexing homotopy types on $\mathbb{D}(e)$ is functorial and that S has an object. If the product projection $S \times T \to S$ is a $\mathbb{D}$-equivalence, then $T \to e$ is a $\mathbb{D}$-equivalence.

Proof. Choose $s : e \to S$ and write $p : S \to e$. Then $ps = 1_e$. For each coefficient M, let $\alpha_M : T \times_{\mathbb{D}} M \to M$ be the augmentation. Functoriality gives a retract diagram in the arrow category of $\mathbb{D}(e)$,

$$\alpha_M \longrightarrow S \times_{\mathbb{D}} \alpha_M \longrightarrow \alpha_M,$$

whose composite is the identity: the first map is induced by s, the second by p. The middle arrow is an isomorphism by the product hypothesis and Fubini for homology. A retract of an isomorphism is an isomorphism. Explicitly, if an arrow a is a retract of an invertible arrow b, with inclusions i_0, i_1 and retractions r_0, r_1, then $r_0 b^{-1} i_1$ is an inverse of a, as the two commutative squares show. Hence every α_M is invertible. This is the asserted $\mathbb{D}$-contractibility of T. □

The nonempty-base hypothesis cannot be omitted: $\varnothing \times T \to \varnothing$ is an isomorphism for every T. The argument establishes that the proposed product example cannot work; it does not establish the analogous assertion for a bundle with monodromy. The next example exploits exactly that distinction.

Voici un *contre-exemple*[42] que je donne d'abord dans le contexte des espaces topologiques, au lieu de $\mathcal{C}at$. Je vais construire une fibration localement triviale et non triviale [page 87]

$$\begin{array}{ccc} X & \supset & S^1 \\ {\scriptstyle f}\downarrow & & \\ S & = & S^1 \end{array} \quad ,$$

42. Voir un contre-exemple encore plus simple pages 93, 94. (Mais il a l'inconvenient de ne pas être à fibres connexes.)

de fibre S^1, telle que f soit une $\mathbb{D}$-équivalence pour tout $\mathbb{D} = \mathsf{Der}(k\text{-}\mathsf{Mod})$, k étant un anneau où 2 est inversible. Cela signifie que

$$H_*(X,k) \longrightarrow H_*(S,k)$$

est un isomorphisme modulo 2-torsion (noyau et conoyau sont annulés par une puissance de 2 - en fait par 2 ici), ou encore $H_*(X,k) \xrightarrow{\sim} H_*(S,k)$ si 2 inversible dans k. Mais la fibre S^1 n'est pas $\mathbb{D}$-contractile (sauf si $k = 0!$). [43]

La fibration est donnée à isomorphisme unique près, en se fixant un point $s \in S$, et en se donnant un automorphisme u de la fibre X_s ("monodromie"). (La classe d'isomorphie du fibré ne dépend que de la classe d'isotopie de u). Je prend pour u la symétrie (inversant l'orientation) $z \mapsto z^{-1}$ du cercle standard $\{z \in \mathbb{C} \mid |z| = 1\}$. Cette fibration "se réalise" par des ensembles ordonés $X \to S$, S^1 étant représenté (sur la base, comme sur les fibres) par

$$S \;=\; \begin{array}{ccccc} & & a & & \\ & \nearrow & & \nwarrow & \\ 0 & & & & 0' \\ & \searrow & & \swarrow & \\ & & b & & \end{array} \;=\; S' \amalg_R S'' \quad ,$$

où R est la catégorie discrète ayant deux éléments a, b. On définit X comme $X' \amalg_Y X''$, où $X' = X|S'$, $X'' = X|S''$, $Y = X|R$. [44]

On pose

ed. 54

[page 88]

$$X' = S' \times \bar{S} \qquad\qquad X'' = S'' \times \bar{S}$$

($\bar{S}$ copie conforme de S, cf ci-dessous) et il faut, pour recoller X' et X'', se donner un isomorphisme entre $X'|R \simeq R \times \bar{S} = \bar{S} \amalg \bar{S}$ et $X''|R \simeq R \times \bar{S} = \bar{S} \amalg \bar{S}$ qui soit un R-foncteur, *i.e.* qui provient de deux isomorphismes

$$\begin{aligned} \bar{S} &\xrightarrow{u_a} \bar{S} \\ \bar{S} &\xrightarrow{u_b} \bar{S} \qquad . \end{aligned}$$

On prend

$$\begin{aligned} u_a &= \mathsf{id}_{\bar{S}} \\ u_b &= \text{symétrie par rapport à l'axe } \bar{0}, \bar{0}' \text{ } \textit{i.e.} \\ &\qquad u_b \text{ laisse fixes } \bar{0}, \bar{0}' \text{ et intervertit } \bar{a} \text{ et } \bar{b}. \end{aligned}$$

(C'est plus clair si on désidentifie la base et la fibre, en prenant fibre

$$\bar{S} \;=\; \begin{array}{ccccc} & & \bar{a} & & \\ & \nearrow & & \nwarrow & \\ \bar{0} & & & & \bar{0}' \\ & \searrow & & \swarrow & \\ & & \bar{b} & & \end{array} \qquad).$$

43. Exemple beaucoup plus simple encore : on prend $X = S^1$, et $X \to S$ le revêtement à deux feuillets. Si on prend le revêtement à n feuillets, c'est aussi OK si k anneau où n est inversible.

44. N.B. S', S'', $R = S' \cap S''$ fermés dans S, X', X'', $Y = X' \cap X''$ fermés dans X.

Commentary · Examples [ms. 88]

The Klein bottle and its sign coefficient

Take a nonzero commutative ring k in which 2 is invertible. Let $r : S^1 \to S^1$ be complex conjugation and form its mapping torus

$$K = (S^1 \times [0,1])/((z,1) \sim (r(z),0)).$$

Projection to $[0,1]/(0 \sim 1)$ gives the Klein-bottle bundle $f : K \to S^1$. We use the cohomological convention in which $k[-1]$ has its copy of k in degree 1. Grothendieck's displayed $k[1]$ is explicitly annotated "en degré 1" and should be translated accordingly, not corrected as a transcription error.

A cell structure has one vertex, two edges a, b, and one two-cell with attaching word $aba^{-1}b$. Here a projects once around the base and b runs around the fibre. The cellular complex is

$$0 \longrightarrow k \xrightarrow{(0,2)} ka \oplus kb \xrightarrow{0} k \longrightarrow 0.$$

The map to the cellular complex of the base sends a to its generator and kills b and the two-cell. Its kernel is the two-term complex $k \xrightarrow{2} k$, which is contractible. Consequently the projection induces an equivalence with every constant derived k-module coefficient, including unbounded complexes: the displayed chain contraction survives applying the appropriate Hom complex. Integrally, one instead gets $H_1(K;\mathbb{Z}) = \mathbb{Z} \oplus \mathbb{Z}/2$, and the kernel of the map to $H_1(S^1;\mathbb{Z})$ is the indicated 2-torsion. The fibre still has $H_1(S^1;k) = k$ and is not $\mathbb{D}$-contractible.

The same computation in local-coefficient language explains why global cohomology loses the fibre. Let L be the rank-one local system on the base with monodromy -1. The fibre cohomology gives

$$Rf_*k_K \simeq k_{S^1} \oplus L[-1].$$

This splitting can be obtained from the cellular circle complex with its reflection action. Alternatively, the fixed point of the reflection gives a section and splits the degree-zero summand. The remaining summand is $L[-1]$. Global sections of L are computed by $k \xrightarrow{-2} k$, in degrees $0, 1$; the complex is zero in the derived category. Thus the extra summand is visible over each point and invisible after taking global sections.

The finite categorical model in the text has four objects in the base and four in each fibre. Choose $S' = \{0, a, b\}$ and $S'' = \{0', a, b\}$. Their intersection is the discrete category $\{a, b\}$. Gluing the products with the four-object circle by the identity over a and by reflection over b produces sixteen objects. Each arrow in the base transports the fibre by an isomorphism. The projection is therefore both a Grothendieck fibration and an opfibration, and remains so after every base change. Its nerve realizes the same monodromy bundle. This supplies the categorical counterexample required by the manuscript, without appealing only to a topological analogy. Cellular calculations and the general language of local coefficients are reviewed in Hatcher (2002, §§2.2, 3.H).

Pour voir que X est une $\mathbb{D}$-fibration sur S (quelque soit $\mathbb{D}$) prouvons qu'il est *propre*[45] sur S - on est ramenés à voir que $X' \to S'$ et $X'' \to S''$ sont propres, ce qui est trivial. Pour voir que c'est une $\mathbb{D}$-fibration, on est ramenés également au cas de $X' \to S'$ et $X'' \to S''$, où c'est aussi trivial. On a utilisé le :

Lemme. *Soient $f : X \to S$, $(S_i)_{i\in I}$ une famille de sous-catégories fermées recouvrant S. Pour tout i, soit $X_i = X \times_S S_i \xrightarrow{f_i} S_i$. Pour que f soit propre, il faut et il suffit que les f_i le soient. Pour que f soit une $\mathbb{D}$-fibration propre il faut et il suffit que les f_i le soient.*

Commentary · Exposition [ms. 88]

Why the closed-cover test is sufficient

The gluing lemma has a local proof which does not require a descent theorem for arbitrary closed covers. A closed full subcategory here is a cosieve: whenever it contains the source of an arrow it contains its target. In the lifting-category criterion for properness, fix $x \in X$ and an arrow

45. N.B. $f : X \to S$ est également *lisse*, car c'est un fibré trivial (un produit) au dessus de deux ouverts $S - \{a\}$, $S - \{b\}$ qui recouvrent S. Mieux : f est à la fois $\mathcal{C}at$-fibrant et $\mathcal{C}at$-cofibrant (car cette condition n'utilise que les propriétés des $X \times_S \mathbf{\Delta}_2 \to \mathbf{\Delta}_2$, pour $\mathbf{\Delta}_2 \to S$).

$f(x) \to s$ in the base. Choose a member S_i of the cover containing $f(x)$. Its cosieve property forces s and every intermediate object relevant to this lift into S_i. The entire category of lifts is therefore the same one computed in $X_i \to S_i$. Its $\mathbb{D}$-contractibility follows from properness there. Necessity follows by base change.

Once properness has been obtained globally, the fibration condition asks whether the fibre-cohomology comparison along each arrow is invertible. Choose S_i containing its source; the arrow and both endpoints lie in that subcategory. The local condition proves the comparison, and the pointwise criterion proves the global condition. This explains both assertions of the lemma. For the displayed four-object circle, the two closed subcategories S' and S'' contain respectively 0 and $0'$, together with both targets a, b, so they meet exactly these requirements. The dual open-cover argument explains smoothness.

Voici le petit calcul qui montre que $f : X \to S$ est une $\mathbb{D}$-équivalence. On fait le calcul en cohomologie. [46] On doit prouver que [page 89]

$$(*) \qquad H^*(S,k) \longrightarrow H^*(X,k)$$

est un isomorphisme (et de même pour tout coefficient constant M sur S). Or ed. 55

$$H^*(X,k) \overset{\text{def}}{=} \mathbb{R}\Gamma_X(k_X) = \mathbb{R}\Gamma_S(\mathbb{R}f_*(k_X)) \quad ,$$

et $(*)$ est induit par

$$i : k_S \longrightarrow \mathbb{R}f_*k_X \quad .$$

Or on a

$$\mathbb{R}f_*k_X \simeq \underbrace{k_S}_{=\mathsf{Im}(i)} \quad \oplus \quad \underbrace{k_S[1]}_{k_S \text{ en degré } 1} \quad \underline{\text{tordu}}$$

savoir "tordu" par l'action de monodromie sur $S = S^1$, laquelle est la symétrie $\lambda \mapsto -\lambda$. On a

$$\mathbb{R}\Gamma_S(k_S[1]^{\text{tordu}}) = H^1(\underbrace{\pi_1(S)}_{=\mathbb{Z}}, k_S^{\text{tordu}}) = k_{(\mathbb{Z})} = k/(u - \mathsf{id})k = k/2k = 0 \ ,$$

d'où le résultat.

Notons que si on regarde

$$X' = X \times_S X \xrightarrow{f'} S \quad ,$$

on a par Künneth relatif

$$\mathbb{R}f'_*(k_{X'}) \simeq \mathbb{R}f_*(k_X) \otimes^{\mathbb{L}} \mathbb{R}f_*(k_X) \simeq k_S \oplus k_S[1]^t \oplus k_S[1]^t \oplus \underbrace{k_S[1]^t \otimes k_S[1]^t}_{\simeq k_S[2] \text{ non tordu}} \ ,$$

d'où

$$H^*_{\mathbb{D}}(X',k) \simeq \mathbb{R}\Gamma_{X'}(k_{X'}) \simeq \mathbb{R}\Gamma_S(\mathbb{R}f'_*(k_{X'})) \simeq \mathbb{R}\Gamma_S(k_S) \oplus \mathbb{R}\Gamma_S(k_S)[2]$$

et

$$H^*_{\mathbb{D}}(S,k) \longrightarrow H^*_{\mathbb{D}}(X',k)$$

n'est *pas* un isomorphisme.

Ainsi $f : X \to S$ qui est une $\mathbb{D}$ fibration (propre et lisse) satisfait bien les conditions équivalentes $b), b')$ de la proposition 2 (page 79), mais pas la condition $a)$, puisque le changement de base [page 90]

$$\begin{array}{ccc} X' = X \times_S X & \xrightarrow{q=pr_1} & X \\ {\scriptstyle f'=pr_2}\downarrow & & \downarrow{\scriptstyle f} \\ S' = X & \xrightarrow[p=f]{} & S \end{array}$$

46. Mais dans le cas du revêtement à 2 feuillets de S, il n'y a pas même de calcul à faire!

est une $\mathbb{D}$-équivalence $S' \to S$, alors que $X' \to X$ ne l'est pas.

Commentary · Examples [ms. 90]

Self-pullback restores the missing cohomology

The self-pullback $K \times_{S^1} K$ is the mapping torus of $r \times r : T^2 \to T^2$. Its fibre has cohomology k in degrees 0 and 2, and k^2 in degree 1. The monodromy acts trivially in degrees $0, 2$ and as -1 on both degree-one generators. The degree-two action is $(-1)(-1) = 1$. The two sign summands again have acyclic global sections, whereas the degree-two summand does not. Hence

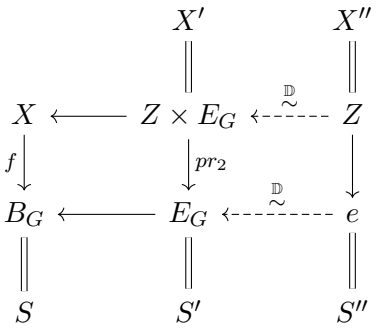
$$H^j(K \times_{S^1} K; k) = \begin{cases} k, & j = 0, 1, 2, 3, \\ 0, & \text{otherwise.} \end{cases}$$

The same conclusion follows directly from the mapping-torus complex: in each fibre degree its extra differential is $1 - (r \times r)^*$, which is either zero or multiplication by 2. This calculation avoids extension ambiguities and is valid over the stated ring.

The map $K \to S^1$ is a constant-coefficient equivalence, but its pullback $K \times_{S^1} K \to K$ cannot be one, because the source has the additional nonzero groups in degrees $2, 3$. Thus even a bundle which is both proper and smooth in the categorical sense does not preserve all constant-coefficient equivalences under pullback. Properness controls the base-change comparison for a direct-image functor; it does not assert that the base-change map is an equivalence for whichever weak-equivalence class one has chosen on the base.

The easier covering example in footnote 43 exhibits the same distinction. The degree-n map $S^1 \to S^1$ is a k-homology equivalence when n is invertible in k, since it is the identity in degree 0 and multiplication by n in degree 1. Its strict fibre has n points. Its self-pullback is a disjoint union of n circles, so the pulled-back projection fails already on H_0 for $n > 1$. This example also avoids any question about a derived splitting.

Voici un autre contre-exemple, sur le même principe mais un peu plus simple. Soit G un groupe fini (par exemple $G = \mathbb{Z}/2\mathbb{Z}$), faisons le opérer sur un objet Z de $\mathcal{C}at$, soit $S = [G] = B_G$ la catégorie réduite à un objet a, avec $G = \mathsf{End}(a)$. Soit E_G la catégorie (isomorphe à $(B_G)/a$)



$$\mathsf{Ob}\ E_G = G \quad , \qquad \mathsf{Hom}_{E_G}(g, g') = \{h \in G \mid g = g'h\} \quad ,$$

composition évidente - alors E_G est un groupoïde trivial (1-connexe). Le goupe G y opère à gauche librement par translations, et $B_G = E_G/G$.

Si G opère à gauche sur Z, on peut alors l'utiliser pour tordre Z, par ed. 56

$$X = E_G \times_G Z = (E_G \times Z)/\text{opérations “diagonales” de G} \quad . \qquad \text{[page 91]}$$

Donc on a un diagramme cartésien

Comme le changement de base $S' = E_G = (B_G)/a \to B_G = S$ transforme X sur B_G en un produit (lequel est un $\mathbb{D}$-fibré propre et lisse sur S'), on voit que X sur B_G est un $\mathbb{D}$-fibré propre et lisse (car c'est là une condition locale sur B_G).

On suppose maintenant que G est fini d'ordre $n > 1$, et soit k un anneau où n est invesible, $\mathbb{D} = \mathsf{Der}(k - \mathsf{Mod})$. Alors $E_G \to B_G$ est une $\mathbb{D}$-équivalence, ou ce qui revient au même $e \to B_G$ l'est.[47] Pourtant, après changement de base soit par $S' = E_G$, soit par $S'' = e$, $X' \to X$ (ou

47. En fait, e, E_G, B_G sont $\mathbb{D}$-asphériques.

ce qui revient au même, $X'' \to X$) n'a guère de raison d'en être aussi. On a en cohomologie

$$\mathbb{R}\Gamma_X(k_X) \simeq \mathbb{R}\Gamma_{BG}(f_*(k_X)) \simeq \mathbb{R}\Gamma_G(G, H^*(Z,k))$$

donc (n étant inversible dans k) :

$$H^*(X,k) = \mathbb{R}\Gamma_X(k_X) \simeq H^*(Z,k)^G \longrightarrow H^*(Z,k) \quad , \qquad \text{[page 92]}$$

ce n'est pas en général un isomorphisme. On peut prendre par exemple $G = \mathbb{Z}/2\mathbb{Z}$, $Z \sim S^1$ comme avant, et G opérant par symétrie de S^1 comme précédemment.

Cet exemple est particulièrement convainquant, car c'est un exemple *avec S, S' $\mathbb{D}$-asphériques,* et $S' \to S$ un isomorphisme local (en fait, un revêtement principal de S). C'est aussi un exemple d'un $\mathbb{D}$-fibré lisse et propre $X \to S$, sur une base *asphérique* S, et tel que l'inclusion d'une fibre dans X

$$X_s \longrightarrow X$$

ne soit *pas* une $\mathbb{D}$-équivalence.

Le seul reproche qu'on puisse faire à cet exemple, en comparaison avec le précédent, c'est que les catégories X, S ne sont pas des ensembles ordonnés. Et S ne peut être un ensemble ordonné fini, car l'espace classifiant d'un groupe fini a de la cohomologie en toutes dimensions (sauf erreur).

Commentary · Examples [ms. 92]

Averaging over a finite group

The second counterexample places the same phenomenon over a base which is already $\mathbb{D}$-acyclic. Let G be finite of order invertible in k. The category E_G has one arrow between every ordered pair of objects of G; in particular each object is both initial and final. The quotient by left translation is BG. A G-category Z gives an associated bundle

$$X = (E_G \times Z)/G \longrightarrow BG.$$

An arrow in the base acts on the fibre by an isomorphism, so this is again a fibration and an opfibration with universally locally constant fibre transport. Pulling back to the unique object of BG recovers Z.

For a $k[G]$-module V, the averaging operator

$$e_G(v) = |G|^{-1} \sum_{g \in G} gv$$

is an idempotent with image V^G. More than a splitting, it proves exactness of invariants: an invariant element of a quotient can be lifted arbitrarily and its lift averaged. The same argument applies degreewise to complexes, so cohomology commutes with invariants. Thus

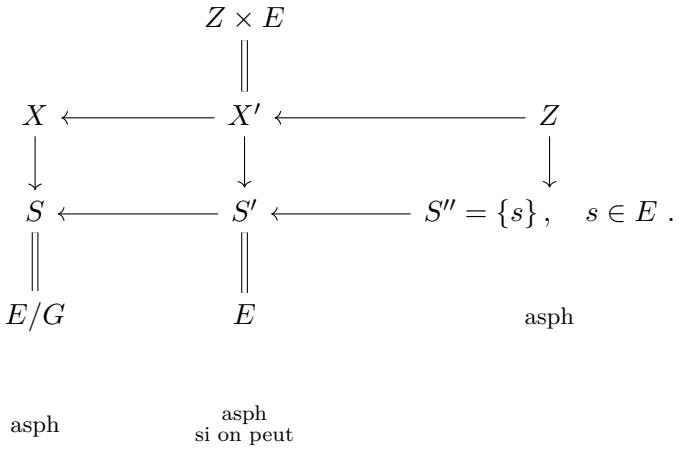
$$H^*(X;k) = H^*(Z;k)^G, \qquad H^*(BG;k) = k$$

with the second k in degree zero. The first formula is a formula for cohomology; a functorial complex-level statement uses derived sections of Z with their action, followed by invariants. It does not require choosing a splitting of an arbitrary complex into its cohomology groups.

Take $G = C_2$ and let Z be the four-object circle with reflection. Its cohomology is the trivial representation in degree zero and the sign representation in degree one. Therefore X and BG are $\mathbb{D}$-acyclic, whereas their common fibre Z is not. This disproves the qualification "OK si S est $\mathbb{D}$-contractile" in footnote 40 as well as the unqualified necessity assertion of Proposition 6(b). The replacement needed there is complete $\mathbb{D}$-asphericity, which controls locally constant coefficients, or ordinary weak contractibility under the appropriate axiom.

An even smaller choice is the discrete regular G-set $Z = G$. Then X is equivalent to the contractible category E_G, while its fibre has $|G|$ connected components. This is a wholly categorical example with finitely many objects, although its nerve is not finite-dimensional. A nontrivial finite group cannot have a finite-poset classifying space: if it did, the finite covering corresponding to its universal cover would be a finite contractible complex, so its Euler characteristic would be both 1 and $|G|$ times an integer. The phrase "cohomology in all dimensions" in the manuscript should be read as the obstruction to a bounded-dimensional classifying space, not as a claim of nonvanishing in every positive degree for every coefficient ring.

Mais on peut s'inspirer de cet exemple pour le modifier de façon qu'il se transpose à des ed. 57
ensembles ordonnés. Il suffit de réaliser, pour G donné : [page 93]



a) Une opération *libre* de G sur un objet E de $\mathcal{C}at$, telle que $H^*(E,k)^G \simeq k$, *i.e.* $B = E/G$ soit $\mathbb{D}$-asphérique.

b) Une opération de G sur un objet Z, telle que l'inclusion

$$H^*(Z,k)^G \longrightarrow H^*(Z,k)^G$$

ne soit pas [un] isomorphisme.

c) Choisir pour E, Z des ensembles ordonnés, et s'assurer que $B = E/G$ est également représenté par une catégorie ordonnée. Sauf erreur, il en sera de même pour $X = E \times Z/G$. On aura en tout les cas

Cela donne encore un exemple avec X $\mathbb{D}$-fibré propre et lisse, sur une base S $\mathbb{D}$-asphérique, tel que l'inclusion d'une fibre X_s dans X ne soit pas une $\mathbb{D}$-équivalence. On peut même se débrouiller pour que $H^*(Z,k)^G \simeq k$ ce qui implique que X est lui aussi asphérique (mais les fibres de $X \to S$ ne sont pas $\mathbb{D}$-asphériques). Cela donne donc un autre contre-exemple au b) [page 94]
de la prop. 6 (p. 84).

Voici la façon la plus économique, je crois, de réaliser la situation que j'ai dite. Topologiquement, je prend

$G = \{\pm 1\}$	
$E = S^2$	sphère euclidienne, sur laquelle $\{\pm 1\}$
	opère par antipodisme $x \mapsto -x$
$B = S^2/\{\pm 1\}$	plan projectif réel
$Z = S^1$	où G opère comme précédemment par la symétrie.

C'est donc un exemple très proche de celui du début (p. 87), où on pouvait aussi considérer la base ($B = S^1$) comme quotient d'un E ($= S^1$) par $G = \{\pm 1\}$ opérant librement (par l'antipodisme $z \mapsto -z$ dans $\mathbb{C} \simeq \mathbb{R}^2$). Mais dans cet exemple, la base n'était pas $\mathbb{D}$-asphérique. ed. 58

La façon la plus économique de réaliser la sphère S^2 par un ensemble ordonné est sans doute par sa décomposition "globulaire" par trois paires de cellules de dimension 0, 1, 2,

donnant l'ensemble ordonné

$$I \quad = \quad \begin{array}{ccc} S_2^- & & S_2^+ \\ \uparrow & \nwarrow\!\nearrow & \uparrow \\ S_1^- & & S_1^+ \\ \uparrow & \nwarrow\!\nearrow & \uparrow \\ S_0^- & & S_0^+ \end{array}$$

et l'antipodisme échange S_i^- et S_i^+, mais le quotient n'est pas ordonné, c'est la catégorie (importante pour la théorie des 2-catégories) :

[page 95]

$$\begin{array}{c} S_2 \\ {\scriptstyle p_1^-}\uparrow\uparrow{\scriptstyle p_1^+} \\ S_1 \\ {\scriptstyle p_0^-}\uparrow\uparrow{\scriptstyle p_0^+} \\ S_0 \end{array} \qquad \text{avec} \qquad \begin{cases} p_1^- p_0^- = p_1^- p_0^+ \\ p_1^+ p_0^- = p_1^+ p_0^+ \end{cases}$$

Mais prenons la subdivision barycentrique de la décomposition cellulaire précédente de S dont les sommets correspondent aux éléments de $\mathsf{Ob}\ I$, les simplexes aux parties totalement ordonnés de $\mathsf{Ob}\ I$. On trouve l'octaèdre, ayant 6 sommets, 12 arêtes, 8 faces, et G opère librement sur l'ensemble des simplexes, donc le quotient : 3 sommets, 6 arêtes, 4 faces, décomposition cellulaire du plan projectif. (Sa décomposition par trois droites.) On présente S^1 par l'ensemble ordonné (comme au début)

$$\begin{array}{ccc} S_1^- & & S_1^+ \\ \uparrow & \nwarrow\!\nearrow & \uparrow \\ S_0^- & & S_0^+ \end{array} \qquad \textit{i.e.} \qquad \begin{array}{ccc} & S_1^+ & \\ \nearrow & & \nwarrow \\ 0 = S_0^- & & S_0^+ = 0' \\ \searrow & & \swarrow \\ & S_1^- & \end{array}$$

et G y opère par symétrie échangeant S_1^- et S_1^+. Donc l'ensemble ordonné X aura $4 \times 13 = 52$ sommets et c'est modeste …

Commentary · Development (commentators') [ms. 95]

The finite poset and its residual top class

The passage to finite posets deserves a complete computation. The number 52 in the text is correct. The claimed acyclicity of the resulting total space is not. We give both verifications, retaining the printed construction and its error in the source. The transfer calculation used below is standard; see Hatcher (2002, §3.G). We did not find a published discussion of this particular 52-object calculation in the sources checked.

Footnote 42 describes the later example as having disconnected fibres, whereas the explicit choice $Z = S^1$ on manuscript page 94 has connected fibres. The covering alternative of footnote 43 and a discrete regular G-set instead give disconnected fibres; the intended reference in footnote 42 cannot be fixed unambiguously.

The corrected finite model. [ours] Let E be the face poset of the boundary of an octahedron. Its vertices are $\{\pm1, \pm2, \pm3\}$; a nonempty face is a subset containing at most one element of each antipodal pair. There are $6 + 12 + 8 = 26$ faces. The involution τ negates every vertex. Let Z be the four-object circle poset with two vertices v_0, v_1 below two edges e_0, e_1, and let τ fix the vertices and exchange the edges. Then $B = E/C_2$ and $X = (E \times Z)/C_2$ are posets with 13 and 52 objects. Their realizations satisfy

$$|NB| \simeq \mathbb{RP}^2, \qquad |NX| \simeq (S^2 \times S^1)/((x, z) \sim (-x, \bar{z})).$$

For $2 \in k^\times$, their cohomology is

$$H^*(B; k) = k, \qquad H^j(X; k) = \begin{cases} k, & j = 0, 3, \\ 0, & \text{otherwise.} \end{cases}$$

The fibre is a circle, so its inclusion into X is not a k-cohomology equivalence, but $X \to B$ is not a k-cohomology equivalence either.

Proof. If nonempty faces σ, ρ satisfy both $\sigma \subseteq \rho$ and $\sigma \subseteq -\rho$, then ρ contains an antipodal pair, which is impossible. Hence for fixed representatives there is at most one group element transporting a possible upper face to a face containing the lower one. Quotient incidence therefore gives at most one morphism between two orbit objects. Ranks prevent nontrivial cycles. The same argument applied to the first coordinate proves the assertion for $E \times Z$. Every chain in either quotient lifts uniquely once its first object is chosen, so the nerve of the quotient is the quotient of the nerve. The nerve of E is the barycentric subdivision of the octahedral sphere, and the nerve of Z is a circle. Realization commutes with these finite products and these free simplicial quotients. This proves the assertions about realization and object counts.

For a finite regular covering with group G, pullback identifies cochains on the quotient with invariant cochains upstairs: every simplex has $|G|$ lifts, permuted freely and transitively. Averaging makes invariants exact when $|G|$ is invertible. Consequently the quotient cohomology is the invariant part of the covering-space cohomology. The antipodal map on S^2 acts by -1 on H^2, whereas reflection on S^1 acts by -1 on H^1. In $H^*(S^2 \times S^1; k)$ the actions in degrees $0, 1, 2, 3$ are respectively $+1, -1, -1, +1$. This gives exactly the displayed answer. The product of the two anti-invariant generators is invariant and survives in degree 3. It is the term omitted by the proposed implication on manuscript pages 93–94. □

There is an earlier incidence slip on the same page. For the six-object globular poset, label the two orbits of arrows between consecutive levels by the product of the endpoint signs. Composition multiplies these signs. The orbit relations are consequently

$$p_1^- p_0^- = p_1^+ p_0^+, \qquad p_1^- p_0^+ = p_1^+ p_0^-.$$

The displayed relations in the edition instead hold p_1 fixed while changing p_0; they do not describe this antipodal quotient. This does not affect the face-poset construction just proved, which gives an unambiguous replacement.

The broader recipe (a)–(c) also needs care. If E is the discrete regular G-set, then E/G is a point and $X = (E \times Z)/G \cong Z$. Taking a nontrivial action on $H^*(Z; k)$ satisfies the proposed invariant-cohomology conditions, yet the fibre inclusion is the identity. Thus those conditions alone do not force a counterexample. For the selected connected $E = S^2$ the fibre inclusion does fail, as calculated above, but invariants of the separate factors do not determine invariants of their tensor product.

As an independent check, the accompanying exact rational chain computation gives simplex counts $(13, 36, 24)$ for NB, with boundary ranks $(12, 24)$, and $(52, 340, 576, 288)$ for NX, with boundary ranks $(51, 289, 287)$. The resulting Betti numbers are $(1, 0, 0)$ and $(1, 0, 0, 1)$. These finite calculations corroborate the proof; they are not used to infer the missing degree-three class.

Finalement, il semble qu'il ne reste plus rien de la proposition 2 (p.79) introduisant la notion de $\mathbb{D}$-fibration – pas même l'équivalence des deux conditions b) et b') ($\mathbb{D}$-fibration à gauche universelle, $\mathbb{D}$-fibration à droite universelle). On songe à leur relation à une condition a) modifiée ainsi (pour $f : X \to Y$) : ed. 59 [page 96]

a) Pour tout $Y'' \to Y' \to Y$, avec Y' et Y'' Hot-asphériques (et pas seulement $\mathbb{D}$-

asphériques) $X'' = X \times_Y Y'' \to X' = X \times_Y Y'$ est une $\mathbb{D}$-équivalence. (Quand on suppose que Y'' et Y' ont des éléments finaux, c'est la condition que f soit une $\mathbb{D}$-fibration à gauche universelle; quand on suppose que Y'' et Y' ont des éléments initiaux, c'est la condition $\mathbb{D}$-fibration à droite universelle.) [48]

On a évidemment $a) \Rightarrow b)$ et $a) \Rightarrow b')$ et on aimerait que ce soient des équivalences. Voici un axiome intéressant [49] sur $\mathbb{D}$, qui semble vérifié dans tous les cas connus, qui assure l'équivalence souhaitée. Je vais en même temps reformuler **Der 3** en trois volets (*cf.* p. 67).

Der 3 a) Si $Z \in$ Dia est Hot-asphérique, alors $p : Z \to e$ est une $\mathbb{D}$-équivalence, *i.e.* par exemple $p^* : \mathcal{A} = \mathbb{D}(e) \to \mathbb{D}(Z)$ est pleinement fidèle.

[page 97]

b) Soit $f : Z \to Z'$ une flèche dans Dia. Si f est une Hot-équivalence, c'est une $\mathbb{D}$-équivalence (*i.e.* $f^* : \mathbb{D}(Z') \to \mathbb{D}(Z)$ induit une équivalence entre les sous-catégories de Z, Z' [plutôt de $\mathbb{D}(Z)$, $\mathbb{D}(Z')$] formées des objets constants).

a') (Précise considérablement a). Si $Z \in$ Dia est Hot-asphérique, alors on a a), et l'image essentielle de $\mathbb{D}(e) = \mathcal{A}$ dans $\mathbb{D}(Z)$ est formée des objets localement constants de Z, *i.e.* des objets tels que le foncteur

$$Z^\circ \longrightarrow \mathcal{A} \qquad z \longmapsto F_z$$

soit localement constant (*i.e.* transforme toute flèche en isomorphisme) donc isomorphe à un foncteur constant (puisque Z est Hot-asphérique, donc 1-connexe).

Commentary · Later developments [ms. 97]

Locally constant objects as a homotopy invariant

The additional axiom sought here became a theorem for the usual derivator framework. Cisinski (2009, Corollary 3.8) proves that a weak equivalence of nerves induces an equivalence on locally constant objects for every derivator on small categories. The model-category statement is Theorem 1.3 of the same paper; Theorem 3.13 organizes locally constant objects into a derivator. Thus Der 3 b′ is available under those modern hypotheses, rather than remaining an unresolved extra condition. This does not retroactively prove the assertion from only the provisional axioms currently being tried in the manuscript.

The modern interpretation uses the fundamental ∞-groupoid $\Pi_\infty|NZ|$. For a coefficient ∞-category $\mathcal{C}$ presenting the homotopy theory, locally constant coherent diagrams are functors from this groupoid to $\mathcal{C}$, and the category denoted $\mathbb{D}(Z)_{\mathrm{lc}}$ is their homotopy category. If $|NZ|$ is contractible, evaluation gives the desired equivalence with $\mathbb{D}(e)$. Constancy of the underlying functor into $\mathbb{D}(e)$ alone is weaker: it forgets higher coherence. This is the same distinction emphasized in the commentary at manuscript p. 7 ("Coherent squares and what the axioms remember"), now applied to local systems.

Il faut bien noter que dans a'), il ne suffit pas de supposer que Z soit $\mathbb{D}$-asphérique, au lieu de Hot-asphérique. Dès que la $\mathbb{D}$-équivalence est strictement plus faible que Hot, il semble que a') devient toujours faux, en tant que condition sur $\mathbb{D}$, si on y suppose seulement que Z soit $\mathbb{D}$-asphérique. Par exemple, même si $\mathbb{D} = \mathbb{D}_i$ (théorie des i-types d'homotopie relative), la catégorie des objets localement constants sur Z s'exprime en termes du $(i+1)$-type d'homotopie, mais pas en termes de son i-type d'homotopie seul.

[page 98]

Commentary · Examples [ms. 98]

Sets already detect the missing monodromy

The shift from an i-type to an $(i+1)$-type has a concrete beginning. For the represented derivator $\mathbb{D}_0(A) = \mathsf{Set}^{A^{\mathrm{op}}}$, natural maps between constant diagrams on a nonempty connected category are simply maps of sets. Hence $e \to BG$ is a $\mathbb{D}_0$-equivalence for every group G. Locally constant set-valued diagrams on BG, however, are G-sets, and restriction to e forgets the action.

48. Il faut expliciter le raisonnement. Il suffit de tester même sur $Y'' \to Y'$, où Y'' est ponctuelle, et où Y' a un objet final (resp. initial).

49. *cf.* **Der 3** a') page suivante.

For a nontrivial G, this functor is not full: there are maps of sets from a one-point set to the regular G-set, but no equivariant such map. Thus a 0-type records connected components, while local systems of 0-types already record the fundamental group.

This also supplies a direct test of footnote 36. Take $G = C_2$ and the covering $f : E_G \to BG$. Its strict fibres are the discrete two-element set G. Since the covering is a discrete fibration and a discrete opfibration, every base change is a covering of the same kind. Right Kan extension of a constant set M has fibre M^G, and left Kan extension has fibre $G \times M$; arrows in the base act by permutations of G. Both resulting diagrams are locally constant and both Kan extensions calculate on strict fibres. Therefore conditions (b) and (b′) hold universally for $\mathbb{D}_0$.

Now pull back along $e \to BG$. The induced map of total categories is $G_{\mathrm{disc}} \to E_G$. It is not a $\mathbb{D}_0$-equivalence: for a two-element coefficient set M, the constant-coefficient limit on the connected category E_G is M, whereas on the discrete fibre it is M^2. The comparison is the diagonal map and is not bijective. Thus (b) does not imply (a), even for the derivator of 0-types. The correct positive assertion for ordinary weak homotopy equivalences uses their invariance of locally constant coefficients, as in the preceding block; it does not replace them by $\mathbb{D}_0$-equivalences. If Dia is restricted to finite posets, the connected double cover of the four-object circle gives the same counterexample. Its total poset has eight objects and its self-pullback is the disjoint union of two copies of that total poset. Both bases are connected, while the pulled-back total categories have different numbers of components.

Il semble bien que ce soit l'axiome **Der** 3 (a') qui assure l'existence d'une bonne notion ("bilatère") de $\mathbb{D}$-fibration, qui soit stable par changement de base, et qui se réduise soit à "$\mathbb{D}$-fibration à gauche universelle" soit à "$\mathbb{D}$-fibration à droite universelle" et donc qui soit en plus une condition vérifiable pratiquement. Dans le cas où f est propre ou lisse, le critère est particulièrement simple, puisque il se borne à la condition que les $f_* f^* a_Y$, ou les $f_! f^* a_Y$ (pour $a \in \mathcal{A}$), soient des objets localements constants sur Y (donc constants si Y est Hot-asphérique, en vertu de **Der** 3 (a'). ed. 60

Je vais également introduire une variante renforcée de **Der** 3 b) :

Der 3 b') Soit $Z' \to Z$ une Hot-équivalence dans Dia. Alors $f^* : \mathbb{D}(Z) \to \mathbb{D}(Z')$ induit une équivalence entre les catégories des coefficients localements constants sur Z et sur Z'.[50]

Dans certaines questions il suffit de savoir que le dit foncteur est pleinement fidèle. Cela implique que [page 99]

$$H^*_{\mathbb{D}}(Z, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(Z', f^* F)$$

quand F est localement constant sur Z[51] (mais il n'est pas clair que cette condition implique toujours la pleine fidélité[52]) et de même pour l'homologie

$$H^{\mathbb{D}}_*(Z', f^* F) \longrightarrow H^{\mathbb{D}}_*(Z, F) \quad .$$

Moyennant cette condition, on a la :

Proposition : *On suppose* **Der** 3 b′) *satisfait. Soit $f : X \to Y$ dans* Dia. *Pour que f soit une $\mathbb{D}$-fibration, il faut et il suffit que pour $Y'' \to Y'$ sur Y qui soit une* Hot*-équivalence, $X'' = X \times_Y Y'' \to X' = X \times_Y Y'$ soit une $\mathbb{D}$-équivalence.*

À vrai dire, on peut énoncer quelque chose de raisonnable, sans supposer l'axiome **Der** 3 b'). On doit introduire la :

Définition : Soit $f : Z' \to Z$ dans Dia. On dit que f et une $\mathbb{D}$-équivalence 1-*complète* si le foncteur $f^* : \mathbb{D}(Z) \to \mathbb{D}(Z')$ est pleinement fidèle sur la sous-catégorie pleine de $\mathbb{D}(Z)$ formée

50. **Der** 3 b'_0) : le foncteur est fidèle
b'_1) : le foncteur est pleinement fidèle
b'_2) : le foncteur est une équivalence

51. On pourra dire que $f : Z' \to Z$ est une $\mathbb{D}$-équivalence 0-*complète à gauche,* et 0-*complète à droite* dans le cas homologique.

52. Mais c'est OK si on a des Hom internes dans $\mathbb{D}(Z)_{\mathrm{loc.const.}}$ satisfaisant

$$\mathsf{Hom}(F, G) \simeq \mathsf{Hom}(e_Z, \underline{\mathsf{Hom}}(F, G)) \quad ,$$

où e est l'élément final de $\mathcal{A}$, les Hom étant compatibles aux images inverses.

des coefficients localement constants. On dit que f est une $\mathbb{D}$-équivalence 2-*complète* si elle induit une équivalence entre les catégories des coefficients localement constants.

On dit que Z est *complètement* $\mathbb{D}$-*asphérique*, si $Z \to e$ est une $\mathbb{D}$-équivalence 2-complète.

Ainsi, l'axiome **Der** 3 a') peut se reformuler, en disant que si Z est Hot-asphérique, alors Z est complètement $\mathbb{D}$-asphérique. Et de même, **Der** 3 b') en disant que si $f : X \to Y$ dans Dia est une Hot-équivalence, alors f est une $\mathbb{D}$-équivalence 2-complète. Nous allons donner une variante affaiblie, de **Der** 3 a'), qui suffit pour donner une notion raisonnable de $\mathbb{D}$-fibration : [ed. 61 [page 100]]

Der 3 a'') Tout Z dans Dia qui a soit un objet final, soit un objet initial, est complètement $\mathbb{D}$-asphérique.

Définition. On dit que $f : X \to Y$ dans Dia est une $\mathbb{D}$-fibration, si pour

$$Y'' \longrightarrow Y' \longrightarrow Y$$

avec $Y'' \to Y'$ une $\mathbb{D}$-équivalence 1-complète (par exemple Y' et Y'' complètement $\mathbb{D}$-asphèriques), $X'' = X \times_Y Y'' \longrightarrow X' = X \times_Y Y'$ est une $\mathbb{D}$-équivalence.

Cela équivaut à chacune des conditions b), b') de la prop. 2 (page 79), *i.e.* que f soit universellement une $\mathbb{D}$ fibration à gauche, ou universellement une $\mathbb{D}$-fibration à droite (grâce à **Der 3** b'' `[plutôt` a''`]`).

Définition 1. $f : X \to Y$ dans Dia est appelé $\mathbb{D}$-*équivalence cohomologique* (sous-entendu : *complète*) si pour tout $F \in \mathsf{Ob}\,\mathbb{D}(Y)$, F localement constant, on a [page 101]

$$H^*_{\mathbb{D}}(Y, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(X, f^*(F)) \quad .$$

Notion duale $\mathbb{D}$-*équivalence homologique*

$$H^{\mathbb{D}}_*(X, f^*(F)) \xrightarrow{\sim} H^{\mathbb{D}}_*(Y, F) \quad .$$

Si Y est complètement $\mathbb{D}$-asphérique, alors les coefficients localement constants sur Y sont constants, et f est une $\mathbb{D}$-équivalence cohomologique (resp. homologique) si et seulement si c'est une $\mathbb{D}$-équivalence *i.e.* si X est $\mathbb{D}$-asphérique. [53]

Proposition 1 (Soritale). *Soient $X \xrightarrow{f} Y \xrightarrow{g} Z$. Si f et g sont des $\mathbb{D}$-équivalences cohomologiques, alors gf aussi. Si gf et f sont des $\mathbb{D}$-équivalences cohomologiques, alors g aussi. Si gf est une $\mathbb{D}$-équivalence cohomologique, et si g est une $\mathbb{D}$-équivalence 2-complète* (donc tout F localement constant sur Y provient d'un G localement constant sur Z), *alors f est une $\mathbb{D}$-équivalence cohomologique.*

Commentary · Exposition [ms. 101]

Complete equivalences repair the base change argument

The adjective "complete" records which coefficients are being tested. A 1-complete equivalence is fully faithful on the category of locally constant objects. A 2-complete equivalence is in addition essentially surjective there. These are levels of categorical information, not degrees of homology. In particular a 1-complete equivalence $p : Y' \to Y$ compares both homology and cohomology with every locally constant coefficient F on Y.

For cohomology, adjunction gives

$$\mathsf{Hom}_{\mathbb{D}(e)}(M, H^*_{\mathbb{D}}(Y, F)) = \mathsf{Hom}_{\mathbb{D}(Y)}(M_Y, F).$$

Both arguments on the right are locally constant. Full faithfulness identifies this group of morphisms with $\mathsf{Hom}_{\mathbb{D}(Y')}(M_{Y'}, p^*F)$, naturally in M. Yoneda gives the asserted cohomology isomorphism. Applying the same argument to morphisms from F to a constant object proves homological invariance. The internal-Hom qualification in footnote 52 is a converse criterion: if locally constant internal Homs exist and commute with pullback, cohomological invariance applied to $\underline{\mathsf{Hom}}(F, G)$ yields full faithfulness. Its unit must be the stated cartesian unit, or an explicitly chosen monoidal unit; the zero object of a stable theory cannot play that role merely by being terminal.

53. L'axiome **Der** 3 b'_1) implique que toute Hot-équivalence est une $\mathbb{D}$-équivalence cohomologique.

We can now complete the repaired proof. Suppose f is universally cohomological, and let p be 1-complete. For a constant coefficient M, put $F = f_*M_X$. The coefficient F is locally constant, and universal fibre calculation identifies p^*F with $f'_*M_{X'}$. The preceding Yoneda argument compares the global cohomology of these two objects and proves that $X' \to X$ is a $\mathbb{D}$-equivalence. This establishes the new pullback-preservation condition. Conversely, under Der 3 a$''$, every functor between categories having final objects is 2-complete, because both locally constant categories are equivalent to $\mathbb{D}(e)$ and the restriction agrees with the identity on constants. Testing the new condition on $\{y\} \to Y/y$ and on transitions between slices therefore gives universal cohomological fibre calculation. Categories with initial objects give the homological condition. These arguments prove both directions and explain why the weaker endpoint axiom suffices at this stage.

The cancellation statements on manuscript page 101 have the same logic. Composing two comparisons proves closure under composition; cancelling the comparison for f proves the implication from gf and f to g. To recover f from gf, one must first express an arbitrary locally constant coefficient on Y as the pullback of a coefficient on Z. The 2-complete hypothesis on g supplies exactly that essential-surjectivity step, and its full faithfulness supplies the comparison for g. Ordinary two-out-of-three would have omitted the coefficient which must descend.

Définition 2. 1°) $f : X \to Y$ dans Dia est appelé une $\mathbb{D}$-*fibration cohomologique complète,* je dis bien complète, si

a) Pour tout $y \in \mathsf{Ob}\, Y$, $X_y \to X/y$ est une $\mathbb{D}$-équivalence cohomologique (complète).

b) Pour tout $y' \to y$ dans Y, $X/y' \to X/y$ est une $\mathbb{D}$-équivalence cohomologique (complète).

c) Ces conditions restent satisfaites après tout changement de base $Y' \to Y$. ed. 62

2°) Notion duale de fibration homologique complète. [page 102]

Exemple. Si f est Hot-propre, les flèches des *a*) et *b*) sont des Hot-équivalences, donc en vertu de **Der 3** b'_1) (qu'il faut admettre), ce sont des $\mathbb{D}$-équivalences cohomologiques. Cela signifie que *a*) et *b*) sont valables, et *c*) aussi, car la notion de flèche Hot-propre est stable par changement de base.

Commentary · Exposition [ms. 102]

What the completion requires

The quantifier on the coefficients is the decisive change. A weak cohomological fibration is tested by the constant objects M_X. A complete cohomological fibration must work with every locally constant object of each category obtained by base change. Such an object need not descend from X, and need not become constant on X. The monodromy examples just discussed explain why that distinction cannot be suppressed. The role of completion is to make the coefficients produced by one direct image admissible for a second direct image.

We keep the variance of the manuscript: objects of $\mathbb{D}(X)$ behave as coherent contravariant diagrams, and the pointwise formula for a right direct image is

$$(f_*F)_y \simeq H^*_{\mathbb{D}}(X/y, F|_{X/y}).$$

Write $\mathcal{L}(X) \subseteq \mathbb{D}(X)$ for the full subcategory of locally constant objects. Local constancy means that every transition morphism is invertible; it does not mean that an isomorphism to a constant object has been chosen. For $r : A \to B$, the cohomological condition is the isomorphism

$$H^*_{\mathbb{D}}(B, L) \longrightarrow H^*_{\mathbb{D}}(A, r^*L) \qquad (L \in \mathcal{L}(B)).$$

The conditions on $X_y \to X/y$ therefore compare a true fibre with a comma category for every local system on the latter. The conditions on $X/y \to X/y'$ then control the transport of those cohomology objects along the base. Universal repetition of the first comparison is what makes the resulting fibre formula compatible with arbitrary base changes.

The example immediately preceding Proposition 2 contains a genuine slip: Hot-properness gives the fibre-to-comma comparison, but does not make the comma categories locally constant as y varies. Take the inclusion $\{1\} \hookrightarrow [1]$, where $[1] = \{0 \to 1\}$. This is a closed immersion and hence proper, but its comma categories at 0 and 1 are respectively empty and terminal. The transition $\varnothing \to e$ is not a weak homotopy equivalence. Thus the example becomes correct after adding the transport condition, or by assuming that f is both Hot-proper and a weak HOT-fibration. This is precisely the hypothesis separated out on manuscript page 107 and proved usable in Proposition 6 on page 118. The printed assertion is retained in the source and is audited as false as written.

Proposition 2. *Soient $f : X \to Y$ $\mathbb{D}$-fibration cohomologique complète, $F \in \mathsf{Ob}\,\mathbb{D}(X)$ localement constant sur X. Alors $f_*(F)$ est localement constant, sa formation commute à tout changement de base, et en particulier se calcule fibre par fibre.*[54]

Corollaire 1. *Soit un diagramme cartésien*

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow{p} & Y' \end{array} \quad .$$

On suppose f $\mathbb{D}$-fibration cohomologique et p une $\mathbb{D}$-équivalence cohomologique. Alors q est une $\mathbb{D}$-équivalence cohomologique.

En effet, on a pour F localement constant sur X

$$H^*_{\mathbb{D}}(X,F) \simeq H^*_{\mathbb{D}}(Y,f_*F) \xrightarrow{\sim} H^*_{\mathbb{D}}(Y',p^*f_*F) \simeq H^*_{\mathbb{D}}(Y',f'_*q^*F) \simeq H^*_{\mathbb{D}}(X',q^*F) \qquad \text{[page 103]}$$

qed.

Proposition 3. *La notion de $\mathbb{D}$-fibration cohomologique complète est stable par changement de base* (trivial) *et par composition.*

Pour la stabilité par composition, il suffit de noter le corollaire suivant de la proposition 2.

Corollaire 2 (de prop. 2). *Soit $f : X \to Y$. Pour que f soit une $\mathbb{D}$-fibration cohomologique complète, il faut et il suffit que pour tout $Y'' \xrightarrow{p} Y' \to Y$ sur Y, avec p une $\mathbb{D}$-équivalence cohomologique, la flèche correspondante $X'' = X \times_Y Y'' \longrightarrow X' = X \times_Y Y'$ soit aussi une $\mathbb{D}$-équivalence cohomologique.*

C'est nécessaire par le corollaire 1, compte tenu que $f' : X' = X \times_Y Y' \to Y'$ est aussi une $\mathbb{D}$-fibration cohomologique. C'est suffisant, car il suffit de l'appliquer aux cas $\{y\} \to Y/\{y\}$, $Y/y \to Y/y'$, qui sont des $\mathbb{D}$-équivalences cohomologiques en vertu de **Der** 3 b'_1) (ou seulement **Der** 3 a')).

[page 104] ed. 63

Proposition 4. *On suppose que* **Der** 3 a′) *est satisfait* (*i.e.* tout Z dans Dia qui est Hot-asphérique, est complètement $\mathbb{D}$-asphérique). *Soit $f : X \to Y$ dans* Dia. *Les conditions suivantes sont équivalentes*

1°) *f est une $\mathbb{D}$-fibration cohomologique complète* (conditions *a*), *b*), *c*) de `[la]` définition 2, page 101).

2°) *Pour tout $F \in \mathsf{Ob}\,\mathbb{D}(X)$, localement constant, $f_*(F)$ est localement constant, se calcule fibre par fibre; et ça reste vrai après tout changement de base $Y' \to Y$ (avec F' localement constant sur $X' = X \times_Y Y'$). (Alors la formation de $f_*(F)$ commute à tout changement de base).*

3°) *Pour tout $Y'' \xrightarrow{p} Y'$ sur Y, si p est une $\mathbb{D}$-équivalence cohomologique, alors $X'' = X \times_Y Y'' \longrightarrow X' = X \times_Y Y'$ aussi.*

3′) *Comme 3, en supposant que Y'' est la catégorie ponctuelle, et que Y' a un élément final : il faut que $X'' \to X'$ soit une $\mathbb{D}$-équivalence cohomologique.*

Commentary · Exposition [ms. 104]

The universal criterion, with the quantifiers restored

Proposition 4 is more than a convenient restatement: it supplies the missing reason that the strengthened notion composes. We give the argument, keeping the hypothesis that every weakly contractible indexing category has only constant local systems, as in **Der** 3 a'. The same argument will apply to Proposition 9, after the terminology is revised.

First assume the comma-category conditions of Definition 2, universally in the base. If $F \in \mathcal{L}(X)$, its restriction to X/y is locally constant. The comparison $X_y \to X/y$ gives

$$(f_*F)_y \simeq H^*_{\mathbb{D}}(X_y, F|_{X_y}).$$

54. Il y a une réciproque *cf.* prop. 3′.

For an arrow $y \to y'$, the functor $X/y \to X/y'$ is a cohomological equivalence, so the resulting transition $(f_*F)_{y'} \to (f_*F)_y$ is an isomorphism. Thus f_*F is locally constant. In a pullback square with base map $p : Y' \to Y$ and induced maps f', q, evaluate the base-change map

$$p^* f_* F \longrightarrow f'_* q^* F$$

at y'. Both sides identify with the cohomology of the same strict fibre $X_{p(y')}$ with the same restricted coefficient. The identification of the comparison with the identity is the naturality of the pointwise Kan-extension formula. Pointwise detection of isomorphisms proves base change.

Suppose now that this direct-image property holds after every base change. For a cohomological equivalence $p : Y'' \to Y'$, and $L \in \mathcal{L}(X')$, put $G = f'_* L$. The preceding property makes G locally constant and identifies p^*G with $f''_* q^* L$. The canonical comparison is consequently the composite

$$H^*_{\mathbb{D}}(X', L) \simeq H^*_{\mathbb{D}}(Y', G) \longrightarrow H^*_{\mathbb{D}}(Y'', p^*G) \simeq H^*_{\mathbb{D}}(X'', q^*L),$$

whose middle map is invertible. This proves the universal preservation criterion. Notice that it tests all L on X', rather than just coefficients pulled back from X.

It remains to recover the comma conditions from the apparently much smaller test in $3'$. Every functor $e \to B$ with B admitting a terminal object is a cohomological equivalence under a': all local systems on B are constant and B is $\mathbb{D}$-aspherical. Apply the test to the base change $Y/y \to Y$, selecting the terminal object 1_y. Its inverse image is X_y, and the total space is X/y. This gives the first comma comparison. For $u : y \to y'$, use $Y/y' \to Y$ and select its object u. We get a cohomological equivalence $X_y \to X/y'$. It factors as

$$X_y \longrightarrow X/y \longrightarrow X/y'.$$

The first map and the composite are cohomological equivalences. Testing a local system on X/y' in the two comparisons shows that the second map is also one. This is the valid cancellation direction from Proposition 1 on manuscript page 101; no unqualified two-out-of-three assertion for cohomological equivalences is being used. As the point test was required over every base change, all the comparisons are universal.

These arguments also justify the parenthesis in Proposition 9 that only the fibre comparison needs to be imposed universally. Applied to Y/y' and to its arbitrary object u, that one comparison already recovers transport. They explain why the converse concerns arbitrary locally constant coefficients on the pullbacks. Merely proving the fibre formula for restrictions of coefficients from the original X would leave a real gap.

Définition 3. On dit que $f : X \to Y$ dans Dia est une $\mathbb{D}$-*fibration complète* si c'est une $\mathbb{D}$-fibration cohomologique complète et une $\mathbb{D}$-fibration homologique complète. [page 105]

C'est stable par changement de base, par composition.

La définition 3 équivaut à ceci : pour tout $p : Y'' \to Y'$ sur Y, avec Y'' et Y' Hot-asphériques, le morphisme correspondant $X'' \to X'$ est à la fois une $\mathbb{D}$-équivalence cohomologique, et une $\mathbb{D}$-équivalence homologique. (Et il suffit même de le supposer pour $Y'' = e$ et pour Y' avec objet final ou objet initial.) On peut songer à renforcer encore cette condition en exigeant (sans regarder à gauche ni à droite) que $X'' \to X'$ soit une $\mathbb{D}$-équivalence 1-complète. Mais il n'est pas clair que cette notion renforcée soit stable par composition – à moins de la renforcer encore, en exigeant que si $Y'' \to Y'$ est une $\mathbb{D}$-équivalence 1-complète, alors $X'' \to X'$ l'est aussi. L'ennui avec cette définition renforcée, c'est que faute d'avoir une description cohomologique ou homologique de la notion de $\mathbb{D}$-équivalence 1-complète, je ne me sens pas capable de donner des exemples intéressants (non totalement triviaux) de $\mathbb{D}$-fibrations en ce sens très fort. Sauf les Hot-fibrations triviales (*i.e.* à fibres Hot-asphériques) – mais ce n'est pas drôle! [page 106]

Mais quand on a des produits $*$ associatifs et unitaires et des $\underline{\mathsf{Hom}}$ internes correspondants dans les $\mathbb{D}(X)_{\text{loc. const.}}$, compatibles avec `[les]` images inverses, donc on aura sur X si F et G sont localement constants dans $\mathbb{D}(X)$, et si ε_X désigne l'unité pour $*$ dans $\mathbb{D}(X)$,

$$\mathsf{Hom}(F, G) \simeq \mathsf{Hom}(\varepsilon_X * F, G) \simeq \mathsf{Hom}(\varepsilon_X, \underline{\mathsf{Hom}}(F, G)) \simeq \mathsf{Hom}_{\mathcal{A}}(\varepsilon_e, p_* \underline{\mathsf{Hom}}(F, G)) \ ,$$

car $\varepsilon_X = p^*(\varepsilon_e)$, où $p : X \to e$, donc dans ce cas une flèche $f : X \to Y$ dans Dia est une $\mathbb{D}$-équivalence 1-complète si (et seulement si) c'est une $\mathbb{D}$-équivalence cohomologique. Donc dans ce cas, si f est une $\mathbb{D}$-fibration cohomologique complète, c'est aussi une $\mathbb{D}$-fibration homologique complète, donc aussi une $\mathbb{D}$-fibration complète (définition 3). (Et même au sens soit-disant renforcé de tantôt : si $Y'' \to Y'$ sur Y est une $\mathbb{D}$-équivalence 1-complète ($\Leftrightarrow$ une $\mathbb{D}$-équivalence cohomologique!) alors $X'' \to X'$ aussi.

Commentary · Exposition [ms. 106]

What internal Hom does, and what it does not do

The internal-Hom argument is sound, provided its compatibility hypotheses are stated at the level where they are used. Suppose that each $\mathcal{L}(X)$ is a closed monoidal category, that its tensor unit is $\varepsilon_X = p_X^*\varepsilon_e$, and that restriction preserves the internal Hom between locally constant objects. For $F, G \in \mathcal{L}(Y)$, adjunction gives

$$\mathsf{Hom}_{\mathbb{D}(Y)}(F, G) \simeq \mathsf{Hom}_{\mathbb{D}(e)}\big(\varepsilon_e, p_{Y*}\underline{\mathsf{Hom}}_Y(F, G)\big).$$

If $f : X \to Y$ is a cohomological equivalence, apply its defining comparison to the locally constant object $\underline{\mathsf{Hom}}_Y(F, G)$. The assumed comparison

$$f^*\underline{\mathsf{Hom}}_Y(F, G) \simeq \underline{\mathsf{Hom}}_X(f^*F, f^*G)$$

then identifies the displayed Hom set with $\mathsf{Hom}_{\mathbb{D}(X)}(f^*F, f^*G)$. Thus f^* is fully faithful on $\mathcal{L}(Y)$: f is 1-complete.

Conversely, full faithfulness on local systems compares the morphisms from every constant object M_Y to $F \in \mathcal{L}(Y)$. By adjunction these are the morphisms from M to $p_{Y*}F$. Yoneda gives the cohomological comparison. Comparing morphisms from F to every M_Y, instead, gives the homological comparison. This last argument needs no tensor product. It proves the two outgoing implications from 1-completeness in the diagram on page 113, while the internal-Hom hypothesis supplies the converse only on the cohomological side.

There is no need to assume that the unit detects isomorphisms. In the forward direction the cohomological comparison is already an isomorphism before $\mathsf{Hom}(\varepsilon_e, -)$ is applied; in the reverse direction Yoneda uses every M. Nor does the argument identify 1-completeness with 2-completeness: essential surjectivity of local systems is an additional demand.

One must also retain the adjective "cohomological". On page 122 the printed sentence says that an unqualified $\mathbb{D}$-equivalence is already 1-complete in the presence of internal Homs. That stronger assertion is false. For example, with $\mathbb{D} = \mathsf{Der}(\mathbb{Q}\text{-}\mathsf{Mod})$ and $G = C_2$, the map $e \to BG$ is a constant-coefficient equivalence, but restriction sends the sign representation to a one-dimensional vector space. There are no G-equivariant maps from the trivial representation to the sign representation, whereas after restriction there are nonzero maps. The categories of local systems have the usual derived tensor and internal Hom. The wording on pages 106 and 113, and the diagram on page 123, supply the correct repair: cohomological equivalence, not constant-coefficient equivalence.

Il se pose la question de trouver des f qui soient des $\mathbb{D}$-fibrations cohomologiques, ou homologiques. Je ne sais si je serai capable d'en trouver, qui ne soient déjà des HOT-fibrations cohomologiques, ou homologiques (cela revient maintenant au même [55]), car pratiquement je ne sais guère dire qu'une flèche $Z' \to Z$ dans $\mathcal{C}at$ est une $\mathbb{D}$-équivalence cohomologique complète, que si cette flèche est une HOT-équivalence (et en admettant l'axiome **Der** 3 b'_1), ou sa variante affaiblie cohomologique). ed. 64 [page 107]

Commentary · Examples [ms. 107]

A complete fibration beyond ordinary homotopy

The request for examples that are not already HOT-fibrations has a simple answer with rational coefficients. Let $G = C_2$, let BG denote its one-object category, and take the Grothendieck opfibration

$$f : E = \int_{[1]} (BG \longrightarrow e) \longrightarrow [1].$$

55. Les HOT-équivalences cohomologiques = HOT-équivalences homologiques = HOT-équivalences sans plus.

Explicitly, E has objects a and t, with $\mathrm{End}(a) = G$, $\mathrm{End}(t) = \{1\}$, one arrow $a \to t$, and no arrow $t \to a$. The unique arrow to t absorbs every $g \in G$. The fibres are BG and e, and the transport is the collapse $r : BG \to e$.

For $\mathbb{D} = \mathsf{Der}(\mathbb{Q}\text{-}\mathsf{Mod})$, the functor r is a cohomological equivalence. All coefficients on its target are constant, and invariants for a finite group over $\mathbb{Q}$ are exact. Indeed, averaging $v \mapsto |G|^{-1} \sum_{g \in G} gv$ is a natural projection onto invariants, and averaging a lift proves that invariants preserve epimorphisms. Consequently their right derived functor on any complex is computed degreewise. On a trivial G-complex M, this gives $R\Gamma(BG, M) = M$.

More generally, an opfibration whose transport functors are cohomological equivalences is a complete cohomological fibration. Properness supplies the fibre formula for every coefficient. For a locally constant coefficient L on the total category and an arrow in the base, the cocartesian arrows give an isomorphism between L on the source fibre and the pullback of L on the target fibre. The cohomological equivalence of transport therefore makes the direct-image transition invertible. This argument survives an arbitrary pullback, since the new transport functors are the old ones indexed by the new arrows. Proposition 4, or Proposition 9 in the revised terminology, proves the assertion.

Applying this observation to f shows that it is a complete cohomological fibration. Derived tensor products and internal Homs on rational local systems satisfy the hypotheses explained at page 106, so it is a complete homological fibration as well. It is not a HOT-fibration: its transport $BG \to e$ is not a weak homotopy equivalence, since $\pi_1(BG) = C_2$. Thus stronger coefficient invariance is still relative to the chosen coefficients. Reversing the transport to $e \to BG$ destroys cohomological equivalence, and is exactly the feature exploited by the composition counterexample at manuscript page 118.

Je vais donc chercher les HOT-fibrations, *i.e.* les $f : X \to Y$ tels que pour tout $Y'' \to Y' \to Y$, avec Y'' et Y' asphériques (sous-entendu : pour HOT), $X'' \to X'$ est une Hot-équivalence. (Il suffit même de supposer Y'' réduit à un point, Y' avec objet final ...)

Supposons par exemple f propre (*i.e.* HOT-propre), donc la condition a) de la définition 2, p. 101 satisfaite et de même après tout changement de base. Suffit-il de vérifier de plus la condition b), *i.e.* que

$$X/y \longrightarrow X/y' \quad , \qquad \text{pour } y \to y' \text{ dans } Y \ ,$$

sont des Hot-équivalences? (J'entends en restant sur Y, sans supposer aussi d'avoir la même chose après changement de base). Mais cela reste-il vrai après tout changement de base?

La situation semble ici meilleur pour f lisse (au lieu de propre), en interprétant les conditions a) et b) sous forme homologique, comme signifiant que $f_!(e_X)$ est un objet localement constant de $\mathsf{HOT}(Y)$, qui se calcule fibre par fibre. Comme f lisse implique que $f_!$ commute à tout changement de base, cette hypothèse sur f (que f soit une HOT-fibration cohomologique, peut-être pas complète) est stable par changement de base, donc implique que c'est une HOT-fibration cohomologique complète. Mais cet argument utilise les propriétés générales des dérivateurs pour HOT, que je n'ai pas encore établies - surtout pas dans le domaine $\mathcal{C}at$ tout entier! Donc il est sain de me méfier. Je préfère tâter la difficulté en restant d'abord dans le cadre du formalisme cohomologique (non commutatif), dont j'ai une certaine maîtrise. Je suppose donc f propre à nouveau, et que les [page 108]

$$X_y \longrightarrow X/y \quad , \qquad X/y \longrightarrow X/y'$$

soient des HOT-équivalences, je veux prouver la même chose après tout changement de base, au moins que dans la situation [page 109]

$$\begin{array}{ccccc} X & \xleftarrow{q} & X' & \xleftarrow{q'} & X'' \\ {\scriptstyle f}\downarrow & & {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f''} \\ Y & \xleftarrow[p]{} & Y' & \xleftarrow[p']{} & Y'' \end{array}$$

si Y', Y'' sont asphériques, alors q' est une Hot-équivalence. Si je veux l'établir par critère cohomologique, je dois commencer par prendre sur X' un faisceau d'*ensembles* localement constant F, et prouver que $\Gamma(X', F) \xrightarrow{\sim} \Gamma(X'', q'^* F)$. Comme ce faisceau ne provient pas de X, je suis ennuyé pour appliquer l'hypothèse sur f, qui concerne à priori des faisceaux d'ensembles constants sur X, ou sur les X/y. Mais on devrait avoir ceci : ed. 65

Lemme. *Soit $f : X'' \to X'$. Alors f est une* HOT-*équivalence* i.e.

$$H^*_{\mathsf{HOT}}(X', a_{X'}) \xrightarrow{\sim} H^*_{\mathsf{HOT}}(X'', a_{X''})$$

est [un] *isomorphisme pour tout $a \in \mathsf{Hot} = \mathsf{HOT}(e)$, si et seulement si f est une* Hot-*équivalence,*[56] *et alors f est même une* HOT-*équivalence* 2-*complète* (j'ai besoin seulement de : HOT-équivalence cohomologique et homologique complète) i.e. *pour tout $\xi \in \mathbb{D}(X')$ localement constant sur X', on a*[57]

$$H^*_{\mathsf{HOT}}(X', \xi) \xrightarrow{\sim} H^*_{\mathsf{HOT}}(X'', q'^*(\xi)) \quad .$$

La première assertion doit résulter des formules [page 110]

$$(*) \qquad H^*_{\mathsf{HOT}}(Z, a_Z) \simeq \underline{\mathsf{Hom}}_{\mathsf{Hot}}(\mathsf{hot}(Z), a)$$

$$\text{(et aussi} \qquad H^{\mathsf{HOT}}_*(Z, a_Z) \simeq \mathsf{hot}(Z) \times a \qquad \text{)}$$

donc si

$$(**) \qquad \mathsf{hot}(X'') \xrightarrow{\sim} \mathsf{hot}(X')$$

est [un] isomorphisme, alors

$$H^*_{\mathsf{HOT}}(X', a_{X'}) \longrightarrow H^*_{\mathsf{HOT}}(X'', a_{X''})$$

est [un] isomorphisme, puisque c'est déduit de $(*)$ en prenant $\underline{\mathsf{Hom}}_{\mathsf{Hot}}(\,.\,, a)$. Inversement, si $(*)$ est toujours [un] isomorphisme, exprimant les deux membres [mot illisible] de $\underline{\mathsf{Hom}}_{\mathsf{Hot}}(\,.\,, a)$ et prenant les π_0, on trouve que

$$\mathsf{Hom}_{\mathsf{Hot}}(\mathsf{hot}(X'), a) \xrightarrow{\sim} \mathsf{Hom}_{\mathsf{Hot}}(\mathsf{hot}(X''), a)$$

est un isomorphisme pour tout a, donc $(**)$ est un isomorphisme.

Mais le fait que ça implique que f'' soit une HOT-équivalence cohomologique complète, *i.e.* que la relation $(*)$ reste vraie pour un $\xi \in \mathbb{D}(X')$ localement constant sur X', me paraît une propriété délicate du dérivateur HOT, sur laquelle il me faudra revenir.

Donc le lemme est loin d'être établi, faute d'avoir seulement construit le dérivateur HOT, sans même parler d'en établir les propriétés spéciales délicates! Mais je n'ai aucune raison de douter du lemme, il fait partie de la kyrielle des intuitions de base que je voudrais fonder solidement.

Commentary · Later developments [ms. 110]

The lemma for spaces

The lemma on pages 109–110 is proved by the modern theory of locally constant diagrams. We can separate its two assertions, which need different arguments. Put $BX = |NX|$, and let $\mathcal{S}$ denote the homotopy theory of spaces. In the homotopy derivator HOT, the constant-diagram formulas are

$$H^*_{\mathsf{HOT}}(X, M_X) \simeq \mathrm{Map}(BX, M), \qquad H^{\mathsf{HOT}}_*(X, M_X) \simeq BX \times M.$$

56. Attention ici [mot illisible] la distinction entre HOT-équivalence et Hot-équivalence.

57. Est-ce vrai aussi pour les dérivateurs $\mathbb{D}_i$?

These are derived mapping spaces and derived products, viewed in Hot. Thus a weak equivalence $BX \to BY$ induces both constant-coefficient comparisons. Conversely, if all the cohomological comparisons are isomorphisms, their sets of components give bijections

$$[BY, M] \longrightarrow [BX, M]$$

for every homotopy type M. Yoneda in Hot makes $BX \to BY$ an isomorphism. Homologically one can simply take $M = e$. This proves the identification of the manuscript's uppercase HOT-equivalences with lowercase Hot-equivalences, without conflating the homotopy derivator with its value at a point.

The local-coefficient assertion has another content: all coherence in a locally constant diagram must be transportable along a weak homotopy equivalence of the base. An invariant modern formulation identifies locally constant space-valued diagrams on X with space-valued functors on the homotopy groupoid $\Pi_\infty(BX)$. Restriction along an equivalence of these groupoids is an equivalence of functor categories, and remains so on passing to homotopy categories. Hence a Hot-equivalence is 2-complete for HOT. It preserves cohomology and homology with every local coefficient by the adjunction argument in the preceding block.

A precise derivator reference is Cisinski (2009, Theorem 1.3 and Corollary 3.8): a nerve weak equivalence induces an equivalence of categories of locally constant objects, for model categories and, in the latter result, for arbitrary Grothendieck derivators on small categories. The construction of those local systems as a derivator, with both adjoints to its inclusion into the diagram derivator, is Theorem 3.13. Thus the strongest b-axiom proposed below is available in the usual modern setting; it is not a currently unproved property of spaces.

The higher-categorical description is compatible with straightening and unstraightening (Lurie, 2009, Theorem 2.2.1.2); the homotopy limit of a space-valued local system is its space of sections (Lurie, 2009, Corollary 3.3.3.4). This gives a geometric reading of the two comparisons: transport the family, then compare its sections or its total homotopy colimit. It also indicates exactly what is absent from the ordinary diagram in the homotopy category: the coherence of transport around paths and higher simplices.

Footnote 57 requires a qualification. If its question asks whether a genuine Hot-equivalence induces 2-completeness for the derivators of truncated homotopy types, the answer is yes, by the same invariance theorem. If it asks whether a $\mathbb{D}_i$-equivalence alone has the same consequence, the answer is no already for $i = 0$. The example in "Sets already detect the missing monodromy" at manuscript page 98 has $e \to BC_2$ a constant-coefficient equivalence for sets, while restriction of C_2-sets is not full: a map from the one-point trivial action to the regular action exists after forgetting the action and does not exist before. Truncating the coefficients can lose information about the base that the category of local systems still retains.

Le lemme implique qu'une $\mathbb{D} = \mathsf{HOT}$-fibration (au sens de la définition 2 page 81, revue et corrigée à la page 96-97) est en fait déjà une HOT-fibration cohomologique et homologique complète. Or on a vu que si f est propre, f est une $\mathbb{D}$-fibration si et seulement si les conditions précédentes sur Y (sans changement de base) sont satisfaites. Et dualement pour f lisse. ed. 66 [page 111]

11.11.90

Je sens le besoin de revoir les notions de $\mathbb{D}$-fibrations en tous genres (p. 76 ff). D'abord les diverses variantes utiles de l'axiome **Der** 3 sur les dérivateurs :

Der 3 a) [58] Si $Z \in$ Dia est Hot-asphérique, il est $\mathbb{D}$-asphérique *i.e.* $\mathcal{A} = \mathbb{D}(e) \to \mathbb{D}(Z)$ est pleinement fidèle.

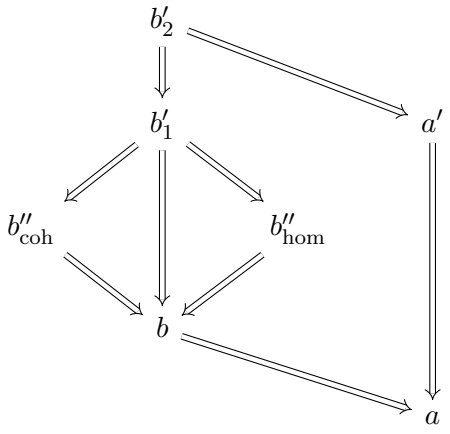
a') Comme a), avec en plus la caractérisation de l'image essentielle de $\mathcal{A}$ dans $\mathbb{D}(Z)$, comme formée des $\mathbb{D}$-coefficients localements constants.

Der 3 b) Si $f : Z' \to Z$ dans Dia est une Hot-équivalence, alors c'est une $\mathbb{D}$-équivalence, *i.e.* le foncteur $f^* : \mathbb{D}(Z) \to \mathbb{D}(Z')$ induit une équivalence entre les sous-catégories formées des coefficients constants (ou encore un foncteur pleinement fidèle $\mathbb{D}(Z)_{\text{loc. const.}} \longrightarrow \mathbb{D}(Z')$).

58. *cf.* aussi la série **Der 3** $c\ldots$, page 124 ff.

b'_1) Si f comme ci-dessus, alors f est une $\mathbb{D}$-équivalence 1-complète, *i.e.* le foncteur $f^* : \mathbb{D}(Z) \to \mathbb{D}(Z')$ induit un foncteur pleinement fidèle entre les sous-catégories pleines formées des objets localement constants. [page 112]

b'_2) Comme b'_1), mais avec $\mathbb{D}$-équivalence 2-complète au lieu de 1-complète, *i.e.* f^* induit une équivalence entre les sous-catégories formées des coefficients localement constants.



b''_{coh}) Si $f : Z' \to Z$ dans Dia est une Hot-équivalence, alors c'est une $\mathbb{D}$-équivalence cohomologique complète, *i.e.* pour tout $F \in \mathsf{Ob}\ \mathbb{D}(Z)$ qui est localement constant, on a

$$H^*_{\mathbb{D}}(Z, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(Z', f^*F) \quad .$$

b''_{hom}) Si $f : Z' \to Z$ dans Dia est une Hot-équivalence, c'est une $\mathbb{D}$-équivalence homologique complète, *i.e.* pour tout $F \in \mathsf{Ob}\ \mathbb{D}(Z)$ qui est localement constant, on a [59]

$$H^{\mathbb{D}}_*(Z', f^*F) \xrightarrow{\sim} H^{\mathbb{D}}_*(Z, F) \quad .$$

On a le diagramme d'implications tautologiques pour les variantes de **Der** 3 : ed. 67

.

Dans tous les cas à ma connaissance, les dérivateurs satisfont la condition la plus forte **Der** 3 b'_2.

[page 113]

Commentary · Exposition [ms. 112]

Two families of axioms with different antecedents

The *a*- and *b*-conditions should be read as assertions about the strength of the coefficient theory, not as successive definitions of the same phrase. Condition *a* says that a weakly contractible base does not create new morphisms between constant coefficients. Condition a' adds that it does not create new locally constant objects either. The *b*-conditions ask for analogous invariance under arbitrary weak homotopy equivalences, rather than just maps to a point.

Here is a direct check of the diagram. If f^* is an equivalence on local systems, it is fully faithful there. Full faithfulness gives cohomological and homological invariance by testing morphisms from and to all constant objects. Each of these implies invariance for constant coefficients. Applying the latter to $Z \to e$ proves *a*. Applying the equivalence on local systems to this same map proves a', because every object at e is constant. Finally a' contains *a* by definition. These are the arrows drawn in the source; the diagram does not claim that full faithfulness alone gives essential surjectivity.

There is a small but consequential inconsistency in the parenthesis defining *b* on page 111. Its first wording concerns constant coefficients, but the parenthesis writes $\mathbb{D}(Z)_{\mathrm{loc.const.}}$. Taken literally this is b'_1, the stronger condition introduced on the next line. For the displayed implication diagram and the earlier definition of a $\mathbb{D}$-equivalence, the subscript in that parenthesis must be read as "constant". We retain the edition's wording and record the distinction in the audit.

Modern homotopy invariance supplies b'_2 for ordinary Grothendieck derivators with all small categories as shapes. A restricted diagram domain still requires care: the statement must only

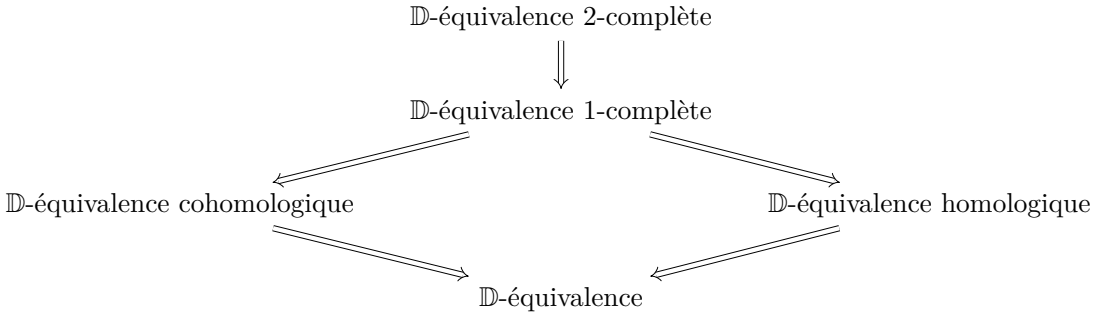
59. *cf.* variante ± spéciale pour HOT pages 124-125.

> quantify over shapes in that domain, and a proof that passes through simplicial resolutions or larger indexing categories cannot be imported without an extension hypothesis. This is the reason the manuscript continues to list these properties as separate assumptions. Its present calculation needs the explicitly stated hypothesis, not an unannounced change of domain.

Je rappelle aussi la :

Définition 1 : Soit $f : X \to Y$ dans Dia. On dit que f est une $\mathbb{D}$-*équivalence cohomologique* (sous-entendu : "*complète*") si pour tout $\mathbb{D}$-coefficient F localement constant sur Y,

$$H^*_{\mathbb{D}}(Y, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(X, f^*F) \quad ;$$



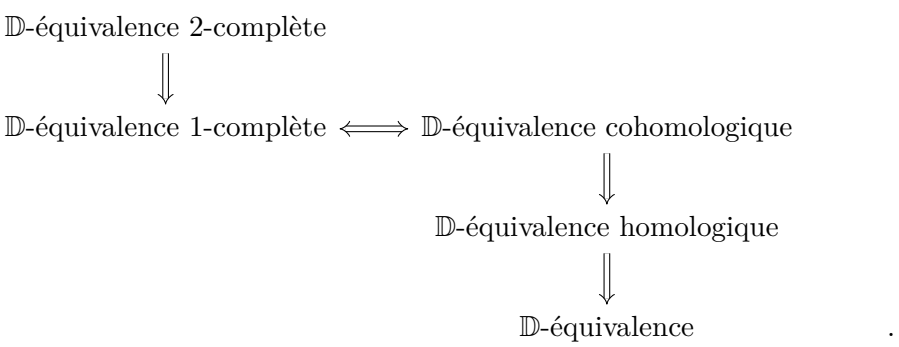
on dit que f est une $\mathbb{D}$-*équivalence homologique* ("*complète*") si pour tout F comme [ci-]dessus,

$$H^{\mathbb{D}}_*(X, f^*F) \xrightarrow{\sim} H^{\mathbb{D}}_*(Y, F) \quad .$$

On dit que f est une $\mathbb{D}$-*équivalence* 1-*complète* (resp. 2-*complète*) si le foncteur

$$f^* : \mathbb{D}(Y)_{\text{loc. const.}} \longrightarrow \mathbb{D}(X)_{\text{loc. const.}}$$

est pleinement fidèle (resp. une équivalence).



Si dans les sous-catégories $\mathbb{D}(X)_{\text{loc. const.}}$ il y a une loi $*$ (associative, unitaire, commutative) et des Hom internes associés, préservés par les images inverses, alors les $\mathbb{D}$-équivalences cohomologiques sont déjà 1-complètes et sont donc des $\mathbb{D}$-équivalences homologiques, donc dans ce cas particulier

ed. 68

[114: vide]

[page 115]

Dans $\mathbb{D} = \mathsf{HOT}$, toutes ces notions devraient être équivalentes, et équivalentes à la condition encore plus faible en apparence, que $f : X \to Y$ soit une Hot-équivalence. Mais je ne connais que HOT comme dérivateur où la $\mathbb{D}$-équivalence d'une flèche $f : X \to Y$ dans Dia implique déjà la $\mathbb{D}$-équivalence cohomologique (complète), ou la $\mathbb{D}$-équivalence homologique (complète), voire même la $\mathbb{D}$-équivalence 1-complète. (Je reviendrai là-dessus tantôt.)

Proposition 1. *Soit $f : X \to Y$ dans* Dia. *Conditions équivalentes :*

a) *Pour tout $y \in \mathsf{Ob}\, Y$, l'inclusion $X_y \to X/y$ est une $\mathbb{D}$-équivalence, et pour toute flèche $y' \to y$ dans Y, $X/y' \to X/y$ est une $\mathbb{D}$-équivalence.*

b) *Pour tout coefficient constant F sur Y, f_*f^*F est localement constant, et se calcule "fibre par fibre".*

(C'est la prop. 1, p. 76).

Proposition 1′. Dual.

Définition 2. Sous les conditions équivalentes de la proposition 1, on dit que f est une $\mathbb{D}$-*fibration cohomologique faible.* Sous les conditions duales, que f est une $\mathbb{D}$-*fibration homologique faible.* [page 116]

C'est ce que dans la définition 1, p. 77 j'appelais "$\mathbb{D}$-fibration cohomologique" ou "$\mathbb{D}$-fibration à gauche", et dualement. Maintenant la notion me paraît trop faible pour mériter ce nom, que je réserve pour le cas "complet".

Proposition 2. *Les $\mathbb{D}$-fibrations cohomologiques faibles sont stables par changements de base lisses, les $\mathbb{D}$-fibrations homologiques faibles stables par changements de base propres.*

Je devrais construire un exemple où f est une $\mathbb{D}$-fibration cohomologique faible, et ne l'est plus après changement de base.

Commentary · Development (commentators') [ms. 116]

A failure already among finite posets

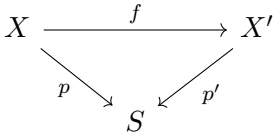
The example at manuscript page 77 uses isomorphisms in the base to expose the failure of arbitrary base change. The same failure occurs for finite posets; it is therefore relevant even to the restricted domains repeatedly considered in these pages.

A four-object example. [ours] Let $Y = [2] = \{0 < 1 < 2\}$ and let X be the poset whose distinct nonidentity relations are

$$x < a, \qquad b < a, \qquad b < z.$$

Define $f : X \to Y$ by $f(x) = 0$, $f(a) = f(b) = 1$, and $f(z) = 2$. Then f is both a weak cohomological and a weak homological HOT-fibration. Its pullback along the long edge $[1] \to [2]$, selecting 0 and 2, is neither.

To prove the first assertion, the strict fibres are $\{x\}$, $\{b < a\}$, and $\{z\}$, all contractible. Since Y is a poset, the overcategories X/y are the subposets on the elements mapping to $\{0, \dots, y\}$. They are respectively



$$\{x\}, \qquad \{x \to a \leftarrow b\}, \qquad X.$$

Their nerves realize to a point, an interval subdivided into two edges, and an interval subdivided into three edges. They are all contractible. Every fibre-to-overcategory inclusion and every induced transition between these categories is consequently a weak homotopy equivalence. This is exactly the criterion for a weak cohomological fibration. Dually, the undercategories $y\backslash X$ are X, the poset $\{a \leftarrow b \to z\}$, and $\{z\}$; the same argument proves the weak homological condition.

In the pullback, only x and z remain. There is no morphism $x \to z$ in X: the connecting path in its nerve traverses $b \to a$ backwards. Thus the pullback category X' is the discrete two-point category, mapping to the two endpoints of $[1]$. The overcategory at the terminal endpoint is all of X', whereas that strict fibre is a point. Its inclusion is not an equivalence on components. The dual failure occurs at the initial endpoint. Even ordinary degree-zero cohomology detects the defect: for a nonzero coefficient field k, the relevant comparison is $k \times k \to k$, not an isomorphism.

This settles the request for an example on page 116 without any infinite category or nontrivial automorphism. The original weak conditions hold for every coefficient derivator in which weakly contractible shapes are completely aspherical; the failure is visible for both spaces and ordinary derived coefficients. The construction is supplied here with no priority claim. We checked the local-system and smoothness treatments cited in this commentary and did not locate this precise four-object example. In particular, the "weakly smooth" functors of Maltsiniotis (2005, Definition 4.1 and Proposition 4.3) have a different, comma-asphericity condition; their terminology must not be substituted for the weak cohomological condition used here.

Proposition 3. *Soit*

dans Dia*, avec p et p' des $\mathbb{D}$-fibrations cohomologiques faibles* (resp. *des $\mathbb{D}$-fibrations homologiques faibles*)*, soit $S_0 \subset S$ tel que $\pi_0(S_0) \to \pi_0(S)$ soit surjective. Pour que f soit une $\mathbb{D}$-équivalence, il suffit que les $f_s : X_s \to X'_s$, pour $s \in S_0$, le soient.*

Proposition 4. *Si $f : X \to Y$ dans* Dia *est $\mathbb{D}$-propre* (resp. *$\mathbb{D}$-lisse*)*, alors f est une $\mathbb{D}$-fibration cohomologique* (resp. *homologique*) *faible si et seulement si pour tout F constant sur Y, f_*f^*F* (resp. *$f_!f^*F$*) *est localement constant sur Y. Et s'il en est ainsi, pour tout $Y' \to Y$ dans* Dia*, $f' : X' = X \times_Y Y' \to Y'$ est encore une $\mathbb{D}$-fibration cohomologique* (resp. *homologique*) *faible.*

Immédiat sur le critère *b*) de la proposition 1.

Proposition 5. *Soit $f : X \to Y$ dans* Dia*. Considérons les conditions suivantes :*

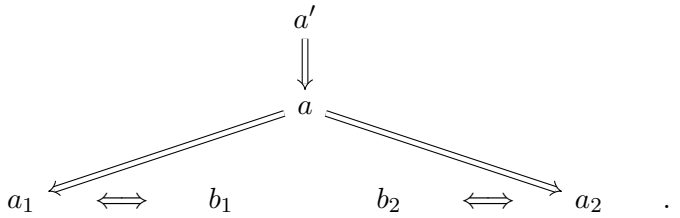
a) *Pour tout $Y'' \to Y'$ sur Y dans* Dia*, si Y'' et Y' sont* Hot*-asphériques, alors* [page 117]

$$X'' = X \times_Y Y'' \longrightarrow X' = X \times_Y Y'$$

est une $\mathbb{D}$-équivalence.

$$\begin{array}{ccccc} X & \longleftarrow & X' & \longleftarrow & X'' \\ \downarrow & & \downarrow & & \downarrow \\ Y & \longleftarrow & Y' & \underset{p}{\longleftarrow} & Y'' \end{array}$$

a′) *Comme* a)*, mais en supposant $p : Y'' \to Y'$ une* Hot*-équivalence (au lieu de supposer Y', Y''* Hot*-asphériques).*



a$_1$) *Comme* a)*, mais en supposant (au lieu de l'asphéricité) que Y' a un objet final, et Y'' est la catégorie unité.*

a$_2$) *Comme* a)*, mais en supposant que Y' a un objet cofinal, et Y'' est la catégorie unité.*

b$_1$) *f est une $\mathbb{D}$-fibration cohomologique faible, et le reste après tout changement de base.*

b$_2$) *f est une $\mathbb{D}$-fibration homologique faible, et le reste après tout changement de base.*

On a alors le diagramme d'implications tautologiques ed. 70

Lorsque $\mathbb{D}$ satisfait à l'axiome **Der** 3 a′ (p. 111)*, alors toutes ces conditions, sauf* a′)*, sont équivalentes. Lorsque $\mathbb{D}$ satisfait à l'axiome* **Der** 3 b$'_1$ *(ou seulement* **Der** 3 b$''_{\text{coh}}$ ou b$''_{\text{hom}}$*), alors toutes les conditions (y inclus* a′*) sont équivalentes.*

Pour simplifier, on va par la suite supposer que l'axiome **Der** 3 *a*′) est satisfait.

Définition 3. Sous les conditions équivalentes a, a_1, b_1, a_2, b_2 de la proposition 4, on dit que f est une $\mathbb{D}$-*fibration*.

Commentary · Exposition [ms. 117]

Why universality identifies the two weak conditions

Proposition 5 organizes the earlier failed argument by changing its input. Under a', one may pull back between weakly contractible bases. The preceding example shows why this is an additional requirement; it is not implied by the fibre criterion on the original base.

Suppose first that the weak cohomological condition holds after every base change. Over a category B with a terminal object, the direct image of a constant coefficient is locally constant and hence constant by a'. Its cohomology over B is therefore its value at any selected object b. The pointwise formula identifies that value with the cohomology of the strict fibre. Hence every point inclusion into such a base produces a $\mathbb{D}$-equivalence on total categories. Conversely, these point tests applied over Y/y, and then at its objects $u : y \to y'$, give the fibre and transport comparisons, exactly as in the proof of Proposition 4 above, now with constant coefficients only. This proves $a_1 \Leftrightarrow b_1$.

More generally, take a pullback $p : B' \to B$ with both bases weakly contractible. Put $G = f_* M_X$ and $G' = f'_* M_{X'}$. They are locally constant. Their pointwise comparison is an isomorphism because both universal weak fibre formulas use the same strict fibre; thus $G' \simeq p^* G$. Since G is constant by a', the comparison of its cohomology over the two contractible bases is invertible. This proves $b_1 \Rightarrow a$. The dual proof gives $b_2 \Rightarrow a$, and the remaining implications are immediate. In a_2, the printed "objet cofinal" must carry the dual, initial-object meaning required by this argument.

If the stronger b''_{coh} is assumed, the same calculation works with an arbitrary Hot-equivalence p: G need not become constant, because p preserves cohomology of every locally constant coefficient. That proves a'. The homological version is dual. Thus the two different uses of the prime on a' must be kept apart: **Der** 3 a' is an axiom about coefficients on contractible categories, whereas condition a' of Proposition 5 is a universal pullback test using all weak homotopy equivalences.

Proposition 6. *Supposons que $f : X \to Y$ dans* Dia *soit $\mathbb{D}$-propre* (resp. $\mathbb{D}$-*lisse*). *Conditions équivalentes :* [page 118]

a) *f est une $\mathbb{D}$-fibration.*

b) *f est une $\mathbb{D}$-fibration cohomologique* (resp. *homologique*) *faible.*

c) *Pour tout $y' \to y$ dans Y, $X/y' \to X/y$* (resp. $y\backslash X \to y'\backslash X$) *est une $\mathbb{D}$-équivalence.*

d) *Pour tout F constant sur Y, $f_* f^* F$* (resp. $f_! f^* F$) *est localement constant sur Y.*

d′) *Pour tout F localement constant sur Y, $f_* f^* F$* (resp. $f_! f^* F$) *est localement constant sur Y.*

Cela résulte formellement de Prop. 4 et Prop. 5.

Corollaire. *Supposons $f : X \to Y$ $\mathcal{C}at$-fibrant* (resp. $\mathcal{C}at$-*cofibrant*). *Pour que f soit une $\mathbb{D}$-fibration, il faut et il suffit que pour tout $u : y \to y'$ dans Y, $u^* : X_{y'} \to X_y$* (resp. $u_* : X_y \to X_{y'}$) *soit une $\mathbb{D}$-équivalence.*

Il est immédiat que la notion de $\mathbb{D}$-fibration est stable par changement de base, mais il est douteux qu'elle le soit par composition.[60] (Ici encore, j'ai omis de faire un contre-exemple, avec des dérivateurs $\mathbb{D} = \mathsf{Der}(k\text{-}\mathsf{Mod})$ disons.) Autre lacune de la notion : il n'est pas clair, si f est une $\mathbb{D}$-fibration et F un $\mathbb{D}$-coefficient sur Y, si

$$f_* f^* F \qquad \text{et} \qquad f_! f^* F$$

se calculent "fibre par fibre", comme on s'attendrait dans le cas d'un "fibré". ed. 71

Par contre, voici un résultat sympa :

Commentary · Development (commentators') [ms. 118]

Two fibrations whose composite is not a fibration

The doubt about composition can be settled by a small categorical example. It uses the same loss of monodromy information as the preceding counterexamples, but places that loss in a transition functor. We work with $\mathbb{D} = \mathsf{Der}(\mathbb{Q}\text{-}\mathsf{Mod})$ on all small categories and with the final definition of $\mathbb{D}$-fibration on page 117, which includes universality under base change.

Proposition (failure of composition). [ours] There are $\mathbb{D}$-fibrations $p : X \to Y$ and $q : Y \to [1]$ such that qp is not even a weak cohomological $\mathbb{D}$-fibration. The first map can be chosen to be a covering functor, hence both proper and smooth; the second is a Grothendieck opfibration.

60. N.B. Si les $\mathbb{D}$-équivalences sont déjà des Hot-équivalences, alors la notion coïncide avec celle de Hot-fibration, et elle est stable par composition. Également, si les $\mathbb{D}$-équivalences sont au sens des $\mathbb{D}$-équivalences cohomologiques, ou homologiques, alors la notion coïncide avec celle des $\mathbb{D}$-fibrations cohomologiques (resp. homologiques) ci-dessous, et est également stable par composition.

Let $G = C_2 = \{1, \sigma\}$. Define Y to have two objects a, b, with

$$Y(a,a) = \{1_a\}, \quad Y(b,b) = G, \quad Y(a,b) = G, \quad Y(b,a) = \varnothing.$$

Composition on $Y(b,b)$ is multiplication, and postcomposition of the arrow $g : a \to b$ by $h \in G$ is the arrow hg. Send a to 0 and b to 1. This defines $q : Y \to [1]$. It is the Grothendieck construction of the functor $e \to BG$. More explicitly, any arrow $g : a \to b$ is opcartesian: for every arrow $k : a \to b$, the unique factorization through g is multiplication by kg^{-1}. Its endpoint fibres are e and BG, and its transition functor is $e \to BG$.

This transition is a $\mathbb{D}$-equivalence. For a complex M of rational vector spaces with trivial G-action, averaging by $(1+\sigma)/2$ makes invariants exact, and coinvariants are exact for the same reason. Thus

$$\mathbb{R}\Gamma(G, M) = M, \qquad \mathbb{Q} \otimes^{\mathbb{L}}_{\mathbb{Q}[G]} M = M.$$

These identities are natural for arbitrary, including unbounded, complexes: the trivial module is projective over $\mathbb{Q}[G]$, and the averaging contraction is degreewise compatible with the differential. The opfibration criterion on page 118 now makes q a $\mathbb{D}$-fibration, with all base changes covered by that criterion.

Let Z be the discrete category on the set G. Define a functor $L : Y \to \mathcal{C}at$ by $L(a) = L(b) = Z$, and let every arrow labeled g act by left translation $z \mapsto gz$. Put $X = \int_Y L$ and let p be the projection. All its transport functors are isomorphisms. Every arrow of Y therefore has a unique lift with either prescribed source or prescribed target. In particular p is both a discrete fibration and a discrete opfibration, and the transport criterion makes it a $\mathbb{D}$-fibration (indeed a HOT-fibration).

The composite qp is an opfibration whose fibre at 0 is the discrete two-point category Z. Its fibre at 1 is the action groupoid $G \ltimes G$ for the left regular action. There is exactly one arrow between any ordered pair of objects of this groupoid, so it is equivalent to the terminal category. The transition functor is the inclusion

$$Z_{\mathrm{disc}} \longrightarrow G \ltimes G.$$

On cohomology in degree zero it induces

$$\mathbb{Q} \longrightarrow \mathbb{Q}^2, \qquad r \longmapsto (r, r),$$

which is not an isomorphism. Since qp is proper, the criterion of Proposition 6 identifies this failure with failure to be a weak cohomological fibration. Equivalently, $(qp)_*\mathbb{Q}_X$ has values $\mathbb{Q}^2$ at 0 and $\mathbb{Q}$ at 1, and its transition is the displayed diagonal. This completes the construction and the proof.□

The example explains why the positive answer concerning f_*f^*F does not force closure under composition. The coefficient $p_*\mathbb{Q}_X$ on Y is the permutation local system attached to the regular G-set. It is not pulled back from a coefficient on [1]: every such pullback has trivial G-action at b. The constant-coefficient test for q cannot control this local system. The stronger cohomological fibrations introduced on page 121 impose exactly the missing condition. Our literature check covered the smooth-functor formalism of Maltsiniotis (2005) and the locally constant coefficient theory of Cisinski (2009); we did not find this particular composition counterexample there. It is an elementary development of the mechanism already present in Grothendieck's finite-group example.

Proposition 7. *Soit $f : X \to Y$ dans* Dia. *Conditions équivalentes :*

a) *f est une $\mathbb{D}$-équivalence "universelle",* i.e. *pour tout $Y' \to Y$ dans* Dia, *$f' : X' = X \times_Y Y' \to Y'$ est une $\mathbb{D}$-équivalence.* [page 119]

b) *f est une $\mathbb{D}$-fibration à fibres $\mathbb{D}$-asphériques.*

Définition 4. Sous les conditions équivalentes de la proposition 7, on dit que f est une $\mathbb{D}$-fibration *triviale*.

Mais attention, f peut-être une $\mathbb{D}$-fibration et une $\mathbb{D}$-équivalence, sans que la $\mathbb{D}$-fibration soit triviale *i.e.* sans que les fibres soient $\mathbb{D}$-asphériques, cf. p. 87 et suivantes. Et également (devrait remonter) même si $\mathbb{D}$ satisfait **Der** 3 b_2 (la plus forte des variantes de **Der** 3), donc quand <u>toutes</u> les conditions de la proposition 5, y inclus a'), sont équivalentes, celles-ci (*i.e.* que f soit une $\mathbb{D}$-fibration) n'impliquent pourtant pas, en général, que dans la condition a') on puisse se borner à $p : Y'' \to Y'$ une $\mathbb{D}$-équivalence (au lieu d'une Hot-équivalence). En

d'autres termes, si on a un diagramme cartésien dans Dia

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow[p]{} & Y' \end{array} \quad ,$$

avec f une $\mathbb{D}$-fibration, et p une $\mathbb{D}$-équivalence, il ne s'ensuit pas forcément que q soit une $\mathbb{D}$-équivalence. (Mais ce sera pourtant le cas, "bien sûr", si $\mathbb{D} = \mathsf{HOT}$.)

Par contre, on a :

Proposition 8. *Soit $f : X \to Y$ dans* Dia*. Conditions équivalentes :* [page 120]

a) *f est une $\mathbb{D}$-fibration.*

b) *Pour tout $p : Y'' \to Y'$ sur Y, si p est une $\mathbb{D}$-équivalence* 1*-complète* (déf. 1, p. 113)*, alors $q : X'' \to X'$ est une $\mathbb{D}$-équivalence.*

$$\begin{array}{ccccc} X & \longleftarrow & X' & \xleftarrow{q} & X'' \\ {\scriptstyle f}\downarrow & & {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f''} \\ Y & \longleftarrow & Y' & \xleftarrow[p]{} & Y'' \end{array}$$

Corollaire. *Supposons que dans* Dia*, toute $\mathbb{D}$-équivalence soit* 1*-complète.* (N.B. Je ne connais que le dérivateur HOT pour satisfaire à cette condition, qui paraît quasiment caractéristique de HOT.) *Alors $f : X \to Y$ est une $\mathbb{D}$-fibration si et seulement si pour tout $p : Y'' \to Y'$ sur Y, si p est une $\mathbb{D}$-équivalence, alors $q : X'' \to X'$ aussi. Dans ce cas exceptionnel parmi les dérivateurs, la notion de $\mathbb{D}$-fibration est stable par composition* (ce qui est tautologique sur le critère que je viens de donner.)

Commentary · Exposition [ms. 120]

Universal equivalence and the 1-complete test

Two different universal assertions occur here. A universal $\mathbb{D}$-equivalence is a functor whose every base change is a $\mathbb{D}$-equivalence. A $\mathbb{D}$-fibration preserves certain equivalences in diagrams over its base; it need not itself be a $\mathbb{D}$-equivalence. Proposition 7 identifies their intersection with the condition that all strict fibres be $\mathbb{D}$-aspherical. For the forward implication, base change to each point gives aspherical fibres, while the two-out-of-three property applied to the two universally equivalent projections gives the fibration criterion. For the reverse implication, the universal weak fibre formula makes f_*M_X a constant object M_Y: its unit is an isomorphism at every y because X_y is $\mathbb{D}$-aspherical. Taking global cohomology proves the equivalence, and the same argument applies after base change.

This result does not permit replacement of "universal" by "ordinary". The rational monodromy examples already show that a fibration which is a $\mathbb{D}$-equivalence can have a fibre that is not $\mathbb{D}$-aspherical. The issue is not a failure of the fibre formula, but a loss of information upon taking global cohomology of a nonconstant local system.

Proposition 8 repairs the pullback assertion by strengthening the equivalence in the base. If $p : Y'' \to Y'$ is 1-complete, it preserves cohomology of every local system. For a constant M, universality of the weak fibration condition makes $f'_*M_{X'}$ locally constant and identifies its pullback with $f''_*M_{X''}$. Taking cohomology proves that $X'' \to X'$ is a $\mathbb{D}$-equivalence. Conversely, apply the preservation assertion to $e \to B$ with B weakly contractible. Under a', restriction on local systems is an equivalence and hence 1-complete, so the point tests of Proposition 5 follow.

There is a useful distinction between the result here and the stronger definition below. Proposition 8 asks that pulling back a 1-complete equivalence produce a constant-coefficient equivalence. It does not assert that the pullback is itself 1-complete. Demanding that stronger conclusion supplies a composition-stable class by definition, but it is an extra condition unless the internal-Hom argument identifies the relevant equivalence classes.

On va renforcer la notion de $\mathbb{D}$-fibration, pour la rendre plus souple, et notamment stable par composition.

Proposition 9. *Soit $f : X \to Y$ dans* Dia. *Conditions équivalentes :*

a) *Pour tout $y \in Y$, $X_y \to X/y$ est une $\mathbb{D}$-équivalence cohomologique* (déf. 1, p. 113), *et de même pour $X/y \to X/y'$ pour toute flèche $y \to y'$ dans Y. Et ces conditions sur f restent valables après tout changement de base* (N.B. il suffit que la première de ces conditions le reste).

b) *pour tout $F \in \mathsf{Ob}\ \mathbb{D}(X)$ localement constant, f_*F est localement constant sur Y et se calcule "fibre par fibre" – et itou après tout changement de base.* [page 121]

c) *Pour tout $p : Y'' \to Y'$ sur Y, si p est une $\mathbb{D}$-équivalence cohomologique, alors il en est de même de $q : X'' \to X'$.*

c′) *Comme* c, *mais en supposant comme hypothèse sur p que Y'' soit la catégorie finale, et Y' ait un objet final.*

Démonstration. Dans l'ordre (± tautologique)

$$\mathrm{a} \Longrightarrow \mathrm{b} \Longrightarrow \mathrm{c} \Longrightarrow \mathrm{c}' \Longrightarrow \mathrm{a} \quad .$$

Définition 5. Sous les conditions équivalentes de la proposition 9, on dit que f est une $\mathbb{D}$-*fibration cohomologique*. Sous les conditions duales, on dit que f est une $\mathbb{D}$-*fibration homologique*. On dit que f est une $\mathbb{D}$-*fibration forte*, si c'est à la fois une $\mathbb{D}$-fibration cohomologique et une $\mathbb{D}$-fibration homologique.

Ces notions renforcent la notion de $\mathbb{D}$-fibration. Elles ont l'avantage de plus d'être stables par composition, non seulement par changement de base.

Commentary · Exposition [ms. 121]

The reason the strong notion composes

We may now prove the composition assertion without an appeal to intuition about bundles. Let $X \xrightarrow{f} Y \xrightarrow{g} Z$ be cohomological fibrations in the revised sense. For $L \in \mathcal{L}(X)$, the object f_*L is locally constant on Y, and then g_*f_*L is locally constant on Z. The canonical composition isomorphism identifies it with $(gf)_*L$. This is the coefficient condition that was missing for the earlier notion.

For the universal base-change assertion, pull back the composite along any $Z' \to Z$, and factor the resulting rectangle into the two cartesian squares for g and f. The comparison for g, applied to the locally constant object f_*L, is invertible. The comparison for f, applied to L, is invertible. Pasting gives the comparison for gf. The same reasoning works for every locally constant coefficient on the new total category, because the hypotheses on f and g were universal. Specializing to a point in Z gives the fibre formula. Alternatively, condition c of Proposition 9 proves composition by applying two successive pullbacks to a cohomological equivalence. The two arguments express the same closure property at the levels of coefficients and indexing categories.

The dual reasoning applies to homological fibrations, and hence to strong fibrations. It does not prove that every $\mathbb{D}$-fibration composes: a weak fibration controls direct images of constant coefficients, whereas the first direct image in a composite is usually only locally constant. The explicit counterexample at page 118 realizes exactly this obstruction. The questions about f_*f^*F and $f_!f^*F$, for an arbitrary coefficient on the base, are different again; the factorization-category argument at page 82 proves the required fibre formulas under the stated domain hypotheses. There is no conflict, because a locally constant object produced on the intermediate category need not be pulled back from the final base.

For the proposed 1-complete and 2-complete fibrations of page 122, the phrase "not stable under composition (as far as I know)" supplies no proof. In the compatible closed monoidal situation, the 1-complete variant reduces to the cohomological one and therefore composes. The 2-complete variant nevertheless fails to compose, even for the represented set-valued derivator: the development "The 2-complete variant also fails to compose" constructs two functors between finite categories from a normalized C_2-valued cocycle on a triangulated two-sphere. Their composite fails a permitted contractible-base test because restriction gives only trivial C_2-actions. This restriction is fully faithful but not essentially surjective. An internal Hom controls morphisms between objects already

descended; it does not supply descent of every local system. The counterexample thus settles the 2-complete question without extending its negative conclusion to the 1-complete class.

La notion de $\mathbb{D}$-fibration forte a été choisie pour coiffer les deux notions duales de $\mathbb{D}$-fibration cohomologique et homologique (à défaut d'une meilleur notion) tout en restant stable par composition. On pourrait exiger que pour tout [page 122]

$$Y'' \longrightarrow Y'$$

sur Y, avec Y', Y'' Hot-asphériques, $q : X'' \to X'$ soit une $\mathbb{D}$-équivalence 1-complète (voire même 2-complète), appeler ça les $\mathbb{D}$-*fibrations* 1-*complètes* (resp. 2-*complètes*). Ça renforce de façon assez élégante la notion de $\mathbb{D}$-fibration forte, mais a le grand tort de ne pas être stable par composition (que je sache!), sauf dans le cas particulier où on a des $\underline{\mathsf{Hom}}$ internes sympas (cf. bas de la page 113), auquel cas la notion de $\mathbb{D}$-équivalence implique déjà celle de $\mathbb{D}$-équivalence 1-complète, donc aussi celle de $\mathbb{D}$-équivalence homologique. Donc dans ce cas ed. 73

[page 123]

$$\begin{array}{ccc} \mathbb{D}\text{-fibration cohomologique} & \Longleftrightarrow & \mathbb{D}\text{-fibration 1-complète} \\ \Big\Downarrow & & \\ \mathbb{D}\text{-fibration homologique} & , & \end{array}$$

et il n'y a pas à chercher plus loin que les $\mathbb{D}$-fibrations cohomologiques.

Commentary · Development (commentators') [ms. 122]

The 2-complete variant also fails to compose

The qualification "que je sache" is not a proof of failure. Nevertheless, the proposed 2-complete class really need not be closed under composition, even for a represented derivator with all small categories as shapes. We give a categorical counterexample, including the coherence responsible for the failure. The existence of the local-systems derivator in Cisinski (2009, Theorem 3.13) does not supply the missing composition property. We checked the local-systems treatment just cited and did not find this particular construction there. The construction below is a verification given here, without a claim of priority.

Proposition. [ours] Let $\mathbb{D}_{\mathrm{set}}(A) = \mathrm{Fun}(A^{\mathrm{op}}, \mathsf{Set})$. There are functors

$$X \xrightarrow{p} Y \xrightarrow{q} [1]$$

which are both 2-complete fibrations in the precise sense proposed on manuscript page 122, while qp is not one. The categories X and Y are finite, and the functor p is even a HOT-fibration. Thus the failure persists in the usual domain of all small categories, with cartesian closed coefficients.

Write $\Pi_1(A)$ for the fundamental groupoid of $|NA|$, or equivalently the groupoid obtained by inverting all arrows of A. A locally constant set-valued presheaf factors through this groupoid. Consequently

$$\mathcal{L}_{\mathrm{set}}(A) \simeq \mathrm{Fun}(\Pi_1(A)^{\mathrm{op}}, \mathsf{Set}).$$

In particular, an equivalence of fundamental groupoids induces a 2-complete equivalence. We will verify this condition for the two factors, and exhibit an object which cannot descend for the composite.

Let B be the poset of nonempty proper subsets of $\{0,1,2,3\}$, ordered by inclusion. Its nerve is the barycentric subdivision of the boundary of a tetrahedron, so $|NB|$ is a two-sphere. Fix the maximal chain

$$\sigma = (\{0\} < \{0,1\} < \{0,1,2\}).$$

Write $C_2 = \mathbb{Z}/2\mathbb{Z}$ additively. For composable arrows $u : b \to b'$ and $v : b' \to b''$, set $c(u,v) = 1$ when they constitute this chain, and set $c(u,v) = 0$ otherwise. In particular it is zero if either arrow is an identity. This is a normalized C_2-valued 2-cocycle: there is no chain of three nonidentity arrows in B, and the cocycle identity with an identity arrow cancels term by term.

Define E_c to have the same objects as B, with one arrow (u, n) for each arrow u of B and label $n \in C_2$. Put

$$(v, n) \circ (u, m) = (vu, m + n + c(u, v)), \qquad 1_b = (1_b, 0).$$

The cocycle identity is precisely associativity. The projection $E_c \to B$ is both a Grothendieck fibration and an opfibration. Indeed, after fixing a lift of one base arrow, any required factorization is obtained by uniquely solving for the C_2-label of the other lift. Its fibre at each object is the one-object groupoid BC_2, and its transport functors act identically on C_2. The coherence is nontrivial, although the individual transport functors are identities.

We need the fundamental group of E_c, not the full homotopy type of its nerve. Put $t_b = (1_b, 1)$ and $h_{bb'} = (b \leq b', 0)$. Its groupoid completion has these generators and the relations

$$t_b^2 = 1, \qquad t_{b'} h_{bb'} = h_{bb'} t_b, \qquad h_{b'b''} h_{bb'} = h_{bb''} t_b^{c(b,b',b'')}.$$

Choose a spanning tree of the one-skeleton of NB and use it to identify all objects. The first relations identify the t_b with a single central generator t, with $t^2 = 1$. Every triangle other than σ gives the ordinary, untwisted edge relation. These relations kill all remaining edge generators, because the complex obtained from the triangulated sphere by removing the interior of σ is a disk, with the same one-skeleton. The remaining triangle relation then says $1 = t$. This proves that E_c is connected and that $\Pi_1(E_c)$ is equivalent to the terminal groupoid.

Now choose $b_0 = \{0\}$ and let

$$q : Y = \int_{[1]} (e \xrightarrow{b_0} B) \longrightarrow [1]$$

be the Grothendieck construction. Concretely, Y consists of B and one new object a, with

$$Y(a, b) = B(b_0, b), \quad Y(b, a) = \varnothing, \quad Y(a, a) = \{1_a\}.$$

The functor q sends a to 0 and B to 1. There is a retraction $r : Y \to B$ sending a to b_0. If $i : B \hookrightarrow Y$ is the inclusion, then $ri = 1$ and the arrow $a \to b_0$ gives a natural transformation $1_Y \to ir$. Finally define

$$X = Y \times_B E_c, \qquad p : X \longrightarrow Y.$$

The retraction and its natural transformation lift to $X \to E_c$, using the arrow of C_2-label zero over $a \to b_0$. Naturality follows from the normalization of c, since this arrow maps to 1_{b_0} under r. Hence $|NX| \simeq |NE_c|$, and X is simply connected. The strict fibre of qp at 0 is BC_2.

We now check the universal quantifiers in the definition. First, p is a pullback of the opfibration $E_c \to B$; all its transports are equivalences of groupoids. The opfibration criterion already established on page 118 therefore makes p a HOT-fibration, after every base change. A functor between weakly contractible bases is a nerve weak equivalence. Pullback along p consequently gives a nerve weak equivalence, and hence a 2-complete equivalence for sets.

There is also a direct verification of this last assertion. For any weakly contractible category $A \to Y$, the pulled-back cocycle on A is a coboundary, since $H^2(|NA|; C_2) = 0$. Writing it as δd and replacing the label n of an arrow u by $n + d(u)$ identifies the pulled-back category with $A \times BC_2$. Choose d normalized, so that this identification preserves the vertical C_2-loops. A comparison induced by a functor between two such bases preserves their vertical generator, and hence induces an isomorphism of their fundamental groups, both equal to C_2. Both total categories are connected. Thus their fundamental groupoids are equivalent, as required.

For q, we prove a stronger assertion. For every $A \to [1]$, with no contractibility assumption, the projection

$$q_A : Y_A = Y \times_{[1]} A \longrightarrow A$$

induces an equivalence of fundamental groupoids. Its strict fibres are e or B, and it has a section selecting a over 0 and b_0 over 1. The transport functors preserve these selected objects. Within each fibre there is a unique morphism in its fundamental groupoid from the selected object to any given object, because the fibre is connected and simply connected. These fibre paths give a natural isomorphism, in $\Pi_1(Y_A)$, from the section followed by the projection to the identity. For naturality, factor an arrow into its opcartesian lift and a vertical arrow; transport of the chosen path and composition with the vertical arrow give the same path in the target fibre, by uniqueness. The section is therefore a quasi-inverse to $\Pi_1(q_A)$.

If $A' \to A$ is a functor over [1] with both bases weakly contractible, the two projections just considered and the equivalence $\Pi_1(A') \to \Pi_1(A)$ show that $Y_{A'} \to Y_A$ is a 2-complete equivalence. This proves exactly the page-122 condition for q.

For the composite, use the permitted test $\{0\} \to [1]$. Both bases are contractible, but the upstairs comparison is

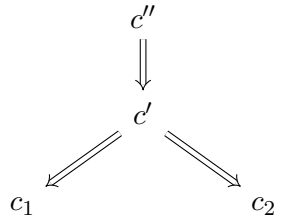
$$BC_2 = X_0 \longrightarrow X.$$

Since X is connected and simply connected, all its locally constant set-valued presheaves are constant. Restriction to BC_2 therefore has only trivial C_2-actions in its essential image. A two-element set on which $1 \in C_2$ exchanges the two elements is a locally constant coefficient on BC_2 which does not extend to X. Restriction is not essentially surjective, so the comparison is not 2-complete. This proves the proposition. □

The failure is precisely in descent of objects. In this final test the functor from sets to C_2-sets with trivial action is fully faithful; the obstruction does not concern morphisms between objects already descended. Thus the example is consistent with closure of the 1-complete class under the internal-Hom hypotheses, and explains why that argument cannot settle the 2-complete variant. Theorem 3.13 of Cisinski constructs coherent diagrams of local systems for a fixed indexing category; it does not assert that the restricted pullback tests defining the proposed class preserve essential surjectivity under a composite.

On pourrait songer, il est vrai, à définir (dans le cas général) une notion plus forte, en exigeant que pour tout $p : Y'' \to Y'$ sur Y qui soit une $\mathbb{D}$-équivalence 1-complète, $q : X'' \to X'$ soit aussi une $\mathbb{D}$-équivalence 1-complète. Cette fois-ci, la notion est stable par composition, mais elle me paraît néanmoins inutilisable (en dehors du cas qu'on vient de dire, où elle coïncide avec la notion de $\mathbb{D}$-fibration cohomologique, ou encore de $\mathbb{D}$-fibration forte), car n'étant pas en mesure de décrire les $\mathbb{D}$-équivalences 1-complètes, je suis aussi incapable de donner des exemples non triviaux de $\mathbb{D}$-fibrations "strictement 1-complètes".

Pour vérifier qu'une $f : X \to Y$ dans Dia est une $\mathbb{D}$-fibration cohomologique, il faut savoir vérifier que des flèches $q : Z' \to Z$ dans Dia sont des $\mathbb{D}$-équivalences cohomologiques, donc que $H^*_{\mathbb{D}}(Z, F) \xrightarrow{\sim} H^*_{\mathbb{D}}(Z', q^*(F))$ est [un] isomorphisme pour tout $F \in \mathsf{Ob}\ \mathbb{D}(Z)$ qui est localement constant sur Z. Or je ne sais vérifier un énoncé de cette nature (en dehors du cas où je sais d'avance que Z est complètement $\mathbb{D}$-asphérique, *i.e.* que les coefficients localement constants sur Z sont en fait constant) que si q est déjà une Hot-équivalence. C'est dire que je ne sais exhiber des $\mathbb{D}$-fibrations cohomologiques, que quand ce sont déjà des HOT-fibrations cohomologiques. Je veux, dans la suite, donner des critères utilisables pour des HOT-fibrations. Mais on va axiomatiser ces développements, en gardant un $\mathbb{D}$ général, sur lequel je vais faire une hypothèse si draconienne que pratiquement, je ne connais que le dérivateur HOT qui y satisfait. Il s'agit de c_1 ci dessous. [page 124]



Der 3 c_1) Toute $\mathbb{D}$-équivalence est une $\mathbb{D}$-équivalence cohomologique.

c_2) Toute $\mathbb{D}$-équivalence est une $\mathbb{D}$-équivalence homologique.

c') Toute $\mathbb{D}$-équivalence est 1-complète.

c'') Toute $\mathbb{D}$-équivalence est 2-complète. [page 125]

N.B. On a

tautologiquement. Je ne connais que HOT pour satisfaire l'ensemble des deux plus faibles conditions c_1, c_2. Et en fait, sous réserve d'écrire la théorie du dérivateur HOT, il doit être vrai qu'elle satisfait même la forme la plus forte c''. (Et les HOT-équivalences doivent être simplement les Hot-équivalences.) (Cf. le "lemme" p. 109.) ed. 74

La proposition suivante est une tautologie.

Proposition 10. *Supposons que* $\mathbb{D}$ *satisfasse la condition* **Der** 3 c_1 (p. 124), *par exemple* $\mathbb{D} = \mathsf{HOT}$. *Alors la notion de* $\mathbb{D}$*-fibration coïncide avec celle de* $\mathbb{D}$*-fibration cohomologique. Elle est donc stable par composition. Pour que* $f : X \to Y$ *soit une* $\mathbb{D}$*-fibration, il faut et il suffit que pour* $p : Y'' \to Y'$ *sur* Y*, si* p *est une* $\mathbb{D}$*-équivalence, il en est de même de* $q : X'' \to X'$.

Corollaire 1. *Si* $f : X \to Y$ *dans* Dia *est* $\mathbb{D}$*-propre, alors* f *est une* $\mathbb{D}$*-fibration cohomologique si et seulement si pour toute flèche* $y' \to y$ *dans* Y*,* $X/y' \to X/y$ *est une* $\mathbb{D}$*-équivalence* (i.e. *si et seulement si* f *est une* $\mathbb{D}$*-fibration cohomologique faible*).

Appliquer le critère c) de `[1a]` prop. 6.

Corollaire 2. *Supposons que* $\mathbb{D}$ *satisfasse* **Der** 3 (c_1, c_2) (par exemple $\mathbb{D} = \mathsf{HOT}$). *Alors pour une flèche* $f : X \to Y$ *dans* Dia*, il revient au même que* f *soit une* $\mathbb{D}$*-fibration, une* $\mathbb{D}$*-fibration cohomologique, ou une* $\mathbb{D}$*-fibration homologique. Si* f *est propre* (resp. *lisse*)*, il revient au même de dire que* f *est une* $\mathbb{D}$*-fibration cohomologique* (resp. *homologique*)*, faible.* [page 126]

Commentary · Present state [ms. 126]

The closing axioms and the theorem they isolate

The c-conditions have an antecedent different from that of the b-conditions. They start with a $\mathbb{D}$-equivalence, which may be much weaker than a weak homotopy equivalence of nerves. Thus the modern validity of b'_2 does not make the c-conditions automatic. Rational coefficients and the map $e \to BC_2$ already separate them: all the homotopy-invariance axioms hold, while invariance for constant coefficients does not imply invariance for the sign local system.

For spaces, the argument at page 110 proves all of c_1, c_2, c', c''. Propositions 5 and 9 therefore describe one class, and the criterion says that its members preserve weak homotopy equivalences under arbitrary pullback over their base. This is the intrinsic categorical fibration property being isolated here. It should not be identified with the class of fibrations in every model structure on categories, or with an assertion that the realization of the displayed functor is a literal Serre fibration. The invariant content is the comparison with homotopy fibres and the stability of the appropriate pullback squares.

The transition criterion has a classical source. In the dual form of Quillen (1973, §1, Theorem B and its corollary), weak equivalences between the comma categories along every arrow identify these comma categories with homotopy fibres of the induced map of classifying spaces. For an opfibration, transport functors between strict fibres provide the corresponding test. Properness then gives the strict-fibre-to-comma comparison required in the manuscript. The resulting criterion is the content of Corollary 1 here; its dual gives Corollary 2. These statements were not awaiting a new homotopy group calculation: they were awaiting a coefficient formalism in which the calculation could be made functorial and self-dual.

The scope of the later theorems is worth stating exactly. The ordinary homotopy derivator exists on all small categories (Cisinski, 2003, Theorem 6.11), and its locally constant objects have the invariance needed in the lemma. Within that setting, the question on pages 107–111 and the final conditional assertions are settled affirmatively. The weaker notions for other coefficient derivators retain the distinctions exposed by the examples in these pages. The manuscript's remark that HOT is the only example known to him is autobiographical, not a uniqueness theorem: for instance a product of HOT with another derivator satisfying b'_2 still detects nerve weak equivalences and satisfies c''.

The last statement follows directly. A map is an equivalence for the product derivator exactly when it is one for both factors. The HOT factor forces it to be a nerve weak equivalence. The b'_2 property of each factor then makes restriction an equivalence on their local systems, and local systems in a product are computed factorwise. This proves c'' for the product without identifying the coefficient category with spaces. What the axiom singles out is the strength of detection and transport, not a unique presentation of the theory.

On voit donc que dans $\mathcal{C}at$, on doit avoir une seule notion raisonnable de HOT-fibration, qui coïncidera avec celle de HOT-fibration cohomologique ou homologique. Mais pour que cette notion soit dès à présent disponible, il faudrait que le dérivateur HOT soit déjà construit sur le domaine $\mathsf{Dia} = \mathcal{C}at$ tout entier. Or ce n'est pas chose faite encore (et il n'a donc pas pu

être question de prouver les propriétés de HOT dont il vient d'être question, disons la plus forte **Der** 3 c'').

Néanmoins, je voudrais développer de façon directe ("élémentaire") la notion de Hot-fibration, sans me référer à la théorie du dérivateur HOT, et aux développements théoriques précédents.

Commentary · Context [ms. 126]

The later letter and the meaning of a fibration

There is a useful chronological comparison at this stopping point. In his letter to Thomason of 2 April 1991, Section 1, Grothendieck starts with a category equipped with a class W of weak equivalences and defines its W-fibrations by requiring pullback to carry W-equivalences to W-equivalences (Grothendieck, 1991a). Closure under composition then follows by composing pullback functors. This is the strong universal preservation condition proposed on manuscript page 79, and it becomes the final condition in this chapter when the supplementary assumptions on $\mathbb{D}$ identify the appropriate equivalence classes.

The comparison explains why the word "fibration" must always be accompanied by its test class. A W-fibration defined by preservation of W has a formal closure property. A $\mathbb{D}$-fibration defined by preservation of weak equivalences of nerves only as $\mathbb{D}$-equivalences has two different test classes, so that formal argument does not apply. The composition example on page 118 makes the difference explicit. In the case $\mathbb{D} = \mathsf{HOT}$, the classes agree and the difficulty disappears.

The earlier motivation in Section 69 of *Pursuing Stacks* was to retain coherent diagram categories and the two Kan extensions as part of the coefficient theory (Grothendieck, 1983). The present pages show why that enrichment matters even before stability or triangulated categories enter: the coefficient produced by one direct image can have nontrivial transport, and the next direct image must retain it. The mathematical work of these pages is the progressive adjustment of the admissible coefficients and the admissible base changes until this operation can be iterated. It should be read with those successive adjustments intact.

Overview · I-b

Coefficients, monodromy, and the search for a usable fibration.

These pages of Chapter I begin with a correction to an overly strong use of cofinality and end with a programme for a theory of fibrations in the category of small categories. Their continuity lies in a single question: which coefficients must a comparison preserve if that comparison is to remain useful after another operation? Preservation of constant coefficients is enough to define a class of weak equivalences. It is not, in general, enough to carry out base change or to compose fibrations. The passage from constants to locally constant coherent coefficients is therefore the principal mathematical movement of the text.

These are pages 34–74 of the edition, manuscript pages 60–126. The text follows the editors' electronic edition (Grothendieck, 1990–1991a). Manuscript pages 60–66 also close the first part of the chapter, where their commentary, claims and readings are given. Printed and manuscript numbers are kept distinct throughout. No assertion in the commentary silently corrects a mathematical mistake in the French source: genuine transcription errors are corrected, whereas errors already present in the edition remain visible and are explained where they affect the argument.

We use the manuscript's convention that an object of $\mathbb{D}(X)$ has underlying diagram $X^{\mathrm{op}} \to \mathbb{D}(e)$. Thus the value of a right Kan extension f_*F at y is calculated on X/y, and the value of the left Kan extension $f_!F$ is calculated on $y\backslash X$. The symbols $H^*_{\mathbb{D}}$ and $H^{\mathbb{D}}_*$ denote objects in the coefficient category, not merely lists of cohomology or homology groups. This convention is responsible for several apparently reversed statements when one compares the manuscript with modern covariant-diagram treatments; the variance distinction is explained explicitly in Groth et al. (2014a, Warning 2.2).

From constant equivalences to base change.

For $f : X \to Y$, with terminal projections p and q, a $\mathbb{D}$-equivalence means that restriction induces bijections

$$\mathrm{Hom}_{\mathbb{D}(Y)}(q^*M, q^*N) \longrightarrow \mathrm{Hom}_{\mathbb{D}(X)}(p^*M, p^*N)$$

for all $M, N \in \mathbb{D}(e)$. Adjunction and Yoneda identify this with invariance of constant-coefficient homology or cohomology whenever the relevant Kan extensions exist. It does not say that f^* is fully faithful on all of $\mathbb{D}(Y)$. The distinction is already decisive for an endpoint inclusion in the walking arrow.

Theorem 1 on manuscript page 67 gives the stronger cofinality test actually needed: cohomological invariance for every coefficient on Y is equivalent to asphericity of the comma categories $y\backslash X$. The proof uses the counit $f_!p^*M \to q^*M$. One adjunction reads it as a cohomology comparison; pointwise evaluation reads it as constant homology of a comma category. This explains the apparent use of homology inside a cohomological theorem without adding a missing hypothesis to a valid argument.

The proper and smooth base-change results then have a precise local content. Properness requires the categories of lifts of every arrow $f(x) \to y$ starting at x to be $\mathbb{D}$-aspherical. The requirement involves both objects and their morphisms, rather than mere nonemptiness of the set of lifts. A Grothendieck opfibration satisfies it because an opcartesian lift is an initial object of the corresponding lift category. The dual account gives smoothness. The commentary supplies the omitted implications among the endpoint, lifting, and base-change tests in Theorem 2, while preserving the edition's mistyped objects and cross-references as source readings.

This vocabulary retains the geometry of proper and smooth base change, but defines a property of functors relative to a coefficient theory. The later theory of asphericity structures provides an appropriate comparison, rather than an identification with topological proper maps (Maltsiniotis, 2005, Theorems 1.2, 4.13, and 5.4). The intervening construction $\Phi(X)$, now called the twisted-arrow category, gives natural comparisons between X and X^{op}. Both

endpoint projections are opfibrations with contractible fibres. Their universal equivalence proves that taking opposites preserves the equivalence class detected by $\mathbb{D}$. This is a comparison of homotopy information, not an equivalence of the original categories.

What the counterexamples distinguish.

From manuscript page 76 onward, the word "fibration" changes meaning as the argument develops. Its first version asks that the actual fibre and its comma-category model have the same constant-coefficient theory and that transport between comma categories preserve that theory. Requiring this after every base change is an additional condition. We exhibit both a two-object example and an example involving only finite posets where the first condition holds but fails after a strict base change.

The more substantial failure concerns the proposed implication that a universal fibration must preserve every $\mathbb{D}$-equivalence of bases. For rational complexes, a base can be cohomologically indistinguishable from a point while still carrying nontrivial local systems. Grothendieck's reflected-circle bundle over the circle makes the point concretely. The degree-one cohomology of its fibres is a sign local system on the base circle; its derived cohomology has differential multiplication by -2, hence is zero over $\mathbb{Q}$. The projection from the Klein bottle is consequently a rational constant-coefficient equivalence although its circle fibres are not rationally aspherical. In a fibre square the tensor square of the orientation local system becomes untwisted, and the extra cohomology reappears. The commentary calculates the full complexes and the comparison maps, including the degree-zero term omitted from the source's abbreviated group-cohomology calculation.

The finite-group version replaces this computation by the averaging idempotent. It also shows why the proposed extension to truncated homotopy theories needs care: already the point mapping into BC_2 is an equivalence for the represented set-valued derivator, whereas locally constant C_2-sets retain the action. The corresponding assertions about complete equivalences cannot be inferred from connectedness.

One further correction is necessary in the proposed finite-poset model. The action on S^2 is antipodal and the action on S^1 is a reflection. Their product acts trivially on the top class of degree three. Hence

$$H^*((S^2 \times S^1)/C_2; \mathbb{Q}) \cong \mathbb{Q} \quad \text{in degrees } 0, 3,$$

and vanishes in other degrees. The base $\mathbb{RP}^2$ is rationally aspherical, but this total space is not. The example still disproves invariance under inclusion of a fibre; it does not supply the additional aspherical-total-space claim. An exact rational chain calculation for the thirteen-object base and fifty-two-object total poset independently confirms these Betti numbers. The orbit-category relations printed before this construction also require correction, which is explained separately in the commentary.

The final distinctions and their present interpretation.

The later definitions separate constant-coefficient equivalence, invariance of cohomology with every locally constant coefficient, and full faithfulness or equivalence on the entire category of locally constant objects. The last two are called 1- and 2-complete equivalence. A closed internal-Hom formalism identifies cohomological equivalence with 1-complete equivalence, under the stated compatibility assumptions. It does not identify ordinary constant-coefficient equivalence with either of them. The missing word "cohomological" in the sentence on manuscript page 122 is therefore a material slip.

The nerve-invariance assertions eventually formulated as the b' variants of **Der 3** have a precise later answer. Cisinski (2009, Theorem 1.3 and Corollary 3.8) proves invariance of locally constant coefficients under weak equivalences of indexing nerves, first in the model-category setting and then for derivators. In the space-valued case these coefficients can be read as coherent functors out of the fundamental infinity-groupoid. A weak equivalence changes

neither that groupoid nor its coefficient categories. This establishes the strong form of the lemma about HOT that Grothendieck had deferred; it does not collapse the distinctions for a fixed linear coefficient theory. The minimal-localizer theorem places the ordinary weak-equivalence class inside the broader framework that motivated these pages (Cisinski, 2004, Theorem 2.2.11).

Two developments in the commentary on these pages address unfinished questions directly. First, for a universally weak cohomological fibration, the formula for $f_* f^* F$ holds for every coefficient F on the base, with no local-constancy assumption. A factorization category for each arrow $z \to y$ reduces the left mate of the desired comparison to constant homology. The dual proof applies to $f_! f^* F$. As a consequence, a universal $\mathbb{D}$-equivalence induces fully faithful restriction on the whole coefficient category. The required closure of the diagram domain is stated explicitly. These arguments use the factorization method underlying homotopy exactness (Groth et al., 2014a, Theorem 3.8), and the full-faithfulness conclusion for universal weak equivalences of nerves also follows from the modern homotopical epimorphism criterion (Groth and Šťovíček, 2016, Theorem 6.10).

Second, the intermediate $\mathbb{D}$-fibrations are not closed under composition. Over $\mathbb{Q}$, take the opfibration over [1] with transition $e \to BC_2$ and then the covering determined by the regular C_2-set. Both factors satisfy the universal constant-coefficient condition. Their composite has transition from two discrete points to a contractible action groupoid, and fails already in degree-zero cohomology. The stronger cohomological and homological fibrations on manuscript page 121 control locally constant coefficients on the total category and are closed under composition. A separate example with transition $BC_2 \to e$ shows that this stronger relative theory has examples beyond HOT-fibrations. The proposed 2-complete variant also fails to compose for the represented set-valued derivator: a C_2-valued cocycle on the tetrahedral boundary face poset gives two functors between finite categories whose composite fails the required test. The obstructed restriction includes sets as trivial C_2-sets; its failure of essential surjectivity distinguishes this counterexample from the 1-complete case, which composes under the internal-Hom hypotheses.

The mathematical status is thus stated at the level of the actual assertions. The main cofinality and base-change theorems hold with their conventions and domain hypotheses made explicit; the false implications have concrete counterexamples; several stated questions admit the supplied proofs or the cited later theorems. A failure to locate a particular construction in the sources checked is recorded as such, never converted into a claim that it is an open problem or a new result. The label [ours] marks proofs and constructions given in the commentary; it carries no priority claim.

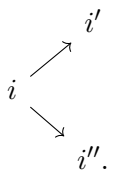
1 Cofinalité cohomologique

p. 1
[1]



Soit

$$\alpha : C' \longrightarrow C$$

un foncteur de (petites) catégories, $\mathcal{M}$ une catégorie ayant les $\varprojlim$ pertinentes, F un préfaisceau (donc contravariant en i) sur C à valeurs dans $\mathcal{M}$. On a un homomorphisme canonique dans $\mathcal{M}$

$$\varprojlim_{C} F \longrightarrow \varprojlim_{C'} \underbrace{\alpha^*(F)}_{F\circ\alpha} \tag{1}$$

et on veut des conditions sur α pour que ce soit toujours un isomorphisme ([1]). On est ramené aussitôt au cas où $\mathcal{M} = (\mathrm{Ens})$. Disons qu'une catégorie I est *faiblement filtrante à gauche* si $I \neq \emptyset$ et si $\forall\, i', i'' \in \mathrm{Ob}\, I$, $\exists\, i \in \mathrm{Ob}\, I$ et des flèches

Cela signifie aussi que $\mathrm{Ob}\, I$ en tant qu'ensemble ordonné est filtrant à gauche.

Commentary · Exposition [ms. 1]

The presheaf represented by a change of index

Grothendieck begins again with ordinary limits because their elementary descent argument already contains the object which the cohomological theory must derive. We keep his variance throughout: a presheaf on C is a functor $C^{\mathrm{op}} \to \mathrm{Set}$, and c/α, also written $c\backslash C'$, has objects $(a, f : c \to \alpha a)$. The arrow in the first proposition is printed in the opposite direction; its intended direction is fixed both by this notation and by the proof on manuscript page 6. This is an edition slip, not a change of convention.

Put $K_\alpha(c) = \pi_0(c/\alpha)$. Precomposition with $c_0 \to c_1$ defines $K_\alpha(c_1) \to K_\alpha(c_0)$, so K_α is a presheaf. There is a natural bijection

$$\varprojlim_{C'^{\mathrm{op}}} \alpha^* F \;\cong\; \mathrm{Nat}(K_\alpha, F).$$

Indeed a compatible family (s_a) determines the map $[a, f] \mapsto F(f)(s_a)$. A morphism $(a, f) \to (b, g)$ in c/α gives $g = \alpha(h)f$, and compatibility gives $s_a = F(\alpha h)(s_b)$; hence the value is constant along every zigzag. Naturality in c follows by composition. Conversely, from $t : K_\alpha \to F$, put $s_a = t_{\alpha a}[a, 1_{\alpha a}]$. For $h : a \to b$, the arrow $(a, 1) \to (b, \alpha h)$ and naturality of t prove compatibility. These constructions are inverse.

Equivalently, $K_\alpha = \alpha_! 1_{C'}$. Thus the restriction map on limits is induced by the augmentation $K_\alpha \to 1_C$. Yoneda, applied in the presheaf category, proves the exact criterion:

$$\text{restriction preserves every presheaf limit} \quad\Longleftrightarrow\quad \pi_0(c/\alpha) = \{*\} \quad (c \in C).$$

The nonempty, connected comma categories are what matter. A common predecessor for each pair of objects is a stronger sufficient condition; it has no equalization requirement. For coefficients in a locally small category $\mathcal{M}$, apply $\mathrm{Hom}_{\mathcal{M}}(M, -)$ for every M. These functors preserve existing limits and jointly reflect isomorphisms, which justifies the reduction to sets without imposing extra completeness on $\mathcal{M}$.

In current covariant terminology, α is a final functor, while α^{op} is initial; the latter is the functor acting on the diagrams whose limits are written here. SGA 4 uses the cofinal terminology followed in the manuscript (Artin et al., 1972, Exposé I, §8.1). Proposition 3.2 below returns to precisely this criterion. We shall use the representing presheaf again there, rather than repeat the elementwise argument.

1. On dit alors que α est *cofinal,* cf. SGA 4, I 8.1, ou 3.3, p. 45.

Proposition. *Pour que* (1) *soit toujours un isomorphisme* (α *'anodin pour* $\varprojlim$ *'), il suffit que pour tout* $x_0 \in \mathrm{Ob}\, C$, *la catégorie* $x_0\backslash C'$ *des couples* (x', u), *avec* $x' \in \mathrm{Ob}\, C'$, $u : \alpha(x') \longrightarrow x$, *soit faiblement filtrante à gauche* ([2], [3]).

Ceci n'implique pas la conclusion plus forte

$$F \underbrace{\xrightarrow{\sim}}_{\text{adj.}} \alpha_* \alpha^* F$$

que le morphisme d'adjonction canonique soit un isomorphisme. Pour qu'il soit ainsi, il suffit que $\forall\, x_0 \in C$, le foncteur $\alpha/x_0 : C'/x_0 \longrightarrow C/x_0$ induit par α soit 'anodin pour les $\varprojlim$ ', ce qui signifie aussi que pour toute flèche $u : x_1 \longrightarrow x_0$ dans C, la catégorie $C'_{\vee u}$ formée des triples (x', ξ, η) avec $x' \in \mathrm{Ob}\, C'$ et $\xi : x_1 \longrightarrow \alpha(x')$, $\eta : \alpha(x') \longrightarrow x_0$ rendant commutatif le diagramme [2] p. 2

$$\begin{array}{ccc} x_1 & \xrightarrow{\quad u \quad} & x_0 \\ & {\scriptstyle\xi}\searrow \quad \nearrow{\scriptstyle\eta} & \\ & \alpha(x'), & \end{array}$$

est faiblement filtrante à gauche.

Plus généralement, considérons

$$\begin{array}{ccc} X' = C' & \xrightarrow{\quad \alpha \quad} & C = X \\ & {\scriptstyle f'}\searrow \quad \swarrow{\scriptstyle f} & \\ & S & \end{array}$$

et posons nous la question quand l'homomorphisme fonctoriel, par rapport à un préfaisceau F variable sur X,

$$f_*(F) \longrightarrow f'_*(\alpha^*(F))$$

est toujours un isomorphisme. (Le cas précédent est celui où $S = X$, $f = \mathrm{id}_X$.) On trouve qu'il suffit que $\forall\, s_0 \in \mathrm{Ob}\, S$, le foncteur

$$\alpha/s_0 : X'/s_0 \longrightarrow X/s_0$$

soit 'anodin pour les $\varprojlim$ ', et pour ceci, il suffit que pour `[tout]` objet (x_0, u_0) de X/s_0 (où

$$f(x_0) \xrightarrow{u_0} s_0)$$

la catégorie $(x_0, u_0)\backslash(X'/s_0)$ soit faiblement filtrante à gauche.

Cette catégorie s'interprète comme celle des triples (x', ξ, u) avec

$$\begin{cases} x' \in \mathrm{Ob}\, C' \\ u : g(x') = f(\alpha(x')) \longrightarrow s_0 \\ \xi : x_0 \longrightarrow \alpha(x') \end{cases}$$ [3]

`[plutôt` $f'(x')$ `au lieu de` $g(x')$`]` de façon à rendre commutatif le diagramme

$$\begin{array}{ccc} f(x_0) & \xrightarrow{\quad u_0 \quad} & s_0 \\ & {\scriptstyle f(\xi)}\searrow \quad \nearrow{\scriptstyle u} & \\ & f(\alpha(x')). & \end{array}$$

Je voudrais dégager des variantes de ces énoncés dans le cadre cohomologique, les foncteurs $\varprojlim$ étant remplacés par des $R\Gamma$ (de préfaisceaux abéliens p.ex. - mais on pense aussi aux 'cas non commutatifs', définis par des dérivateurs notamment.)

2. Cf. amélioration des remarques p. 5.
3. Cf. 3.2, p. 43-44, pour conditions nécessaires et suffisantes de cofinalité.

Si I est une catégorie *ordonnée finie*, la condition `[faiblement]` filtrante à gauche équivaut à l'existence d'un objet initial, ce qui implique que I est contractile. Dans les énoncés précedents, il se pourrait que la bonne philosophie soit de remplacer partout 'faiblement filtrante à gauche' par 'contractile'. Si p.ex. C est la catégorie finale, alors remplacer la condition que C' soit filtrante à gauche, par l'acyclicité. C'est en tous cas en accord avec l'esprit de l'axiome Der_5 (cas où J est la catégorie finale). En effet, dans le cas où $C = e$, la condition que α soit anodin pour les $\varprojlim$ équivaut visiblement à dire que le foncteur $\alpha^* : \mathcal{M} \longrightarrow \underline{\mathrm{Hom}}(C'^o, \mathcal{M})$, associant à tout $F \in \mathcal{M}$ le préfaisceau constant de valeur F sur C', donne un morphisme d'adjonction [4]

$$\varprojlim_e F = F \longrightarrow \alpha_*(\alpha^*(F)) = \varprojlim_{C'} \alpha^* F$$

qui est un isomorphisme. Et l'axiome Der_5 assure qu'il doit en être ainsi si C' est contractile.

Commentary · Exposition [ms. 3]

Why the relative problem has two endpoints

The passage from global sections to a direct image introduces a second endpoint. For $f : X \to S$ and a presheaf F, the pointwise right Kan extension formula is

$$(f_*F)(s) = \lim_{(f/s)^{\mathrm{op}}} F(x), \qquad (f/s) = \{(x, f(x) \to s)\}.$$

This is the ordinary comma-category formula for a Kan extension (Riehl, n.d., Theorem 6.2.1 and Corollary 6.2.9). If $f' = f\alpha$, the comparison at s is restriction along α/s. Its comma category at (x_0, u_0) consists exactly of factorizations

$$f(x_0) \xrightarrow{f(\xi)} f(\alpha a) \xrightarrow{u} s, \qquad uf(\xi) = u_0.$$

Connectedness and nonemptiness of these categories therefore suffice. The weak cofiltering condition written here also suffices, but the phrase "ce qui signifie aussi" on manuscript page 1 should not turn that sufficient condition into a necessary one.

When $S = X$ and $f = 1_X$, the test concerns factorizations of each arrow $x_0 \to x_1$ through αa. It is stronger than the test involving only x_0/α. This is the same distinction already isolated in the commentary on Chapter I, manuscript p. 49 ("The factorization category controls base change"); Proposition 4.1 will identify its ordinary categorical form. Keeping the two endpoints visible prevents an erroneous inference from invariance of global sections to full faithfulness of restriction.

La condition filtrante dans la proposition est d'ailleurs une condition *suffisante* d'anodinité, mais nullement nécessaire. Si p.ex. C est la catégorie finale, alors la condition d'anodinité pour $C' \longrightarrow C$ est simplement que C' soit connexe non vide, i.e. $\pi_0(C') = \{0\}$. (Condition qui visiblement néglige les π_i supérieurs.)

Soit $\boxed{\alpha : X' \longrightarrow X}$ un foncteur de petites catégories. La condition suggérée par la proposition, que les $x_0\backslash X'$ soient contractiles, signifie que α est une hot-équivalence co-stricte, i.e. que $\alpha^o : X'^o \longrightarrow X^o$ est une hot-équivalence 'localement sur X^o', donc aussi globalement. Si α lui-même était une hot-équivalence stricte, au lieu de α^o, alors on aurait par Der_5, [5] que pour $F \in \mathbf{D}(X)$, $F \xrightarrow{\sim} \alpha_*\alpha^*F$ ($\mathbf{D}$ dérivateur à gauche), ce qui est bien plus fort que $\Gamma_{\mathbf{D}}(X, F) \xrightarrow[\sim]{\alpha^*} \Gamma_{\mathbf{D}}(X', \alpha^*F)$. La condition duale implique (si $\mathbf{D}$ `[est un]` dérivateur à droite) $\alpha_!\alpha^*F \xrightarrow{\sim} F$. Mais est-il raisonnable de s'attendre qu'elle implique aussi la condition 'du côté cohomologie, au lieu de l'homologie',

$$\Gamma_{\mathbf{D}}(X, F) \xrightarrow{\sim} \Gamma_{\mathbf{D}}(X', \alpha^*(F)) \quad ?$$

Le premier cas, qui devrait emporter conviction, est celui du dérivateur DerAb, i.e. des catégories dérivées des faisceaux abéliens :

Question. *Soit $\alpha : X' \longrightarrow X$ une* hot-*équivalence co-stricte, F un préfaisceau abélien sur X. A-t-on alors $H^i(X, F) \xrightarrow[\sim]{\alpha^*} H^i(X', \alpha^*(F))$ pour tout $i \in \mathbf{Z}$?*

Si X admet un objet initial $\emptyset$, alors $\emptyset\backslash X' \simeq X'$, donc X' contractile, donc c'est OK pour F constant.

Commentary · Later developments [ms. 5]

Cohomological cofinality and the derived weight

Grothendieck's question about abelian coefficients has an affirmative answer. Its proof can follow the argument he has just discovered, provided that the presheaf K_α is replaced by its chain-level predecessor. We give the argument for a commutative ring k; $k = \mathbb{Z}$ answers the stated question. Write $D(C; k)$ for the derived category of k-module presheaves and use $\mathbf{R}\operatorname{Hom}_{C;k}$ for the *global* derived Hom, valued in $D(k)$.

Derived adjunction gives, naturally in F,

$$\mathbf{R}\Gamma(C', \alpha^* F) \simeq \mathbf{R}\operatorname{Hom}_{C;k}(\mathbf{L}\alpha_! k_{C'}, F).$$

For clarity, this can be constructed without assuming the disputed internal formula on manuscript page 10. Resolve $k_{C'}$ by the augmented simplicial presheaf of free modules whose degree n is

$$P_n = \bigoplus_{a_0 \to \cdots \to a_n} k \operatorname{Hom}_{C'}(-, a_0).$$

At a, its augmented chain complex is the nerve complex of a/C', contracted by its initial object 1_a. Each P_n is projective. Its normalized complex, in nonpositive cohomological degrees, is therefore a projective resolution. Since restriction is exact, $\alpha_!$ takes these projectives to projectives. Evaluating $\alpha_! P_\bullet$ at c gives the free chain complex of c/α. In particular

$$(\mathbf{L}\alpha_! k_{C'})(c) \simeq C_*(N(c/\alpha); k),$$

where a chain degree n is placed in cohomological degree $-n$. The usual formulation using the opposite comma category gives the same complex up to signed reversal.

If every $N(c/\alpha)$ is weakly contractible, its augmented complex is quasi-isomorphic to k. Consequently $\mathbf{L}\alpha_! k_{C'} \to k_C$ is an isomorphism. Applying derived Hom yields the desired comparison in every degree, and indeed for every complex F. This proof needs only k-acyclicity of these nerves; weak contractibility is the uniform condition which works for homotopy types as well. The two conditions must not be confused with mere connectedness. For example, $BG \to e$ is cofinal for ordinary presheaf limits whenever G is a group, but for $G = \mathbb{Z}$ and the constant coefficient $\mathbb{Z}$ one has $H^1(BG; \mathbb{Z}) = \mathbb{Z}$.

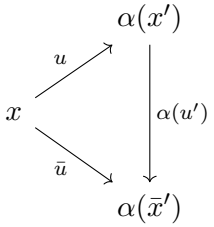
For spaces, the corresponding weight is $c \mapsto B(c/\alpha)$ in $\operatorname{Fun}(C^{\mathrm{op}}, \mathcal{S})$. The same mapping-object adjunction proves cofinality; the general higher categorical criterion is Lurie (2009, Theorem 4.1.3.1, together with Proposition 4.1.1.8), applied with the appropriate opposites. Its corollary 4.1.3.3 is Quillen's Theorem A. These results settle the question on page 5, without requiring the stronger unit or counit assertions in its preceding paragraph. Those assertions are conditional there on the manuscript's invocation of Der_5; interpreted as consequences of comma-category asphericity under present derivator axioms, they are false. The endpoint calculation in the next block makes the distinction explicit, continuing the caution about the changing axioms in the commentary on Chapter I, manuscript p. 43 ("What the localization axioms do and do not say").

Remarque. Je m'aperçois que dans la proposition 1, au lieu de la condition que les $x\backslash C'$ soient faiblement filtrantes à gauche, il suffirait qu'elles soient non vides et connexes, i.e.

0-connexes ([4]). Le fait que les $x\backslash C'$ non vide implique que $\varprojlim_C \longrightarrow \varprojlim_{C'}$ soit *injectif*. Pour p. 4
la sujectivité, si $\xi' \in \varprojlim_{C'}$ (cas ensembliste), on définit $\xi \in \varprojlim_C$ par les $\xi(x) \in F(x)$ à l'aide de [6]

$$x \xrightarrow{u} \alpha(x')$$

4. Cela signifie aussi que α est W_0-coasphérique. Pour un traitement ab ovo, cf. prop. 3.2, page 43.



en prenant $u^*(\xi(x'))$ (où $\xi(x') \in (\alpha^*(F))(x') = F(\alpha(x'))$), le point essentiel est de montrer que les $u^*(\xi(x'))$ ne dépendent que de x, pas du choix de $(x', u) \in x\backslash C'$. Or pour (x', u) variable dans $x\backslash C'$, l'application

$$\begin{array}{rcl} \varphi : \mathrm{Ob}(x\backslash C') & \longrightarrow & F(x) \\ (x', u) & \longmapsto & u^*(\xi(x')) \end{array}$$

est telle que s'il existe une flèche

$$(x', u) \xrightarrow{u'} (\bar{x}', \bar{u}) \qquad \text{où} \qquad u' : x' \longrightarrow \bar{x}'$$

(donc le diagramme

est commutatif), alors $\varphi(x', u) = \varphi(\bar{x}', \bar{u})$. Donc φ est constant sur les composantes connexes de $x\backslash C'$, donc constant si $x\backslash C'$ est 0-connexe, d'où $\xi(x)$. On prouve alors aussitôt que pour x variable,

$$\xi \overset{\text{déf}}{=} (\xi(x))_{x \in \mathrm{Ob}\, C} \simeq \varprojlim F, \qquad \texttt{[plutôt} \in \varprojlim F, \texttt{]}$$

et que $\alpha^*(\xi) = \xi'$, cqfd.

On peut dire que pour $x_0 \in \mathrm{Ob}\, C_0$ fixé, si on regarde le préfaisceau *constant* sur $x_0\backslash C'$ de valeur $F(x_0)$, soit Φ_{x_0}, l'application

$$(x', u) \longmapsto \xi^*(u') : x_0\backslash C' \longrightarrow F(x_0)$$

peut être regardée comme une section de ce préfaisceau sur $x\backslash C'$, défini par $\xi' \in \varprojlim_{C'} \alpha^* F$, donc on a

$$\varprojlim_{C'} \alpha^* F \xrightarrow{c_{x_0}} \Gamma(x_0\backslash C', \Phi_{x_0}) \qquad (\xleftarrow{\sim} F(x_0) \text{ si } x_0\backslash C \text{ 0-connexe}).$$

Si on a $\boxed{x_0 \xrightarrow{v} x_1}$ dans C', on en déduit

$$x_1\backslash C' \xrightarrow{V} x_0\backslash C'$$

(les $x\backslash C'$ sont les fibres d'une *catégorie fibrée* $C\backslash C'$ sur C …) et on a $F(x_1) \longrightarrow F(x_0)$, d'où $\boxed{\Phi_{x_1} \longrightarrow V^*\Phi_{x_0}}$ pour les faisceaux constants correspondants sur $x_0\backslash C'$ resp. $x_1\backslash C'$ et on a commutativité dans

p. 5
[7]

$$\begin{array}{ccc} \varprojlim_{C'} \alpha^* F & \xrightarrow{c_{x_1}} & \Gamma(x_0\backslash C', F(x_0)) \simeq \mathrm{Hom}(\pi_0(x_0\backslash C'), F(x_0)) \\ {\scriptstyle c_{x_0}}\downarrow & & \downarrow{\scriptstyle V^*} \\ \mathrm{Hom}(\pi_0(x_1\backslash C'), F(x_1)) \simeq \Gamma(x_1\backslash C', F(x_1)) & \xrightarrow[(F(x_1)\to F(x_0))]{v^*} & \Gamma(x_1\backslash C', F(x_0)) \simeq \mathrm{Hom}(\pi_0(x_1\backslash C'), F(x_0)) \end{array}$$

$$\begin{array}{ccc} \pi_0(x_1\backslash C') & \xrightarrow{\pi_0(V)} & \pi_0(x_0\backslash C') \\ \vdots & & \vdots \\ F(x_1) & \xrightarrow{F(v)} & F(x_0) \end{array} \qquad \text{commutatif.}$$

On considère le préfaisceau d'ensembles

$$x \longmapsto \pi_0(x\backslash C') \qquad \text{sur } C,$$

appelons-le $\pi_0(C'/C)$, on aura un morphisme canonique

$$\varinjlim_{C'} \alpha^*(F) \xrightarrow{\sim} \mathrm{Hom}_{\substack{\text{préfaisceaux} \\ \text{d'ensembles sur } C}}(\pi_0(C'/C), F),$$

sans doute toujours [un] isomorphisme.

Si on travaille dans la catégorie dérivée des préfaisceaux des k-modules (k un anneau), la formule précédente suggère conjecturalement

$$\mathbf{R}\Gamma(C', \alpha^*F) \simeq \mathbf{R}\underbrace{\mathrm{Hom}}_{\text{Hom internes}}(\underbrace{\mathbf{L}\alpha_!(k_{C'})}_{\substack{\text{homologie} \\ \text{relative de} \\ C' \text{ sur } C}}, F).$$

L'augmentation canonique [8]

$$\mathbf{L}\alpha_!(k_{C'}) \longrightarrow k_C$$

redonne, en prenant les $\mathbf{R}$Hom dans F,

$$\mathbf{R}\Gamma(C, F) \longrightarrow \mathbf{R}\,\mathrm{Hom}(\mathbf{L}\alpha_!(k_{C'}), F) \xleftarrow{\sim} \mathbf{R}\Gamma(C', \alpha^*F)$$

l'homomorphisme canonique de 'contravariance' de la cohomologie.

Si par contre on travaille avec le dérivateur non additif HOT, donc F un 'type d'homotopie relatif' sur C, on doit avoir

$$\mathbf{R}\Gamma_{\mathrm{HOT}}(C', \alpha^*F) \xrightarrow{\sim} \mathbf{R}\Gamma(C\,,\ \underbrace{\mathrm{Hom}}_{\substack{\text{Hom interne} \\ \text{de la catégorie des} \\ \text{types d'homotopie} \\ \text{relatifs sur } C}}(\ \alpha_!\ (\ \underbrace{e_{C'}}_{\substack{\text{objet final} \\ \text{de HOT}(C'), \\ \text{type d'homotopie} \\ \text{relatif final} \\ \text{sur } C'}}\ ),\ F)).$$

Commentary · Examples [ms. 8]

Global adjunction does not identify an internal Hom

The proposed formula is useful because its global version is right. The difficulty begins only when its two sides are compared as objects over C. For presheaves of spaces, the correct equivalence is

$$\mathrm{Map}_{\mathcal{P}(C')}(1, \alpha^*F) \simeq \mathrm{Map}_{\mathcal{P}(C)}(\alpha_!1, F), \qquad \mathcal{P}(C) = \mathrm{Fun}(C^{\mathrm{op}}, \mathcal{S}).$$

Since $\mathcal{P}(C)$ is cartesian closed, the right side is also $\mathbf{R}\Gamma(C, \underline{\mathrm{Hom}}(\alpha_!1, F))$. This proves exactly the globally sectioned formula on page 8. The analogous abelian formula on page 7 takes values in $D(k)$ when "Hom internes" means the k-enriched global Hom. A sheaf-valued internal Hom would require an additional $\mathbf{R}\Gamma(C, -)$.

To see what global sections forget, take $C = [1] = (0 \to 1)$ and $i : e \to C$ with $i(*) = 1$. A presheaf is an arrow $F_1 \to F_0$. Direct calculation of all three adjoints gives

$$i^*F = F_1, \qquad i_!A = (A \xrightarrow{1} A), \qquad i_*A = (A \to *).$$

Here the displayed order is always the restriction map from value at 1 to value at 0. Every c/i is terminal, so i passes even the contractible-comma criterion; $\Gamma(C, F) = F_1$ and the comparison with $\Gamma(e, i^*F)$ is an identity. Nevertheless the unit has component $F_0 \to *$ at 0, and the counit $i_!i^*F \to F$ has component $F_1 \to F_0$ there. Neither is generally invertible.

Moreover, $i_!1 = 1_C$, hence

$$\underline{\mathrm{Hom}}_C(i_!1, F) = F, \qquad i_*i^*F = (F_1 \to *).$$

Taking $F = (\{*\} \to \{0, 1\})$ disproves the internal identification. Applying global sections to both sides gives $\{*\}$, as it should. With $j(*) = 0$ instead, every j/c is terminal, whereas $j_*j^*F = (F_0 \xrightarrow{1} F_0)$;

thus the opposite comma orientation also fails to imply the universal unit assertion. The same examples work in $D(k)$, replacing $*$ by the zero module and choosing an arrow which is not an isomorphism.

The shift argument on page 9 establishes the expected Hom groups once the derived adjunction is available. Recovering an equivalence of enriched Hom objects requires the enriched adjunction itself, or a constructed comparison and a conservativity argument. It is not supplied merely by a bijection on π_0 in the space-valued case. No such extra step is needed for the explicit bar-resolution proof above.

En fait, ces formules sont quasi-tautologiques, si on admet l'existence des foncteurs $\alpha_!$ p. 6
comme adjoints *à gauche* des α^*. Dans le cas abélien, disons, l'isomorphie des H^0 des deux [9]
membres est la formule d'adjonction

$$\mathrm{Hom}_{C'}(k_{C'}, \alpha^* F) \simeq \mathrm{Hom}_C(\alpha_!(k_{C'}), F),$$

d'où l'isomorphie pour les H^i des deux membres, par décalage. De même dans le cas de HOT, l'isomorphie canonique des π_0 des deux membres est la formule d'adjonction. Pour avoir l'isomorphisme plus fin dans $\mathbf{D}(e)$, la catégorie fondamentale du dérivateur envisagé, en termes de Hom internes, on doit admettre l'existence d'objets unité (les k_X dans un cas, les e_X `[plutôt` ε_X`]` dans l'autre), compatibles avec images inverses, de telle façon `[que]` $\mathrm{Hom\,int}(\varepsilon_X, \underbrace{F}_{\in \mathbf{D}_X}) \simeq F$. On aura

$$\Gamma(C', \alpha^* F) \overset{\text{déf}}{=} f'_*(\alpha^*(F)) \simeq f_*(\alpha_* \alpha^*(F)),$$

et la question est donc de donner une interprétation de $\alpha_* \alpha^* F$ comme

$$\alpha_* \alpha^* F \simeq \mathrm{Hom\,int}(\alpha_!(\varepsilon_{C'}), F) \qquad \text{dans } \mathbf{D}(C).$$

Pour ceci, on va écrire

$$\alpha^*(F) \simeq \mathrm{Hom\,int}(\varepsilon_{C'}, F),$$

et la formule doit résulter d'une 'formule d'adjonction interne'

$$? \qquad \boxed{\alpha_*(\mathrm{Hom\,int}_{C'}(G', \alpha^* F)) \simeq \mathrm{Hom\,int}_C(\alpha_! G', F).} \qquad [10]$$

(*Formule d'adjonction 'interne',* pour $\alpha_!$ et α^*, valable en principe pour *tout* $\alpha : C' \longrightarrow C$ dans Diag, tout G' dans $\mathbf{D}(C')$ et tout F dans $\mathbf{D}(C)$.)

Commentary · Exposition [ms. 9]

The projection formula is an extra property

Grothendieck correctly reduces the proposed internal adjunction to a projection formula. What fails is the expectation that every change of indexing category has this property. In a closed symmetric monoidal setting, write $L = \alpha_!$, $R = \alpha^*$ and $U = \alpha_*$. The canonical map supplied by the adjunction $L \dashv R$ has direction

$$L(RG \otimes G') \longrightarrow G \otimes LG'.$$

It is adjoint to $RG \otimes G' \to RG \otimes RLG'$, using the unit and the monoidal structure of R. The arrow printed on page 10 points in the inverse direction; such an inverse is available only after invertibility has been established.

For every H, the adjunctions give

$$\mathrm{Hom}(H, U\underline{\mathrm{Hom}}(G', RF)) \cong \mathrm{Hom}(L(RH \otimes G'), F),$$
$$\mathrm{Hom}(H, \underline{\mathrm{Hom}}(LG', F)) \cong \mathrm{Hom}(H \otimes LG', F).$$

Thus the canonical internal comparison $\underline{\mathrm{Hom}}(LG', F) \to U\underline{\mathrm{Hom}}(G', RF)$ is invertible for all F, G' exactly when the projection maps are invertible for all H, G'. This proves the reduction, and also locates the additional hypothesis precisely.

For cartesian products this property is called Frobenius reciprocity. An essential geometric morphism need not satisfy it. Moreover, Frobenius reciprocity itself is weaker than its validity in every slice, the latter being the condition appropriate to a locally connected geometric morphism. Garner and Streicher (2021, §1) explicitly distinguish these conditions; they also recall the equivalence between Frobenius reciprocity and preservation of exponentials by the right adjoint of an adjunction between cartesian closed categories. These later distinctions explain why existence of both Kan extensions does not settle the question. They should not be replaced by an unrestricted "projection formula for derivators".

Comment prouver cette formule ? En prenant l'opération produit $\otimes$ associé à l'opération Hom int, on est ramené (en prenant les foncteurs contravariants associés) à une formule

$$G \otimes \alpha_! G' \xrightarrow{\sim} \alpha_!(\alpha^* G \otimes G').$$

On trouve par adjonction un homomorphisme canonique, il faut voir s'il est toujours [un] isomorphisme.

Commentary · Development (commentators') [ms. 10]

The exact obstruction for a point inclusion

The walking-arrow example can be sharpened to measure exactly which restriction maps obstruct the projection formula. This makes the question on page 10 concrete even before a general theory of Frobenius adjunctions is introduced.

Point-inclusion criterion. [ours] Let d be an object of a small category C, and let $i : e \to C$ select d. For a set-valued presheaf G, the projection map

$$i_!(i^* G \times A) \longrightarrow G \times i_! A$$

is invertible for every set A if and only if $G(f) : G(d) \to G(c)$ is bijective for every arrow $f : c \to d$. Consequently the formula holds for all G, A if and only if every arrow with codomain d is an isomorphism.

Proof. The left adjoint to evaluation at d is $i_! A = A \times h_d$, where $h_d(c) = C(c, d)$. At c the projection map is

$$A \times G(d) \times C(c,d) \longrightarrow A \times G(c) \times C(c,d), \qquad (a, s, f) \longmapsto (a, G(f)s, f).$$

For $A = 1$ it is a disjoint union, indexed by f, of the maps $G(f)$; it is bijective precisely when each of them is. This also suffices for every A. If every f is invertible, every $G(f)$ is bijective. Conversely, suppose the formula holds for every presheaf. Taking $G = h_z$ gives a bijection $C(d, z) \to C(c, z)$ by precomposition with f, for every z. With $z = c$, obtain $g : d \to c$ such that $gf = 1_c$. With $z = d$, injectivity and $(fg)f = f = 1_d f$ imply $fg = 1_d$. Thus f is invertible. □

This includes the object 1 of [1], where the noninvertible incoming arrow is exactly the obstruction. It also explains why the analogous formula for a group action behaves differently: all indexing arrows are invertible. For a fixed G, local constancy along the arrows entering d is the precise repair; no conclusion about all coefficients follows from connectedness of a comma category.

We checked the pointwise Kan-extension treatment of Riehl (n.d., §6.2) and the Frobenius discussion of Garner and Streicher (2021, §1), and searched for the point-evaluation formulation. We could not find this elementary criterion stated there in this form. It is recorded as our worked continuation of the calculation, with no claim of priority.

p. 7
[11]

Commentary · Context [ms. 10]

Why the argument passes through toposes

The change of subject at the beginning of §2 is part of the cofinality problem. Grothendieck wants conditions on indexing categories which survive passage to categories of coefficients and which force the relevant homotopy types to disappear. A formulation in terms of the presheaf topos can detect all objects over the category, whereas the underlying preorder remembers only whether an arrow exists.

This is a small-scale instance of the program described in Grothendieck (1983, §69, especially the discussion of diagram categories on pp. 1–3 of the excerpt): the derived category of coefficients is accompanied by derived categories of diagrams of every shape. The concern there comes from operations on coherent diagrams which a single triangulated category does not retain. The present calculation asks what changing the shape does to sections and their derived functors. In parallel, Heller (1988, Chapter II, §1; Chapter III, §2) axiomatizes homotopy theories and develops the computation of homotopy Kan extensions. These references explain the setting, not a historical claim that one author's argument was taken from the other.

The additional tensor language on pages 7–10 needs separate structure. Heller's Chapter IV treats tensor and cotensor operations; the preceding projection counterexample shows why that structure cannot be inferred from the mere existence of left and right Kan extensions. We now return to a question for which the ordinary presheaf topos is already sufficient: which part of the filtering conditions is visible in the behavior of its connected objects?

2 Les catégories localement filtrantes sont les catégories localement totalement 0-connexes

Soit $\mathcal{T}$ un topos. On dit que $\mathcal{T}$ est *irréductible* si l'ensemble ordonné $\mathrm{Ouv}(\mathcal{T})$ des sous-objets de $e_{\mathcal{T}}$ a la propriété suivante : a) $\mathrm{Ouv}(\mathcal{T})$ n'est pas réduit à un élément, i.e. $\emptyset_{\mathcal{T}} \longrightarrow e_{\mathcal{T}}$ n'est pas un isomorphisme ($\mathcal{T}$ n'est pas identique à son sous-topos vide). b) Si U', U'' sont deux objets 'non vides', i.e. non initiaux, de $\mathrm{Ouv}(\mathcal{T})$, leur intersection est 'non vide'. Il revient au même pour b) de dire que si $\mathcal{T}'$, $\mathcal{T}''$ sont deux sous-topos fermés distinct de $\mathcal{T}$, alors leur supremum $\mathcal{T}' \cup \mathcal{T}''$ est distinct de $\mathcal{T}$, ou encore que tout ouvert de $\mathcal{T}$ est connexe. On dit que $\mathcal{T}$ est *localement irréductible* si a) $\mathcal{T}$ est localement connexe (i.e. chaque faisceau sur $\mathcal{T}$ est somme de faisceaux 0-connexes), et si b) pour tout faisceau 0-connexe U sur $\mathcal{T}$, le topos induit $\mathcal{T}/U$ est irréductible (i.e. l'ensemble ordonné $\mathrm{Ouv}(U)$ des sous-objets de U a la propriété b) ci-dessus (a) signifie simplement que $U \not\simeq \emptyset_{\mathcal{T}}$, i.e. que U n'est pas objet initial dans $\mathcal{T}^{\wedge}$; ou plus simplement) : tout sous-faisceau d'un faisceau connexe est connexe ([5]) ([6]).

Commentary · Exposition [ms. 11]

Irreducibility of an object and of its support

Grothendieck is distinguishing two ways to forget morphisms. The space $\mathrm{Esp}(X)$ remembers downward-closed sets of objects; the topos $\widehat{X} = \mathrm{Fun}(X^{\mathrm{op}}, \mathrm{Set})$ also remembers every category of elements. The first sees a common predecessor of two objects. The second must see common predecessors compatible with prescribed arrows.

Here an object is *connected* if it has no decomposition into two noninitial disjoint summands; "0-connected" adds noninitiality. Thus the assertion that every subobject of a connected object is connected allows the initial subobject. An object A is irreducible when it is noninitial and any two noninitial subobjects of A meet. Equivalently, every subobject is connected: a disconnected subobject gives two disjoint nonempty subobjects, while disjoint subobjects have a disconnected union. Applied to $A = 1$, this gives the definition of an irreducible topos. Applied to every nonempty connected A, after assuming local connectedness, it gives the local definition.

For $\widehat{X}$, subterminal objects are precisely sieves of objects: if x belongs and $y \to x$ exists, then y belongs. Any two nonempty such sieves meet exactly when each pair of objects has a common predecessor. This proves

$$\widehat{X} \text{ irreducible} \quad \Longleftrightarrow \quad X \neq \varnothing \text{ and } (\forall x, y)(\exists z)(z \to x, z \to y).$$

It is a condition on the associated preorder, not on equalities of arrows. A least class in that preorder need not give an initial object: uniqueness of arrows has been discarded. If the preorder quotient is

5. **NB** Irréductible n'implique pas localement irréductible, pas plus que connexe n'implique pas localement connexe etc.

6. $\mathcal{T}$ est localement irréductible si et seulement s'il a un ensemble des générateurs (U_α), avec les U_α irréductibles (donc 0-connexes, donc $\mathcal{T}$ est localement connexe).

artinian, a minimal class exists, and common lower bounds force it below every other class; this proves the assertion on page 13. Finite principal lower sets suffice as well. "Locally finite" here must have that meaning, as indicated by the finite slices X/x; finiteness of intervals alone would fail, for example for the ordered set $\mathbb{Z}$.

The list of equivalences on pages 12–13 is provisional. Its claim about components being weakly cofiltered is too weak, and its subsequent inclusion of PS 2 is too strong. The annotations and Proposition 2.1 correct these in opposite directions. The surviving characterization is PS 1 alone. We prove it below, retaining the successive formulations as part of the text's development.

Quand $\mathcal{T}$ est de la forme $\mathrm{Top}(T)$, où T est un espace topologique, alors $\mathcal{T}$ irréductible signifie que T est irréductible (car alors $\mathrm{Ouv}(\mathcal{T}) \simeq \mathrm{Ouv}(T)$). Cela implique déjà trivialement que T est localement connexe (tout ouvert est somme disjoint d'ouverts connexes), donc $\mathrm{Top}(\mathcal{T})$ est localement connexe. De plus, cela implique aussi que $\mathrm{Top}(T)$ est localement irréductible ([7]). (**NB** Les objets 0-connexes de $\mathrm{Top}(T)^\wedge$, i.e. les faisceaux d'ensembles 0-connexes sur T, [12] sont ceux dont la 'fibre générique' a exactement un point …) Aussi $\mathcal{T} = \mathrm{Top}(T)$ est localement irréductible si et seulement si T `[est]` localement connexe, et les composantes connexes de T sont irréductibles, i.e. si et seulement si $T = \coprod_i T_i$, les T_i irréductibles.

Commentary · Examples [ms. 12]

The generic fibre without a generic point

The topological case supplies the intuition for the definition, but it also calls for a precise interpretation of "generic fibre". An irreducible space need not possess a generic point. For a sheaf F on a nonempty irreducible space T, define instead

$$\gamma(F) = \operatorname*{colim}_{\varnothing \neq U \subseteq T} F(U),$$

where transition maps are restrictions as U shrinks. Nonempty opens form a filtering system under intersection. If a generic point exists, this is its stalk; otherwise it is the stalk at the corresponding point of the soberification. The following direct argument avoids requiring that point.

For every nonempty open U, a section of $F(U)$ has a well-defined generic germ. Because U is connected, the constant sheaf with value $\gamma(F)$ has sections $\gamma(F)$ on U. We obtain a map $F \to \underline{\gamma(F)}$ and a decomposition

$$F \cong \coprod_{g \in \gamma(F)} F_g$$

into its fibres. Every F_g is noninitial because g has a representative section. If A, B are two noninitial subobjects of F_g, choose sections $a \in A(U)$ and $b \in B(V)$ on nonempty opens. They have the same generic germ, so on some nonempty $W \subseteq U \cap V$ their restrictions agree. This supplies a section of $A \cap B$, proving that F_g is irreducible.

Consequently these fibres are exactly the connected components of F, and F is 0-connected if and only if $\gamma(F)$ is a singleton. This proves both the assertion about the generic fibre and the missing implication in footnote 7: the sheaf topos of an irreducible space is locally irreducible. More generally, if T is a disjoint union of open irreducible spaces, the conclusion follows component by component. Conversely, a locally irreducible sheaf topos is locally connected; its terminal object decomposes into connected subterminal objects, which are disjoint open subsets of T, and each is irreducible. This proves the topological characterization stated here.

For a general presheaf topos, no generic point of the underlying preorder can replace this argument. Parallel arrows produce different objects in slices, even when they have the same source and target. The next example shows exactly where the analogy with topological spaces ceases to suffice.

Si $\mathcal{T}$ est de la forme $\mathrm{Top}(X)$, X une catégorie, on sait que $\mathcal{T}$ est localement connexe (et même localement ∞-connexe). On voit d'autre part que $\mathcal{T}$ est irréductible si et seulement si $\mathrm{Esp}(X)$ (l'espace topologique associé, dont l'ensemble sous-jacent est $\mathrm{Ob}\, X$) est irréductible

7. expliciter la démonstration.

([8]); et on dit alors que X est irréductible ([9]). Comme les composantes connexes de X et celles de $\mathrm{Esp}(X)$ ou $\mathrm{Top}(X) = \mathcal{T}$ se correspondent, on voit donc que les conditions suivantes sont équivalentes : a) le topos $\mathrm{Top}(X)$ est localement irréductible, b) $\mathrm{Esp}(X)$ est localement irréductible, c) les composantes connexes de X sont irréductibles, d) les X/x [sont] irréductibles. On dit alors que X est localement irréductible ([10]). p. 8

Cela implique donc que pour tout X' étale sur X, avec X' 0-connexe, X' est irréductible.

Dire conditions équivalentes.

a) $\mathrm{Top}(X)$ est localement irréductible.

b) Les X/x [sont] irréductibles.

c) Tout objet 0-connexe de $X^\wedge$ est irréductible.

d) Les composantes connexes de X sont faiblement cofiltrantes (i.e. faiblement filtrantes à gauche).

e) Condition PS 1_g de SGA 4, I 2.

Si X est [une] catégorie, X irréductible signifie aussi que $X \neq \emptyset$ et $\forall\, x, y \in \mathrm{Ob}\, X$, [il] existe [un] s avec $s \nearrow x$, $s \searrow y$. (Cela signifie aussi que X est *faiblement filtrante* ([11]) à gauche, ou faiblement cofiltrante.) X localement irreductible signifie que pour x, y *appartenant à une même composante connexe,* [il] existe [un] s avec $s \nearrow x$, $s \searrow y$, i.e. $X/[x] \cap X/[y] \neq \emptyset$ (où $[x]$ est considéré comme élément de l'ensemble ordonné $\mathrm{Ob}\, X$). Il revient encore au même de dire que les catégories induites X/x sont irréductibles ([12]). [13]

Exemple. Une catégorie *ayant un objet initiale,* ou seulement un 'plus petit objet', est irréductible. Inversement, si l'ensemble *ordonné* $\mathrm{Ord}(X)$ associé à X (quotient de $\mathrm{Ob}(X)$ par la relation d'équivalence associé à son préordre) est fini, p.ex. X fini, ou seulement localement fini, p.ex. X localement fini (i.e. les catégories X/x finies), alors si X est irréductible, $\mathrm{Ob}\, X$ a un plus petit élément, i.e. X a un plus petit objet. C'est vrai plus généralement encore, si $\mathrm{Ord}(X)$ est artinien, i.e. toute suite décroissante dans $\mathrm{Ord}(X)$ est stationnaire.

Mais la condition intéressante est la condition topossique de *locale* irréductibilité, qui équivaut : I pseudo-filtrante à gauche, i.e. les composantes connexes de I filtrantes, i.e. les conditions PS 1, PS 2

PS 1 Tout diagramme $x \searrow$, $y \nearrow$ s se complète en $z \nearrow x$, $z \searrow y$, $x \searrow$, $y \nearrow$ s *commutatif.*

PS 2 Pour toute double flèche $x \rightrightarrows y$, [il] existe un égalisateur $z \longrightarrow x \rightrightarrows y$.

En résumé, on a la p. 9

Proposition 2.1. *Soit X un objet de* Cat. *Conditions équivalentes :* [14]

---

8. car les ouverts de $\mathrm{Top}(X)$, ceux de $\mathrm{Esp}(X)$ et ceux de X se correspondent.

9. Cela signifie aussi que pour x, y dans X, $\exists\, z$ avec $z \nearrow x$, $z \searrow y$, i.e. $\mathrm{Ord}(X)$ est filtrant à gauche.

10. Faux, on a (a $\iff$ d) $\implies$ (b $\iff$ c) X irréductible n'implique *pas* que les X/x le soient, exemple $X = (0 \overset{\alpha}{\underset{\beta}{\rightrightarrows}} 1)$ $(\alpha \neq \beta)$, on a $X/1 = 0' \searrow$, $0'' \nearrow 1$, qui n'est *pas* irréductible, ni localement irréductible puisqu'il est connexe. Pourtant il est étale sur X.

11. Il est mieux l'appeler *pseudo-filtrante,* et réservons faiblement filtrante à : localement faiblement filtrante + connexe.

12. faux, cf. annotation marginale plus haut.

a) *Le topos associé* $\mathrm{Top}(X)$ *est localement irréductible, i.e. (étant localement connexe) pour tout objet* F *de* $X^\wedge$ *et tout sous-objet* F' *de* F*, si* F *est connexe,* F' *l'est.*

a′) *Pour tout* X' *étale sur* X*, si* X' *est connexe, tout ouvert de* X' *est connexe.*

a″) *Tout ouvert d'une catégorie localisée* X/a *(*$a \in \mathrm{Ob}\, X$*) est connexe (i.e.* X/a *est une catégorie irréductible, i.e. le topos* $\mathrm{Top}(X/a)$ *l'est).*

b) *Pour tout objet* a *de* X*,* $\mathrm{Esp}(X/a)$ *est un espace topologique irréductible.*

c) *Les catégories* X/a *sont faiblement filtrantes à gauche (ou faiblement cofiltrantes), i.e. pour deux objets* ξ*,* η *d'une telle catégorie,* `[il]` *existe un objet* ζ *et deux flèches*

$$\begin{array}{ccc} & & \xi \\ & \nearrow & \\ \zeta & & \end{array} \qquad \begin{array}{ccc} & & \\ & \searrow & \\ & & \eta \end{array}$$

(i.e. l'ensemble ordonné Ord(X/a*) associé à* X/a *est filtrant à gauche)*

c′) *Pour tout diagramme en traits pleins dans* X*,* $\begin{array}{ccccc} & & x & & \\ & \cdots\nearrow & & \searrow & \\ z & & & & s \\ & \cdots\searrow & & \nearrow & \\ & & y & & \end{array}$ *, on peut le compléter en un carré* commutatif *comme indiqué. (Condition* PS 1 *des catégories localement filtrantes.)*

Ces conditions impliquent que toute composante connexe X_α de X est irréductible, ou ce qui revient au même, que $\mathrm{Esp}(X_\alpha)$ est irréductible,
mais ne sont pas impliquées par celle-ci. [15]

Contrexemple, la catégorie 0-connexe $0 \underset{\beta}{\overset{\alpha}{\rightrightarrows}} 1$, avec $\alpha \neq \beta$. On a $X/1 \simeq \begin{array}{ccc} 0 & & \\ & \searrow & \\ & & 1 \\ & \nearrow & \\ 0' & & \end{array}$, qui n'est *pas* irréductible, puisque $\Phi\backslash\{1\} \simeq \varepsilon$ est un ouvert disconnexe `[`$\Phi = X/1$`,` $\varepsilon = \bullet\ \bullet$`]`.

J'aimerais une condition 'topossique' sur X, équivalente à X 'pseudo-filtrante à gauche', i.e. les composantes connexes filtrantes, i.e. PS 1^{opp} (condition c′) ci-dessus) + PS 2^{opp} (condition de la double flèche), et qui de plus implique que tout objet 0-connexe de $X^\wedge$ (i.e. tout objet X' de Cat étale sur X et 0-connexe) soit W_∞-asphérique. Et je songe à la notion de 'totale asphéricité' de Pursuing Stacks.

Commentary · Exposition [ms. 15]

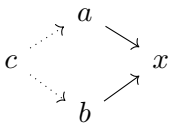
Completing Proposition 2.1

Proposition 2.1 isolates the part of filtering which can be expressed without equalizing parallel arrows. We give its proof because it explains both the corrected statement and the mechanism which will later be strengthened.

Recall that PS 1 says that every cospan $a \to x \leftarrow b$ admits a commuting square with some upper-left object c; no universal property is requested. Suppose PS 1 holds. In any category with this property, the relation "a and b have a common predecessor" is reflexive and symmetric. It is transitive: given $a \leftarrow r \to b$ and $b \leftarrow s \to d$, apply PS 1 to $r \to b \leftarrow s$ and compose the resulting arrows. Every arrow connects objects related in this sense. Hence any two objects in the same connected component have a common predecessor.

For a presheaf F, its category of elements $E = \int_X F \to X$ is a discrete fibration, the meaning of "étale" here. Every arrow into the image of an object has a unique lift into that object. Thus a PS 1 square in X lifts to a PS 1 square in E: the two lifts into the common target agree by uniqueness. Therefore E also satisfies PS 1. Components of E correspond to coproduct components of F. If F is 0-connected, E is nonempty and connected, so the previous paragraph gives common predecessors for every pair of its objects. Subobjects of F correspond to sieves in E; any two nonempty such sieves meet. Thus F is irreducible, and $\widehat{X}$ is locally irreducible.

Conversely, suppose every 0-connected presheaf is irreducible. The representable h_x is 0-connected, since its category of elements X/x has a terminal object. Given arrows $a \to x$ and $b \to x$,



their generated subobjects of h_x are noninitial. Their intersection is noninitial, so it contains some element represented by arrows $c \to a$ and $c \to b$ with equal composite to x. This is PS 1. The descriptions using X/x, its associated space, and open subcategories are equivalent by the preceding sieve argument. This proves all the equivalences of Proposition 2.1.

The counterexample is the category with two objects and distinct arrows $\alpha, \beta : 0 \rightrightarrows 1$. Its objects have the common predecessor 0, so its underlying preorder is the irreducible two-point chain. But in $X/1$, the objects $(0, \alpha)$ and $(0, \beta)$ have no common predecessor: the only endomorphism of 0 is its identity. Their two singleton lower sets are disjoint nonempty subobjects of h_1. Thus $\widehat{X}$ is not locally irreducible. The mistaken converse on page 16 is precisely the assertion that the preorder remembers this equality of composites; the footnotes already retract it.

Définition 2.2. ([13]) Soit X une catégorie.

a) On dit que X est *faiblement filtrante* ([14]) si $X \neq \emptyset$, et si pour $a, b \in \operatorname{Ob} X$, $\exists\, c$ et des flèches $c \to a$, $c \to b$, i.e. $X/[a] \cap X/[b] \neq \emptyset$. (**NB** X est faiblement filtrante ([15]) à gauche si et seulement si $\operatorname{Ord}(X)$ l'est, i.e. est filtrante à gauche. **ReNB** X faiblement filtrante $\Longrightarrow$ X 0-connexe.)

b) On dit que X est *localement faiblement filtrante à gauche* ou plus simplement préfiltrante à gauche si les catégories X/x ($x \in \operatorname{Ob} X$) sont faiblement filtrantes à gauche, i.e. si X satisfait la condition : $\forall$ diagrammes $a \to x \leftarrow b$, $\exists\, c$ dans X et des flèches de c dans a, b rendant *commutatif* le carré

([16]). (**NB** Cette condition implique que $\operatorname{Ord}(X)$ est localement faiblement filtrant, mais n'équivaut pas à cette dernière. Exemple, $X = 0 \overset{\alpha}{\underset{\beta}{\rightrightarrows}} 1$, $X/1 = 0' \to 1 \leftarrow 0''$ n'est pas faiblement filtrante à gauche.)

p. 10

[16]

NB Si X localement faiblement filtrante à gauche, tout X' étale sur X itou.

NB ([17]) X localement faiblement filtrante à gauche $\Longleftrightarrow$ les composantes connexes sont faiblement filtrantes à gauche, ou encore si X est 0-connexe, X localement faiblement filtrante à gauche $\Longleftrightarrow$ X est faiblement filtrante ([18]) à gauche. On a en effet $\Longleftarrow$ tautologiquement ([19]), et $\Longrightarrow$ en montrant que si PS 1 `[est]` satisfait, alors $PS(a, b)$

13. Cf. tableau récapitulatif pages 97, 98 et surtout 99.
14. dire plutôt *pseudo-filtrante*, réserver 'faiblement filtrante' à 'localement faiblement filtrante' (ou *irréductible*) + connexe, condition PS $1'_{\mathrm{g}}$.
15. pseudo-filtrante.
16. Condition PS 1_{g}.
17. **Faux.**
18. pseudo-filtrante.
19. **faux,** ainsi $0 \overset{\alpha}{\underset{\beta}{\rightrightarrows}} 1$ est 0-connexe et faiblement filtrante à gauche, mais non pas localement faiblement filtrante à gauche car $0 \xrightarrow{\alpha} 1 \xleftarrow{\beta} 0$ ne se complète pas en un carré *commutatif.*

défini par $X/[a] \cap X/[b] \neq \emptyset$ est une relation d'équivalence, impliquée par la relation $C(a,b) : \{\mathrm{Hom}(a,b) \neq \emptyset$ *ou* $\mathrm{Hom}(b,a) \neq \emptyset\}$, donc la relation d'équivalence (homotopie) engendrée par $C(a,b)$ est plus fine que $PS(a,b)$.

c) On dit que X est *filtrante à gauche*, ou *cofiltrante,* si elle est faiblement filtrante ([20]) à gauche (donc *non vide*), et satisfait (en plus de la condition PS $1'_{\mathrm{g}}$ de a)) la condition PS 2_{g} suivante :

Pour toute double flèche $a \overset{u}{\underset{v}{\rightrightarrows}} b$, `[il]` existe `[une]` flèche $c \xrightarrow{w} a$ telle que $uw = vw$ ([21]).

Il revient au même de dire que X satisfait les trois conditions a′) X est 0-connexe (plus forte que $X \neq \emptyset$), b′) PS 1, i.e. X localement faiblement filtrante à gauche et c′) PS 2 comme avant.

d) On dit que X est *localement filtrante à gauche* si les composantes connexes sont filtrantes à gauche, i.e. si X satisfait les conditions PS 1 et PS 2 ('pseudo-cofiltrante' dans la terminologie de SGA 4). **NB** Si X est localement filtrante à gauche, il en est de même de tout X' étale sur X, car c'est évident pour PS 1 qui concerne les X/x, et pour PS 2 cela résulte du fait que $X' \longrightarrow X$ est fidèle. Donc si X est localement cofiltrante, les X/a sont filtrantes, mais la réciproque est fausse.

Commentary · Examples [ms. 16]

The equalization condition survives beyond every slice

The definitions now separate PS 1 from the additional condition PS 2. In the latter, "égalisateur" means an *equalizing arrow*: for $u, v : a \rightrightarrows b$ there is $w : c \to a$ with $uw = vw$. It does not mean that a categorical equalizer exists. This is the usual cofiltered condition, dual to SGA 4's PS 2 (Artin et al., 1972, Exposé I, §2.7).

To see why all slices can be cofiltered without the original category being locally cofiltered, take the one-object category BG for a nontrivial group G. It satisfies PS 1: a pair f, g can be completed by 1 and $g^{-1}f$. For its unique object $*$, the slice $BG/*$ has objects $g \in G$ and exactly one arrow from g to h, namely $h^{-1}g$. It is equivalent to the terminal category and is cofiltered. Yet distinct $u, v \in G$ cannot be equalized on the right, since $uw = vw$ and invertibility of w imply $u = v$. Hence BG fails PS 2.

This example also makes the topos distinction visible. Every connected G-set is transitive and therefore irreducible, so the presheaf topos is locally irreducible. Products of connected objects need not remain connected: for the regular right G-set, the diagonal right action on $G \times G$ has one orbit for each value of hg^{-1}. The product condition introduced next detects the missing equalization information. No defect in Proposition 2.1 is involved; its purpose was exactly to isolate PS 1.

On a les notions duales : *faiblement filtrante à droite* (ou simplement faiblement filtrante), et *filtrante à droite* ou simplement filtrante. (Notions duales de a), c) ci-dessus.) Pour la notion duale de b), savoir que les $x\backslash X$ soient faiblement filtrantes, on ne peut plus l'appeler 'localement faiblement filtrante', mais ce serait *co*localement faiblement filtrante. p. 11

Exemple. $X = \left(0 \xrightarrow{\gamma} 1 \overset{\alpha'}{\underset{\beta'}{\rightrightarrows}} 2 \overset{\alpha}{\underset{\beta}{\rightrightarrows}} 3\right)$ avec $(\alpha\alpha' = \beta\beta') \neq (\alpha\beta' = \beta\alpha')$.

Commentary · Development (commentators') [ms. 16]

The finite example and its homotopy type

The example between Definition 2.2 and Proposition 2.3 makes the loss of information in $\mathrm{Ord}(X)$ concrete. We read the displayed graph and its two relations as a presentation of X; in particular, no additional relation is imposed on composites with γ. Put

$$r = \alpha\alpha' = \beta\beta', \qquad s = \alpha\beta' = \beta\alpha', \qquad r \neq s.$$

20. pseudo-filtrante.

21. i.e. trois conditions a) $X \neq \emptyset$ b) PS 1′ habituelle c) PS 2 (double flèche).

Then $\mathrm{Ord}(X)$ is the chain $0 < 1 < 2 < 3$. Every pair of objects has both a common predecessor and a common successor. Nevertheless, 0 is not initial: the arrows $\alpha'\gamma, \beta'\gamma : 0 \rightrightarrows 2$ are distinct. Likewise, 3 is not terminal, since $r, s : 1 \rightrightarrows 3$ are distinct.

The same calculation locates the exact failure of PS 1. A commuting square for the cospan $1 \xrightarrow{\alpha'} 2 \xleftarrow{\beta'} 1$ would require two arrows from an object into 1. Their common source can only be 1 or 0, and both arrows would be respectively 1_1 or γ. Neither choice makes the square commute. Thus the left PS 1 fails, and the pair α', β' also has no equalizing arrow on the left. Dually, a commuting cocone over $3 \xleftarrow{\alpha} 2 \xrightarrow{\beta} 3$ can only use identity arrows out of 3, so the right PS 1 fails; the pair α, β cannot be equalized on the right either. The category is consequently neither locally cofiltered nor locally filtered, although its associated poset satisfies both conditions. This is the point of the paragraph immediately following the example.

The crossed composition relations also admit a useful homotopical interpretation which the manuscript does not develop.

The homotopy type of the finite example. [ours] *For the category presented above, $|NX| \simeq \mathbb{R}P^2$. In particular, its contractible reachability poset does not determine even the fundamental group of its nerve.*

Proof. Let C be the full subcategory on $1, 2, 3$. The functor $q : X \to C$ sends 0 to 1, sends γ to 1_1, and fixes the remaining generators. It respects the defining relations. For the inclusion $j : C \hookrightarrow X$, one has $qj = 1_C$ and a natural transformation $1_X \to jq$ whose component at 0 is γ and whose other components are identities. The resulting homotopy of nerves fixes NC, so $|NX| \simeq |NC|$.

Identify each set $C(i, j)$, for $1 \le i < j \le 3$, with $\mathbf{Z}/2$: label α', α, r by 0 and β', β, s by 1. The two displayed relations say exactly that composition adds these labels. Let P be the poset with objects (i, ε), where $i \in \{1, 2, 3\}$ and $\varepsilon \in \mathbf{Z}/2$, with $(i, \varepsilon) < (j, \delta)$ precisely when $i < j$. Its involution changes every ε to $\varepsilon + 1$. There is an invariant functor $P \to C$ sending (i, ε) to i and an arrow to the label $\delta - \varepsilon$. A chain of arrows in C lifts uniquely after choosing the lift of its first vertex, and the two choices are exchanged by the involution. This proves, degree by degree and compatibly with faces and degeneracies,

$$NP/(\mathbf{Z}/2) \simeq NC.$$

The order complex of P is the join of three two-point sets. Sending their vertices to $\{\pm e_1, \pm e_2, \pm e_3\}$ identifies it with the boundary of the octahedron. Radial projection identifies its realization with S^2, and the involution with the antipodal map. Realization commutes with the quotient, giving

$$|NC| \simeq |NP|/(\mathbf{Z}/2) \cong S^2/(x \sim -x) = \mathbb{R}P^2.$$

Since the sphere is simply connected, this double covering also gives $\pi_1(|NX|) \cong \mathbf{Z}/2$. □

The join and antipodal descriptions are classical (Hatcher, 2002, p. 9 and Example 1.43). Our addition is their explicit identification with this particular presentation. The bounded literature searches did not locate that identification; the result is marked as our calculation, without a claim of priority.

[17] Seule la notion a) (faiblement filtrante ([22]) à gauche) ne dépend que de $\mathrm{Ord}\, X$ - mais bien sûr si X est *pré*ordonnée, toutes trois ne dépendent que de $\mathrm{Ord}\, X$. Notons que dire que ça ne dépend que de $\mathrm{Ord}\, X$, ou que de $\mathrm{Esp}\, \mathrm{sep} X$, revient au même, puisque les deux se déterminent mutuellement. La condition a) signifie que $\mathrm{Esp}\, X$, ou aussi $\mathrm{Top}(X)$, est *irréductible.* On dira que X est *irréductible* (au lieu de pseudo-filtrante). Les trois autres notions ne peuvent s'exprimer en termes de $\mathrm{Esp}\, X$ ou de $\mathrm{Ord}\, X$ seul, mais elles s'expriment en termes du $\mathrm{Topos}\, X$. La condition b) (X localement faiblement filtrante) signifie que $\mathrm{Top}(X)$ est *localement irréductible,* et on dira aussi que X est *localement irréductible* (au lieu de localement faiblement filtrante). Ça signifie que pour tout X' étale sur X et 0-connexe, X' est faiblement filtrante à gauche, i.e. est irréductible.

Reste à exprimer la condition filtrante elle-même en termes de $\mathrm{Top}\, X$. Je rappelle à ce propos :

22. pseudo-filtrant.

Commentary · Exposition [ms. 17]

Products of connected objects

Grothendieck now asks for a condition on the topos which remembers the equalization of parallel arrows. Irreducibility alone cannot do this: it records whether two subobjects meet, whereas equalization concerns two maps with the same source. Proposition 2.3 first isolates the intermediate condition that the component functor preserve products. Throughout the following topos discussion, "connected object" means noninitial and connected, that is, 0-connected; the topos is locally connected. Thus every object is the coproduct of its connected components, and π_0 is left adjoint to the constant-object functor.

Write $\mathcal{E}$ for the category of objects of the topos and let S be the full generating subcategory of connected objects used in the text. The precise statement of 2.3(b) is

$$\pi_0(V \times U) \longrightarrow \pi_0(V) \quad \text{is bijective whenever } U \text{ is connected.}$$

The edition prints $\pi_0(U)$ on the right, although the displayed projection has target V. This is a slip of the edition, retained in the source. Condition (a) implies (c) by decomposing U and V into connected components: products distribute over coproducts in a topos, and each resulting product is connected. Conversely, (c) applied to connected objects gives (a); the same decomposition proves the equivalence with (b).

The reduction to generators deserves the proof which the footnote requests. For $F \in \mathcal{E}$, let S/F have objects $s \to F$, with $s \in S$. The canonical presentation

$$F \simeq \operatorname*{colim}_{(s \to F) \in S/F} s$$

holds in $\mathcal{E}$; it is the density presentation for the canonical site of generators. Applying π_0 gives $\pi_0(F) \simeq \pi_0(S/F)$, since every s is connected. If $s \times t$ is connected for every $s, t \in S$, separate preservation of colimits by products gives

$$\pi_0(F \times G) \simeq \operatorname*{colim}_{S/F \times S/G} \{*\} \simeq \pi_0(S/F) \times \pi_0(S/G).$$

This proves (d)⇒(c). Equivalently, one may use the clopen-partition argument in our block on Lemma 2.9 below; this avoids any choice of a presentation.

Applying (c) to the terminal object shows that the diagonal of $\pi_0(1)$ is a bijection onto its square. Consequently $\pi_0(1)$ has at most one element. The nondegenerate case has exactly one, which explains the separate nonemptiness clause in Definition 2.4. Nothing in this argument annihilates higher homotopy groups. The inference to W_∞-asphericity immediately following 2.3 is explicitly withdrawn in the manuscript's annotation; the stronger hereditary hypothesis introduced in 2.6 is what will support the cohomological argument.

Proposition 2.3. *Les conditions suivantes sur un topos $\mathcal{X}$ sont équivalentes (quand S (comme 'site') désigne une partie génératrice de* $\mathrm{Fais}(\mathcal{X}) = S^\wedge$, formée d'objets 0-connexes ([23])*.)*

a) Si U, V sont deux objets 0-connexes de $\mathrm{Ob}\,\mathcal{X}$*, $U \times V$ est 0-connexe.*

b) Si U est un objet 0-connexe de $\mathcal{X}^\wedge$, alors $U \longrightarrow e$ est 'W₀-asphérique', i.e. pour tout V, la projection $V \times U \longrightarrow V$ induit $\pi_0(U \times V) \xrightarrow{\sim} \pi_0(U)$.

c) Si U, V `[sont]` *dans $\mathcal{X}^\wedge$, alors*

$$\pi_0(U \times V) \xrightarrow{\sim} \pi_0(U) \times \pi_0(V).$$

d) Comme a), avec U, V dans S. (Mais on suppose les objets de S 0-connexes.)

([24]).

De plus, ces conditions impliquent que $\mathcal{X}$ est connexe, donc 0-connexe si $\mathcal{X} \neq \emptyset$. Cela implique [18] de plus que $\mathcal{X}$ est W_∞-asphérique, cf. Pursuing Stacks §35 (Corollary p. 52) ([25]).

23. donc $\mathcal{X}$ est localement 0-connexe.
24. Il faudrait expliciter la démonstation avec celle de 2.9 ci-dessous (p. 25).
25. **Faux,** loc. cit. ne dit rien de tel.

C'est essentiellement Proposition 1 de Pursuing Stacks §65, cf. loc. cit. p. 170-171 ([26]). Cf. aussi Pursuing Stacks, §35, pages 50-55.

p. 12

Définition 2.4. On dit que $\mathcal{X}$ est *totalement* 0*-connexe* s'il est localement connexe, non vide et satisfait les conditions équivalentes de 2.3. (NB c'est un cas particulier de la notion 'totalement W-asphérique' de loc. cit. On a ainsi la notion de totalement n-connexe.)

Notons que pour un objet X de Cat, dire que $\mathrm{Top}(X)$ est totalement 0-connexe revient à dire que $X \neq \emptyset$, et que pour $x, y \in \mathrm{Ob}\, X$, $x \times y$ dans $X^\wedge$ est 0-connexe, i.e. $X/x \times y$ est 0-connexe ([27]). C'est une condition très forte. On dira aussi que X est *totalement* 0*-connexe.* Notons ici

Commentary · Later developments [ms. 18]

The ordinary sifted condition and its variance

The product condition has acquired a useful name, provided that we keep track of the opposite category. For $\widehat{X} = \mathrm{Fun}(X^{\mathrm{op}}, \mathbf{Set})$, the left adjoint to the constant-presheaf functor is

$$\pi_0(F) = \operatorname*{colim}_{X^{\mathrm{op}}} F = \pi_0(X/F).$$

Thus $\widehat{X}$ is totally 0-connected precisely when X^{op} is *sifted*: its colimits in sets commute with finite products. In the ordinary categorical characterization, the indexing category is nonempty and its diagonal is final. For the conventions of these pages, this says that $X \to X \times X$ is co-cofinal. The comma category at (x, y) consists of common cones $z \to x$, $z \to y$, and is exactly $X/(h_x \times h_y)$.

This characterization also explains why binary products suffice. Repeated use of finality of the diagonal gives finality of every finite nonempty diagonal; nonemptiness handles the nullary product. The terminology and its relation to algebraic theories are developed by Adámek et al. (2010). The distinction from filteredness is structural: filtered colimits preserve finite limits, while sifted colimits are required to preserve finite products. Equalizers are precisely the operation absent from the latter requirement.

There is a corresponding distinction in higher category theory, but one must not transfer a statement by changing its vocabulary alone. In the higher version the relevant comma objects must be weakly contractible, rather than merely nonempty and connected. The characterization of filtered colimits by preservation of finite limits in spaces is Lurie (2009, Proposition 5.3.3.3); sifted colimits and geometric realizations are treated in his §5.5.8. Our present identification concerns *ordinary* set-valued colimits. The higher homotopy obstruction which survives it is exhibited later in the commentary on 2.19–2.20.

Proposition 2.5. *Soit $\mathcal{X}$ un topos. Si $\mathcal{X}$ est totalement* 0*-connexe, alors $\mathcal{X}$ est irréductible. (En fait la conclusion vaut, tautologiquement, en supposant seulement que le produit de deux objets* 0*-connexes de $\mathcal{X}^\wedge$ est non vide, et il suffit même de le supposer pour des sous-objets de l'objet final $e_{\mathcal{X}}$.) En particulier, si $\mathcal{X} = Top(X)$, où X est dans* Cat*, alors X est faiblement filtrante à gauche.*

Mais bien sûr, cela n'implique *pas* que $\mathcal{X}$ soit localement irréductible.

[19]

Par exemple la catégorie $\mathbf{\Delta}$, ou toute petite catégorie stable par produits binaires, est totalement 0-connexe, mais $\mathbf{\Delta}$ n'est pas localement irréductible (les catégories induites $\mathbf{\Delta}/\mathbf{\Delta}^n$, pour $n > 0$, ne sont visiblement *pas* irréductibles). (Mais rappelons que si $\mathcal{X} = \mathrm{Top}(T)$, T un espace topologique, alors T irréductible implique que $\mathcal{X}$ est aussi *localement* irréductible. Donc T totalement 0-connexe implique $\mathrm{Top}(T)$ globalement *et* localement irréductible, i.e. pour tout T' étale sur T, et 0-connexe, T' est irréductible.)

26. Mais je m'y borne aux topos de la forme $\mathrm{Top}(A)$, avec A dans Cat.

27. Cela signifie aussi que $\mathrm{diag}_X : X \longrightarrow X \times X$ est co-cofinale, i.e. $X^o \longrightarrow X^o \times X^o$ est cofinale, et implique qu'il en est de même de $X \longrightarrow X^E$ pour tout ensemble *fini* E.

Commentary · Examples [ms. 19]

The simplex category separates the two conditions

Grothendieck's example shows exactly where a global product condition loses the information needed locally. We spell it out because the word "visibly" hides two different computations. Let Δ have the nonempty finite ordinals $[n] = \{0, \dots, n\}$ and monotone maps. For any small category X with binary products, the product of two representables is representable; its category of elements has a terminal object. Such a nonempty X is therefore totally 0-connected. The separate assertion about Δ does not say that Δ has binary products: the ordered square $[1] \times [1]$ is not an ordinal.

For Δ, the product $h_{[m]} \times h_{[n]}$ is the simplicial set $\Delta^m \times \Delta^n$. Its vertices are the pairs (i, j). An edge joins (i, j) to $(i + 1, j)$ whenever the latter exists, and similarly joins (i, j) to $(i, j + 1)$. Hence its vertex graph is connected. Every simplex is joined in its category of elements to each of its vertices by a face map. The category of elements is consequently nonempty and connected, which verifies the generator test of 2.3 for all m, n.

Local irreducibility fails already over [1]. In $\Delta/[1]$, consider the two objects $[0] \xrightarrow{0} [1]$ and $[0] \xrightarrow{1} [1]$. A common predecessor would be a nonempty ordinal $[r]$ mapping to both copies of [0], with equal composites to [1]. Those composites are respectively constant at 0 and 1, so equality is impossible. The two principal sieves have empty intersection. In particular, $\Delta/[1]$ is not irreducible, and Δ is not cofiltered. Equivalently, the parallel vertex maps $[0] \rightrightarrows [1]$ admit no equalizing map into [0].

This example gives an explicit positive answer to the request in footnote 31: total 0-connectedness does not imply local irreducibility. Its opposite also supplies an ordinary sifted category which is not filtered. Neither conclusion requires an argument about derived limits.

Théorème 2.6. *Soit $\mathcal{X}$ un topos localement connexe, $S \subseteq \mathcal{X}^\wedge$ une petite partie génératrice formée d'objets* 0*-connexes. Conditions équivalentes (*sauf *c, c′, qui semblent* ([28]) *plus faibles, cf. démonstration).)*

a) Tout topos induit $\mathcal{X}/U$ sur U 0*-connexe dans $\mathcal{X}^\wedge$ est totalement* 0*-connexe.*

a′) Tout produit fibré $U \times_W V$ d'objets 0*-connexes dans $\mathcal{X}^\wedge$ est* 0*-connexe.*

b) $\mathcal{X}$ est localement irréductible, et ses composantes connexes sont totalement 0*-connexes.*

c) Comme a), avec U dans S, i.e. les $\mathcal{X}/U$ ($U \in \mathrm{Ob}\, S$) sont totalement 0*-connexes.*

c′) Comme a′), avec U, V, W dans S.

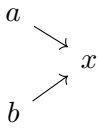
d) S est localement filtrante à gauche, i.e. S satisfait les deux conditions

PS* 1 *Tout diagramme* $\begin{array}{ccc} a & & \\ & \searrow & \\ & & x \\ & \nearrow & \\ b & & \end{array}$ *dans S s'insère dans* $\begin{array}{ccc} & a & \\ c & \swarrow\!\searrow & x \\ & b & \end{array}$ *commutatif.*

PS* 2 *Tout diagramme $a \rightrightarrows b$ s'insère dans un diagramme commutatif $c \longrightarrow a \rightrightarrows b$.*

([29]).

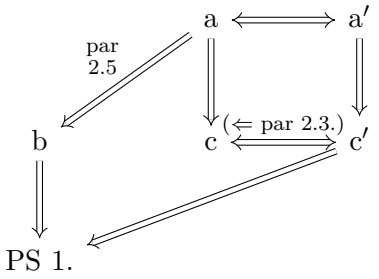
Ces conditions impliquent que les objets 0-connexes de $\mathcal{X}^\wedge$ (en particulier les éléments de S) sont ∞-connexes. p. 13 [20]



Corollaire 2.7 (de l'équivalence b $\iff$ d). *Soit X un objet de* Cat. *Pour que X soit filtrant à gauche il faut et il suffit que $Top(X)$ soit totalement* 0*-connexe et localement (et donc aussi globalement) irréductible (ou encore que X soit totalement* 0*-connexe et que pour tout $x \in \mathrm{Ob}\, X$, la catégorie localisée X/x soit irréductible (elle est même totalement* 0*-connexe),*

28. **sont.**

29. NB On a équivalence de (a), a′), b), d),) qui impliquent c), c′), lesquels sont équivalents. Mais il semble ([30]) que c), c′) soient strictement plus faible. Cf. cependant les variantes e), e′) dans 2.12 (p. 28, 29).



30. Il s'avère. C'est bien vrai, c) et c′) n'impliquent *pas* les autres conditions, cf. annotation marginale p. 28 (cas de $X = B_G$).

ou encore que pour deux objets a, b dans X, $a \times b \in X^\wedge$ soit 0*-connexe, et pour*

dans X, $a \times_x b$ (dans $X^\wedge$) soit 0*-connexe)* ([31]).

Démonstration de 2.6. On a le diagramme d'implications ± tautologiques

Montrons quand même les deux implications c′) $\Longrightarrow$ PS 1 et b $\Longrightarrow$ PS 1.

Commentary · Exposition [ms. 20]

What the hereditary condition adds

Theorem 2.6 makes the product condition stable under passage to a connected object as base. Its surviving equivalence is

$$(a) \iff (a') \iff (b) \iff (d), \qquad (c) \iff (c'),$$

with an implication from the first group to the second. Here the three objects U, V, W in (a') are all connected. Connectedness of W is essential: even in sets, two singleton objects mapping to different elements of a two-element set have empty pullback.

The equivalence of (a) and (a') is the same product test inside $\mathcal{E}/W$. Condition (a) implies local irreducibility by 2.5 and gives the assertion about components in (b). To see the decisive step (b)⇒(d), first use 2.8 for PS 1. Given $u, v : a \rightrightarrows b$ in S, both objects lie over the same connected component of 1. By (b), $b \times b$ is connected. The equalizer is the pullback

$$E = a \times_{b\times b} b, \qquad a \longrightarrow b \times b = (u, v), \quad b \longrightarrow b \times b = \mathrm{diag}\,.$$

Local irreducibility, applied over the connected object $b \times b$, makes E noninitial. A generator mapping to E supplies an equalizing arrow, which is PS 2. The text's "c) est vérifié" at manuscript p. 24 means (b); its reference to $\mathcal{X} \times \mathcal{X}$ should be read as an application of 2.8 in $\mathcal{X}$ itself.

There is a concise exactness interpretation after restricting to any connected component of the topos. Under (a'), decomposition into connected components gives, for arbitrary U, V, W in that component,

$$\pi_0(U \times_W V) \simeq \pi_0(U) \times_{\pi_0(W)} \pi_0(V).$$

Indeed, the summands of the pullback are precisely the products $U_i \times_{W_k} V_j$ for which both factors map to the same component W_k; each is connected by (a'). Since $\pi_0(1) = \{*\}$, π_0 preserves finite limits on this connected topos. We shall use this stronger fact in the cohomological argument. For a disconnected topos one applies it component by component; its global π_0 does not preserve the terminal object.

[21]

C'est contenu dans le

Corollaire 2.8. *Soient $\mathcal{X}$, S comme dans 2.6. Conditions équivalentes :*

31. Exemple de X totalement 0-connexe, mais non cofiltrant, i.e. non localement irréductible ? La catégorie $\mathbf{\Delta}$ des simplexes type est totalement 0-connexe, mais n'est pas cofiltrante car $\mathbf{\Delta}^0 = e \overset{\partial_0}{\underset{\partial_1}{\rightrightarrows}} \mathbf{\Delta}^1$ ne peut être égalisé ! Donc `[la catégorie opposée]` $\mathbf{\Delta}^o = I$ est telle que $I \longrightarrow I^E$ soit cofinal pour tout ensemble fini E, mais I non filtrante.

a) $\mathcal{X}$ est localement irréductible, i.e. les topos induits $\mathcal{X}/U$, où U est 0-connexe, sont irréductibles.

b) Tout produit fibré $U \times_W V$ d'objets 0-connexes U, V est 'non vide'.

b′) Tout produit fibré $U \times_W V$, avec U, V 'non vide', W 0-connexe, est non vide.

c) Les $\mathcal{X}/x$ avec $x \in S$ sont irréductibles.

d) Comme b), avec U, V, W dans S.

e) S est localement faiblement filtrante à gauche, i.e. satisfait PS 1.*

Ici les implications ± évidentes sont

p. 14

$$\begin{array}{ccccc} \mathrm{b}' & \Longrightarrow & \mathrm{b} & \Longrightarrow & \mathrm{a} \\ & & \Downarrow & & \Downarrow \\ & & \mathrm{d} & \Longleftrightarrow \mathrm{e} \Longleftrightarrow & \mathrm{c}. \end{array}$$

Prouvons les implications de la ligne du bas. Considérons d). Si $\begin{smallmatrix} & a & \searrow \\ & & & x \\ & b & \nearrow \end{smallmatrix}$ [est] dans S, dire que le produit fibré dans $\mathcal{X}$ est 'non vide' signifie, puisque S est un système de générateurs et en particulier *non vide,* qu'il existe c dans S et $c \longrightarrow a \times_x b$, ou ce qui revient au même, $\begin{smallmatrix} & a & \\ c & & \\ & b & \end{smallmatrix}$, rendant commutatif le diagramme $\begin{smallmatrix} & a & \searrow & \\ c & & & x \\ & b & \nearrow & \end{smallmatrix}$. Donc d) équivaut à PS 1, i.e. à e) ($\mathcal{X}$ localement faiblement filtrant à gauche). Considérons la condition c) : les $\mathcal{X}/a = (S/a)^\sim$ sont irréductibles. Cela signifie que pour deux sous-objets *non vides* $U, V \subseteq a$ dans $\mathcal{X}^\wedge$, on a $U \cap V \neq \emptyset$, ou encore que pour deux cribles

$\underline{U}$, $\underline{V}$ de S/x, si $\underline{U}$, $\underline{V}$ non vides (ce qui signifie que les sous-objets de x dans $\mathcal{X}^\wedge$ qu'ils définissent sont 'non vides', ou que les objets de S sont 'non vides' dans $\mathcal{X}^\wedge$), alors $\underline{U} \cap \underline{V}$ est non vide. On peut supposer que $\underline{U}$, $\underline{V}$ est engendré chacun par une seule flèche $a \xrightarrow{u} x$, $b \xrightarrow{v} x$. Le crible intersection est formé des objets $c \longrightarrow x$ de S/x tels que $c \longrightarrow x$ se factorise par un $\begin{smallmatrix} & a & \\ c & & \\ & b & \end{smallmatrix}$, donc dire que ce crible n'est pas vide, signifie que PS 1 est satisfait pour les deux flèches données u, v. Donc c) équivaut à la condition PS 1[, i.e. à] e. [22]

Ainsi on a établi

$$\mathrm{b}' \Longrightarrow \mathrm{b} \Longrightarrow \mathrm{a} \Longrightarrow (\mathrm{c} \Longleftrightarrow \mathrm{d} \Longleftrightarrow \mathrm{e}),$$

reste à prouver que c $\Longrightarrow$ b′. Soit donc $\begin{smallmatrix} U & & V \\ & \searrow \quad \swarrow & \\ & W & \end{smallmatrix}$ un diagramme d'objets 'non vides', avec W 0-connexe, il faut prouver que le produit fibré est non vide. Considérant $a \longrightarrow U$ et $b \longrightarrow V$ avec $a, b \in S$, on est ramené au cas où $U = a$, $V = b$ dans S. Prouvons que si $a \times_W b$ est 'vide', alors W est disconnexe. Pour ceci, considérons la sous-catégorie C de S/W formée des $x \longrightarrow W$ tels que $a \times_W x$ soit 'non vide'. Désignant par $w(a)$, $w(x)$ l'image de a, x dans W, cela signifie que $w(a) \cap w(x) \neq \emptyset$.

Notons que tout quotient dans $\mathcal{X}^\wedge$ d'un objet irréductible est irréductible, donc $w(a)$, $w(x)$ sont des objets irréductibles. Cela montre que pour x dans C et x' dans S/W, on a x' dans C, i.e. $w(a) \cap w(x') \neq \emptyset$ si et seulement si $w(x) \cap w(x') \neq \emptyset$. (Lemme direct : dans un objet W d'un topos $\mathcal{X}$, si on a [des] sous-objets W_1, W_2, W_3 irréductibles, si l'un des deux [plutôt trois] rencontre les deux autres, ceux-ci se rencontrent.) Cela montre que C est un crible, puisque $x' \longrightarrow x$ implique $w(x') \subseteq w(x)$, donc $w(x')$ rencontre $w(x)$, donc aussi $w(a)$. Mais alors le co-crible $C' = (S/W) \backslash C$ est également un crible, car si c est dans C', i.e. [si] $w(c)$ ne rencontre pas $w(x)$, a fortiori pas tout x' au-dessus de x, pour lequel on aura $w(x') \subseteq w(x)$. Ainsi, S/W est décomposé en somme de deux ouverts C, C', non vides puisque l'un contient a, l'autre b. Par suite, W est décomposé en somme de deux sous-objets non vides, donc W est non 0-connexe. [23]

p. 15

On a prouvé 2.8, donc aussi (revenant à 2.6) les implications vers PS 1 dans le diagramme page 20. Il reste à prouver

$$\begin{cases} \text{b} \Longrightarrow \text{PS 2},\ \text{c}' \Longrightarrow \text{PS 2} \\ \text{PS 1} + \text{PS 2 (i.e. d)} \Longrightarrow \text{a}' \end{cases}$$

([32]).

Commentary · Exposition [ms. 23]

How irreducible generators control an arbitrary slice

The proof of 2.8 explains why irreducibility, although weaker than filteredness, is genuinely local in the topos. The missing hypothesis in its printed condition (b) is that W be connected. The assertion used in the proof is (b'): noninitial U and V over a connected W have noninitial pullback.

Here is the passage from the generating objects to such a W. Suppose every $s \in S$ is irreducible, and consider the images $W_s \subseteq W$ of all maps $s \to W$. These images cover W and remain irreducible: inverse images of two nonzero subobjects under an epimorphism are nonzero, and their nonzero intersection has nonzero image. On this covering family, declare two images related when they meet. The relation is reflexive and symmetric. It is transitive because, if A and C both meet an irreducible B, the two nonzero subobjects $A \cap B$ and $B \cap C$ of B meet. Thus the equivalence classes give pairwise disjoint unions of subobjects covering W.

These unions are a coproduct decomposition in the topos. Since W is connected, there is only one class. Every pair of generating images therefore meets. Choose a generator mapping into each of the noninitial objects U and V. Their images in W meet, and epimorphisms remain epimorphisms after pullback; consequently $U \times_W V$ is noninitial. This proves the step (c)⇒(b') without assuming that every object of a site is representable as a presheaf on that site.

Finally, the condition that $s \times_x t$ be noninitial is equivalent to the existence of a generator r mapping to that pullback. Such a map is exactly a commutative square completing $s \to x \leftarrow t$, namely PS 1. This proves the equivalence with (d) and (e). The implication (b')⇒(a) follows by taking two nonzero subobjects of a connected object. The remaining implications are restrictions of this same test. Grothendieck's argument is therefore sound after restoring the condition on the base; the diagram of implications is not concealing an additional homotopical assumption.

[24] Nous nous plaçons donc dans l'hypothèse où PS 1 est satisfait (puisque b), c') et d) impliquent PS 1), donc où on est sous les conditions équivalentes de 2.8 - $\mathcal{X}$ est localement irréductible. Considérons alors la condition PS 2, et prouvons qu'elle est impliquée tant par b), que par c'), et qu'elle implique a'). Elle signifie que pour une double flèche $a \overset{u}{\underset{v}{\rightrightarrows}} b$ dans S, le conoyau `[plutôt noyau]` dans $S^\wedge$, ou, ce qui revient au même, dans $\mathcal{X}^\wedge = S^{\widetilde{}} \subseteq S^\wedge$, est 'non vide'. On peut l'écrire sous la forme d'un produit fibré

$$\begin{array}{ccc} a & \xrightarrow{(u,v)} & b \times b \\ \uparrow & & \uparrow{\scriptstyle \text{diag}} \\ \text{Ker}(u,v) & \longrightarrow & b. \end{array}$$

Ici par hypothèse a et b sont des objets 0-connexes de $\mathcal{X}^\wedge$ (ceux de S l'étant), c) est vérifié (($\mathcal{X}$ localement irréductible et) ses composantes connexes `[sont]` totalement 0-connexes), alors $b \times b$ est 0-connexe comme produit de deux objets 0-connexes sur une *même composante connexe,* laquelle est totalement 0-connexe. Comme $\mathcal{X} \times \mathcal{X}$ est localement irréductible, il s'ensuit que le produit fibré est non vide (2.8), donc b) ⟹ d). Prouvons d) ⟹ a), i.e. si

[25] S est localement cofiltrante, alors les topos induits $\mathcal{X}/W$, où W est 0-connexe, sont totalement 0-connexes. Ce topos induit est décrit par le site S/W, i.e. S/W est un système de générateurs. Or si S est localement filtrante, S/W (étale sur S) l'est aussi. Donc on peut supposer $W = e$, et à prouver que si S est localement cofiltrante et $\mathcal{X}$ 0-connexe, alors $\mathcal{X}$ est

32. NB finalement on ne prouve pas c' ⟹ PS 2.

totalement 0-connexe. Notons que $\mathcal{X}$ 0-connexe équivaut à S 0-connexe - il faudrait quand même l'expliciter :

Lemme 2.9. *Soit $\mathcal{X}$ un topos, $S \subseteq \mathcal{X}^\wedge$ une sous-catégorie pleine génératrice formée d'objets* 0-connexes. *Alors $\mathcal{X}$ est* 0*-connexe si et seulement si S l'est - plus généralement, l'ensemble ordonné des sous-objets à la fois ouverts et fermés de S dans* Cat *(ou encore des sous-objets ouverts = cribles de S qui sont aussi fermés, i.e. des cocribles) est isomorphe à* p. 16 *celui des sommandes directs de $\mathcal{X}$.*

Je l'ai utilisé tacitement dans la démonstration de 2.8, pour le topos induit $\mathcal{X}/W$. Je n'explicite pas la démonstration.

Commentary · Exposition [ms. 25]

Connectedness in a category of generators

Lemma 2.9 is what permits the categorical and topos-theoretic arguments to meet. Its content is stronger than the statement that a generating family covers the terminal object: a partition of the generators must descend to an actual coproduct decomposition of that object.

Let $S \subseteq \mathcal{E}$ be full, generating, and formed of connected objects. A decomposition $1 = A \amalg B$ assigns every $s \in S$ entirely to one summand, since the two pullbacks decompose s. Every arrow preserves this assignment. It thus gives a partition $S = S_A \amalg S_B$ into full subcategories with no arrows between them. Conversely, suppose such a partition is given. Let A and B be the unions in 1 of the images of the objects in the respective parts. They cover 1, because S generates. If $A \cap B$ were noninitial, some generator would map into it. Pulling back the epimorphic families defining A and B, and choosing a generator in a noninitial member, would produce an object $t \in S$ with maps to an object of S_A and one of S_B. This contradicts the partition. Hence $A \cap B = 0$, and $A \amalg B \simeq 1$.

The two constructions are inverse: a connected generator whose image lies in A cannot belong to the other part, and the images of all generators assigned to A jointly cover A. The same argument works with any set of parts and proves

$$\pi_0(S) \simeq \pi_0(1_{\mathcal{E}}).$$

It also applies to S/F, which is a full generating subcategory of $\mathcal{E}/F$. An object $s \to F$ is connected in the slice exactly when its domain s is connected, since coproducts in a slice are computed on domains. We obtain the repeatedly used identity

$$\pi_0(S/F) \simeq \pi_0(F).$$

This supplies the proof omitted at manuscript p. 25 and justifies the earlier use of the lemma in 2.8. It also explains why the category of elements, rather than only the set of objects of a site, controls connectedness.

Ainsi (revenant à la démonstration de d) $\Longrightarrow$ c) dans 2.6.) S étant 0-connexe et localement cofiltrante,

`[elle]` est en fait cofiltrante. Donc pour deux objets a, b de S, $\exists$ c avec $c \longrightarrow a$, $c \longrightarrow b$ [26] (condition PS 1′, plus forte que PS 1). Pour prouver que $\mathcal{X}$ est totalement 0-connexe, on est réduit à prouver par 2.3 que les $a \times b$ dans $\mathcal{X}^\wedge$ sont 0-connexes. Par 2.9, il revient au même de prouver qu'ils sont 0-connexes dans $S^\wedge$. Donc on est ramené à prouver le

Lemme 2.10. *Soit S une catégorie cofiltrante. Si a, b sont deux objets de S, $a \times b$ est un objet* 0*-connexe de $S^\wedge$.*

On voit de suite qu'il suffit de prouver (et en fait il revient au même, compte tenu que $a \times b$ est localement irréductible) que si on a deux flèches

$$\begin{array}{ccc} x & \longrightarrow & a \times b \\ & & \uparrow \\ & & y, \end{array}$$

alors $x \times_{a\times b} y \neq \emptyset$, i.e. $\exists\ z$ dans S rendant commutatif

$$\begin{array}{ccc} x & \longrightarrow & a \times b \\ \uparrow & & \uparrow \\ z & \longrightarrow & y. \end{array}$$

Or par PS 1′ il existe bien un z s'envoyant dans x et dans y, mais les deux flèches composées

$$z \rightrightarrows a \times b,$$

i.e. chacune des double flèches

$$(*) \qquad z \rightrightarrows a$$

$$(*') \qquad z \rightrightarrows b$$

peuvent n'être pas égales. Mais par PS 2,
on peut trouver

$$z' \longrightarrow z \qquad [27]$$

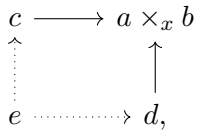
égalisant la double flèche $(*)$, donc on peut supposer que celle-ci est déjà triviale. Appliquant encore une fois PS 2, par un $z'' \longrightarrow z'$, on égalise de même la double flèche $(*')$, et on gagne. p. 17
On a donc prouvé, finalement,

$$\begin{array}{ccccccc} \mathrm{a} & \Longleftrightarrow & \mathrm{a}' & \Longrightarrow & \mathrm{b} & \Longleftrightarrow & \mathrm{d}\ (= \text{PS } 1 + \text{PS } 2) \\ \Downarrow & & & & & & \\ \mathrm{c} & \Longleftrightarrow & \mathrm{c}', & & & & \end{array}$$

mais pas l'implication inverse. En d'autres termes, si les topos induits $\mathcal{X}/a$, pour a dans S, sont totalement 0-connexes, je n'ai pas prouvé qu'il en est de même des $\mathcal{X}/W$, W un objet 0-connexe *quelconque* de $\mathcal{X}^\wedge$. Ainsi, on en est au point suivant

Commentary · Exposition [ms. 27]

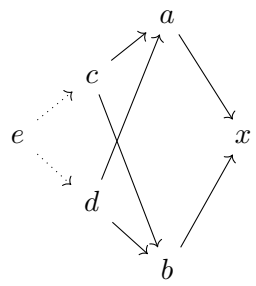
Where both equalizations are used



The completion of 2.6 is a useful instance of the finite-cone argument underlying filteredness. It is not enough to find a common predecessor of two objects: one must also arrange that the resulting maps agree in both factors. This is why the proof of Lemma 2.10 invokes PS 2 twice.

Suppose S is cofiltered. An object of $S/(h_a \times h_b)$ is a triple $(x, r : x \to a, s : x \to b)$. It exists by the common-predecessor axiom. Given two such triples with domains x and y, choose $z \to x$ and $z \to y$. Equalize the two resulting maps $z \rightrightarrows a$ by a map $z' \to z$, then equalize the two maps $z' \rightrightarrows b$ by $z'' \to z'$. The second operation preserves the first equality. The object with domain z'' is a common predecessor in $S/(h_a \times h_b)$. This proves its connectedness, as required in 2.10. In fact it is cofiltered: parallel arrows in it can be equalized after projection to S, and the resulting arrow still belongs to the category of elements.

Now let S merely be locally cofiltered, and let W be connected in the topos. The projection $S/W \to S$ is a discrete fibration. PS 1 lifts along a discrete fibration: once a common predecessor is chosen downstairs, lifting one leg determines the object upstairs, and equality of the two composites gives the other leg. PS 2 lifts for the same reason, using uniqueness of lifts. Thus S/W is locally cofiltered. Lemma 2.9 says it is connected, so it is cofiltered. Applying the preceding argument in this generating category and then the generator test of 2.3 shows that $\mathcal{E}/W$ is totally 0-connected. This is (d)⇒(a).



The proof establishes the announced equivalence of (a), (a'), (b), and (d). It does not establish (c')⇒PS 2, and the annotation correctly removes that assertion. Restricting the base of a pullback to a representable object has lost information: the object $b \times b$ required for the diagonal argument need not be among the chosen generators. The following group example makes this loss explicit.

Perplexité 2.11. *Soit X dans* Cat. *Si X est localement filtrante à gauche, alors les produits fibrés $a \times_x b$ d'objets dans X sont des objets 0-connexes de $X^\wedge$, et cette condition à son tour implique PS 1, i.e. que X est localement irréductible. Mais en présence de cette hypothèse PS 1, ou X localement irréductible, la condition sur les produits fibrés $a \times_x b$ équivaut à la suivante : pour tout diagramme* `[en]` *traits pleins* [28]

avec x, a, b, c, d dans X,

on peut compléter en un diagramme commutatif, *avec e dans X. En d'autre termes, tout diagramme commutatif à traits pleins ci-dessous se complète en y rajoutant un 'objet initial' e*

([33]).

Cette condition est donc impliquée par X localement cofiltrante, et elle est satisfaite aussi par ce qui précède plus généralement si et seulement si ([34]) les X/x sont cofiltrantes ([35]). Mais la réciproque est-elle vraie - cette condition de totale 0-connexité des X/x implique-t-elle que X soit totalement 0-connexe ? Mais je n'ai pas construit d'exemple où les X/x sont cofiltrantes sans que X soit localement cofiltrante (ou ce qui revient au même, de X 0-connexe avec les X/x cofiltrantes sans que X en soit cofiltrante)([36]) ; ni d'exemple où les X/x sont totalement 0-connexes, sans que les X/x soient cofiltrantes. Mais notons le p. 18

Commentary · Examples [ms. 28]

A groupoid invisible to its representable slices

The marginal answer to Perplexity 2.11 is decisive, and it also explains the weaker condition that remains. Let G be a nontrivial group and let BG be its one-object category. The objects of $BG/*$ are the elements $g \in G$, viewed as arrows to the unique object. For any g, h, there is exactly one arrow from g to h, namely the element k satisfying $hk = g$. Hence $BG/*$ is a nonempty indiscrete groupoid, equivalent to the terminal category, and is cofiltered.

The category BG itself is not cofiltered. If $g \neq h$ are parallel arrows, an equalization $gk = hk$ would imply $g = h$ because k is invertible. Its presheaf topos is the category of right G-sets. The representable is the regular G-set G; it is connected. Its square with diagonal action has

$$\pi_0(G \times G) \simeq G, \qquad [(a, b)] \longmapsto ba^{-1},$$

33. Il suffit d'exiger pour e la commutativité des deux carrés (e c b d) et (e d a c).

34. si et seulement si ?

35. Elle signifie que X satisfait PS 1, et la condition

PS′ 2 Tout diagramme commutatif

$$a \rightrightarrows b \longrightarrow x$$

s'insère dans un diagramme commutatif

$$y \longrightarrow a \rightrightarrows b \longrightarrow x.$$

36. Mais il y a un *contre-exemple* évident, si X est un groupoïde 0-connexe, les X/x sont $\approx e$, donc cofiltrantes, mais X n'est cofiltrant (i.e. `[mot(s) illisible(s)]`) que si X est 1-connexe. P.ex. si C est un groupoïde $\neq 1$, alors $X = B_G$ est tel que les X/x sont cofiltrantes, mais X non cofiltrant.

after choosing the corresponding convention for the right action. Thus the square is not connected. This verifies directly that the topos is locally irreducible but is not totally 0-connected, although the slice over the representable is equivalent to sets. The image of the regular object onto the terminal G-set is exactly the quotient missed by the generator-only test.

There is, however, no further example in which *every* X/x is totally 0-connected but some X/x is not cofiltered. Indeed, total 0-connectedness of all X/x makes all these categories irreducible, so X is locally irreducible. For $y \to x$, the slice $(X/x)/(y \to x)$ is isomorphic to X/y, and is therefore irreducible. Hence X/x is both totally 0-connected and locally irreducible. Corollary 2.7, whose proof has just been completed, makes it cofiltered.

In elementary terms, the surviving weaker condition is PS 1 together with

$$a \underset{v}{\overset{u}{\rightrightarrows}} b \xrightarrow{h} x, \quad hu = hv \quad \Longrightarrow \quad \exists\, t : c \to a \text{ with } ut = vt.$$

This is PS′ 2 in footnote 35. It equalizes parallel arrows only when they already become equal after a common outgoing arrow. In a groupoid that antecedent forces equality, so the condition is automatic. PS 2 has no such antecedent. The two questions in the paragraph are therefore settled differently: the first has the groupoid counterexample already supplied by Grothendieck; the second has a negative existence answer from his preceding theorem.

Corollaire 2.12 : *Les conditions équivalentes a), a′), b), d) (à l'exclusion de c), c′), plus faibles apparemment) du théorème 2.6*

équivalent encore à la suivante [29]

e) ∀ *x dans S, le topos induit* $\mathcal{X}/x$ *et le topos induit* $\mathcal{X}/x \times x$ *est irréductible* ([37]),

où encore à la suivante

e′) ∀ *x dans S,* $S^\wedge/x$ *et* $S^\wedge/x{\times}x$ *sont irréductibles, i.e.* S/x *et* $S/x{\times}x$ *sont irréductibles* ([38]).

C'est la forme 'topologique' la plus faible en apparence que je peux trouver pour la condition S localement cofiltrante, i.e. $\mathcal{X}$ (ou Top(S), au choix) localement totalement 0-connexe.

Commentary · Exposition [ms. 29]

Why the square of one generator detects equalizers

Corollary 2.12 is not merely another presentation of a long list of equivalent conditions. It isolates the diagonal as the part of the product test which forces equalization. We can read its criterion entirely in the topos, without treating the chosen site as a space.

Suppose that $s \times s$ is irreducible for every $s \in S$. The diagonal $s \hookrightarrow s \times s$ is a noninitial subobject. Every noninitial subobject of an irreducible object is irreducible, so each s is irreducible and 2.8 gives PS 1. For two maps $u, v : a \rightrightarrows b$ in S, the image of $(u, v) : a \to b \times b$ is noninitial. It meets the diagonal, because $b \times b$ is irreducible. Pullback stability of epimorphisms then says that

$$\mathrm{Eq}(u, v) = a \times_{b \times b} b$$

is noninitial. A generator mapping into this equalizer supplies PS 2. Conversely, PS 1 and PS 2 give local cofilteredness; the category of generators over $b \times b$ is cofiltered by the proof of 2.10, so this product is irreducible.

This also proves the comment that the separate hypothesis on $\mathcal{E}/s$ is redundant. The diagonal is a nonzero open subobject in the language of slice topoi, and irreducibility passes to such an open. Saying instead that s is irreducible and its diagonal is dense gives the same test: density means that the diagonal meets the image of every noninitial object mapping to $s \times s$. The pair (u, v) then gives the equalizer test just used. The relevant "open immersion" is the morphism of topoi associated with a monomorphism in $\mathcal{E}$; it is not an assertion that an arbitrary topological diagonal is open.

37. NB $\mathcal{X}/x$ inutile.

38. S/x inutile, car $x \xrightarrow{\text{diag}} x \times x$ est une immersion ouverte non vide, donc si $x \times x$ est irréductible, x l'est aussi. Mais il revient au même de dire que les S/x sont irréductibles (condition PS* 1, cf. 2.8, p. 21) *et* que les $x \xrightarrow{\text{diag}} x \times x$ sont dominants (ce que implique en effet que $x \times x$ est irréductible). Ceci redonne immédiatement la forme PS* 2 de la condition cofiltrante.

Definition 2.13 packages these equivalent conditions as local total 0-connectedness. The generator category is allowed to vary: once the condition is expressed for all connected slices of the topos, the proof of 2.6 applies to every full generating subcategory of connected objects.

Définition 2.13. On dit qu'un topos $\mathcal{X}$ est *localement totalement* 0-*connexe* s'il satisfait aux conditions équivalentes a, a′, b, d du théorème 2.6, i.e. si $\mathcal{X}$ est localement connexe et si de plus tout topos induit 0-connexe est totalement 0-connexe - le produit fibré de deux objets 0-connexes sur un troisième est 0-connexe. Il revient au même de dire que toute (ou que une) sous-catégorie pleine génératrice S de $\mathcal{X}^\wedge$ formée d'objets 0-connexes est localement cofiltrante (en supposant toujours $\mathcal{X}$ localement connexe, ou ce qui revient au même, l'existence d'un S formé d'objets 0-connexes).

On n'a pas terminé encore la démonstration de 2.6 - il reste à prouver que si $\mathcal{X}$ (supposé localement totalement 0-connexe) est 0-connexe, il est ∞-connexe - ou encore que les composantes connexes de $\mathcal{X}$, supposé localement totalement 0-connexe, sont ∞-connexes, i.e. W_∞-asphériques.

Corollaire 2.14. *Notons quand même que si $\mathcal{X}$ est de la forme Top(T), T un espace topologique, alors $\mathcal{X}$ est localement totalement* 0-*connexe si et seulement si il est localement irréductible, i.e. si et seulement si T est localement irréductible.* [30]

On est ramené à prouver que cette dernière condition implique la condition d) de 2.6, et p. 19
on peut prendre pour S l'ensemble ordonné des ouverts connexes non vides de S, cela devient alors évident.

Ceci dit, il faut se rappeler que la théorie cohomologique des espaces topologiques irréductibles n'est nullement triviale - comme nous le montre FAC de Serre ! D'autre part, c'est Serre qui m'avait fait observer que pour des coefficients *constants,* la cohomologie d'un espace irréductible est triviale.

Commentary · Examples [ms. 30]

Irreducible spaces still have nonconstant cohomology

The reference to Serre separates two coefficient questions which must remain distinct. On an irreducible nonempty topological space T, every nonempty open is connected. For an abelian group M, the constant sheaf $\underline{M}$ consequently has sections M on every nonempty open, with identity restriction maps. Restrictions to the empty open are also surjective. Thus $\underline{M}$ is flabby and

$$H^q(T, \underline{M}) = 0 \quad (q > 0), \qquad H^0(T, \underline{M}) = M.$$

The same argument on each irreducible component applies when the space is a disjoint union of irreducible open components, which is the local condition used in 2.14.

For a concrete contrast, take the Zariski space $T = \mathbf{P}^1_k$, which is irreducible, and the line bundle $\mathcal{O}(-2)$. On the standard affine charts with coordinate t and t^{-1}, its degree-one Čech quotient is

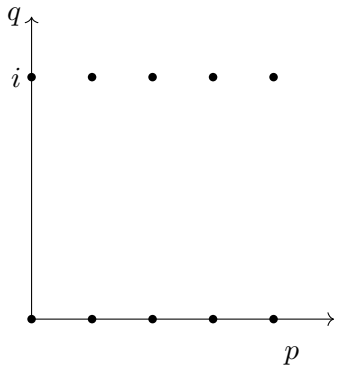
$$\frac{k[t, t^{-1}]}{k[t] + t^{-2}k[t^{-1}]} = k\,[t^{-1}].$$

The first summand removes all nonnegative powers and the second all powers at most -2; exactly the coefficient of t^{-1} remains. The affine charts and their intersection are acyclic for this coherent sheaf, so the quotient is $H^1(\mathbf{P}^1_k, \mathcal{O}(-2)) \simeq k$. The affine-cover comparison used here is Serre (1955, no. 47, Theorem 4); the displayed computation gives the particular example in full.

For 2.14 itself, choose the connected nonempty opens as generators. If the space is locally irreducible in Grothendieck's sense, each such open is irreducible. Two nonempty opens inside it meet, giving PS 1; the generator category is a poset, so parallel arrows are already equal and PS 2 imposes nothing further. The converse follows from local total 0-connectedness implying local irreducibility. This is why the two notions coincide for spaces while the group example separates them for general topoi.

Dans le cas actuel, prouvons déjà, si $\mathcal{X}$ est 0-connexe et localement totalement 0-connexe, que tout revêtement de l'objet final de $\mathcal{X}$ est trivial. Il suffit de voir que si U est 0-connexe,

$U \longrightarrow e$ est un isomorphisme. Mais considérons $U \hookrightarrow U \times U$, on sait que c'est un sommande direct, et comme $U \times U$ est connexe, c'est un isomorphisme. Donc $U \longrightarrow e$ [est un] monomorphisme, donc sommande direct, et comme $U \neq \emptyset$, on a $U \longrightarrow e$ isomorphisme.



Reste à prouver que pour tout faisceau abélien constant F sur $\mathcal{X}$, on a $H^i(X, F) = 0$ [31] pour $i > 0$. On procède par récurrence sur i, c'est déjà fait pour $i = 1$. Supposons que ce soit prouvé pour les $j < i$ (i fixé) pour tout topos *totalement* 0-*connexe.* Soit $\xi \in H^i(\mathcal{X}, F)$, soit $U \longrightarrow e$ [un] épimorphisme tel que $\xi|U = 0$, et considérons la suite spectrale

$$E_2^{pq} = H^p(C(U^*, \mathcal{H}^q(F))) \Longrightarrow H^*(\mathcal{X}, F).$$

On a par hypothèse totalement 0-connexe

$$(*) \qquad \pi_0(U^q) \simeq \pi_0(U)^q,$$

et les composantes connexes de U^q sont totalement 0-asphériques,

donc par hypothèse de récurrence

$$E_1^{pq} = 0 \qquad \text{si } 0 < q < i,$$

donc on trouve une suite exacte

$$0 \longrightarrow H^i(C(U^*, F)) \longrightarrow H^i(\mathcal{X}, F) \longrightarrow H^0(\underbrace{H^i(U^*, F)}_{\substack{\text{complexe} \\ \text{co-semisimplicial} \\ \text{pour } i \\ \text{variable}}}) = \mathrm{Ker}(H^i(U, F) \rightrightarrows H^i(U^2, F)).$$

Commentary · Exposition [ms. 31]

The hereditary hypothesis in the cohomological proof

Grothendieck's induction proves the intended assertion after keeping its hypothesis fixed: the topos must be connected and *locally* totally 0-connected. The word "localement" disappears in the sentence introducing the induction at manuscript p. 31, but it is needed when the argument passes to components of powers of a covering object. Those components define connected slices of the original topos, and hence remain in the same class by 2.6. Mere total 0-connectedness does not provide this inheritance.

First consider a connected locally constant object L. Its diagonal in $L \times L$ is complemented, as one checks after a cover trivializing L. The product is connected, so this noninitial summand is the whole product. Hence $L \to 1$ is monic. Its image is also complemented, by the same local triviality; connectedness of the base and nonemptiness of L give $L \simeq 1$. Every covering object is therefore a coproduct of copies of 1. In the source paragraph, U must still denote a connected component of a *covering*, not an arbitrary connected sheaf.

For the higher cohomology, assume the vanishing in degrees $0 < q < n$ for every connected topos in this hereditary class. Given $\xi \in H^n(\mathcal{E}, \underline{M})$, choose an epimorphism $U \to 1$ killing ξ. Such a cover

exists because a positive-degree cohomology class represented in an injective resolution becomes a boundary locally. The augmented Čech nerve gives the descent spectral sequence

$$E_1^{pq} = H^q(\mathcal{E}/U^{p+1}, \underline{M}) \implies H^{p+q}(\mathcal{E}, \underline{M}).$$

Each U^{p+1} is a coproduct of connected objects whose slices remain in the class; thus the rows $0 < q < n$ vanish. The edge sequence gives

$$0 \longrightarrow H^n(C^\bullet) \longrightarrow H^n(\mathcal{E}, \underline{M}) \longrightarrow \ker\big(H^n(U, \underline{M}) \rightrightarrows H^n(U^2, \underline{M})\big).$$

The last image of ξ is zero by choice of U. If $I = \pi_0(U)$, product preservation identifies

$$C^p = \mathrm{Map}(I^{p+1}, M).$$

Choose $i_* \in I$, which exists since $U \to 1$ is epic. Inserting i_* as first coordinate defines $(sc)(i_0, \dots, i_{p-1}) = c(i_*, i_0, \dots, i_{p-1})$. For the alternating deletion differential, direct cancellation gives $ds + sd = 1$ in positive degrees, with the usual augmentation in degree zero. Thus $H^n(C^\bullet) = 0$ and $\xi = 0$. The "trivial" complex in the manuscript is this contractible augmented complex; its individual groups and differentials are not zero.

p. 20

Par hypothèse sur U, l'image de ξ dans le troisième terme est nulle, donc ξ appartient au premier terme. Mais pour $(*)$, le complexe $C(U^*, F)$ est le complexe *trivial* des puissances de $I = \pi_0(U)$, à coefficients dans M (si $F = M_{\mathcal{X}}$). Sa cohomologie en degrés > 0 est nulle, donc [32] $\xi = 0$, q.e.d.

Commentary · Later developments [ms. 32]

From connected components to the hypercover homotopy type

The stronger homotopical conclusion of 2.6 can also be proved directly, without deducing weak contractibility from an unspecified version of a cohomological Whitehead theorem. On a connected locally totally 0-connected topos, the component functor preserves finite limits, as shown above, and preserves epimorphisms: epimorphisms in a topos are regular, and the left adjoint π_0 preserves their coequalizer presentations. Let $U_\bullet \to 1$ be a hypercover by objects of this topos. Its matching objects are finite limits. Therefore

$$\pi_0\big(M_n(U_\bullet)\big) \simeq M_n\big(\pi_0(U_\bullet)\big),$$

and the hypercover epimorphisms become surjections of sets. The simplicial set $\pi_0(U_\bullet)$ consequently has a filler for every boundary $\partial\Delta^n \to \pi_0(U_\bullet)$, including the nonemptiness condition in degree zero. Its map to a point is a trivial Kan fibration, and it is weakly contractible.

In the hypercover construction of the homotopy type, whose classical setting is Artin and Mazur (1969, §§8–9), every stage is therefore weakly contractible. This proves the W_∞-asphericity meant here, as well as the corresponding assertion for each connected object by passage to its slice. For a presheaf topos it says concretely that every connected category of elements is weakly contractible.

There is also a short algebraic verification of the constant-coefficient calculation. Since π_0 preserves finite limits, it induces an exact functor on abelian group objects, left adjoint to the constant-abelian-sheaf functor. The latter therefore preserves injectives. Applying it to an injective resolution of M, and then taking global sections, recovers the same resolution of M, because the topos is connected. Thus $R\Gamma(\mathcal{E}, \underline{M}) \simeq M[0]$. These proofs make explicit why the hereditary condition repairs the false inference after 2.3. They impose no claim that the topos itself is equivalent to sets; the preceding projective-line example shows that arbitrary coefficients retain substantial information.

Proposition 2.15. ([39]) *Soit X un objet de* Cat. *Conditions équivalentes :*

a) X est filtrant, i.e. X est 0-connexe et X^o satisfait les conditions équivalentes du théorème 2.6 ($X^{o,\wedge}$ est localement totalement 0-connexe).

b) L'objet final de $X^\wedge$ est ind-représentable.

39. C'est déjà dans SGA 4, I 8.

Démonstration. On sait qu'on a

$$e_{X^\wedge} \simeq \varinjlim_{x\in X} x, \tag{2.15.1}$$

limite inductive prise dans $X^\wedge$. En effet, cela signifie aussi que pour tout objet a dans X, on a

$$\varinjlim_{x\in X} \underbrace{x(a)}_{\mathrm{Hom}_X(a,x)} \xrightarrow{\sim} e \qquad \text{(ensemble ponctuel)}$$

Mais considérons l'objet $X' = a\backslash X \longrightarrow X$ coétale sur X, qui est donc Cat-cofibré sur X, on sait que l'on a

$$\pi_0(X') \simeq \varinjlim_{x\in X} \pi_0(X'_x),$$

où $X'_x = \mathrm{Hom}(a, x)$, donc on trouve

$$\varinjlim_{x\in X} \mathrm{Hom}(a, x) = \pi_0(a\backslash X) = e$$

car $a\backslash X$ est 0-connexe.

Commentary · Exposition [ms. 32]

The terminal presheaf as an ind-object

The passage to ind-objects replaces the cone conditions by a representability statement. The general form, recorded in 2.18, is the familiar criterion from Artin et al. (1972, Exposé I, Theorem 8.3.3): a presheaf F on a small category X is a filtered colimit of representables if and only if its category of elements X/F is filtered. We give the argument, since it also supplies all the details of 2.15.

For every presheaf there is the density presentation

$$F \simeq \operatorname*{colim}_{(x,s)\in X/F} h_x.$$

Objectwise, the element represented by a pair $a \to x$, $s \in F(x)$ maps to its pullback in $F(a)$; it has the representative (a, t) with identity map, and the relations identify every other representative with this one. If X/F is filtered, this is the required ind-presentation.

Conversely, write $F = \mathrm{colim}_{i\in I} h_{x_i}$ with I filtered. The category of elements is nonempty, since the image of 1_{x_i} supplies an object. Two elements $s \in F(a)$ and $t \in F(b)$ have representatives at stages i, j; passage to a common stage k supplies arrows from (a, s) and (b, t) to $(x_k, \overline{1}_{x_k})$. Given parallel arrows $u, v : (a, s) \rightrightarrows (b, t)$, represent t by $b \to x_i$. The two composites $a \rightrightarrows x_i$ have the same image in $F(a)$. Equality in a filtered colimit of sets is witnessed at a common later stage. The resulting map $(b, t) \to (x_j, \overline{1}_{x_j})$ equalizes u, v. Thus X/F is filtered.

For $F = 1$, its category of elements is X itself, giving 2.15. The formula $1 = \mathrm{colim}_{x\in X} h_x$ is valid even when X is not filtered: at a its value is $\pi_0(a\backslash X) = \{*\}$ because $(a, 1_a)$ is initial. The condition lies in the possibility of a *filtered* presentation. The reindexing by a directed poset used in the manuscript is Deligne's result, Artin et al. (1972, Exposé I, Proposition 8.1.6); the proof above does not need this extra reindexing.

La formule (2.15.1) montre que si X est filtrant, $e_{X^\wedge}$ est limite inductive filtrante de foncteurs représentables. On sait d'ailleurs qu'on peut réindexer par une catégorie *ordonnée* filtrante (cf. SGA 4, I 8.1.6 (c'est dû à P. Deligne !)). [33]

On a prouvé a $\Longrightarrow$ b, prouvons b $\Longrightarrow$ a. Supposons donc

$$e_{X^\wedge} = \varinjlim_{i\in I} x_i,$$

où I est un (petit) ensemble ordonné filtrant, et $I \longrightarrow X$ un foncteur. Prouvons PS 1′ (forme droite), i.e. pour a, b dans X, `[il]` existe $\begin{matrix} a & \searrow & \\ & & x \\ b & \nearrow & \end{matrix}$. En effet, comme $\varinjlim_I \mathrm{Hom}(a, x_i) = e$, il

s'ensuit que $\mathrm{Hom}(a, x_i) \neq \emptyset$ pour i grand, de même $\mathrm{Hom}(b, x_i) \neq \emptyset$, donc il suffit de prendre $\begin{matrix} a & \searrow \\ & x_i \\ b & \nearrow \end{matrix}$. Prouvons PS 2_{d}, i.e. que pour `[une]` double flèche $a \overset{u}{\underset{v}{\rightrightarrows}} b$, `[il]` existe $b \longrightarrow x$ qui égalise.

Soit ξ_{i_0} dans $\mathrm{Hom}(b, x_{i_0})$, ses deux images dans $\mathrm{Hom}(a, x_{i_0})$ ne sont pas nécessairement égales, mais le deviennent dans la limite inductive, réduite à e, donc deviennent égales en composant avec $x_{i_0} \longrightarrow x_i$ pour i assez grand, donc le composé $b \longrightarrow x_{i_0} \longrightarrow x_i$ p. 21 [34]

$$a \rightrightarrows b \longrightarrow x_{i_0} \longrightarrow x_i$$

égalise la double flèche.

Corollaire 2.16. *Soit W un localiseur fondamental satisfaisant l'axiome des limites* Loc (8). *Si X dans* Cat *est une catégorie filtrante ou cofiltrante, alors X est W-asphérique.*

Plus généralement et agréablement :

Commentary · Later developments [ms. 34]
Filtered categories and the minimal localizer

Corollary 2.16 needs only the standard contractibility of a filtered category, together with the comparison between its weak equivalences and the chosen localizer. Here is the finite-data argument behind the first assertion. In a filtered category, any finite collection of objects has maps into one object. Given finitely many arrows between those objects, successive applications of the parallel-arrow axiom modify the common target so that all the required triangles commute. Thus every finite diagram of objects and arrows occurring in a finite simplicial subset of the nerve admits a compatible cone.

Every map from a finite sphere into the realization of the nerve can, after simplicial approximation, be represented in a finite such subset. The cone makes that map nullhomotopic. The nerve is nonempty and connected, so all its homotopy groups vanish. Reversing the category does not change the homotopy type of its nerve, and gives the cofiltered assertion as well.

The manuscript formulates the conclusion for a fundamental localizer satisfying its axiom Loc(8). A later theorem permits a sharper modern statement: the nerve weak equivalences W_∞ form the smallest fundamental localizer. This is Cisinski (2004, Theorem 2.2.11, p. 136). With the standard modern definition of fundamental localizer, every filtered or cofiltered category is consequently W-aspherical without an additional filtered-limit axiom. This is a later strengthening of the hypothesis in the manuscript, rather than a reason to alter its historical formulation. The finite-cone argument also underlies the higher categorical characterization cited earlier: filtered colimits of spaces commute with finite limits.

Corollaire 2.17. *Soit W comme dans 2.16. Alors toute catégorie filtrante est* totalement W-asphérique ([40]), *i.e. pour toute flèche $f : X \longrightarrow Y$ dans* Cat, *l'objet $f_!(e_X)$ de e_Y (défini aussi comme $y \longmapsto \pi_0(y\backslash X)$, et intervenant dans la factorisation canonique de f en ip, avec p étale et les cofibres* `[?]` *de p 0-connexes) est W-asphérique. En fait, $Y/f_!(e_{X^\wedge})$ est même une catégorie filtrante.* [35]

En effet, le foncteur $f_!$ commute aux limites inductives, donc $f_! e_{X^\wedge}$ est limite inductive filtrante des $f_!(x_i) = f(x_i)$. Donc $Y/f_!(e_{X^\wedge})$ est limite inductive filtrante des $Y/f(x_i)$. Donc c'est même une catégorie filtrante, a fortiori elle est W-asphérique.

Donc finalement, on trouve des exemples non triviaux de catégories totalement W-asphériques, i.e. des exemples donc des catégories sans objet final.

Commentary · Exposition [ms. 35]
Left Kan extension carries the ind-presentation

40. cf. XII, §V pour cette notion, que j'ai beaucoup peiné à dégager et à comprendre !

The reason behind 2.17 is that an ordinary left Kan extension sends a representable to a representable and preserves colimits. If $f : X \to Y$ and X is filtered, then

$$f_!1_X \simeq \operatorname*{colim}_{x\in X} f_!h_x \simeq \operatorname*{colim}_{x\in X} h_{f(x)}.$$

The result is an ind-representable presheaf on Y, so $Y/(f_!1_X)$ is filtered by the criterion just proved. This gives the precise argument for the last assertion of 2.17 and therefore its asphericity conclusion. The proof does not require f to be fully faithful or cofinal.

The canonical factorization mentioned in the statement has the following form:

$$X \xrightarrow{p} Y/(f_!1_X) \xrightarrow{i} Y.$$

Here i is the discrete fibration associated with the presheaf, and

$$(f_!1_X)(y) = \pi_0(y\backslash X).$$

The first map sends x to the component represented by $(x, 1_{f(x)})$. For an object (y, c) of the category of elements, the comma category $(y, c)\backslash X$ is exactly the component c of $y\backslash X$; it is nonempty and connected. Thus p is cofinal in the terminology of these pages. The edition assigns "étale" to p, but it is the second map i which is étale; the connected cofibres belong to p. The phrase "objet $\cdots$ de e_Y" similarly means an object of $\widehat{Y}$.

For the simplest example without a terminal object, take $X = Y = \mathbf{N}$ with its usual order and $f = 1_X$. Its terminal presheaf is the increasing colimit of the representables, and its category of elements is again $\mathbf{N}$. This is filtered and weakly contractible, although no natural number is terminal. It supplies exactly the kind of example for which Grothendieck introduces the ind-object formulation. Corollary 2.18 is the same argument with an arbitrary presheaf in place of the terminal one.

Corollaire 2.18. ([41]) *Soit X dans* Cat*, F dans $X^\wedge$. Pour que F soit ind-représentable il faut et il suffit que X/F soit filtrante.*

En effet, par (2.15), X/F est filtrante si et seulement si l'objet final F de X/F provient d'un ind-objet de X/F, mais cela signifie aussi que F est la limite inductive dans $X^\wedge$ d'un ind-objet de X, i.e. que F est ind-représentable.

Question. *Si X dans* Cat *est totalement W_∞-asphérique, i.e. les $f_!(e_{X^\wedge})$ sont W_∞-asphériques pour toute flèche $f : X \longrightarrow Y$ dans* Cat*, ou encore pour toute telle flèche, avec les $y\backslash Y$ 0-connexes ($y \in \operatorname{Ob} Y$), Y est W_∞-asphérique - cela implique-t-il que X soit filtrante ?* Ça ne m'étonnerait pas - et même en supposant seulement les $f_!(e_{X^\wedge})$ 1-connexes ([42]) (ils sont 0-connexes, dès que X l'est). Mais je ne veux pas m'attarder à présent sur cette question. [36]

Commentary · Exposition [ms. 36]

The quantifier in total asphericity

Grothendieck is asking which indexing categories remain homotopically harmless after an ordinary change of index. The adjective "total" concerns every possible target of a functor; it does not merely strengthen the contractibility of the nerve of the original category. It is useful to isolate the precise condition before reading the proposed answer. Write $BA = |NA|$, and write $T(A)$ for the assertion that BE is weakly contractible whenever $A \longrightarrow E$ is an ordinary cofinal functor. Here and below "cofinal" has the orientation fixed in Section 3: each category $e\backslash A$ must be nonempty and connected.

This formulation is equivalent to the one using $f_!1_A$ on the page. Indeed, for $f : A \longrightarrow Y$, put $P = f_!1_A$, so that

$$P(y) = \pi_0(y\backslash A).$$

Let Y/P be its category of elements. There is a canonical factorization

$$A \xrightarrow{q} Y/P \longrightarrow Y, \qquad a \longmapsto (fa, [a, 1_{fa}]).$$

41. déjà dans SGA 4, I 8.

42. Ils le sont toujours (cf. XII, p. 101), c'est 2-*connexe* qu'il faut lire ici !

For an object (y, c) of Y/P, the comma category $(y, c)\backslash A$ is precisely the connected component c of $y\backslash A$. Thus q is cofinal. Conversely, if f itself is cofinal, then $P = 1_Y$ and $Y/P = Y$. Consequently $T(A)$ says exactly that the category of elements of every ordinary presheaf $f_!1_A$ is weakly contractible. The occurrence of $y\backslash Y$ in the printed question is a slip: it is $y\backslash A$ that must be connected.

A filtered category satisfies T. Its ordinary cofinal images are filtered by Corollary 3.4 below, and their nerves are weakly contractible. The difficult direction is whether this test forces the equalization of parallel arrows. The counterexample inserted on pages 36bis–36ter withdraws the attempted negative answer; it does not prove the converse. The converse holds for monoids and for categories with finitely many objects and fails in general; both are proved in the commentary "Total asphericity is not filteredness" below.

There is a terminological precaution for the later literature. In Maltsiniotis (2020, Definition 1.7.2 and Proposition 1.7.1), a category is called totally aspherical when it is aspherical and its diagonal is aspherical, equivalently when products of representable presheaves are aspherical. This is a different quantifier from $T(A)$. In particular, the fact that the simplex category is a strict test category does not settle the question on this page. We retain $T(A)$ only inside this commentary, to keep the question itself unchanged.

La réponse à la question précédente est négative, comme on voit par la :

Proposition 2.19. ([43]) *Soit X dans* Cat *telle que $diag_X : X \longrightarrow X \times X$ soit cofinal* ([44])*, i.e. telle que X^o soit totalement* 0*-connexe. Alors X est totalement W_∞-asphérique (donc aussi totalement W-asphérique pour tout localiseur fondamental W tel que $W \supseteq W_\infty$).* p. 22

Soit en effet un foncteur cofinal $f : X \longrightarrow Y$, il faut prouver que Y est W_∞-asphérique. Or on sait que totalement 0-connexe implique W_∞-asphérique ([45]) (cf. proposition 2.3, p. 17-18), donc il suffit de voir que Y^o est totalement 0-connexe, i.e. $Y \xrightarrow{d_Y} Y \times Y$ cofinal. Or on a le diagramme commutatif

$$\begin{array}{ccc} X & \xrightarrow{d_X} & X \times X \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f\times f} \\ Y & \xrightarrow{d_Y} & Y \times Y, \end{array}$$

où par hypothèse f, donc aussi $f \times f$, et d_X sont cofinaux. Donc $\varphi = (f \times f) \circ p_X$ [plutôt $\varphi = (f \times f) \circ d_X$] est cofinal, et comme $\varphi = d_Y f$ et f est aussi cofinal, on conclut que d_Y l'est, q.e.d.

Corollaire. $\mathbf{\Delta}$ *étant totalement* 0*-connexe, $\mathbf{\Delta}^o$ est totalement W_∞-asphérique, pourtant elle n'est pas filtrante.*

Question. *X totalement W_∞-asphérique $\Longrightarrow$ X^o totalement* 0*-connexe ? Ou du moins implique PS 1′ ?*

[36bis]

Contrexemple 2.20 à la proposition fausse 2.19.

Soit X un objet de Cat, rajoutons-lui la catégorie finale e comme fermé, i.e. considérons un objet X' de Cat dans lequel X soit un sous-objet ouvert, e le fermé complémentaire :

$$X \overset{i}{\hookrightarrow} X' \overset{j}{\hookleftarrow} e.$$

On sait (cf. XII) qu'une telle opération est déterminée, à isomorphisme près, par la donnée d'un objet

$$H \in \mathrm{Ob}\, X^\wedge$$

en posant

$$H(x) = \mathrm{Hom}_{X'}(x, e),$$

43. **Faux.**
44. cf. définition 3.3, p. 45.
45. C'est **faux.**

la catégorie X/e s'identifiant (à isomorphisme près) à X/H. Elle est donc 0-connexe si et seulement si l'objet H de $X^\wedge$ est 0-connexe. Cela signifie aussi que le morphisme i est cocofinal, i.e. que $i^o : X^o \longrightarrow X'^o$ est cofinal. Supposons maintenant X W_∞-asphérique et totalement 0-connexe, i.e. l'actuel Loc (6), cf. XVI. La proposition 2.19 affirme que, sous ces conditions, X' (qui est lui aussi totalement 0-connexe) est même W-asphérique. Il s'ensuivrait donc que $i \in W_\infty$. Mais par XII, th. 4, cor. 4 (p. 149), il s'ensuivrait que X/e est W_∞-asphérique, i.e. p. 23
H W_∞-asphérique. Ainsi, si X est totalement 0-asphérique, tout objet 0-connexe de $X^\wedge$ serait [36ter]
∞-connexe. Mais c'est manifestement faux, p.ex. si on prend pour X une catégorie-test pour W_∞, p.ex. $X = \mathbf{\Delta}$.

Commentary · Examples [ms. 36]

The retracted proposition and a visible sphere

The useful part of Proposition 2.19 is its elementary calculation with cofinal functors: the ordinary cofinal image of a nonempty sifted category is sifted. The unsupported step is the passage from that ordinary connectedness condition to weak contractibility. The edition marks this step and the proposition as false. The appeal in Counterexample 2.20 to Chapter XII also needs its hypothesis restored: the reflection of a weak equivalence to the attaching category uses the strong form of W(7bis), explicitly required in Grothendieck (1990–1991d, Chapter XII, Section V.3.4, Corollary 4, note 104). That reflection is not valid for arbitrary weak homotopy equivalences. We can make the intended counterexample entirely explicit without using it.

The omitted reflection condition has a concrete obstruction. Choose a finite connected acyclic noncontractible simplicial complex K; a finite presentation complex with this homotopy type is given in Hatcher (2002, Example 2.38 and Theorem 2C.5). Its suspension is simply connected and acyclic, hence contractible by the homology Whitehead theorem. The face posets of the two cones on K are open subcategories covering the face poset of ΣK, with intersection the face poset of K. The two cones and their union are weakly contractible, but their intersection is not. Thus the weak equivalence from one cone into the union does not reflect to a weak equivalence from the intersection into the other cone. This contradicts the strong biconditional W(7bis), while leaving the direct homotopy-pushout theorem intact.

Let $H = \Delta[1]/\partial\Delta[1]$, the simplicial circle, and form the category E with full subcategory Δ, one additional object z, and

$$E([n], z) = H_n, \qquad E(z, [n]) = \varnothing, \qquad E(z, z) = \{1_z\}.$$

Composition into z is the simplicial action of H. Thus $\Delta/z = \Delta/H$, the category of simplices of H. Its classifying space has the homotopy type of $|H| = S^1$; this is the usual category-of-simplices realization, or the test-category equivalence for Δ (Maltsiniotis, 2020, Proposition 1.7.14). Since Δ has terminal object [0], its classifying space is contractible.

There is a direct description of BE. An n-simplex of NE that does not lie in $N\Delta$ consists of a chain in Δ followed by an arrow into z, with possible repetitions of z. The arrow into z and all its composites are exactly a simplex of $N(\Delta/H)$. These simplices glue to the mapping cone of the forgetful map $B(\Delta/H) \longrightarrow B\Delta$. Hence

$$BE \simeq \operatorname{hocolim}\big(B\Delta \longleftarrow B(\Delta/H) \longrightarrow *\big) \simeq \Sigma S^1 \simeq S^2.$$

The cone description can also be read degree by degree: adjoining the last vertex z supplies the cone direction, and deleting that vertex applies the forgetful map. It therefore identifies the attaching maps, not merely the vertices of the two spaces.

The inclusion $i : \Delta \hookrightarrow E$ is ordinary initial: Δ/e has a terminal object when $e \in \Delta$, while $\Delta/z = \Delta/H$ is nonempty and connected. Thus $i^{\mathrm{op}} : \Delta^{\mathrm{op}} \longrightarrow E^{\mathrm{op}}$ is cofinal. The source Δ^{op} is sifted: for $[m], [n]$, its category of common targets is opposite to $\Delta/(\Delta[m] \times \Delta[n])$, which is connected because the product of the two simplices is contractible. The target E^{op} is consequently sifted as well, whereas $B(E^{\mathrm{op}}) \simeq S^2$. This supplies both a counterexample to the implication used in Proposition 2.19 and a direct counterexample to its asserted corollary about Δ^{op}.

The distinction is the same one encountered earlier in the chapter between products of connected objects and their higher homotopy. Here its failure has a specific witness, a two-dimensional sphere. It is not a failure of the composition or cancellation properties of ordinary cofinal functors.

Cela me fait soupçonner que la conjecture

$$X \text{ totalement } W_\infty\text{-asphérique} \Longrightarrow X \text{ filtrante}$$

pourrait être valable.

Commentary · Development (commentators') [ms. 36]

A necessary directedness condition

Grothendieck asks, before returning to cofinality, whether his condition at least forces the existence of common successors. This weaker question admits an elementary answer. The argument below also settles his full question for preorders. We did not find this particular implication isolated in the consulted treatments of sifted categories, asphericity, or lax epimorphisms; the following is our continuation of the argument, with no assertion of priority.

Proposition (the common-successor obstruction). [ours] *If $T(A)$ holds, then A is nonempty and any two objects of A admit arrows to a common object. Consequently, for a preorder A, the condition $T(A)$ is equivalent to filteredness.*

Proof. The identity of A is cofinal, so $T(A)$ implies that BA is weakly contractible. In particular A is nonempty and connected. Suppose that objects a, b have no common successor. Let U be the full subcategory of objects receiving an arrow from a, and let V be the full subcategory of objects receiving an arrow from b. These subcategories are disjoint and closed under passage to successors.

Let P be the three-object category with precisely the nonidentity arrows

$$0 \xrightarrow{p} 1, \qquad 0 \xrightarrow{q} 2.$$

Define $f : A \longrightarrow P$ by sending U to 1, V to 2, and all other objects to 0. Closure under successors makes this a functor: an arrow cannot leave U or V, and there are no arrows between them. The category $0\backslash A$ computed for f is A itself. The other two comma categories are U and V. They are connected, since every object of U receives an arrow from a, and every object of V receives one from b. They need not have initial objects; the existence of those arrows is all that is used. Hence f is cofinal.

We next give P a cofinal image with nonzero second homology. Adjoin an object z and arrows

$$r, s : z \rightrightarrows 0, \qquad v : z \longrightarrow 1, \qquad w : z \longrightarrow 2,$$

subject to $pr = ps = v$ and $qr = qs = w$, and no other nonidentity arrows. Call the resulting category Q. The inclusion $j : P \hookrightarrow Q$ is cofinal. For an object of P, the relevant comma category has an initial object. For z, the category $z\backslash P$ has four objects r, s, v, w and four arrows

$$r \longrightarrow v, \quad r \longrightarrow w, \quad s \longrightarrow v, \quad s \longrightarrow w;$$

it is nonempty and connected.

To see exactly what obstructs contractibility, use normalized simplicial chains of NQ. There are four nondegenerate two-simplices, denoted $(r,p), (s,p), (r,q), (s,q)$, and no nondegenerate simplices in higher dimensions. Their boundaries are

$$\partial(r,p) = p - v + r, \quad \partial(s,p) = p - v + s,$$
$$\partial(r,q) = q - w + r, \quad \partial(s,q) = q - w + s.$$

Therefore

$$c = (r,p) - (s,p) - (r,q) + (s,q)$$

is a nonzero cycle. Since there are no three-simplices, it is not a boundary. More precisely, the coefficients of p, q, r, s, v, w in the boundary show that every two-cycle is an integral multiple of c, so $H_2(BQ; \mathbf{Z}) \cong \mathbf{Z}$. The composite jf is cofinal, contradicting $T(A)$. This proves the common-successor assertion.

In a preorder, parallel arrows are already equal. Nonemptiness and common successors therefore imply filteredness. The converse follows from preservation of filteredness by ordinary cofinal images, as in Corollary 3.4. This proves the last assertion. □

For general categories the argument leaves precisely the parallel-arrow equalization problem. The distinction is substantive: a one-object group category satisfies the common-successor condition for every group, while filteredness forces that group to be trivial. The next commentary settles it: the implication $T(A) \Rightarrow A$ filtered holds when some object receives an arrow from every object, and fails for the category of finite ordinals and increasing injections.

Commentary · Development (commentators') [ms. 36]

Total asphericity is not filteredness

The question whether $T(A)$ forces A to be filtered has a negative answer in general and a positive one for monoids and for categories with finitely many objects. Both rest on a description of $T(A)$ in which no target category appears. For a functor $H : A \to \mathrm{Set}$ write $\mathrm{El}(H)$ for its category of elements: the objects are the pairs (a, h) with $h \in H(a)$, and an arrow $(a, h) \to (a', h')$ is an arrow $v : a \to a'$ with $H(v)h = h'$. The statements below were not found in the sources consulted, except where a reference is given; no priority is claimed.

Theorem (a criterion on set-valued functors). [ours] *For a small category A the following are equivalent: (i) $T(A)$; (ii) A is nonempty and connected, and for every functor $H : A \to \mathrm{Set}$ every connected component of $\mathrm{El}(H)$ has the integral homology of a point; (iii) the same with "is weakly contractible". If they hold, every connected component E of every $\mathrm{El}(H)$ satisfies $T(E)$.*

Proof. Let $K : A \to \mathrm{Set}$ have nonempty connected $\mathrm{El}(K)$, and let A_K be A with one object x adjoined, $A_K(x, a) = K(a)$, no arrows into x but its identity, and composition given by the action of A on K. For the inclusion $A \to A_K$ the category $x\backslash A$ is $\mathrm{El}(K)$, and $a\backslash A$ has an initial object for $a \in A$; so the inclusion is cofinal. A chain of arrows of A_K not contained in A consists of x (possibly repeated) followed by a chain of $\mathrm{El}(K)$. Hence $N(A_K)$ is NA with the cone on $N\,\mathrm{El}(K)$ attached along the forgetful map, and

$$\widetilde{H}_{j+1}(BA_K) \longrightarrow \widetilde{H}_j(B\,\mathrm{El}(K)) \longrightarrow \widetilde{H}_j(BA)$$

is exact. Under (i) both BA and BA_K are weakly contractible, so $\mathrm{El}(K)$ has the homology of a point. A component of $\mathrm{El}(H)$ for an arbitrary H is $\mathrm{El}(K)$ for the subfunctor K of the elements lying in it. This proves (i)⇒(ii).

(ii)⇒(iii). Let E be a component of $\mathrm{El}(H)$ and $L : E \to \mathrm{Set}$ a functor. Then $\mathrm{El}(L) \cong \mathrm{El}(H')$ for the functor $H'(a) = \coprod_h L(a, h)$ on A, the sum over the $h \in H(a)$ with $(a, h) \in E$. So E again has property (ii). Let ΠE be the groupoid obtained by inverting all arrows of E, fix an object e_0, and identify $G = \mathrm{Aut}_{\Pi E}(e_0)$ with $\pi_1(BE, e_0)$. For a subgroup $\Gamma \subseteq G$ the functor $L_\Gamma(e) = \mathrm{Hom}_{\Pi E}(e_0, e)/\Gamma$ has bijective transition maps, and $\mathrm{El}(L_\Gamma) \to E$ is the connected covering with fundamental group Γ. By (ii) for E its first homology Γ^{ab} vanishes. Taking Γ cyclic gives $G = 1$. A simply connected CW complex with the homology of a point is weakly contractible.

(iii)⇒(i). Let $f : A \to B$ be cofinal. For $b \in B$ the category $b\backslash A$ is $\mathrm{El}(a \mapsto B(b, f(a)))$; it is nonempty and connected, hence weakly contractible by (iii), and Quillen's Theorem A makes Bf a weak equivalence. The constant functor with value a point shows that BA is weakly contractible. So is BB. The last assertion was shown in the second step. □

In particular the integral-homology form of $T(A)$ (every cofinal image has the homology of a point) is equivalent to $T(A)$. With coefficients in a nonzero commutative ring R the same proof, with the homology form of Theorem A, gives: every cofinal image of A has the R-homology of a point if and only if A is nonempty and connected and the components of all $\mathrm{El}(H)$ do. For $R = \mathbf{Q}$ this is weaker: a finite group satisfies it.

Proposition (exact colimits suffice). [ours] *If A is nonempty and connected and $\varinjlim_A$ is exact on functors $A \to \mathrm{Ab}$, then $T(A)$.*

Proof. For $H : A \to \mathrm{Set}$ and $F : \mathrm{El}(H) \to \mathrm{Ab}$ put $(\Sigma_H F)(a) = \bigoplus_{h \in H(a)} F(a, h)$. The functor Σ_H is exact and $\varinjlim_{\mathrm{El}(H)} F = \varinjlim_A \Sigma_H F$. So colimits over $\mathrm{El}(H)$ are exact, and so are colimits over a component E (extend by zero). The left derived functors of $\varinjlim_E$ on the constant functor $\mathbf{Z}$ are the groups $H_j(BE)$; they vanish for $j > 0$. Criterion (ii) applies. □

Theorem (a category with T that is not filtered). [ours] *Let Δ' be the category of the ordered sets $[n] = \{0, \dots, n\}$, $n \geq 0$, and strictly increasing maps. Then $T(\Delta')$ holds and Δ' is not filtered; it is not sifted either.*

Proof. The two maps $[0] \to [1]$ are not equalized by any injection, so Δ' is not filtered. A pair of maps $[0] \to [N] \leftarrow [0]$ is two points of $[N]$, and whether the first is smaller than, equal to or larger than the second is preserved by increasing injections; so the category of such pairs has three components and the diagonal of Δ' is not cofinal.

For exactness we show: *for every n there are M and an integral combination $t = \sum_g t_g\, g$ of maps $g : [n] \to [M]$ of Δ', with $\sum_g t_g = 1$, such that $t \circ h$ is the same combination for all maps $h : [m] \to [n]$ with the same m.* For $n = 1$, $M = 2$, one can take $t = (0, 1) - (0, 2) + (1, 2)$, naming a map by its values. In general, a map $g : [n] \to [M]$ is determined by its gaps $e_0 = g(0)$, $e_i = g(i) - g(i-1) - 1$, $e_{n+1} = M - g(n)$, that is, by a monomial z^e of degree $M - n$ in $z_0, \dots, z_{n+1}$;

a combination t becomes a homogeneous polynomial P_t, and $\sum t_g = P_t(1,\dots,1)$. Let D_i be the substitution $z_{i+1} \mapsto z_i$ followed by renumbering to variables $y_0,\dots,y_n$. Omitting the value $g(i)$ merges two gaps and the omitted point, so $P_{t\delta^i} = y_i D_i(P_t)$ for the map $\delta^i : [n-1] \to [n]$ that omits i. We construct, for all $n \ge 0$ and $k \ge 1$, a homogeneous polynomial $C_{n,k}$ with integer coefficients, $C_{n,k}(1,\dots,1) = 1$, such that $y_i^k D_i(C_{n,k})$ does not depend on i. Put $C_{0,k} = 1$. Given $Q = C_{n-1,2k}$ in the variables $y_0,\dots,y_n$, we want $D_i(C_{n,k}) = F_i := Q\prod_{l\ne i} y_l^k$ for all i; then $y_i^k D_i(C_{n,k}) = Q\prod_l y_l^k$. In the coordinates $x_i = z_i - z_{i+1}$ $(0 \le i \le n)$, $u = z_{n+1}$, the map D_i is reduction modulo x_i. The prescriptions agree modulo (x_i, x_j): for $j = i+1$ both give $D_i(Q)\prod_l w_l^k$, and for $j \ge i+2$ they give $w_{j-1}^{2k} D_{j-1}(Q)\prod_{l\ne i,j-1} w_l^k$ and $w_i^{2k} D_i(Q)\prod_{l\ne i,j-1} w_l^k$, which are equal by the property of Q. For a nonempty set S of indices let Φ_S be the common value of the F_i, $i \in S$, after setting $x_i = 0$ for all $i \in S$ (in homogeneous lifts written in the coordinates x, u). Then

$$C_{n,k} = \sum_{S\ne\varnothing} (-1)^{|S|+1}\Phi_S$$

reduces to F_j modulo x_j, because the terms S and $S\cup\{j\}$, $j \notin S$, cancel modulo x_j and the term $S = \{j\}$ remains. It is homogeneous, and its value at $(1,\dots,1)$, a point where all x_i vanish, is $F_0(1,\dots,1) = 1$. Now let t correspond to $C_{n,1}$. Then $s = t\delta^i$ is independent of i, and from $\delta^{b+1}\delta^a = \delta^a\delta^b$ $(a \le b)$ we get $s\delta^a = s\delta^b$; by induction on n, $s \circ h'$ depends only on the source of h', and every non-identity $h : [m] \to [n]$ factors through some δ^i. This proves the claim.

Let $F \subseteq F'$ be functors $\Delta' \to \mathrm{Ab}$. Any two objects of Δ' map to a third, so every element of $\varinjlim F$ is the class of one element $\xi \in F([n])$. Suppose its image in $\varinjlim F'$ is zero. The colimit is the quotient of $\bigoplus_m F'([m])$ by the elements $F'(v)\eta - \eta$, so $\xi = \sum_k (F'(v_k)\eta_k - \eta_k)$ in this direct sum, for finitely many $v_k : [s_k] \to [r_k]$ and $\eta_k \in F'([s_k])$. Choose N and maps $d_m : [m] \to [N]$ for the finitely many m that occur; applying $F'(d_m)$ on each summand gives $F'(d_n)\xi = \sum_k \big(F'(d_{r_k}v_k) - F'(d_{s_k})\big)\eta_k$ in $F'([N])$. Choose t for N and write $F'(t) = \sum_g t_g F'(g)$. Since $t \circ d_{r_k} v_k = t \circ d_{s_k}$, applying $F'(t)$ gives $F'(\tau)\xi = 0$ for $\tau = t \circ d_n$, a combination of maps $[n] \to [M]$ with coefficient sum 1. As $F \subseteq F'$, also $F(\tau)\xi = 0$. The class of $F(g)\xi$ in $\varinjlim F$ is the class of ξ for every g, so the class of $F(\tau)\xi$ is that of ξ; it is zero. So $\varinjlim_{\Delta'}$ preserves monomorphisms and is exact; Δ' is nonempty and connected, and the proposition applies. □

That colimits of abelian groups over this category are exact is attributed to Isbell and Mitchell in Adámek et al. (1981, A.5), together with the general criterion: $\varinjlim_A$ is exact on abelian groups if and only if each component of the category with the same objects and the integral combinations of arrows of coefficient sum 1 as morphisms is filtered. The withdrawn corollary on this page claimed T for Δ^{op}, which is false; the category Δ' is an example of what that corollary was after.

Theorem (monoids; finitely many objects). [ours] *Let A have an object q that receives an arrow from every object. Then $T(A)$ holds if and only if A is filtered. This applies to every monoid, and to every category with finitely many objects, where both $T(A)$ and filteredness provide such an object q.*

Proof. Assume $T(A)$. *Step 1: for parallel arrows $a, b : p \to q'$ there are an object r and an integral combination t of arrows $q' \to r$, with coefficient sum 1, such that $ta = tb$.* Let $P_c = \mathbf{Z}[A(c,-)]$, let $d : P_{q'} \to P_p$ be $c \mapsto ca - cb$, with kernel K and image J, and let H be the quotient of $A(p,-)$ by the relations $ca \sim cb$, so that $0 \to J \to P_p \to \mathbf{Z}[H] \to 0$ is exact. The functors P_c are projective with $\varinjlim P_c = \mathbf{Z}$, and $\varinjlim d = 0$. So $L_1 \varinjlim \mathbf{Z}[H]$ is the kernel of $\varinjlim J \to \varinjlim P_p$; this map is zero, because $\varinjlim P_{q'} \to \varinjlim J$ is surjective and $\varinjlim d = 0$. Hence $L_1 \varinjlim \mathbf{Z}[H] = \varinjlim J = \operatorname{coker}(\varinjlim K \to \mathbf{Z})$, the image of $\varinjlim K$ being generated by the coefficient sums of the elements of the groups $K(r)$. The left side is $H_1(B\,\mathrm{El}(H))$, and $\mathrm{El}(H)$ is connected (every object receives an arrow from the class of id_p); by the criterion it vanishes. So 1 is a sum of coefficient sums of finitely many elements of groups $K(r_i)$; pushing them to a common successor r of the r_i (the common-successor proposition of the preceding commentary) and adding gives t.

Step 2: the monoid $M = A(q,q)$ is filtered. For $x, m \in M$, Step 1 for the pair x, xm, followed by an arrow $r \to q$, gives $t \in \mathbf{Z}[M]$ with coefficient sum 1 and $tx = txm$. The element $\nu = tx$ of $\mathbf{Z}[Mx]$ is invariant under right multiplication ρ by m. Let S be its finite support. Each point of S has a ρ-preimage in S, distinct points have distinct preimages, so ρ permutes S and ν is constant on its cycles; the coefficient sum 1 is thus an integral combination of cycle lengths. Among all points of Mx that are ρ-periodic choose one, w, of least period π. If $\pi > 1$, let ℓ be a prime dividing π and apply the same to w in place of x: some cycle in Mw has length prime to ℓ, and its points w' satisfy $w'm^\pi = w'$ too, so their period is a proper divisor of π, a contradiction. Hence there is y

with $yxm = yx$. Given $m, m' \in M$, take y with $ym = y$ (case $x = 1$), then y' with $y'ym' = y'y$; then $y'ym = y'y = y'ym'$.

Step 3. Let $a, b : p \to q'$ be parallel, choose $g : q' \to q$, and by Step 1 an element $t = \sum n_i c_i \in \mathbf{Z}[M]$ of coefficient sum 1 with $tga = tgb$. In the filtered monoid M there is y with $yc_i = y$ for all i. Then $yga = \sum n_i yc_i ga = \sum n_i yc_i gb = ygb$. With common successors this shows that A is filtered. The converse is the fact that filtered categories satisfy T. □

So Grothendieck's expectation is right in every finite case and for all monoids, and the smallest counterexamples have infinitely many objects. For the monoid $\{1, e, f\}$ with $uv = v$ for $u, v \in \{e, f\}$, which is cofiltered with contractible classifying space, the theorem says that T fails; a cofinal image of the homotopy type of S^2 is obtained by adjoining a source x with two arrows $h, i : x \to *$ on which e and f act by the constant map with value i. Whether $T(A)$ implies exactness of $\varinjlim_A$ on abelian groups, the converse of the proposition, is not decided here.

[37]

3 Retour sur la cofinalité

Il est instructif de relier les questions de cofinalité (pour une flèche $u : I' \longrightarrow I$ dans Cat) au dérivateur HOT_{W_0}, où $W_0 \subseteq \mathrm{Fl}\,\mathrm{Cat}$ est le plus grossier des localiseurs dans Cat satisfaisant l'axiome de connexité Loc 5, i.e.

$$W_0 = \{f \in \mathrm{Fl}\,\mathrm{Cat} \mid \pi_0(f) \text{ bijectif}\}. \tag{3.1}$$

On trouve alors, pour I dans Cat, une équivalence canonique, 2-fonctorielle en I,

$$\mathrm{HOT}_{W_0}(I) \xrightarrow{\sim} I^\wedge \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(I, (\mathrm{Ens})), \quad \texttt{[plutôt } \underline{\mathrm{Hom}}(I^o, \mathrm{Ens})\texttt{]} \tag{3.2}$$

en d'autres termes, on a une équivalence

$$\mathrm{HOT}_{W_0} \simeq \mathbf{D}_{(\mathrm{Ens})}. \tag{3.3}$$

Quand HOT_{W_0} est défini par localisation à partir de la catégorie $\mathrm{Cat}(I) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(I^o, \mathrm{Cat})$, la flèche (3.2) est celle déduite, par localisation, de la flèche

$$\begin{array}{rcl} \pi_0^I : \underline{\mathrm{Hom}}(I^o, \mathrm{Cat}) & \longrightarrow & \underline{\mathrm{Hom}}(I^o, (\mathrm{Ens})) \\ X & \longmapsto & \pi_0 \circ X, \end{array} \tag{3.4}$$

où

$$\pi_0 : \mathrm{Cat} \longrightarrow (\mathrm{Ens}) \tag{3.5}$$

est le foncteur 'composantes connexes'. Si on décrit $\mathrm{HOT}_{W_0}(I)$ comme localisée de Cat/I, (3.2) est déduit de la flèche

$$\left\{ \begin{array}{rcl} \mathrm{Cat}/I & \longrightarrow & I^\wedge = \underline{\mathrm{Hom}}(I^o, (\mathrm{Ens})) \\ X & \longmapsto & \underline{\pi_0}(X/I) = (i \longmapsto \pi_0(i\backslash X)). \end{array} \right. \tag{3.6}$$

Ainsi, les foncteurs familiers, pour une flèche [38]

$$u : I' \longrightarrow I$$

dans Cat

$$\left\{ \begin{array}{ccc} & \xrightarrow{u_!} & \\ I'^\wedge & \xleftarrow{u^*} & I^\wedge, \\ & \xrightarrow{u_*} & \end{array} \right. \tag{3.7}$$

p. 25

s'interprètent comme les foncteurs de même nom pour le dérivateur HOT_{W_0}, ou plus directement, pour le dérivateur (qu'on pourrait faussement considérer comme canularesque) $\mathbf{D}_{(\mathrm{Ens})}$.

Commentary · Exposition [ms. 37]

The represented derivator at dimension zero

Grothendieck now uses sets to separate the genuinely categorical part of cofinality from its higher homotopical refinements. The equivalence $\mathrm{HOT}_{W_0}(I) \simeq \mathrm{Fun}(I^{\mathrm{op}}, \mathrm{Set})$ has a short proof that explains why no hidden higher information survives. Let $d : \mathrm{Set} \longrightarrow \mathrm{Cat}$ assign the discrete category, and let π_0 be connected components. There is an adjunction $\pi_0 \dashv d$, with $\pi_0 d = 1$. For each category C, the unit $C \longrightarrow d\pi_0 C$ is a W_0-equivalence. Applied pointwise to an I^{op}-diagram, these units give a natural objectwise W_0-equivalence from that diagram to its discrete component diagram. Thus the two functors become inverse after localization. Since the construction commutes with restriction, it gives the stated equivalence of diagram theories.

The description by Cat/I requires the relative, rather than the global, component construction. To $X \longrightarrow I$ one associates the presheaf $i \longmapsto \pi_0(i\backslash X)$. Localizing the slice merely at functors that induce a bijection on the components of their total categories would give a different category. The relevant class is detected in all these comma categories, exactly as in the relative localization recalled in the commentary on Chapter I, manuscript p. 43 ("What the localization axioms do and do not say").

The large table then has an economical interpretation. The words "aspherical" and "coaspherical" become ordinary initiality and finality; the proper and smooth conditions say that specified strict lift categories are nonempty and connected. Right and left Kan extensions retain their ordinary meanings. Nothing in this reduction licenses replacing connected lift categories by contractible ones. Conversely, it makes the degree-zero assertions accessible by elementary calculations with connected components, without invoking a construction of general homotopy Kan extensions.

Cela donne un sens à la cohorte des notions cohomologiques associées à un dérivateur, ou plus particulièrement, à un localiseur fondamental W sur Cat (donnant naissance au dérivateur HOT_W). On les désignera par le nom de W_0-fourbi (au lieu de HOT_{W_0}-fourbi, ou

$\mathbf{D}_{(\mathrm{Ens})}$-fourbi), notamment pour une flèche $u : I' \longrightarrow I$ de Cat telle la notion

(3.8)

- W_0-équivalence $\Big(\iff$ $\pi_0(u)$ bijectif.$\Big)$
- W_0-asphérique $\Big(\iff$ les I'/i pour $i \in \mathrm{Ob}\, I$ sont 0-connexes.$\Big)$
- W_0-coasphérique $\Big(\iff$ les $i\backslash I'$ pour $i \in \mathrm{Ob}\, I$ sont 0-connexes.$\Big)$
- W_0-propre ([46]) $\Big(\iff$ les inclusions $I'_i \longrightarrow I'/i$ $(i \in \mathrm{Ob}\, I)$ sont W_0-coasphériques, i.e. les fibres des colocalisées $i'\backslash I' \longrightarrow i\backslash I$ $(i' = u(i))$ `[plutôt` $(i = u(i'))$] sont 0-connexes.$\Big)$

`[page 39]`

- W_0-lisse ([47]) $\Big(\iff$ les inclusions $I'_i \longrightarrow i\backslash I'$ sont W_0-asphériques, i.e. les fibres des flèches localisées $I'/i' \longrightarrow I/i$ $(i = u(i'))$ sont 0-connexes.$\Big)$
- W_0-parfait $\Big(\iff$ W_0-propre et W_0-lisse.$\Big)$
- W_0-équivalence universelle ([48]) $\Big(\iff$ π_0 bijectif et le reste par tout changement de base. Ce sont aussi les W_0-fibrations (ou W_0-fibrations faibles à fibres W_0-asphériques, i.e. 0-connexes.$\Big)$
- W_0-fibration $\Big(\iff$ $u^* : \mathrm{Cat}/I \longrightarrow \mathrm{Cat}/I'$ transforme W_0-équivalences en W_0-équivalences.$\Big)$
- W_0-fibration faible ([49]) $\Big(\iff$ le changement de base $u^* : \mathrm{Cat}/I \longrightarrow \mathrm{Cat}/I'$ transforme homotopismes $J_1 \longrightarrow J_2$ en W_0-équivalences - et il suffit de l'exiger pour l'inclusion d'un objet final (ou au choix initial) et pour l'inclusion d'un point dans $\mathbf{\Delta}^1$.$\Big)$

`[Nous avons une]` implication *stricte* (et comment) p. 26

$$W_0\text{-équivalence universelle} \Longrightarrow W_0\text{-fibration}$$

`[et une]` implication *stricte* (et comment !) ([50])

$$W_0\text{-fibration} \Longrightarrow W_0\text{-fibration faible.}$$

46. Exemple : les Cat-cofibrations.
47. Exemple : les Cat-fibrations.
48. Exemple : les flèches W_0-lisses ou W_0-propres, à fibres 0-connexes.
49. Exemple : les flèches W_0-lisses telles que $\pi_0(I'/I) = (i \longmapsto \pi_0(i\backslash I')) = u_!(e_{I'^\wedge})$ soit localement constant sur I, i.e. $\underline{\pi_0}(I'/I)$ soit un *revêtement* étale de I, ou si u^{opp} satisfait cette condition.
50. Mais si les fibres sont 0-connexes, les deux notions de W_0-fibrations sont équivalentes et signifient qu'on a une W_0-équivalence universelle …

Signalons, comme exemple d'utilisation de ces notions, que pour un diagramme cartésien dans Cat

$$\begin{array}{ccc} I' & \xleftarrow{p'} & J' \\ {\scriptstyle u}\downarrow & & \downarrow{\scriptstyle v} \\ I & \xleftarrow{p} & J, \end{array} \tag{3.9}$$

la flèche de changement de base pour u_*, v_* pour les préfaisceaux est [un] isomorphisme si u est W_0-propre, ou p W_0-lisse, et la flèche de changement de base pour $u_!$, $v_!$ est [un] isomorphisme si u est W_0-lisse ou p W_0 propre ([51]). Je signale à ce propos que ces énoncés, qui a priori se formulent pour les préfaisceaux à valeurs dans (Ens), restent valables pour [40] des préfaisceaux à valeurs dans une catégorie $\mathcal{M}$ quelconque (sous réserve d'existence des operations d'images directes cohomologiques ou homologiques envisagées). Cela se voit p.ex. en notant que

$$W_0\text{-équivalence} \implies \mathbf{D}_{\mathcal{M}}\text{-équivalence} \tag{3.10}$$

pour toute $\mathcal{U}$-catégorie $\mathcal{M}$, d'où résulte que toute ([52]) 'W_0-notion' implique la $\mathbf{D}_{\mathcal{M}}$-notion correspondante, et permet donc d'appliquer à $\mathbf{D}_{\mathcal{M}}$ les résultats le concernant. (Il y a bien sûr un argument direct, moins savant, consistant à se ramener au cas où $\mathcal{M}$ est petite, et à utiliser alors le plongement pleinement fidèle $\mathcal{M} \hookrightarrow \mathcal{M}^\wedge$ resp. $\mathcal{M} \hookrightarrow ((\mathcal{M}^o)^\wedge)^o$.)

Je rappelle pour mémoire une (troisième ?) caractérisation des flèches $u : I' \longrightarrow I$ W_0-propres (resp. W_0-lisses) : ce sont celles pour lesquelles le foncteur changement de base $u^* : \mathrm{Cat}/I \longrightarrow \mathrm{Cat}/I'$ transforme flèches W_0-coasphériques (resp. W_0-asphériques) en itou. Cela gagne en intérêt, du fait que la notion de foncteur W_0-coasphérique (resp. W_0-asphérique) s'interprète comme celle de foncteur cofinal (resp. co-cofinal), cf. plus bas.

La notion de W_0-fibration apparaît comme extrêmement forte - beaucoup plus forte à p. 27 certains égards que celle (disons) de W_∞-fibration ou de W_ω-fibration. Elle équivaut à ceci [41] (comme on voit aussitôt) : pour toute composante connexe I'_α de I', désignant par I_α la composante connexe correspondante de I, et pour tout J_α 0-connexe et au dessus de I_α, le produit fibré $I'_\alpha \times_{I_\alpha} J_\alpha$ est encore 0-connexe. (Ça ressemble aux histoires de totale 0-connexité d'un topos !) Mais cela signifie aussi que $I'_\alpha \longrightarrow I_\alpha$ est une W_0-équivalence universelle. Cela implique que ses fibres sont 0-connexes, et la réciproque est vraie si $u : I' \longrightarrow I$ est W_0-propre ou W_0-lisse. Ainsi, la condition essentielle pour une W_0-fibration est celle que les fibres des flèches induites $I'_\alpha \longrightarrow I_{u(\alpha)}$ [plutôt $I'_\alpha \longrightarrow I_\alpha$] soient 0-connexes. En fait, on a ceci

Commentary · Exposition [ms. 40]

The lift categories behind ordinary base change

The base-change assertion is an application of the lift-category criterion already developed in the commentary on Chapter I, manuscript pp. 68–70 ("The category of lifts behind properness" and "Completing the tests in the proper base-change theorem"). Its present specialization is useful because all the relevant tests are tests of connectedness. For $u : A \longrightarrow B$, properness means that, for every $a \in A$ and arrow $\beta : u(a) \longrightarrow b$, the category

$$L(a, \beta) = \{a \xrightarrow{h} a' \mid u(a') = b, u(h) = \beta\}$$

of strict lifts, with arrows over 1_b, is nonempty and connected. Smoothness is the dual condition on arrows into $u(a)$. An opfibration supplies initial objects in the displayed lift categories; a fibration supplies the dual terminal objects. Connectedness is the exact weakening that suffices for ordinary Kan extensions.

51. Sauf erreur, ca donne *deux caractérisations* des morphismes W_0-propres, ou des morphismes W_0-lisses.

52. Pas tout à fait exacte pour *toute* 'W_0-notion', il faut excepter les deux notions de W_0-fibration forte, et faible.

For a strict pullback square as in (3.9), the comparison of the comma categories computing a right Kan extension is final if u is proper or if the horizontal base-change functor is smooth. The ordinary cofinality theorem therefore gives the right base-change isomorphism. Reversing arrows gives the left formula. The same argument works in any coefficient category in which the requisite comma limits exist, so that these Kan extensions are computed pointwise. One can apply $\mathrm{Hom}(m, -)$ to the limits, or dually $\mathrm{Hom}(-, m)$ to the colimits, and reduce to the set-valued cofinality theorem. This avoids imposing unnecessary completeness assumptions on the coefficient category.

The passage from a W_0-equivalence to an equivalence measured by constant coefficients has a similarly elementary explanation. A limit of a constant diagram is a product indexed by the connected components of its shape, and a colimit is the corresponding coproduct, whenever those objects exist. A bijection on components preserves both. The printed footnote correctly excludes the two fibration notions from the blanket transfer of terminology: preserving a larger class of equivalences under every base change is a stronger requirement, even when the equivalences themselves have a simpler definition. The next proposition measures this effect exactly.

Proposition 3.1. *Soit $u : I' \longrightarrow I$ une flèche dans* Cat.

a) Pour que ce soit une W_0-équivalence universelle, il faut et il suffit que pour toute $\mathbf{\Delta}^1 \longrightarrow I$, i.e. toute flèche α de I, la catégorie $I' \times_I \mathbf{\Delta}^1 \overset{déf}{=} I'|\alpha$ soit 0*-connexe, ou encore que les fibres de I soient* 0*-connexes, et que pour toute flèche* non identique *α de I, $I'|\alpha$ soit* 0*-connexe.*

b) Pour que $u : I' \longrightarrow I$ soit une W_0-fibration, il faut et il suffit que pour toute composante connexe $I'_{\alpha'}$ de I', posant $\alpha = u(\alpha')$, la flèche induite $I'_{\alpha'} \longrightarrow I_\alpha$ soit une W_0-équivalence universelle (cf. critère a) pour cette notion). [42]

c) Pour que ce soit une W_0-fibration faible, il faut *que $\forall\, i \in I$, l'inclusion $I'_i \hookrightarrow i\backslash I'$ soit une W_0-équivalence, i.e. $\pi_0(I'_i) \xrightarrow{\sim} \pi_0(i\backslash I')$ soit bijectif,* et *que $i \longmapsto \pi_0(i\backslash I')$ soit un préfaisceau localement constant sur I (i.e. $\underline{\pi_0}(I'/I)$ soit un* revêtement *étale de I). Cette condition est aussi suffisante, si u est W_0-lisse. De plus (pour mémoire) u est une W_0-fibration faible si et seulement si u^{opp} l'est.*

Commentary · Exposition [ms. 42]

Why arrows detect universal connectedness

Proposition 3.1 says that universal preservation of connected components can be checked on vertices and single arrows. Its proof is a useful model for reading the much stronger componentwise condition in part (b). We give the details because the proposition is stated, rather than proved, here.

Suppose first that $u : A \longrightarrow B$ is a universal W_0-equivalence. Pullback along any $[1] \longrightarrow B$ gives a connected nonempty category, since $[1]$ is connected. Conversely, assume this arrow test. Applying it to an identity arrow at b shows that $A_b \times [1]$, and hence A_b, is connected and nonempty. Let $v : J \longrightarrow B$ be arbitrary. Every object of J has a nonempty fibre in $A \times_B J$, so the map on components is surjective. If two objects of the pullback project to objects joined by a zigzag in J, each edge of that zigzag has a connected pullback by hypothesis. Its endpoints can be joined through that pullback, and the connected vertex fibres join any two choices of endpoints. Concatenating these finite zigzags proves injectivity. Thus

$$\pi_0(A \times_B J) \xrightarrow{\sim} \pi_0(J)$$

for every J, which is the required universal equivalence. Notice that the test concerns strict pullbacks, not comma categories.

Now let A_λ be a connected component of A, mapping to the component B_μ. If pullback by u preserves every W_0-equivalence, apply it to $J \amalg \coprod_{\nu \neq \mu} B_\nu \longrightarrow B$, where $J \longrightarrow B_\mu$ is any connected nonempty category over B_μ. The resulting map on components forces $A_\lambda \times_{B_\mu} J$ to be connected and nonempty. Decomposing an arbitrary category over B_μ into its components then shows that $A_\lambda \longrightarrow B_\mu$ is a universal W_0-equivalence. Conversely, if all these component maps are universal equivalences, then for any $J \longrightarrow B$ there is a natural bijection

$$\pi_0(A \times_B J) \cong \pi_0(A) \times_{\pi_0(B)} \pi_0(J).$$

This formula immediately shows that pullback by u preserves every bijection on connected components. It proves part (b), including components of B not met by A.

The necessary conditions in part (c) come from the same tests with categorical homotopy equivalences. The inclusion of the initial object 1_b into $b\backslash B$ is such an equivalence; its pullback identifies $A_b \longrightarrow b\backslash A$ on components. Testing both endpoints of an arrow in B makes the resulting component presheaf locally constant. When u is smooth, ordinary left base change identifies the component presheaf after every base change with the restriction of this local system. Its colimit depends only on the fundamental groupoid of the indexing category, and categorical homotopy equivalences induce equivalences of those groupoids. This proves the stated sufficiency. The opposite-category assertion follows directly because categorical homotopies and π_0 are unchanged by reversal of arrows.

La plus grande différence entre la notion de W_0-fibration, et celle de W_0-fibration faible, me paraît que les morphismes W_0-parfaits (i.e. W_0-lisses et W_0-propres), et a fortiori les W-parfaits pour un localiseur fondamental $W \subseteq W_0$, sont forcément des W-fibrations faibles, mais (*même si* $W = W_\omega$, le plus fin de tous les localiseurs fondamentaux) ne sont pas des W-fibrations. L'exemple le plus frappant à cet égard est sans doute celui des revêtements étales, qui sont W_ω-parfaits (donc des W_ω-fibrations faibles et a fortiori des W_0-fibrations faibles), mais pas des W_0-fibrations ; car dans le cas où I', I sont 0-connexes, il faudrait que les fibres soient 0-connexes (cf. b) ci-dessus), i.e. que u soit un isomorphisme ! [43]

Commentary · Examples [ms. 43]

Monodromy explains the strictness

The covering example isolates what the componentwise test excludes. This is the same monodromy issue as in the commentary on Chapter I, manuscript p. 98 ("Sets already detect the missing monodromy"), now applied to the two precise definitions in (3.8). Let G be a nontrivial group. Its translation groupoid EG has object set G and exactly one arrow between each ordered pair of objects. The functor

$$EG \longrightarrow BG$$

sends $g \longrightarrow h$ to hg^{-1}. It is a discrete fibration and a discrete opfibration, so the strict lift categories are singletons and the map is proper and smooth. Both total and base categories are connected, but the strict fibre is the discrete set G.

The inclusion of the sole object $* \longrightarrow BG$ is a W_0-equivalence. Its pullback along $EG \longrightarrow BG$ is the map $G_{\mathrm{disc}} \longrightarrow EG$, whose map on components is $G \longrightarrow *$. This proves directly that the covering is not a W_0-fibration. It is a weak W_0-fibration by the smooth criterion of Proposition 3.1(c): the relative component presheaf is the locally constant G-set with regular action. Thus weak fibrations permit monodromy between different fibre components, whereas the strong W_0 condition treats each connected component of the total category separately.

There is a subscript caution in the preceding printed paragraph. The conclusion established by this example is "not necessarily a W_0-fibration." It does not assert that coverings fail to preserve weak homotopy equivalences under pullback. In fact their nerves are simplicial coverings, and they do preserve weak homotopy equivalences. Similarly a W_0-perfect map gives a weak W_0-fibration; a W-perfect map gives the corresponding weak W-fibration. These are distinct assertions when $W \subsetneq W_0$.

Une propriété sympathique des morphismes W_0-lisses (resp. W_0-propres), c'est que ce sont des applications *ouvertes* (resp. fermées) pour les espaces topologiques sous-jacents, ce qui signifie en effet que les fibres locales, i.e. des flèches localisées en haut $I'/i' \longrightarrow I/i$ (resp. colocales, i.e. les flèches colocalisées en bas $i'\backslash I' \longrightarrow i\backslash I$), sont surjectives, i.e. à fibres non-vides (ce qui est impliqué par la condition que celles-ci soient 0-connexes).

Dans tout ça je n'ai encore guère parlé des flèches W_0-asphériques resp. co-asphériques, qui pourtant sont ici une motivation principale pour introduire W_0 ! p. 28

Proposition 3.2. *Conditions équivalentes sur la flèche* $u : I' \longrightarrow I$ *dans* Cat :

a) *Pour toute $\mathcal{U}$-catégorie $\mathcal{M}$ et tout foncteur $F : I \longrightarrow \mathcal{M}$, la flèche canonique (sous réserve que les petites limites inductives soient représentables dans $\mathcal{M}$),*

$$\varinjlim_{I'} u^*(F) \longrightarrow \varinjlim_{I} F \tag{3.2.1}$$

est [un] *isomorphisme.* [44]

a′) *Pour toute $\mathcal{U}$-catégorie $\mathcal{M}$ où les petites limites projectives sont représentables et tout $F \in \mathcal{M}(I) = \underline{\mathrm{Hom}}(I^o, \mathcal{M})$, i.e. tout préfaisceau sur I à valeurs dans $\mathcal{M}$, la flèche canonique*

$$\varprojlim_{I} F \longrightarrow \varprojlim_{I'} u^*(F) \tag{3.2.2}$$

est [un] *isomorphisme.*

a″) ([53]) *Comme a′, avec $\mathcal{M} = (\mathrm{Ens})$, i.e. $F \in \mathrm{Ob}\, I^\wedge$.* ([54]).

b) *La flèche u est W_0-coasphérique, i.e. pour tout $i \in I$, $i\backslash I'$ est 0-connexe.*

L' equivalence de a, a′, a″ est ± tautologique en termes des définitions (cf. SGA 4, I, 8…). La forme a″ s'écrit, posant $\mathbf{D} = \mathrm{HOT}_{W_0}$, que $\forall\, F \in \mathbf{D}(I)$, on veut que

$$\underbrace{H^\bullet_{\mathbf{D}}(I, F)}_{\overset{\text{déf}}{=} p_{I,*}(F)} \longrightarrow \underbrace{H^\bullet_{\mathbf{D}}(I', u^*F)}_{\overset{\text{déf}}{=} p_{I',*}(F)} \qquad \texttt{[plutôt} \quad \underbrace{H^\bullet_{\mathbf{D}}(I', u^*F)}_{\overset{\text{déf}}{=} p_{I',*}(u^*F)} \texttt{]} \tag{3.2.3}$$

($p_I : I \longrightarrow e$ et $p_{I'} : I' \longrightarrow e$ les foncteurs canoniques) soit [un] isomorphisme. On sait que cela équivaut à u $\mathbf{D}$-coasphérique. La démonstration est un jeu amusant entre $u_!$, u^*, u_* à la fois. Il faut exprimer que le Hom d'un objet M de $\mathbf{D}(e)$ (= (Ens) en l'occurence) dans la flèche (3.2.3) est bijective. Ici, il

est plus naturel de prendre $M = e$ (ensemble ponctuel) et d'interpréter la flèche (3.2.3) comme p. 29 [45]

$$\mathrm{Hom}(e_I, F) \longrightarrow \mathrm{Hom}(e_{I'}, u^*F) \tag{3.2.4}$$

et par adjonction de $u_!$, u^* le deuxième membre s'interprète comme $\mathrm{Hom}(u_!(e_{I'}), F)$, et la flèche est déduite de

$$u_! e_{I'} = u_! u^*(e_I) \xrightarrow{\text{adj.}} e_I \tag{3.2.5}$$

en prenant le Hom dans F. Donc dire que (3.2.4) est [un] isomorphisme pour tout F signifie que (3.2.5) est [un] isomorphisme. Passant aux valeurs des deux membres en i, on trouve $\pi_0(i\backslash I') \xrightarrow{\sim} 1$, i.e. que $i\backslash I'$ est 0-connexe, q.e.d.

---

53. C'est une condition sur les morphismes de topos, savoir que si F [est] dans $\mathcal{X}^\wedge$, on a

$$H^0(\mathcal{X}, F) \xrightarrow{\sim} H^0(\mathcal{X}', u^*F).$$

Il y a [une] notion similaire pour les H^i ($i \leq n$), à dégager. Notion de morphismes W_0-coasphériques de topos ! C'est dans la nature d'une condition de 0-connexité relative, duale de la notion W_0-asphérique, qui signifie simplement que pour U 0-connexe dans $U^\wedge$ [plutôt $\mathcal{X}^\wedge$], $f^*(U)$ [plutôt $u^*(U)$] est 0-connexe. De même, on a sans doute des notions ('duales' des précédentes) de W_n-coasphéricité (bien comprise en principe si $\mathcal{X}$ est localement n-asphérique) (La W_n-coasphéricité, étant celle évoquée plus haut.)

54. **NB** On peut introduire

a‴) Comme a), mais avec $\mathcal{M} = (\mathrm{Ens})$.

a^{IV}) Comme a), avec le foncteur canonique $I' \longrightarrow I'^\wedge$.

Commentary · Exposition [ms. 45]

What the ordinary cofinality theorem tests

Grothendieck has now proved the criterion announced on the opening page, with the sufficient directedness condition replaced by the exact connectedness condition. The proof is the representability calculation already explained in "The presheaf represented by a change of index": the functor $F \longmapsto \Gamma(I', u^*F)$ is represented by $u_!1_{I'}$, and

$$(u_!1_{I'})(i) = \pi_0(i\backslash I').$$

Consequently the comparison on all set-valued presheaves is an isomorphism precisely when $u_!1_{I'} \longrightarrow 1_I$ is an isomorphism. Applying ordinary Hom functors reduces arbitrary existing limits and colimits to this case. This is the classical theorem of SGA 4, Exposé I, Section 8.1, in the variance used throughout these pages (Artin et al., 1972).

Two small examples distinguish its quantifiers. The inclusion $\{1\} \hookrightarrow [1]$ is cofinal, because each $i\backslash\{1\}$ is a point. For a presheaf $F(1) \longrightarrow F(0)$, its limit is therefore $F(1)$. But the restriction functor forgets $F(0)$ and is not fully faithful. On the other hand, for any nonempty connected category C, the projection $C \longrightarrow *$ is cofinal even when BC has nontrivial homotopy groups. Ordinary cofinality is therefore stronger than a bijection on components of arbitrary source and target, weaker than full faithfulness of restriction, and weaker than homotopy cofinality in a different direction. These comparisons refer to different properties of a functor, not to alternative conventions for the same word.

Footnote 53 distinguishes two degree-zero conditions on a morphism of topoi $f : \mathcal{E}' \longrightarrow \mathcal{E}$. Its coasphericity condition preserves global sections of every object. Its asphericity condition instead requires f^*U to be noninitial and connected whenever U is. For locally connected topoi, the latter is equivalent to preservation of component sets: decompose U into its noninitial connected components and use preservation of coproducts by f^*. For the morphism induced by $u : I' \longrightarrow I$, the restricted representable u^*h_i has category of elements I'/i. Thus this asphericity condition is ordinary initiality of u, by the cofinality theorem with arrows reversed; the section condition is finality. The two endpoints of [1] distinguish them: inclusion of 0 is initial, while inclusion of 1 is final.

The supplementary Yoneda test in footnote 54 should use the functor $I \longrightarrow I^\wedge$. Its colimit is 1_I, whereas its restriction along u has colimit $u_!1_{I'}$. The printed $I' \longrightarrow I'^\wedge$ has the wrong domain for the test as stated. The further suggestion in footnote 53 about higher cohomology should be read with coefficients specified: preservation of all set-valued sections, preservation of abelian cohomology through a fixed degree, and equivalence on all homotopy-valued diagrams detect different truncations. The earlier cohomological cofinality block supplies the derived comparison; the ordinary theorem here establishes its degree-zero model.

Définition 3.3.

a) Quand les conditions équivalentes de 3.2 sont satisfaites, donc quand les $i\backslash I'$ ($i \in \mathrm{Ob}\, I$) sont 0-connexes, on dit que $u : I' \longrightarrow I$ est un foncteur *cofinal.* On dit que u est *co-cofinal* si $u^o : I'^o \longrightarrow I^o$ est cofinal, i.e. si les localisées I'/i de I' sur I ($i \in \mathrm{Ob}\, I$) sont 0-connexes.

b) Si I' est une *sous-catégorie* de I, on dit que I' *est cofinale dans* I si le foncteur d'inclusion est cofinal, *co-cofinale* si ce foncteur est co-cofinal.

Corollaire 3.4. ([55])

a) Pour que u soit cofinal, il faut *que les catégories colocalisées $i\backslash I'$ soient non-vides, i.e. qu'on ait*

F 0) $\pi_0(f)$ `[plutôt` $\pi_0(u)$`]` *est bijectif.* [46]

F 1) Pour tout $i \in \mathrm{Ob}\, I$, `[il]` *existe* `[un]` $i' \in I'$ *et une flèche* $i \longrightarrow u(i')$ *dans* I.

([56]).

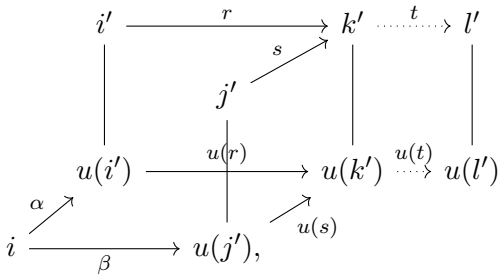
55. **NB** Pour un énoncé complémentaire de cofinalité, cf. XVIII prop. 4.9.6.3 (p. 224-225, 228-242). Il faudrait un énoncé qui coiffe les deux.

56. **NB** F 1 implique déjà `[la]` surjectivité de π_0, donc sa bijectivité si I' est 0-connexe - dans ce cas F 0 résulte de F 1.

b) Si I' est faiblement filtrante, pour que u soit cofinale, il suffit *qu'elle satisfasse F 1, ainsi que la condition :*

F 2) Pour toute double flèche $i \overset{\beta}{\underset{\gamma}{\rightrightarrows}} u(i')$ (avec $i \in \mathrm{Ob}\, I$, $i' \in \mathrm{Ob}\, I'$), `[il]` *existe une flèche $i' \xrightarrow{\alpha'} j'$ dans I', de telle façon que $u(\alpha')$ égalise (β, γ), i.e. $u(\alpha')\beta = u(\alpha')\gamma$.*

et ces conditions F 1, F 2 impliquent que les $i\backslash I'$ sont faiblement filtrantes, et I aussi ([57]).



p. 30

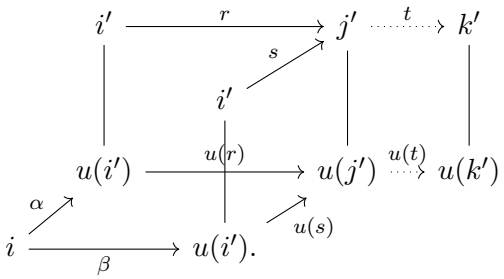
c) Si I' est filtrante, alors u est cofinal si et seulement s'*il satisfait les deux conditions F1, F2, ou encore si et seulement si les $i\backslash I'$ sont* filtrantes *(et non seulement* 0*-connexes). Et cela implique que I' est également filtrante* ([58]).

d) Si I est préfiltrante (= localement faiblement filtrante, i.e. PS 1), et u pleinement fidèle, *pour que u soit cofinal, il* faut *et il* suffit *que u satisfasse la condition F 1 plus haut. Et alors I' est également préfiltrante, et les $i\backslash I'$ sont faiblement filtrantes. Si de plus I est filtrante, les $i\backslash I'$ et I' le sont également. (Comparer SGA 4, I 8.1.3.)*

Démonstration. a) F 1 est évident, car 0-connexe $\Longrightarrow$ non vide. F 0 car W_0-coasphérique [47] $\Longrightarrow$ W_0-équivalence, i.e. $\pi_0(u)$ bijectif.

Pour *prouver* b), il suffit de prouver que F 1, F 2 (si I' est faiblement filtrante) impliquent que les $i\backslash I'$ sont faiblement filtrantes (a fortiori 0-connexes) et de plus que I l'est également. On sait déjà qu'ils sont non vides par F 1, reste à voir que si (i', α), (j', β) sont dans $i\backslash I'$, alors ils sont 'majorés' par un troisième objet de $i\backslash I'$. Comme I' est faiblement filtrante, on trouve $\begin{matrix} i' & \overset{r}{\searrow} & \\ & & k' \\ j' & \underset{s}{\nearrow} & \end{matrix}$, d'où $u(r)$, $u(s)$ dans I (cf. diagramme)

appliquant F 2 à la double flèche $u(r)\alpha, u(s)\beta : i \rightrightarrows u(k')$, on trouve $k' \xrightarrow{t} l'$ (en pointillés sur `[le]` diagramme) telle que $(u(t)u(r))\alpha = (u(t)u(s))\beta$, soit γ, ce qui montre que l'objet $(l', \gamma : i \longrightarrow u(l'))$ majore (i', α) et (j', β).



La démonstration que si I' est faiblement filtrante et u satisfait F 1, alors I est faiblement filtrante, est immédiate.

Prouvons c). Il reste à prouver que si I' est *filtrante* (non seulement faiblement filtrante), alors si u `[est]` cofinal, alors F 2 est vérifiée, et de plus les $i\backslash I'$ et I sont filtrantes (pas seulement faiblement filtrantes). Mais notons tout de suite que $i\backslash I' \longrightarrow I'$ est coétale, donc I' filtrante, donc localement filtrante implique que $i\backslash I'$ est aussi localement filtrante ; comme par hypothèse les $i\backslash I'$ sont 0-connexes, ils sont donc filtrantes. La condition F 2 sort facilement à présent :

p. 31

57. Si I' est localement faiblement filtrante (= préfiltrante), alors pour la cofinalité de u, il suffit qu'on ait F [48] 0, F 1, F 2, et alors les $i\backslash I'$ sont faiblement filtrantes, et I est préfiltrante tout comme I'.

58. Si I' est localement filtrante, u est cofinal si et seulement si elle satisfait F 0, F 1, F 2, i.e. si et seulement si les $i\backslash I'$ sont filtrantes, et alors I est localement filtrante.

Comme $i\backslash I'$ est filtrante, donc faiblement filtrante (PS 1), on peut trouver $i' \overset{r}{\underset{s}{\rightrightarrows}} j'$ telles que

$$u(r)\alpha = u(s)\beta,$$

et comme I' est filtrante, on peut trouver $t : j' \longrightarrow k'$ qui égalise la double flèche (r, s) :

$$tr = ts(\overset{\text{déf}}{=} \tau),$$

alors

$$\underbrace{u(t)u(r)}_{u(tr)}\,\alpha = \underbrace{u(t)u(s)}_{u(ts)}\,\beta \qquad \text{i.e.} \qquad u(\tau)\alpha = u(\tau)\beta,$$

i.e. on a vérifié F 2.

Reste à prouver que I est filtrante (si I' l'est et `[si]` $u : I' \longrightarrow I$ est cofinal). On sait déjà que I est faiblement filtrante par b), reste à vérifier la condition de la double flèche

$$i \overset{\alpha}{\underset{\beta}{\rightrightarrows}} j$$

(PS 2). Soit i' dans I' et $j \longrightarrow u(i')$, et considérons

$$i \overset{\gamma\alpha}{\underset{\gamma\beta}{\rightrightarrows}} u(i'),$$

par hypothèse F 2 $\exists\, r : i' \longrightarrow j'$ dans I' telle que $u(r)(\gamma\alpha) = u(r)(\gamma\beta)$, donc $u(r)\gamma$ égalise (α, β), q.e.d. [49]

La vérification de d) par AQT `[abréviation dont le sens échappe aux éditeurs]`.

Commentary · Development (commentators') [ms. 49]

The filtered criterion and eventual lifting

Corollary 3.4 converts connectedness of comma categories into the two concrete operations needed for filtered colimits: reaching the image of u, and equalizing parallel arrows after reaching it. The proof of parts (b) and (c) is present on the page. There is one harmless slip in the statement of (c): its last assertion concerns filteredness of I, not the already assumed filteredness of I'. Part (d) is left under the abbreviation AQT. Its proof uses full faithfulness in two different places.

One variance qualification is essential. Definition 2.2 called the completion of a cospan by a common predecessor PS 1 and explicitly called its right-hand dual "colocalement faiblement filtrante." Here part (d) and footnote 57 instead use "préfiltrante" or "localement faiblement filtrante" for the right-hand condition: a span must admit a commuting square with a common successor. The proof requires that interpretation. Under the earlier left-hand reading, part (d) would be false: the poset $I = (0 \longrightarrow 1,\ 0 \longrightarrow 2)$ satisfies left PS 1, and the full inclusion $\{1, 2\} \hookrightarrow I$ satisfies F 1, but its comma category under 0 is a discrete two-point category. Thus this is a necessary clarification of the printed terminology, not a variance-neutral use of PS 1.

Assume that I satisfies the right-hand Ore condition PS 1, that $u : I' \longrightarrow I$ is fully faithful, and that F 1 holds. Given objects $(a, \alpha : i \longrightarrow ua)$ and $(b, \beta : i \longrightarrow ub)$ of $i\backslash I'$, PS 1 supplies arrows $r : ua \longrightarrow j$ and $s : ub \longrightarrow j$ with $r\alpha = s\beta$. Choose $j \longrightarrow uc$ by F 1. Fullness lifts the two resulting

arrows $ua \longrightarrow uc$ and $ub \longrightarrow uc$ to arrows in I', and they give a common successor of the original two objects in $i\backslash I'$. F 1 also makes that comma category nonempty. It is therefore weakly filtered, hence connected, and u is cofinal.

To transfer PS 1 itself to I', start with a span $a \longrightarrow b$, $a \longrightarrow c$ in I'. Complete its image in I to a commuting square, reach an object in the image of u by F 1, and lift the two new arrows by fullness. Faithfulness ensures that the lifted square commutes. Thus I' satisfies PS 1. If I is filtered, a parallel pair $r, s : a \rightrightarrows b$ in I' can likewise be equalized in I, followed by an arrow to uc and lifted to an equalizer arrow $b \longrightarrow c$ in I'. Faithfulness again supplies the equality. Nonemptiness follows from F 1, so I' is filtered. The same reasoning, or the discrete-opfibration projection $i\backslash I' \longrightarrow I'$, makes each comma category filtered.

For locally filtered categories, the additional condition F 0 in footnotes 57–58 ensures that objects whose images lie in the same component already lie in the same source component. The arguments can then be carried out in that component. Without this component condition, F 1 and F 2 do not prevent several disconnected copies of one indexing category from being mapped onto it. This is why the global filtered statement and its local variant have different hypotheses.

Footnote 55 asks for a statement encompassing this corollary and Chapter XVIII. The exact later result is Lemma 4.9.6.3, part 1, manuscript p. 224, whose proof is in §4.9.6.7. Its additional condition is eventual lifting:

$$\text{F 3:}\quad \theta : u(a) \longrightarrow u(b) \implies \exists\, v : b \longrightarrow c,\ w : a \longrightarrow c, \qquad u(v)\theta = u(w).$$

For a faithful functor into a filtered category, the lemma identifies F 1 and F 3 with filteredness of the source together with cofinality (Grothendieck, 1990–1991n, Lemma 4.9.6.3(1), pp. 81–82). The following finite formulation combines the two arguments, retaining only the right Ore hypothesis where that suffices. It is our proof-level synthesis of the cited passages, without a claim of priority.

A finite comparison with eventual lifting. [ours] *If the target satisfies right PS 1, F 1 and F 3 make u cofinal. If u is faithful, its source also satisfies right PS 1 and is filtered whenever the target is filtered.*

Indeed, given (a, α) and (b, β) under i, right PS 1 followed by F 1 produces $\rho_a : u(a) \to u(c)$ and $\rho_b : u(b) \to u(c)$ with $\rho_a\alpha = \rho_b\beta$. Apply F 3 first to ρ_a, obtaining $v : c \to d$, $w : a \to d$, and then to $u(v)\rho_b$, obtaining $t : d \to e$, $z : b \to e$. The equality

$$u(tw)\alpha = u(t)u(v)\rho_a\alpha = u(t)u(v)\rho_b\beta = u(z)\beta$$

gives a common successor in the comma category. F 1 gives nonemptiness, hence cofinality. For a span in the source, this construction makes its two composites equal after applying u; faithfulness makes them equal before applying it. If the target is filtered, equalize the images of any parallel pair, reach another image object by F 1, and lift the resulting arrow eventually by F 3. Faithfulness then gives an equalizing arrow in the source. Cofinality supplies connectedness and nonemptiness, completing filteredness. Conversely, when the source is filtered and u cofinal, the already proved filteredness of $u(a)\backslash I'$ gives F 3 by taking a common successor of $(a, 1)$ and (b, θ).

Full faithfulness makes F 3 automatic, recovering part (d). The source-filtered case is the F 1–F 2 criterion in part (c). Thus the finite comparison requested in footnote 55 is explicit. Part 2 of the later lemma strengthens F 3 to simultaneous lifting for families of bounded cardinality and imposes the corresponding larger filtering hypotheses; that cardinal refinement is a separate assertion, not a consequence of the finite conditions alone.

p. 32

4 Foncteurs biasphériques

Soit encore

$$u : I' \longrightarrow I$$

une flèche de Cat, soit $\mathcal{M}$ une catégorie, d'où

$$u^* : \mathcal{M}(I) \longrightarrow \mathcal{M}(I'); \tag{4.1}$$

nous cherchons des conditions sur u, $\mathcal{M}$ pour que ce foncteur soit pleinement fidèle. Si le foncteur adjoint à gauche $u_!$ (resp. adjoint à droite u_*) existe, on sait qu'il revient au même

de dire que le morphisme d'adjonction

$$u_! u^* F \longrightarrow F \tag{4.2}$$

resp.

$$u_* u^* F \longleftarrow F \tag{4.2 bis}$$

soit [un] isomorphisme pour tout F dans $\mathcal{M}(I)$. Disons alors que u est $\mathcal{M}$-connexe, ou $\mathcal{M}$-biasphérique, cette terminologie sous-entendant que c'est là une propriété qui se réfère au dérivateur $\mathbf{D}_{\mathcal{M}} = (S \longmapsto \mathcal{M}(S))$ sur Cat défini par $\mathcal{M}$. Notons que

(4.3) Si u est $\mathcal{M}$-connexe, alors il est aussi $\mathcal{M}(S)$-connexe, pour tout S dans Cat, puisque $\mathcal{M}(S)(I) \simeq \mathcal{M}(I)(S) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(S^o, \mathcal{M}(I))$,

et [50]

(4.4) Si $\mathcal{M}' \hookrightarrow \mathcal{M}$ est pleinement fidèle, alors $\mathcal{M}$-connexe implique $\mathcal{M}'$-connexe,

enfin, inversement,

(4.5) pour que u soit $\mathcal{M}$-connexe, il faut et il suffit que pour toute *petite* sous-catégorie pleine $\mathcal{M}'$ de $\mathcal{M}$, u soit $\mathcal{M}'$-connexe.

Comme toute petite $\mathcal{M}'$ se plonge dans $\mathcal{M}'^{\wedge} = \mathrm{Ens}(\mathcal{M}')$, il résulte de (4.3), (4.4), (4.5) que

(4.6) Si u est Ens-connexe, il est $\mathcal{M}$-connexe pour toute catégorie $\mathcal{M}$,

car c'est le cas si $\mathcal{M}$ est petite par (4.3), donc pour tout $\mathcal{M}$ par (4.5).

Disons qu'un foncteur u dans Cat est $\mathcal{M}$-*cofinal* ou $\mathcal{M}$-coasphérique si l'homomorphisme fonctoriel

$$\varprojlim_{I} F \longrightarrow \varprojlim_{I'} u^*(F) \tag{4.7}$$

(flèche dans $\underline{\mathrm{Hom}}(\mathcal{M}(I), \mathcal{M})$ si les $\varprojlim$ de types I, I' existent dans $\mathcal{M}$, sinon flèche dans $\underline{\mathrm{Hom}}(\mathcal{M}(I), \mathcal{M}^{\wedge})$) est un isomorphisme. En se ramenant au cas de petites catégories $\mathcal{M}$, chacune plongée dans $\mathcal{M}^{\wedge}$, on voit par le critère (4.2 bis) que

(4.8) u est $\mathcal{M}$-connexe si pour tout $i \in \mathrm{Ob}\, I$,

le foncteur induit $I'/i \longrightarrow I/i$ est $\mathcal{M}$-cofinal. La réciproque n'est pas claire, car u est $\mathcal{M}$-connexe si et seulement si pour tout $i \in \mathrm{Ob}\, I$ et tout $\mathcal{M}$-préfaisceau F_i sur I/i *induit par un préfaisceau F sur I,* l'homomorphisme $\varprojlim_{I/i} F_i \longrightarrow \varprojlim_{I'/i} (u/i)^*(F/i)$ est [un] isomorphisme. p. 33 [51]

On ne peut donc affirmer d'emblée que cela implique itou pour *tout* F_i sur I/i, que si on sait que $(u/i)^* : \mathcal{M}(I) \longrightarrow \mathcal{M}(I/i)$ est essentiellement surjectif. Il en est ainsi pour tout i quand I est *ordonné,* car alors $I/i \longrightarrow I$ est pleinement fidèle, donc $\mathcal{M}(I/i) \longrightarrow \mathcal{M}(I)$ [est] pleinement fidèle, donc $\mathcal{M}(I) \longrightarrow \mathcal{M}(I/i)$ [est] un foncteur de localisation, en particulier essentiellement surjectif.

Mais quand $\mathcal{M} = (\mathrm{Ens})$, cette perplexité disparaît. On trouve la [52]

Commentary · Exposition [ms. 51]

The missing pointwise limit hypothesis

Grothendieck isolates a real difference between testing every coefficient on a slice and testing only coefficients restricted from the ambient category. There is also a second issue here: full faithfulness for coefficients in $\mathcal{M}$ does not imply full faithfulness after replacing $\mathcal{M}$ by its presheaf completion. The sufficient implication (4.8) is valid. The converse discussed on page 51, including its asserted ordered case, requires hypotheses ensuring that the relevant pointwise Kan-extension limits exist in $\mathcal{M}$.

Take $I = [1] = (0 \longrightarrow 1)$, $I' = \{1\}$, and let $\mathcal{M}$ be the discrete category on two objects m, n. Every $\mathcal{M}$-valued presheaf on I is constant, so restriction $\mathcal{M}(I) \longrightarrow \mathcal{M}(I')$ is an equivalence. Nevertheless, at $i = 0$ the induced functor on slices is $\varnothing \longrightarrow *$. In $\mathcal{M}^\wedge \simeq \mathrm{Set} \times \mathrm{Set}$, the Yoneda image of m is $(1, \varnothing)$, whereas the limit of the empty diagram is $(1, 1)$. Thus the comparison

$$\varprojlim_{I/0} y(m) = (1, \varnothing) \longrightarrow \varprojlim_{I'/0} y(m) = (1, 1)$$

is not invertible. This coefficient on $I/0$ even extends to I. Hence the intermediate assertion that $\mathcal{M}$-connectedness is equivalent to the slice comparison for restricted coefficients fails without pointwise limit hypotheses.

Existence of an abstract adjoint alone is insufficient: in this example restriction is an equivalence and has both adjoints. What fails is the formula that would compute its right adjoint by an empty limit inside $\mathcal{M}$. Completeness of $\mathcal{M}$, or existence of all the particular comma limits involved, supplies the needed repair.

The extension observation for posets is independently correct. Identify I/i with $A = \{x \mid x \leq i\}$. The map $r : I \longrightarrow A$ sending x to itself when $x \leq i$ and to i otherwise is order preserving: no arrow can enter A from outside, and an arrow leaving A is sent to $x \leq i$. With $j : A \hookrightarrow I$, one has $rj = 1_A$, so every coefficient on A extends by r^{op}. Under the pointwise limit hypotheses this proves the ordered-case converse. It does not remove those hypotheses. Proposition 4.1 subsequently quantifies over all coefficient categories and can use sets from the start; its intended theorem is unaffected by this coefficient-specific error.

Proposition 4.1. *Soit $u : I' \longrightarrow I$ une flèche dans* Cat. *Conditions équivalentes :*

a) Pour toute catégorie $\mathcal{M}$, $u^*_{\mathcal{M}} : \mathcal{M}(I) \longrightarrow \mathcal{M}(I')$ est pleinement fidèle (i.e. u est $\mathcal{M}$-connexe).

a′) Pour toute catégorie $\mathcal{M}$ où les limites inductives de type I, I' existent, la flèche d'adjonction pour F dans $\mathcal{M}(I)$

$$u_! u^* F \xrightarrow{\sim} F$$

est [un] *isomorphisme.*

a″) Dual de a′), avec [la] *flèche d'adjonction*

$$u_* u^* \xleftarrow{\sim} F.$$

b) b′) b″) Comme a) a′) a″), avec $\mathcal{M} =$ (Ens).

c) Comme b′), avec F représentable, i.e. de la forme $j \longmapsto \mathrm{Hom}_I(j, i)$.

d) Pour tout I dans I, $I'/i \longrightarrow I/i$ est cofinal.

d′) Pour tout i dans I, $i\backslash I' \longrightarrow i\backslash I$ est cofinal.

d″) Pour toute flèche $i_0 \xrightarrow{\alpha} i_1$ dans I, la catégorie $i_0\backslash\underset{\alpha}{I'}/i_1 \overset{\text{déf}}{=} I' \times_I \underbrace{i_0\backslash\underset{\alpha}{I}/i_1}_{\substack{\text{catégorie biïnduite} \\ (i_0,\alpha)\backslash(I/i_1) \simeq (i_0\backslash I)/(i_1,\alpha)}}$

est

0-*connexe.*

[53]

Démonstration. On sait déjà, par les préliminaires, l'équivalence de a, a′, a″, b, b′, b″, soit A cette condition - nous dirons que u est W_0-*connexe* ou W_0-*biasphérique,* si ces conditions équivalentes sont satisfaites. On a de plus l'autodualité

(4.8) u est W_0-connexe si et seulement si u^o l'est,

car on a évidemment

(4.9) u est $\mathcal{M}$-connexe si et seulement si u^o est $\mathcal{M}^o$-connexe.

Commentary · Later developments [ms. 53]

Biasphericity, lax epimorphisms, and factorization categories

The new question in Section 4 is whether a diagram and all its natural transformations can be recovered after restriction. The answer is governed by factorizations of arrows, just as ordinary cofinality was governed by objects of comma categories. This is the ordinary version of the factorization test encountered in the commentary on Chapter I, manuscript p. 49 ("The factorization category controls base change"). The proof of Proposition 4.1 continues beyond these pages; we give the complete argument for its corrected statement here.

For $u : A \longrightarrow B$ and $\gamma : b_0 \longrightarrow b_1$, let $\mathcal{F}_u(\gamma)$ have objects

$$(a, p, q), \qquad b_0 \xrightarrow{p} ua \xrightarrow{q} b_1, \quad qp = \gamma,$$

and arrows $h : a \longrightarrow a'$ satisfying $u(h)p = p'$ and $q'u(h) = q$. Then the following conditions are equivalent: restriction on presheaves is fully faithful for every coefficient category; it is fully faithful for sets; and every $\mathcal{F}_u(\gamma)$ is nonempty and connected.

To prove this, first work with sets, where both Kan extensions exist. Full faithfulness of u^* is equivalent to the counit $u_!u^*F \longrightarrow F$ being an isomorphism. Both sides preserve colimits in F, and every presheaf is a colimit of representables, so it suffices to take $F = h_{b_1} = B(-, b_1)$. At b_0 the pointwise colimit formula gives

$$(u_!u^*h_{b_1})(b_0) \cong \coprod_{\gamma \in B(b_0, b_1)} \pi_0 \mathcal{F}_u(\gamma).$$

Indeed, the generators are pairs $b_0 \longrightarrow ua \longrightarrow b_1$, and the colimit relations are exactly the zigzags induced by arrows of $\mathcal{F}_u(\gamma)$. Composition labels every such relation by the same γ. The counit sends a connected component to that composite. It is bijective if and only if each indicated category is nonempty and connected.

The set-valued criterion implies the version for arbitrary coefficients. It first implies full faithfulness for coefficients in every presheaf category, by applying the set-valued statement in each variable. A small category $\mathcal{M}$ embeds fully faithfully into its presheaf category by Yoneda; the full-faithfulness property descends to this full subcategory. For a possibly large locally small $\mathcal{M}$, any two diagrams on the small category B take values in a small full subcategory. Applying the preceding argument there descends every natural transformation and proves uniqueness. This establishes the reductions (4.3)–(4.6), with the usual universe enlargement when necessary.

For fixed b_1, the comma category of the induced functor $A/b_1 \longrightarrow B/b_1$ under (b_0, γ) is $\mathcal{F}_u(\gamma)$. Thus condition (d) is equivalent to the factorization criterion. Its dual says that

$$b_0\backslash A \longrightarrow b_0\backslash B \quad \text{is } \textit{co-cofinal}\text{, that is, initial.}$$

The edition instead prints "cofinal" in (d′). That cannot be retained as a mathematical equivalence. The inclusion $u : \{1\} \hookrightarrow [1]$ satisfies the printed condition: for $i = 0$ it induces the final-vertex inclusion into $[1]$, and for $i = 1$ it induces the identity of a point. Yet restriction on presheaves is not faithful: take $F(1) = \varnothing$, $F(0) = \{0, 1\}$; its identity and the automorphism transposing $0, 1$ become the same map after restriction. The corrected dual condition has comma categories opposite to $\mathcal{F}_u(\gamma)$, so it gives exactly the required connectedness. The two adjunction formulations and self-duality now follow, proving all the intended equivalences.

In later terminology these functors are *lax epimorphisms*, also called absolutely dense functors. Adámek et al. (2001) identify them by full faithfulness of set-valued restriction and by connected

categories of factorizations; the latter characterization is restated explicitly in Lucatelli Nunes and Sousa (2022, Theorem 4.1). For derivators, Groth and Šťovíček (2016, Theorem 6.10) replace connectedness by weak contractibility of the same factorization categories and obtain *homotopical epimorphisms*. Thus the arrowwise obstruction persists; the homotopy theory changes the required strength of its vanishing.

A quotient group displays the difference concretely. For a surjective homomorphism $\rho : H \twoheadrightarrow G$, restriction of G-sets to H-sets is fully faithful, because equivariance under H is equivalent to equivariance under its image G. For any $g \in G$, the category $\mathcal{F}_{B\rho}(g)$ is the transitive action groupoid with object set G, on which H acts through ρ; its stabilizer is $\ker \rho$. It is therefore equivalent to $B \ker \rho$. The functor $B\rho$ is an ordinary lax epimorphism, but it is a homotopical epimorphism only when $\ker \rho$ is trivial. With $\rho : \mathbf{Z} \twoheadrightarrow \mathbf{Z}/n\mathbf{Z}$, the obstruction has the homotopy type of a circle. The full-faithfulness statement about ordinary diagrams is correct; it simply does not recover that circle.

Overview · II-a

Cofinality, connected objects, and the recovery of diagrams.

Chapter II begins by asking when a change of indexing category leaves sections unchanged (Grothendieck, 1990–1991b). It ends this first part with the stronger question of when restriction recovers a whole diagram and every natural transformation between diagrams. Between these questions Grothendieck develops a topos-theoretic account of filtering, examines the homotopy information lost by ordinary connectedness, and specializes the language of derivators to sets. The movement is deliberate. Ordinary cofinality is not merely an elementary preliminary to the derived theory: its proof identifies the object which must be derived, and its limitations identify the higher information which a derivator must retain.

The conventions are essential. A coefficient on C is a contravariant functor, and the category denoted $c\backslash C'$ has objects $c \to \alpha(c')$. Thus a cofinal functor in these pages is final in the usual covariant terminology; its opposite is initial for the diagrams whose limits are being taken. Under this convention the first question has a representability answer. The presheaf

$$K_\alpha(c) = \pi_0(c\backslash C') = (\alpha_! 1_{C'})(c)$$

represents $F \mapsto \Gamma(C', \alpha^* F)$. The comparison with $\Gamma(C, F)$ is induced by $K_\alpha \to 1_C$. It is an isomorphism for all F exactly when every indicated comma category is nonempty and connected. This is the classical cofinality theorem of SGA 4, Exposé I, §8.1 (Artin et al., 1972). The initial weak cofiltering hypothesis is sufficient, and Grothendieck replaces it by the exact connectedness criterion as the argument develops.

The same proof suggests its own derived form. For a commutative ring k, replace the component presheaf by the derived weight $\mathbf{L}\alpha_! k_{C'}$. Its value at c is represented by chains on $N(c\backslash C')$. Derived adjunction then gives

$$\mathbf{R}\Gamma(C', \alpha^* F) \simeq \mathbf{R}\operatorname{Hom}_{C;k}(\mathbf{L}\alpha_! k_{C'}, F).$$

Consequently weak contractibility of all the comma nerves implies cohomological cofinality, answering the question on manuscript page 5 affirmatively. For these fixed linear coefficients, their k-acyclicity already suffices. For spaces the weight is the corresponding presheaf of classifying spaces, and the mapping-space adjunction gives the homotopical statement. Modern higher category theory places this argument within the general criterion for cofinality (Lurie, 2009, Theorem 4.1.3.1). The commentary constructs the linear comparison by a bar resolution, so the answer does not depend on the internal-Hom formula subsequently proposed in the manuscript.

That formula is a genuine point of failure. The global derived Hom belongs to the category of coefficients at a point; a sheaf-valued internal Hom belongs to the diagram category. Applying global sections can identify two such objects without identifying the objects themselves. For the terminal-vertex inclusion $i : \{1\} \hookrightarrow [1]$, a presheaf is an arrow $F_1 \to F_0$, and

$$i_! A = (A \xrightarrow{1} A), \qquad i_* A = (A \to *).$$

The comma categories for cofinality are points, and global sections are F_1. Nevertheless $i_* i^* F$ need not be F, while $\underline{\operatorname{Hom}}(i_! 1, F) = F$. This disproves the unrestricted internal identification in sets, hence already before derived complications arise. The correct internal comparison is equivalent to an additional projection-formula property, whose canonical arrow has the opposite direction from the one displayed in the manuscript. Our point-inclusion calculation identifies its obstruction exactly: for a fixed presheaf, every restriction along an arrow into the chosen object must be invertible. The formula holds for all coefficients precisely when all those incoming arrows are isomorphisms.

The turn to toposes is motivated by a different problem: how to recognize the equalization part of filtering without inspecting individual arrows. An irreducible presheaf topos records

common predecessors of objects, a condition visible in the underlying preorder. Local irreducibility records common predecessors compatible with a prescribed pair of arrows, namely PS 1. It still does not supply PS 2, the equalization of arbitrary parallel arrows. The parallel-arrow category $0 \rightrightarrows 1$ separates the first two conditions. A nontrivial group category BG separates local irreducibility from local cofilteredness: every representable slice is equivalent to a point, but cancellation prevents the equalization of distinct group elements. Several preliminary identifications in the manuscript are explicitly withdrawn by its annotations. The audit preserves this sequence of correction and distinguishes it from errors of transcription.

Total 0-connectedness adds preservation of products by the component functor. For $\widehat{X} = \mathrm{Fun}(X^{\mathrm{op}}, \mathrm{Set})$, it says that X^{op} is an ordinary sifted category. Sifted colimits preserve finite products; filtered colimits preserve finite limits, including equalizers (Adámek et al., 2010). The simplex category supplies the instructive distinction. The products of its representables have connected categories of elements, but the two vertices of [1] admit no common predecessor over [1]. Thus its presheaf topos is totally 0-connected without being locally irreducible. Nothing about this ordinary product test alone makes all the relevant nerves weakly contractible.

The surviving theorem in 2.6 makes the product condition hereditary under connected slices. Its equivalent formulations are (a), (a'), (b), and (d); the generator-slice conditions (c) and (c') are strictly weaker. The diagonal $b \to b \times b$ explains the distinction. Once $b \times b$ is connected and the topos is locally irreducible, its pullback against $(u, v) : a \to b \times b$ is noninitial and yields an equalizing arrow. Conversely, PS 1 and PS 2 lift to categories of elements, giving connected products in every connected slice. The commentary supplies the omitted generator-component lemma and the successive equalizations in this argument. It also restores connectedness of the base where the printed formulation of 2.8 omits it.

On a connected topos satisfying this hereditary condition, π_0 preserves finite limits. This makes the later cohomological argument precise. The induction must run over connected, locally totally 0-connected toposes, since it repeatedly passes to connected components of slice toposes. The degree-zero row of the covering spectral sequence is the augmented complex of functions $I^{p+1} \to M$, where I is the component set of a covering object. Inserting a chosen element of I contracts that complex. The stronger homotopical conclusion follows from hypercovers: applying the exact component functor to their matching-object diagrams gives boundary fillers in every degree, so the resulting simplicial sets are weakly contractible. This connects the argument to the classical hypercover construction of homotopy types (Artin and Mazur, 1969, §§8–9). It concerns constant coefficients and shape. It does not trivialize arbitrary sheaf cohomology, as the worked calculation $H^1(\mathbf{P}^1_k, \mathcal{O}(-2)) \cong k$ illustrates.

The ind-object reformulation in 2.15–2.18 returns to a classical theorem: a presheaf is a filtered colimit of representables exactly when its category of elements is filtered (Artin et al., 1972, Exposé I, Theorem 8.3.3). Taking the terminal presheaf recovers filteredness of the indexing category. Taking its ordinary left Kan extension along an arbitrary functor shows that the resulting category of elements is again filtered. The modern minimal-localizer theorem supplies the asphericity conclusion for every fundamental localizer, without the additional limit axiom used in the historical formulation (Cisinski, 2004, Theorem 2.2.11).

The converse question on page 36 has a stronger quantifier than later uses of the phrase "totally aspherical". In the commentary we denote by $T(A)$ the condition that every ordinary cofinal target of A have weakly contractible nerve. Filtered categories satisfy it. The attempted proof that ordinary siftedness suffices is retracted on pages 36bis–36ter; our explicit completion of the counterexample uses the simplicial circle and a one-point collage whose classifying space is S^2. We also prove a necessary common-successor condition for $T(A)$. Its obstruction is a four-object category with a cofinal three-object subcategory and a nonzero integral two-cycle. This settles $T(A) \Leftrightarrow A$ filtered for preorders. For general categories the remaining issue is equalization of parallel arrows. We did not locate a resolution under this exact universal

quantifier in the sources checked; this is a report of that bounded search, not a declaration of a recognized open problem. Results developed here are marked as the commentators' work and carry no claim of priority.

Section 3 shows how much of the earlier derivator terminology can be tested with sets. Pointwise localization of category-valued diagrams at component equivalences yields the represented derivator of sets. Properness and smoothness become connectedness of strict lift categories. A universal W_0-equivalence can be tested over vertices and arrows; a strong W_0-fibration is characterized component by component by those universal equivalences. Coverings explain why the weak condition is weaker: monodromy can connect different fibre components without making each fibre connected. The comparison with the commentary on Chapter I is made at the precise lifting and monodromy arguments, rather than repeating its whole discussion.

The final transition is from preservation of global sections to full faithfulness of restriction. Proposition 4.1 characterizes the latter by nonempty connected categories of factorizations

$$b_0 \longrightarrow u(a) \longrightarrow b_1$$

of every arrow $b_0 \to b_1$. These are the lax epimorphisms, or absolutely dense functors, of the later literature (Adámek et al., 2001). The homotopical version requires weakly contractible factorization categories (Groth and Šťovíček, 2016, Theorem 6.10). A quotient of groups gives a particularly concrete distinction: the factorization category has the homotopy type of the classifying space of the kernel. Two qualifications belong to the audit. The printed coslice condition in 4.1(d') must be initial, not final. Also the coefficient-specific discussion on page 51 invokes pointwise Kan-extension formulas without the necessary comma limits; a discrete coefficient category on two objects gives a counterexample even when the indexing category is ordered. The corrected theorem quantified over all coefficient categories is established by its set-valued case and Yoneda embeddings.

The historical setting is the program of coherent diagram categories described in Grothendieck (1983, §69), alongside the systematic homotopy Kan extensions of Heller (1988). The commentary keeps the successive formulations, counterexamples, and marginal revisions visible. It distinguishes a proof supplied here from a proof actually written in these pages, and distinguishes a settled theorem from an unsuccessful search for a later treatment.

Ceci montre l'équivalence de d, d′, qui se voit aussi par l'equivalence de chacune de ces deux conditions avec d″, par le critère de cofinalité du paragraphe précedent. Soit D cette condition sur u. On a par (4.8) D $\Longrightarrow$ A, donc p. 34

$$\mathrm{D} \Longrightarrow \mathrm{A} \Longrightarrow \mathrm{c},$$

il reste à prouver que c $\Longrightarrow$ D, plus précisément c $\Longrightarrow$ d″ et c′ $\Longrightarrow$ d″ [c′?]. Explicitons le morphisme d'adjonction (pour i dans I)

$$u_! \underbrace{u^* i} \longrightarrow i,$$

i.e. pour j dans I

$$\underbrace{(u_! u^* i)(j)}_{\pi_0(j\backslash(I'/u^*(i)))} \longrightarrow i(j) = \mathrm{Hom}(j, i).$$

Or $I'/u^*(i) \simeq I'/i$, donc on a la flèche [page 54]

$$(u_! u^*(i))(j) \simeq \pi_0(j\backslash(I'/i)) \longrightarrow \mathrm{Hom}_I(j, i). \tag{4.10}$$

Or on voit aussitôt que pour $\alpha : j \longrightarrow i$ dans $\mathrm{Hom}(j, i)$, la fibre de (4.10) en u s'identifie à $\pi_0(j\backslash\underset{\alpha}{I'}/i\,)$, de façon plus précise, $j\backslash\underset{\alpha}{I'}/i$ est la sous-catégorie ouverte et fermée de $J = j\backslash(I'/i)$ correspondant à la partie du $\pi_0(J)$ qui est au dessus de α dans (4.10). Cela achève la démonstration de 4.1.

Commentary · Exposition [ms. 54]

Reading the two-sided criterion

Grothendieck has now converted full faithfulness of restriction into a condition on individual arrows. This is the point at which the cofinality theorem becomes a tool for reconstructing an entire diagram. The commentary at manuscript p. 53 ("Biasphericity, lax epimorphisms, and factorization categories") already discusses these pages; we retain its notation and add two clarifications needed by the argument that follows.

For $u : A \to B$ and $\gamma : b_0 \to b_1$, write $\mathrm{Fact}_u(\gamma)$ for the category whose objects are triples (a, r, s) with $r : b_0 \to u(a)$, $s : u(a) \to b_1$, and $sr = \gamma$. A morphism to (a', r', s') is $h : a \to a'$ with $u(h)r = r'$ and $s'u(h) = s$. The map of connected components in (4.10) has precisely $\pi_0 \mathrm{Fact}_u(\gamma)$ as its fibre over γ. Its being a bijection therefore says that every arrow has a factorization through u, unique up to a finite zigzag of such factorizations. This is stronger than merely obtaining a connected comma category at each object.

The direction in 4.1(d′) must accordingly be read with care. For B/b_1, the relevant comma category is $\gamma\backslash(A/b_1)$, so its projection must be *cofinal* in the convention of Definition 3.3. For $b_0\backslash B$, the relevant category is $(b_0\backslash A)/\gamma$, so the dual projection must be *co-cofinal*. The edition prints "cofinal" in both places. Taken literally, the second condition is too weak: the inclusion $\{1\} \to [1]$ satisfies it, although restriction of presheaves to the terminal object is not fully faithful. The corrected orientation is also the one used in Proposition 4.4(b).

There is a separate existence issue in 4.1(a′), already isolated in the commentary at manuscript p. 51 ("The missing pointwise limit hypothesis"). The left Kan extension requires the colimits over the appropriate comma categories, not merely colimits of shapes I and I'. Working in a cocomplete coefficient category is sufficient. Once the adjoints exist, the full-faithfulness equivalences are formal, and the representable counit test is valid because both $u_! u^*$ and the identity preserve colimits. No comparable argument makes the representable *unit* test sufficient: its exact meaning is different.

NB Une autre façon de prouver que c $\Longrightarrow$ A c'est de noter que les deux membres dans le morphisme d'adjonction $u_! u^* F \longrightarrow F$ dans $I^\wedge$ sont des foncteurs $I^\wedge \longrightarrow I^\wedge$ qui commutent aux $\varinjlim$ quelconques. Donc pour vérifier que c'est [un] isomorphisme, il suffit de le vérifier pour $\overrightarrow{F}$ dans I, puisque I engendre $I^\wedge$ par $\varinjlim$. Par contre, un argument de ce type ne semble [page 55]

pas prouver que pour vérifier que l'on a un *isomorphisme* $F \longrightarrow u_* u^* F$, il suffise de le faire pour F représentable, i.e. de vérifier b″ pour F représentable.

Il resterait à voir si c′ $\Longrightarrow$ d″ [c′?].

Explicitons le morphisme d'adjonction

$$i \longrightarrow u_* u^* i$$

(pour $i \in \mathrm{Ob}\, I$) par ses valeurs sur j

$$(*) \qquad \underbrace{i(j)}_{\mathrm{Hom}(j,i)} \longrightarrow \Gamma(I'/j, u^* i).$$

Soit donc

$$u_j : I'/j \longrightarrow I,$$

on a

$$\Gamma(I'/j, \underbrace{u^*(i)|I'/j}_{u_j^*(i)}) \simeq \mathrm{Hom}(e_{I'/j}, u^*(i)) \qquad \text{p. 35}$$

$$\overset{\mathrm{adj}}{\simeq} \mathrm{Hom}(u_{j,!} e_{I'/j}, i),$$

et la flèche $(*)$, fonctorielle en i, est déduite d'une flèche

$$(**) \qquad u_{j,!}(e_{I'/j}) \longrightarrow j.$$

On voit tout de suite, comme ci-dessus, que $(**)$ est [un] isomorphisme si et seulement si pour tout $\alpha : k \longrightarrow j$, la catégorie $k \backslash \underset{\alpha}{I'/j}$ est 0-connexe, et si on l'exige pour tout j, k, α, c'est la condition d″. Mais il n'est pas clair que pour qu'on ait $(**)$ isomorphisme, il suffise que le Hom des deux membres à valeurs dans tout i dans I (et non tout F dans $I^\wedge$) soit [un] isomorphisme. La difficulté provient du fait que $u_{j,!}(e_{I'/j})$ n'est pas forcément représentable, et qu'un F quelconque dans $I^\wedge$ n'est pas forcément $\varinjlim$ de foncteurs représentables. Donc il est douteux que c′ [c′?] suffise à entraîner que u est $\overline{W_0}$-connexe. [page 56]

Commentary · Examples [ms. 56]

The unit on representables tests density

Grothendieck's hesitation on pages 54–56 identifies a genuine distinction. He asks whether knowing every representable presheaf can be recovered by right Kan extension already recovers all presheaves. The condition has a familiar modern interpretation: it says that u is dense. Density reconstructs the objects of the original category from their restricted Yoneda images; it does not reconstruct its entire presheaf category.

Indeed, let $y_B(b) = B(-, b)$. By adjunction, the component at c of the unit on $y_B(b)$ is the map

$$B(c, b) \longrightarrow \mathrm{Nat}\big(B(u-, c), B(u-, b)\big).$$

Thus the unit is invertible on all representables exactly when the restricted Yoneda functor $B \to \mathrm{Set}^{A^{\mathrm{op}}}$ is fully faithful. This is the definition of a dense functor; see Riehl (n.d., Definition 6.5.11). It has a different quantifier from the full faithfulness of u^* on *all* presheaves.

A finite example settles the question without any existence qualifications. Let B be the full subcategory of sets on the objects $1 = \{*\}$ and $2 = \{0, 1\}$, and let $u : e \to B$ select 1. For $b, c \in \{1, 2\}$, evaluation on elements gives

$$B(c, b) \xrightarrow{\sim} \mathrm{Set}\big(B(1, c), B(1, b)\big).$$

Both sides are simply the set of functions $c \to b$, and the displayed map is the identity under the indicated identifications. Hence every unit on a representable is an isomorphism. On the other hand, $\mathrm{Fact}_u(\mathrm{id}_2)$ is empty: any composite $2 \to 1 \to 2$ is constant, whereas id_2 is not. Proposition 4.1 therefore shows that u is not W_0-connected.

One can see the failure directly at the counit. The presheaf $u_! u^* y_B(2)$ evaluated at 2 parametrizes factorizations $2 \to 1 \to 2$; its image in $B(2, 2)$ consists of the two constant functions and misses the

identity and the transposition. The representable unit has nevertheless passed every test. The two adjunction maps carry different information.

This is an instance of the standard distinction between density and absolute density. Adámek et al. (2001) identify lax epimorphisms with absolutely dense functors and with the connected-factorization condition. The construction above applies that distinction to the question left here; we do not claim a new density theorem. It also explains the failed proof: representables generate a presheaf category by colimits, whereas the proposed right-adjoint argument would require an appropriate cogeneration statement, which is absent.

Corollaire 4.2. *Pour que u soit W_0-connexe, il* suffit *qu'il soit une W_0-équivalence universelle, i.e. (cf. 3.1) que les fibres soient 0-connexes, et que pour toute flèche non identique dans I, définissant $\mathbf{\Delta}^1 \longrightarrow I$, $I' \times_I \mathbf{\Delta}^1$ soit 0-connexe.*

4.3. Cette condition de W_0-équivalence universelle est cependant *strictement* plus forte que la W_0-connexité, comme on le voit sur l'exemple où u est une *équivalence de catégories* non surjective sur les objets (p.ex. l'inclusion d'un sommet dans un groupoïde 1-connexe ayant plus d'un objet). Plus généralement, tout foncteur de localisation est W_0-connexe, alors que ses fibres ne sont pas forcément connexes, et a fortiori ce n'est pas une W_0-équivalence universelle.

Cependant, si tout endomorphisme p d'un i dans I, tel que $p^2 = p$ (projecteur) est l'identité, et si $I' \longrightarrow I$ est 'transportable', p.ex. si dans I tout isomorphisme est une identité, alors u [page 57]
W_0-connexe implique que les fibres de u sont 0-connexes, comme on voit en exprimant d'' pour α flèche identique. Les conditions envisagées sur I sont satisfaites si I est ordonnée. Mais même si I' et I sont toutes deux ordonnées, u peut être W_0-connexe, sans être une W_0-équivalence universelle. Voici un exemple avec $I = \mathbf{\Delta}^2$:

$$I' = \left\{ \begin{array}{ccc} & & 1' \longrightarrow 2 \\ & & \downarrow \\ 0 & \longrightarrow & 1 \end{array} \right\} \qquad \downarrow$$

$$I = \left\{ 0 \longrightarrow 1 \longrightarrow 2 \right\}.$$

Les catégories bilocalisées de I sont les trois sommets $\{0\}$, $\{1\}$, $\{2\}$, et les trois segments p. 36
$[0,1]$, $[1,2]$ et $[0,2] = I$, les images inverses sont respectivement

$$\bullet\,, \quad \downarrow\,, \quad \bullet\,, \quad \begin{array}{c} \longrightarrow \\ \longrightarrow\downarrow \end{array}\,, \quad \begin{array}{c} \longrightarrow \\ \downarrow \end{array}\,, \quad I'\,,$$

elles sont toutes 0-connexes, i.e. W_0-asphériques, et même contractiles donc W_ω-asphériques (donc u est même W_ω-connexe, i.e. W_ω-biasphérique). Mais ce n'est pas une W_0-équivalence universelle, car l'image inverse de I' par $\mathbf{\Delta}^1 \xrightarrow{\partial} \mathbf{\Delta}^2$, $\partial(0) = 0$, $\partial(1) = 2$, est la catégorie disconnexe $\varepsilon = \{\bullet \quad \bullet\}$. [page 58]

J'avais espéré un moment que les foncteurs W_0-connexes $I' \xrightarrow{u} I$ seraient ceux qui se factorisent en $I' \xrightarrow{u_0} I'' \xrightarrow{v} I$, avec u_0 une équivalence, et v une W_0-équivalence universelle. Mais l'exemple précédent le met en défaut, avec u même W_ω-connexe. En effet, I'' serait déduit d'un ensemble préordonné, et v se factoriserait par l'ensemble ordonné correspondant, savoir I', donc serait de la forme

$$I'' \longrightarrow I' \xrightarrow{u} I,$$

où $I'' \longrightarrow I'$ est un passage au quotient, et l'image inverse de $\mathbf{\Delta}^1 \xrightarrow{\partial} I$ serait encore disconnexe (un π_0 de cardinal 2). Donc c'est vraiment sans espoir.

Commentary · Examples [ms. 58]

A contractible replacement which loses an edge

Grothendieck next tests whether full faithfulness might conceal a stronger, universally preserved equivalence. His four-object example separates these requirements even for finite posets. It deserves to be read as a complete computation, since the obstruction lies in a strict pullback which the homotopy type of the total category cannot detect.

Write A for the poset with precisely the nonidentity arrows

$$0 \longrightarrow 1, \qquad 1' \longrightarrow 1, \qquad 1' \longrightarrow 2,$$

and let $u : A \to [2]$ identify $1'$ with 1. For the three identity arrows of [2], the factorization categories are respectively the point $\{0\}$, the interval $1' \to 1$, and the point $\{2\}$. For $0 \to 1$ and $1 \to 2$, they are the full subposets $0 \to 1 \leftarrow 1'$ and $1 \leftarrow 1' \to 2$. The former has a terminal object and the latter an initial object. For $0 \to 2$, the factorization category is all of A: its nerve has no nondegenerate simplices above dimension one, and its realization is the tree with successive vertices $0, 1, 1', 2$. All six nerves are contractible. Thus this is a homotopical epimorphism, and restriction is fully faithful for every derivator; the later criterion is Groth and Ševčík (2016, Theorem 6.10).

Now pull back along the edge $[1] \to [2]$ selecting $0 \to 2$. The only objects left are 0 and 2, and A contains no arrow between them. The pullback is the discrete two-point category, whose map to [1] is not a W_0-equivalence. Full faithfulness has survived every factorization test and failed this base-change test.

The same computation rules out the proposed factorization through an equivalence followed by a universal equivalence. Suppose $A \xrightarrow{v} C \xrightarrow{w} [2]$ were such a factorization, with v an equivalence. Since A is a poset, C is a preorder, and its poset of isomorphism classes identifies with A. Any functor from C to [2] is constant on isomorphism classes. The inverse image of the edge $0 \to 2$ consequently has two nonempty components, corresponding to the objects 0 and 2 of A, and no morphism joining them. It cannot be connected. This argument uses the skeletal quotient only to count components; it does not assume that an arbitrary strict pullback preserves an equivalence.

Cependant

Corollaire 4.3. *Supposons que u soit W_0-lisse, ou W_0-propre, ou une W_0-fibration faible. Alors u est W_0-connexe si et seulement si c'est une W_0-équivalence universelle, i.e. si et seulement si a) ses fibres sont 0-connexes et b) $I' \times_I \mathbf{\Delta}^1$ [est] 0-connexe pour tout $\mathbf{\Delta}^1 \longrightarrow I$ (correspondant à une flèche non identique).*

Dans les trois cas on sait que u est une W_0-équivalence universelle si et seulement si ses fibres sont W_0-connexes. Or la W_0-lissité implique que $\forall i \in \mathrm{Ob}\, I$, l'inclusion [page 59]

$$I'_i \longrightarrow i\backslash I'$$

est une W_0-équivalence, d'autre part $i\backslash I' \longrightarrow i\backslash I$ étant W_0-asphérique, donc une W_0-équivalence par hypothèse, $i\backslash I'$ est 0-connexe, donc I'_i aussi. Le cas u W_0-propre est dual. Dans le cas [où] u [est] une W_0-fibration faible, on sait encore que $I'_i \longrightarrow i\backslash I'$ est une W_0-équivalence, et on conclut comme dans le cas lisse (ou, au choix, via $I'_i \longrightarrow I'/i$).

Mais l'idée me vient que les foncteurs W_0-connexes pourraient être exactement les foncteurs de localisation ? Il revient au même de dire qu'un foncteur $u : I' \longrightarrow I$ *conservatif* (i.e. $u(\alpha)$ isomorphisme $\Longrightarrow \alpha$ isomorphisme) qui est W_0-connexe, est une équivalence. Mais c'est faux, comme on voit en prenant $I = e$, I' un groupoïde 0-connexe et non 1-connexe : $I' \longrightarrow e$ est W_0-connexe (et même une W_0-équivalence universelle), mais ce n'est pas une équivalence (et pas un foncteur de localisation).

Commentary · Later developments [ms. 59]

The quantifier in homotopical epimorphisms

Grothendieck has separated three operations that are easy to conflate: localizing a category, embedding its diagram theory by restriction, and preserving an equivalence after every strict base change. The example $BG \to e$ at the end of this page separates the first two in dimension zero.

Constant G-sets form a full subcategory of G-sets, so restriction from sets is fully faithful; yet a localization of a groupoid at any collection of its arrows is equivalent to that groupoid, since all those arrows are already invertible. For $G \neq 1$, its projection to e is therefore not a localization.

The modern term *homotopical epimorphism* adds a quantifier absent from the fixed-$\mathbf{D}$ problem about to begin: restriction must be fully faithful for *every* derivator. Groth and Šťovíček (2016, Definition 6.1 and Theorem 6.10), in the arXiv v3 numbering, characterize this condition by weak contractibility of all the factorization categories. Their Remark 6.3(ii) expressly distinguishes full faithfulness for one specified derivator. The space-valued theory detects the universal condition; a particular theory of coefficients can forget more.

This development follows the path from Heller's homotopy theories and Cisinski's comparison results to a calculus of homotopy exact squares. For the present pages, the decisive feature is concrete: connected components in 4.1 are replaced by weakly contractible nerves. The application in tilting theory is equally concrete: a homotopical epimorphism identifies a category of coherent diagrams with a full subcategory of another one, described by unit or counit conditions. No claim that every such functor is an ordinary localization is required.

Je voudrais généraliser la notion de flèche W_0-biasphérique au cas d'un dérivateur $\mathbf{D}$ quelconque.

[page 60]

Commentary · Exposition [ms. 60]

Recovering a global diagram from its slices

Grothendieck now wants the factorization criterion to work with an arbitrary theory of coefficients. The difficulty is no longer the adjunction: a right adjoint is fully faithful exactly when its counit is invertible, and a left adjoint exactly when its unit is invertible. The issue is whether the tests visible from global diagrams detect every diagram on a slice. Proposition 4.4 isolates a sufficient detection condition instead of assuming such a property implicitly.

Put $q = u/i : A/i \to B/i$, $\alpha : B/i \to B$, and let ξ lie in $\mathbf{D}(e)$. With the variance of the manuscript, the comparison of homotopy limits on B/i and A/i is induced, after applying $\mathrm{Hom}(\xi, -)$, by the counit

$$c_\xi : q_! q^*(\xi_{B/i}) \longrightarrow \xi_{B/i} \qquad \text{in } \mathbf{D}(B/i).$$

The subscripts in the edition's $(***)$ should be B/i on the object to which q^* is applied and on the target. The printed I'/i in both places makes that display ill-typed; the argument itself determines the correction.

If all c_ξ are invertible, then for every $G \in \mathbf{D}(B/i)$ the maps $\mathrm{Hom}(c_\xi, G)$ are bijections. By adjunction and Yoneda, the induced comparison of homotopy limits is invertible. Taking $G = \alpha^* F$ and using the pointwise right Kan extension formula proves that $F \to u_* u^* F$ is invertible at i. As this holds for every i, the derivator axiom detecting isomorphisms pointwise gives full faithfulness. This proves the sufficient direction without requiring every slice diagram to extend globally.

For the converse, full faithfulness supplies only

$$\mathrm{Hom}_{\mathbf{D}(B/i)}(c_\xi, \alpha^* F) \quad \text{bijective for every } F \in \mathbf{D}(B).$$

Adjunction turns this into bijectivity of $\mathrm{Hom}_{\mathbf{D}(B)}(\alpha_! c_\xi, F)$ for every F, so Yoneda says exactly that $\alpha_! c_\xi$ is invertible. Conservativity of $\alpha_!$ then proves that c_ξ is invertible. This is condition 3°; the proof needs conservativity only on this family of counits, although the stronger formulation is easier to use.

Condition 2° implies 3° by an elementary adjunction argument. If $L \dashv R$ and R is essentially surjective, then an arrow h for which Lh is invertible induces bijections on Hom into every Rd, hence into every object; therefore h is invertible. If B is a preorder, $B/i \to B$ is fully faithful. Its left Kan extension is fully faithful, so the unit $G \to \alpha^* \alpha_! G$ is invertible and α^* is essentially surjective. Thus 1° implies 2°, which implies 3°.

The hypothesis on coproducts in 4.7 will make 3° available in many coefficient theories, including pointed ones. It is a property of those coefficients, not a formal property of every derivator. The modern axioms used here—pointwise calculation of Kan extensions and pointwise detection of isomorphisms—are recorded in Groth (2013, Definition 1.5); their different roles will matter for the parenthetical assertion about faithfulness.

Proposition 4.4. *Soit* $\mathbf{D}$ *un dérivateur sur* Diag, *et* $u : I' \longrightarrow I$ *une flèche dans* Diag. *Supposons que* u_* *et* $u_!$ *existent, et se calculent de façon standard, pour tout flèche* u *dans* Diag. *(En fait, il suffit que ce soit le cas pour* u *et ses localisées* $u/i : I'/i \longrightarrow I/i$, *ou* u *et ses colocalisées* $i\backslash u : i\backslash I' \longrightarrow i\backslash I$.*) Considérons les conditions :*

a) $u^* : \mathbf{D}(I) \longrightarrow \mathbf{D}(I')$ `[est]` *pleinement fidèle.*

a′) $\forall$ F *dans* $\mathbf{D}(I)$, *la flèche*

$$u_! u^* F \longrightarrow F$$

est un isomorphisme.

a″) $\forall$ F *dans* $\mathbf{D}(I)$, *la flèche*

$$u_* u^* F \longleftarrow F$$

est un isomorphisme.

b) $\forall$ i *dans* I, *la flèche* $i\backslash I' \longrightarrow i\backslash I$ *est* $\mathbf{D}$*-asphérique.*

b′) $\forall$ i *dans* I, *la flèche* $I'/i \longrightarrow I/i$ *est* $\mathbf{D}$*-coasphérique.*

b″) $\forall$ $\alpha : i_0 \longrightarrow i_1$ *dans* I, *la catégorie* $i_0\backslash I'/i_1$ *est* $\mathbf{D}$*-asphérique.*

On a alors les implications

$$(b \Longleftrightarrow b' \Longleftrightarrow b'') \Longrightarrow (a \Longleftrightarrow a' \Longleftrightarrow a'').$$

On a $a \Longrightarrow b$ *(i.e. toutes les conditions licites envisagées sont équivalentes) dans chacun des cas suivants.* [page 61]

1° I *est préordonné.*

2° $\forall$ i *dans* I, $\alpha_i^* : \mathbf{D}(I) \longrightarrow \mathbf{D}(I/i)$ *est essentiellement surjectif.*

3° $\forall$ i *dans* I, *considérant* $\alpha_i : I/i \longrightarrow I$, *le foncteur* $\alpha_{i,!} : \mathbf{D}(I/i) \longrightarrow \mathbf{D}(I)$ *est conservatif.*

4° $\mathcal{D} = \mathrm{HOT}_{W_0} \approx \mathbf{D}_{\mathrm{Ens}}$.

DÉMONSTRATION. L'équivalence de a, a′, a″ est claire, soit A. De même l'equivalence de b, b′, b″, soit B.

Prouvons

$$B \Longrightarrow A$$

en supposant p.ex. l'existence de u_*. On admet tacitement, avec l'existence de $u_* : \mathbf{D}(I') \longrightarrow \mathbf{D}(I)$, le mode de calcul des fibres de $u_*(-)$. Donc A, via a″, équivaut à

$$H^\bullet_{\mathbf{D}}(I'/i, u^*F) \overset{iso}{\longleftarrow} H^\bullet_{\mathbf{D}}(I/i, F) \simeq F(i)$$

pour tout F dans $\mathbf{D}(I)$, tout i dans I. p. 38

Soit

$$\alpha_i : I/i \longrightarrow F, \qquad F_i = \alpha_i^*(F),$$

on doit donc exprimer que pour tout F_i provenant d'un F, on a

$$(*) \qquad H^\bullet_{\mathbf{D}}(I/i, F_i) \xrightarrow{\text{iso}} H^\bullet_{\mathbf{D}}(I'/i, (u/i)^*(F_i)).$$

Or sous réserve d'existence de $(u/i)_!$, dire que $(*)$ est `[un]` isomorphisme pour *tout* F_i de $\mathbf{D}(I/i)$, signifie que

$$u/i : I'/i \longrightarrow I/i$$

est $\mathbf{D}$-coasphérique, d'où b′ $\Longrightarrow$ a″. Il est clair que l'implication inverse est valable si α_i^* est essentiellement surjectif, c'est le cas 2°. Or 2° est satisfait si I est préordonné, d'où le cas 1°. [page 62]

Le cas 4° a déjà été traité (4.1). Il faut encore traiter le cas 3°, qui contient d'ailleurs le cas 2°, donc le cas 1° (et aussi le cas 4°, cf. plus bas).

Il faut exprimer l'isomorphie de la flèche $(*)$ pour F_i de la forme $\alpha_i^*(F)$. Soit ξ [un] objet de $\mathcal{A} = \mathcal{D}(e)$, il faut exprimer l'isomorphie de $\mathrm{Hom}(\xi, -)$ dans les deux membres de $(*)$, i.e. de

$$(**) \qquad \begin{array}{ccc} \mathrm{Hom}(I/i, F_i) & \longrightarrow & \mathrm{Hom}(\xi'_{I'/i}, (u/i)^*(F_i)) \\ & \overset{\text{adj.}}{\simeq} & \mathrm{Hom}((u/i)_!(\xi'_{I'/i}), F_i), \end{array}$$

[plutôt $\xi_{I'/i}$] flèche qui se déduit de

$$(***) \qquad (u/i)_!(u/i)^*(\xi_{I'/i}) \xrightarrow{\text{adj.}} \xi_{I'/i}$$

en prenant le Hom dans F_i. La condition u/i coasphérique (i.e. b′) signifie que $(***)$ est un isomorphisme pour tout ξ dans $\mathcal{A}$. *Suffit*-il pour ceci que son Hom dans un F_i soit bijectif, quand on restreint F_i dans $\mathbf{D}(I/i)$ à être dans l'image de $\mathbf{D}(I)$ par α_i^* ? Or cette flèche $(**)$, pour $F_i = \alpha_i^* F$, s'explicite par la formule d'adjonction relative au foncteur α_i, comme [page 63]

$$\mathrm{Hom}(\alpha_{i,!}(\xi_{I/i}), F) \longrightarrow \mathrm{Hom}(\alpha_{i,!}(\ldots), F).$$

Dire que c'est un isomorphisme pour tout F, signifie donc *exactement* que la transformée de la flèche $(***)$ par $\alpha_!$ est un isomorphisme. Pour en conclure que $(***)$ elle-même est [un] isomorphisme, la condition naturelle à imposer est donc que $\alpha_{i,!} : \mathbf{D}(I/i) \longrightarrow \mathbf{D}(I)$ soit conservatif. C'est le cas 3°. Cela achève la démonstration de 4.4.

4.5. Montrons que la condition 3° sur I n'est pas toujours satisfaite, dans le cas de $\mathbf{D} = (\mathrm{HOT}_{W_0})^{\mathrm{opp}} \approx (\mathbf{D}_{\mathrm{Ens}})^{\mathrm{opp}}$, bien que dans ce cas, il soit pourtant vrai que pour toute I' sur

I satisfaisant la condition a″ (autoduale), la condition b′ (elle aussi autoduale) est aussi satisfaite (par cas 4° ci-dessus). Je dis donc qu'il existe I et i dans I, tels que p. 39

$$\beta_{i,*} : (i\backslash I)^\wedge \longrightarrow I^\wedge$$

ne soit pas conservatif. (**NB** Par contre $\alpha_{i,!} : (I/i)^\wedge \longrightarrow I^\wedge$ est toujours conservatif, ce qui redonne le cas 4° comme cas particulier de 3°). Comme $\beta_i : i\backslash I \longrightarrow I$ est W_0-propre (et même W_ω-propre !), $\beta_{i,*}$ 'se calcule fibre par fibre', donc on a [page 64]

$$\beta_{i,*}(G)(j) \simeq \prod_{\alpha \in \mathrm{Hom}(i,j)} G(\alpha),$$

la fibre en question en j étant discrète. Prenons

$$I = 0 \underset{\beta}{\overset{\alpha}{\rightrightarrows}} 1, \qquad \text{avec } \alpha \neq \beta,$$

alors $0\backslash I$ est $\Psi = \begin{array}{ccc} & \overset{\alpha'}{\nearrow} & 1 \\ 0 & & \\ & \underset{\beta'}{\searrow} & 1' \end{array}$, et $\Psi^\wedge$ est la catégorie des diagrammes d'ensembles $G = \begin{array}{ccc} & \overset{\lambda}{\swarrow} & G_1 \\ G_0 & & \\ & \underset{\mu}{\nwarrow} & G_{1'} \end{array}$. Le foncteur β_* déduit de $\beta : i\backslash I \longrightarrow I$ transforme ce diagramme en

$$G_1 \times G_{1'} \underset{\lambda\,\mathrm{pr}_2}{\overset{\lambda\,\mathrm{pr}_1}{\rightrightarrows}} G_0.$$

[plutôt $\mu\,\mathrm{pr}_2$]. Si on se borne aux diagrammes G pour lesquels $G_{1'} = \emptyset$, β_* sur ceux-ci donne

$$\emptyset \rightrightarrows G_0,$$

donc la restriction de β_* à cette sous-catégorie (équivalente à $(\mathbf{\Delta}^1)^\wedge$) n'est pas fidèle, ni conservative, ne tenant compte que de la composante G_0, et non pas de G_1.

Commentary · Examples [ms. 64]

A product erases a component

Grothendieck's example explains why the conservative-slice hypothesis cannot simply be imposed on one chosen side of every derivator. A right Kan extension over a discrete fibre is a product, and the empty set can erase every other factor. This is an obstruction in ordinary presheaf theory, before any passage to homotopy categories.

Let B have two distinct arrows $\alpha, \beta : 0 \rightrightarrows 1$, and let $p : 0\backslash B \to B$ be the projection. Its domain has the shape $a \to b$, $a \to c$, with $p(a) = 0$ and $p(b) = p(c) = 1$. A presheaf G is a diagram $G_b \xrightarrow{\lambda} G_a \xleftarrow{\mu} G_c$, and

$$(p_*G)(0) = G_a, \qquad (p_*G)(1) = G_b \times G_c.$$

The two restriction maps are $\lambda\,\mathrm{pr}_1$ and $\mu\,\mathrm{pr}_2$. Take $G_a = 1$, $G_b = \varnothing$, $G_c = \varnothing$, and $H_a = 1$, $H_b = 1$, $H_c = \varnothing$. The evident map $G \to H$ is not an isomorphism, but $p_*G \to p_*H$ is the identity of the presheaf $\varnothing \rightrightarrows 1$. To see nonfaithfulness as well, take $G_b = 1$, $H_b = 2$ while keeping the a-values equal to 1 and the c-values empty; the two distinct maps on the b-component have identical direct images.

For the other variance, $B/i \to B$ is a discrete fibration and its left Kan extension is a disjoint union over each fibre. In sets, a map between two such unions that preserves the indexing is bijective exactly when each component is bijective. This proves the conservativity used in 4.4 for set coefficients. Dualizing the derivator exchanges these two mechanisms, which is why failure of the particular sufficient condition does not refute the equivalence of full faithfulness and biasphericity for sets or their opposite theory.

Definition 4.6. *On dit que $u : I' \longrightarrow I$ dans* Diag *est* **D**-biasphérique *si elle satisfait les conditions équivalentes b, b′, b″ de 4.4,* **D**-connexe *si elle satisfait la condition a, ou encore (sous réserve d'existence de $u_!$ resp. de u_*) les conditions équivalentes a′, a″.* [page 63bis]

Ainsi, **D**-biasphérique implique **D**-connexe, et la réciproque est vraie quand I satisfait (par rapport à **D**) la condition 3° de 4.4 (donc aussi, si elle satisfait l'une des conditions plus faibles 2°, 1°), ou la condition duale de celle-ci (vu que les notions **D**-biasphérique, **D**-connexe sont autoduales). À cet égard, notons le

Corollaire 4.7. *Supposons que $\mathcal{A} = \mathbf{D}(e)$ satisfasse la condition suivante : le foncteur*

$$\begin{cases} \mathcal{A} \times \mathcal{A} \longrightarrow \mathcal{A} \\ (\xi \quad , \quad \eta) \longrightarrow \xi \amalg \eta \end{cases}$$

est conservatif (resp. fidèle). Alors pour toute flèche étale $u : J \longrightarrow I$ dans Diag *(et en particulier pour $I/i \longrightarrow I$), le foncteur $u_! : \mathbf{D}(J) \longrightarrow \mathbf{D}(I)$ est conservatif (resp. fidèle)* ([1]). *Si cette condition, ou la condition duale, impliquant les produits $\xi \times \eta$ (ξ, η dans $\mathcal{A}$), est satisfaite, alors pour toute flèche $u : I' \longrightarrow I$ dans* Diag, *u est* **D***-connexe si et seulement si u est* **D***-biasphérique.* p. 40 [page 64bis]

Démonstration. L'hypothèse de conservativité, ou de fidélité se transporte aux sommes indexées par un ensemble quelconque (sous réserve d'existence), comme on voit en écrivant $\coprod_\lambda \xi_\lambda = \xi_{\lambda_0} \amalg \coprod_{\lambda \neq \lambda_0} \xi_\lambda$. L'assertion faite sur $u_!$ résulte alors du calcul de $u_!$ fibre par fibre (qui est valable vu que u est étale donc lisse), en tenant compte que les fibres sont discrètes.

1. **NB** Cette condition est satisfaite si $\forall \xi, \eta \in \mathcal{A}$ on a $\mathrm{Hom}(\xi, \eta) \neq \emptyset$, (car on se ramène à ceci : si u_1, u_2 sont deux flèches dans Ens entre ensembles *non vides,* et si $u_1 \times u_2$ est [un] isomorphisme, u_1, u_2 sont [des] isomorphismes). Cela s'applique en particulier si $\mathcal{A}$ admet un objet neutre, p.ex. si $\mathcal{A}$ est additive.

Commentary · Development (commentators') [ms. 64bis]

Faithfulness does not follow from the fibre calculation

Grothendieck uses disjoint fibres to promote a property of coproducts in $\mathbf{D}(e)$ to a property of $u_!$ on coherent diagrams. For conservativity, the argument is complete: an invertible $u_!h$ gives an invertible component h_j at every j, and the derivator axiom then makes h invertible. For faithfulness, pointwise evaluation does not provide the analogous conclusion. A small derived example shows that the parenthetical assertion is false.

An étale direct image killing a nonzero extension. [ours] Let k be a field and take $\mathbf{D}(K) = D(\mathrm{Vect}_k^{K^{\mathrm{op}}})$. There is a discrete fibration $p : J \to I$ for which $p_!$ is not faithful, although binary coproducts in $\mathbf{D}(e) = D(k)$ are faithful.

Proof. Take $I = (0 \to 1)$ and let J have objects a, b, c and the two nonidentity arrows $a \to b$, $a \to c$. Send a to 0 and both b, c to 1. The unique lifting condition for arrows with a fixed target verifies that p is a discrete fibration. A presheaf on J is written $(B \to A \leftarrow C)$. Its left Kan extension is

$$p_!(B \xrightarrow{f} A \xleftarrow{g} C) = (B \oplus C \xrightarrow{(f,g)} A).$$

This functor is exact, since it is computed by finite direct sums at each vertex. Its derived functor is consequently given by the same formula on complexes.

Consider the three representations

$$M = (k \to 0 \leftarrow 0), \qquad N = (0 \to k \xleftarrow{\mathrm{id}} k), \qquad E = (k \xrightarrow{\mathrm{id}} k \xleftarrow{\mathrm{id}} k).$$

There is a short exact sequence $0 \to N \to E \to M \to 0$: the inclusion is the identity at a, c and zero at b, and the quotient is the identity at b and zero elsewhere. It does not split. A section $M \to E$ would have to be the identity at b and zero at a; commutativity along $a \to b$ for the contravariant diagrams would then assert $\mathrm{id}_k = 0$. Therefore its class

$$\delta \in \mathrm{Ext}^1_{\mathrm{Vect}_k^{J^{\mathrm{op}}}}(M, N) = \mathrm{Hom}_{\mathbf{D}(J)}(M, N[1])$$

is nonzero. The equality is the usual identification of extension classes with degree-one derived morphisms; here all objects are representations of a finite acyclic quiver.

After applying $p_!$, the middle representation is $(k \oplus k \xrightarrow{(1,1)} k)$ and the quotient is $(k \to 0)$. The map at the source sending t to $(t, -t)$, together with the zero map at the target, gives a section of that quotient. Hence the image extension splits and $p_!\delta = 0$. Binary direct sum on $D(k)$ is faithful because each summand of a morphism is recovered by composing with the canonical inclusion and projection. This proves the assertion. □

The example concerns only "resp. fidèle". It leaves the conservative conclusion, and therefore the final equivalence in 4.7, intact. For represented derivators the evaluation functors are jointly faithful and the parenthetical argument does work; it also works under an explicit joint-faithfulness hypothesis on $\mathbf{D}(J) \to \mathbf{D}(e)^{\mathrm{Ob}\, J}$. We checked the distinction between coherent and incoherent diagram categories in Groth (2013, Introduction and Definition 1.5) and the treatment of homotopical epimorphisms in Groth and Šťovíček (2016, §6); we did not find this particular counterexample to 4.7 there. The calculation is included as a repair of the statement, without a claim of priority.

Je ne connais pas d'exemple d'un couple $(\mathbf{D}, u)$ d'un dérivateur $\mathbf{D}$ et d'une flèche u dans Diag, pour lesquels u soit $\mathbf{D}$-connexe sans être $\mathbf{D}$-asphérique. On a donné des conditions sur $\mathbf{D}$, qui assurent équivalence des deux notions. Si $\mathbf{D}$ est de la forme $\mathbf{D}_{\mathcal{M}}$, et si $\mathcal{M}$ satisfait la condition dite dans 4.7 ou sa duale, alors par 4.7 c'est OK. Donc un contrexemple avec un $\mathbf{D}_{\mathcal{M}}$ devrait en tenir compte. Je ne vais pas m'obstiner pour tirer au clair ce qui en est.

Commentary · Development (commentators') [ms. 64bis]

A connected restriction with an empty factorization category

Grothendieck asks whether the sufficient conditions just proved leave a genuine distinction between $\mathbf{D}$-connectedness and $\mathbf{D}$-biasphericity. The edition says "sans être $\mathbf{D}$-asphérique", but that literal question has an immediate negative answer: full faithfulness makes the unit invertible on constant objects, hence implies asphericity. The surrounding discussion and the next diagram concern *biasphericity*. A represented derivator supplies the requested separating example.

A two-valued coefficient theory. [ours] Let $L = \{0 < 1\}$ be the complete lattice, regarded as a category, and let $\mathbf{D}_L(K) = \mathrm{Fun}(K^{\mathrm{op}}, L)$. Let B be the free category on the directed cycle $x \xrightarrow{s} y \xrightarrow{t} x$, and let $u : e \to B$ select y. Then u is $\mathbf{D}_L$-connected and is not $\mathbf{D}_L$-biaspherical.

Proof. The complete lattice L has every small limit and colimit, given respectively by infima and suprema. Thus its represented prederivator is a derivator: restriction has both pointwise Kan extensions, disjoint unions of indexing categories give products of functor categories, and natural transformations are invertible exactly when their components are. It is also strong, since currying gives the required coherent-arrow identifications. These are the standard represented examples recalled in Groth (2013, Examples 1.2(1), 1.6 and Definitions 1.5, 1.8), with the manuscript's contravariant diagram convention.

An object F of $\mathbf{D}_L(B)$ gives inequalities $F(y) \le F(x)$ and $F(x) \le F(y)$. Antisymmetry forces equality. All arrows of B then have the unique endomorphism of that value as image. Every diagram is therefore constant, and a natural transformation between the two possible diagrams is precisely an inequality in L. Evaluation at y identifies $u^* : \mathbf{D}_L(B) \to L$ with an isomorphism of categories. In particular it is fully faithful.

For the identity of the omitted object, however,

$$\mathrm{Fact}_u(\mathrm{id}_x) = \varnothing.$$

Indeed, a factorization through y would be a path $x \to y$ followed by a path $y \to x$. Both have positive length, and in a free category their composite cannot be the length-zero identity. The empty category is not $\mathbf{D}_L$-aspherical: its homotopy colimit of the constant value 1 is the initial object 0, and the comparison $0 \to 1$ is not invertible. Equivalently, $L \to \mathbf{D}_L(\varnothing) = e$ is not fully faithful. Condition 4.4(b″) fails. □

Both potential escapes supplied by 4.7 genuinely fail here. Coproduct is maximum, so the map $(0,1) \to (1,1)$ becomes an identity after taking coproducts although its first component is not invertible. Product is minimum, so $(0,0) \to (1,0)$ gives the dual failure. The counterexample therefore does not contradict the conservative-coproduct theorem, nor the preorder-base case: the indexing category B is a free category with nontrivial endomorphisms, not a preorder.

The example isolates the information lost by the coefficient theory. It sees mutual reachability of objects but cannot distinguish the identity from a nonidentity cycle; the factorization condition still distinguishes them. This coefficient theory is also the classical derivator of truth values, or homotopy (-1)-types; see Shulman (2023, p. 33). We checked that discussion, the density and lax-epimorphism literature cited above, the fixed-derivator qualification in Groth and Šťovíček (2016, Remark 6.3(ii)), and searches for biasphericity in the derivator literature. We could not find this counterexample there. The claim here is the explicit proposition and proof, rather than an assertion that it has no earlier occurrence.

Corollaire 4.8. *Une flèche u de* Diag *qui est une* **D***-équivalence universelle est* **D***-biasphérique, et* a fortiori **D***-connexe. Inversement, si u est soit* **D***-lisse, soit* **D***-propre, soit une* **D***-fibration faible, et si u est* **D***-biasphérique, c'est une* **D***-équivalence universelle.* [page 65]

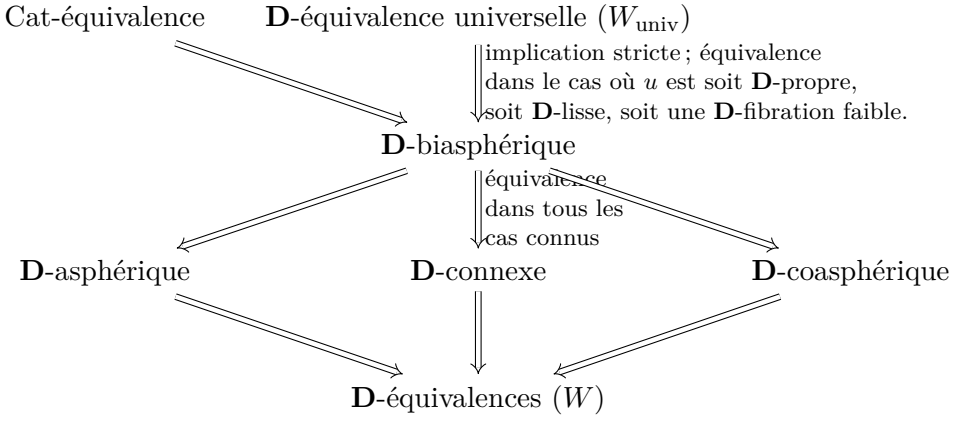
Commentary · Exposition [ms. 65]

What the seven classes retain

Grothendieck's diagram organizes the preceding tests by the amount of coefficient information they preserve. Its arrows remain useful, but the two observations below are needed to read the diagram after the preceding counterexample.

First, **D**-connectedness is stable under composition. If $u : A \to B$ and $v : B \to C$ are **D**-connected, then

$$(vu)^* \simeq u^* v^*$$



is a composite of fully faithful functors and is fully faithful. Thus the exception printed in the footnote cannot be an exception to closure under composition. This is a formal fact, independent of any Kan-extension existence hypothesis. The footnote's further assertion that all seven classes depend only on $W_{\mathbf{D}}$ requires an independent argument for the fixed-coefficient connectedness class; it does not follow from the stated factorization criterion, whose converse has just failed.

Second, connectedness always implies both asphericity and coasphericity. The adjunction unit and counit are invertible on every $F \in \mathbf{D}(B)$, hence on constant F in particular. The distinction

established above is between this global full faithfulness and the two-sided slice tests defining biasphericity. The label "équivalence dans tous les cas connus" records the author's experience at this stage, not an additional theorem.

For universal equivalences the factorization test still gives the implication in 4.8. The category of factorizations of a fixed arrow $\gamma : b_0 \to b_1$ through arbitrary objects of B has an initial object $(b_0, \mathrm{id}, \gamma)$ and a terminal object $(b_1, \gamma, \mathrm{id})$. Pulling u back to that category produces $\mathrm{Fact}_u(\gamma)$. A universal $W_{\mathbf{D}}$-equivalence therefore makes this category $\mathbf{D}$-aspherical. Under the smooth, proper, or weak-fibration hypotheses, the fibre-to-comma comparisons give the converse exactly as in 4.3. These hypotheses are what connect strict base changes to the homotopy calculation; the four-object example shows why they cannot simply be omitted.

La démonstration est celle du cas particulier 4.3. On a donc un diagramme d'implications :

([2]). Rappelons que pour $u : I' \longrightarrow I$ donné

a) u est $\mathbf{D}$-asphérique si et seulement si $\forall\, F$ *constant* dans $\mathbf{D}(I)$

$$(*) \qquad F \xrightarrow[\sim]{\text{adj.}} u_* u^* F \qquad \text{est } \texttt{[un]} \text{ isomorphisme.}$$

p. 41

b) u est $\mathbf{D}$-coasphérique si et seulement si $\forall\, F$ *constant* dans $\mathbf{D}(I)$

$$(**) \qquad F \xleftarrow[\sim]{\text{adj.}} u_! u^* F \qquad \text{est } \texttt{[un]} \text{ isomorphisme.}$$

c) u est $\mathbf{D}$-connexe si et seulement si pour *tout* F dans $\mathbf{D}(I)$ (pas forcément constant, ni localement constant), $(*)$ est `[un]` isomorphisme, ou ce qui revient au même, pour tout F $(**)$ est `[un]` isomorphisme.

Rappelons que la classe W_{asph} `[des]` flèches W-asphériques et celle, Liss_W, des flèches W-lisses, se déterminent mutuellement, ainsi [page 66]

$$(4.10) \qquad \begin{cases} (f : X \longrightarrow Y) \in W_{\mathrm{asph}} & \iff & \forall\, (Y' \xrightarrow{u} Y) \in \mathrm{Liss}_W, \\ & & X' = X \times_Y Y' \longrightarrow X' \text{ est } \in W. \\ (f : Y' \longrightarrow Y) \in \mathrm{Liss}_W & \iff & \text{Le foncteur } X \longmapsto X' = X \times_Y Y' \\ & & \text{de } \mathrm{Cat}/Y \text{ dans } \mathrm{Cat}/Y' \text{ transforme} \\ & & \text{flèches dans } W_{\mathrm{asph}} \text{ dans } \texttt{[plutôt en]} \\ & & \text{flèches dans } W_{\mathrm{asph}}. \end{cases}$$

2. **NB** Ces sept classes de morphismes dans Cat sont stables par composition sauf la notion de $\mathbf{D}$-connexité, toutes ces notions ne dépendent que de l'ensemble $W = W_{\mathbf{D}}$ des $\mathbf{D}$-équivalences.

Pour toute partie A de Fl(Cat) stable par isomorphismes, on peut associer une partie $\mathbf{L}(A)$ de Fl(Cat), par la relation

$$(u : Y' \longrightarrow Y) \in \mathbf{L}(A) \iff \begin{array}{l} u^* : \mathrm{Cat}/Y \longrightarrow \mathrm{Cat}/Y' \\ \text{transforme flèches} \\ \in A \text{ en flèches } \in A. \end{array} \tag{4.11}$$

On voit que $\mathbf{L}(A)$ contient les isomorphismes, est stable par composition, et est stable aussi par changement de base (comme c'est le cas de Liss_W). Inversement, à une partie L de Fl(Cat), stable par isomorphismes, on associe une partie $\mathbf{A}_W(L)$ par

$$(f : X \longrightarrow Y) \in \mathbf{A}_W(L) \iff \begin{array}{l} \forall\, (Y' \longrightarrow Y) \text{ dans } L, \\ X' = X \times_Y Y' \longrightarrow Y' \\ \text{est dans } W. \end{array} \tag{4.12}$$

Si L est stable par changement de base, alors $\mathbf{A}_W(L)$ est stable par composition. Il contient les isomorphismes (car W les contient), est contenu dans W si L contient les identités. Mais aucune raison qu'il soit stable par changement de base quelconque (et en fait, W_{asph} ne l'est pas). [page 67]

Commentary · Exposition [ms. 66]

What survives the cancelled argument

Grothendieck is seeking a way to recover the classes of smooth and proper maps from the weak equivalences alone. The two tests in (4.10) already suggest an order-theoretic correspondence, but they use different notions of preservation. This distinction explains the cancellation on the next page; it does not make every formula in the cancelled passage false.

To see exactly what is involved, write $S(A)$ for the stabilizer of A: a map $p : Y' \to Y$ belongs to $S(A)$ when its pullback functor on slices sends every arrow of A to another arrow of A. Write $N(L) = \mathbf{A}_W(L)$ for the arrows whose pullbacks along maps of L belong to W. Here W contains isomorphisms and is closed under composition. Classes are invariant under isomorphism of arrows, and the ambient category has pullbacks. The quantifier over arrows *in the slice* matters: one tests an arrow $X_1 \to X_2$ together with any structure map $X_2 \to Y$, not merely arrows with codomain exactly Y.

The class $S(A)$ contains isomorphisms and is closed under composition and pullback, by the identity and composition laws for pullback functors. If L is closed under pullback, then $N(L)$ is closed under composition: pull back a composite gf along $p \in L$, and factor its pullback as the pullback of f along a pullback of p, followed by the pullback of g along p. Both factors lie in W. If L also contains identities, $N(L) \subseteq W$; its isomorphisms belong automatically. These are the assertions preceding the cancellation, with their implicit hypotheses made explicit.

For $A \subseteq W$, there are also two useful inclusions:

$$A \subseteq N(S(A)), \qquad L \subseteq S(N(L)),$$

where the second requires L to be closed under pullback and composition. For its proof, let $p \in L$ and $f \in N(L)$ be over the target of p. The pullback p^*f lies in W. Every further test of p^*f along $q \in L$ is a test of f along the composite of q with the appropriate pullback of p. That composite is in L, so $p^*f \in N(L)$.

For classes L containing identities, these inclusions even prove the two displayed idempotence conclusions on page 67. Since N reverses inclusions,

$$NSNS(A) \subseteq NS(A), \qquad NSN(L) \subseteq N(L),$$

and the reverse inclusions follow from $A \subseteq NS(A)$, applied to $NS(A)$ and to $N(L)$; the identity test ensures $N(L) \subseteq W$. Thus NS is idempotent and $SNSN = SN$. However, S need not reverse inclusions. Consequently these calculations do not supply the order-reversing adjunction that the next section needs. In particular, the stronger justification printed there, $S(A)^\flat = S(A)$, does not follow from them and can fail. The repair in §6 is to replace $S(A)$ by a transporter into the fixed class W. That operation is genuinely order-reversing.

There is a further empty-class detail in the cancelled argument. Formula (4.14) does not explicitly require identities in L, whereas (4.12) does not explicitly restrict $N(L)$ to W. For $L = \varnothing$, one has $N(L) = \mathrm{Fl}(\mathrm{Cat})$, so the auxiliary assertion $N(L)^\natural = N(L)$ is false when W is proper: its left side is W_{univ}. Section 6 repairs the domain issue by inserting $f \in W$ into (6.6), and later by requiring isomorphisms in L.

The idempotence of SN itself nevertheless survives in Cat for a fundamental localizer and every class L closed under pullback and composition. If every member of L has empty domain, every test is an identity of the empty category, so $N(L)$ is all functors and $SN(L)$ is all functors; applying SN again gives the same class, since universal W-equivalences are stable under all pullbacks. Otherwise choose $p \in L$ with nonempty domain and pull it back to an object of its target lying in its image. This gives $C \to e$ in L with C nonempty. Further pullback gives $B \times C \to B$ in L for every B. Thus $f \in N(L)$ implies $f \times C \in W$. Choosing an object of C makes f a retract of $f \times C$ in the arrow category, so $f \in W$ by closure under retracts; for fundamental localizers this is Cisinski (2006b, Proposition 4.2.4, p. 183). Hence $N(L) \subseteq W$, and the earlier proof applies. This records the surviving conclusion without endorsing either incorrect auxiliary justification.

([3]). On a, pour un $A \subseteq W \subseteq \mathrm{Fl}(\mathrm{Cat})$ donné, stable par isomorphismes,

$$A \subseteq \mathbf{A}_W(\mathbf{L}(A)) \overset{\text{déf}}{=} A^\natural \subseteq W, \qquad \begin{array}{l}\text{partie stable par composition,}\\ \text{contient [les] isomorphismes,}\end{array} \tag{4.13}$$

et pour toute partie L de Fl(Cat) qui est stable par changement de base, et par composition p. 42

$$L \subseteq \mathbf{L}(\mathbf{A}_W(L)) \overset{\text{déf}}{=} L^\flat, \qquad \begin{array}{l}\text{partie de Fl Cat stable}\\ \text{par composition et par changement}\\ \text{de base, contenant les isomorphismes.}\end{array} \tag{4.14}$$

On a

$$\begin{cases} A^{\natural\natural} &= A^\natural, \quad \text{car } \mathbf{A}_W(L)^\natural = \mathbf{A}_W(L) \\ L^{\flat\flat} &= L^\flat, \quad \text{car } \mathbf{L}(A)^\flat = \mathbf{L}(A). \end{cases}$$

Exemples :

1°) $L = \text{Ét}$, $\mathbf{A}_W(L) = W_{\mathrm{asph}}$, $\mathbf{L}(\mathbf{A}_W(L)) = L^\flat = \mathrm{Liss}_W$.

2°) $L = \text{Coét}$, $\mathbf{A}_W(L) = W_{\mathrm{coas}}$, $\mathbf{L}(\mathbf{A}_W(L)) = L^\flat = \mathrm{Prop}_W$.

3°) $A = W$, $\mathbf{L}(A) = \mathrm{Fib}_W$, $A^\natural = W$.

4°) $L = \mathrm{Fl}\,\mathrm{Cat}$, $\mathbf{A}_W(L) = W_{\mathrm{univ}}$, $L^\flat = L$.

[page 68 vide]

Commentary · Development (commentators') [ms. 67] p. 43 [page 69]

A cancelled justification tested in categories

The cancelled lines are best understood by testing the precise identity used in their justification. The following example keeps the ambient category equal to Cat and uses a fundamental localizer, so the difficulty is not an artefact of passing to an unrelated category.

A stabilizer need not be a closed right-hand class. [ours] Let W be the maximal fundamental localizer, consisting of all functors, and let $A = \mathrm{Equ}$ be the class of equivalences of categories. With S and N as above, $S(A)^\flat \neq S(A)$.

Indeed, every pullback functor takes functors to functors, so $N(L) = \mathrm{Fl}(\mathrm{Cat})$ for every L. Consequently

$$S(A)^\flat = S\big(N(S(A))\big) = S\big(\mathrm{Fl}(\mathrm{Cat})\big) = \mathrm{Fl}(\mathrm{Cat}).$$

To show that $S(A)$ is smaller, let J be the groupoid with two objects $0, 1$ and precisely one morphism between each ordered pair. Each point inclusion $e_i \to J$ is fully faithful and essentially surjective, hence an equivalence. Their strict pullback is empty, because its objects would have to map to both 0 and 1. Pulling $e_1 \to J$ back along $e_0 \to J$ therefore gives $\varnothing \to e_0$, which is not essentially surjective. Thus $e_0 \to J \notin S(A)$, proving the claim.

The same calculation shows why the anticipated polarity fails: although $A \subseteq B = \mathrm{Fl}(\mathrm{Cat})$, one has $S(A) \subsetneq S(B)$, whereas an order-reversing correspondence would require the opposite inclusion. This does not contradict the idempotence of either composite proved in the preceding block. For the present W those composites are particularly degenerate: NS is constant with value all functors, and SN is likewise constant.

This is an elementary diagnostic for the manuscript's cancellation. We checked the subsequent transporter construction in §6 and the preservation definition of smooth functors in Maltsiniotis (2005, Definition 4.6); we did not find this particular counterexample stated there. The mark above records our verification, not a claim of priority. The later block "The stabilizer of categorical equivalences" identifies the whole class $S(\mathrm{Equ})$.

5 Dualité formelle

Soient $\mathcal{P}$, $\mathcal{Q}$ deux ensembles ordonnés. J'essaye de dégager une notion de 'dualité' (formelle) reliant $\mathcal{P}$ et $\mathcal{Q}$. Ce sera une relation entre $\mathcal{P}$ et $\mathcal{Q}$

$$\mathcal{R} \subseteq \mathcal{P} \times \mathcal{Q} \tag{5.1}$$

ayant les propriétés suivantes

(D) Pour toute partie A de $\mathcal{P}$, l'ensemble

$$A^\cup \overset{\text{déf}}{=} \{q \in \mathcal{Q} \mid (p,q) \in \mathcal{R} \text{ pour tout } p \in A, \ \text{ i.e. } A \times \{q\} \subseteq \mathbf{R}\}$$

est une partie ouverte de $\mathcal{Q}$ ayant un plus grand élément $\beta(A) : A^\cup = \mathcal{Q}/\beta(A)$. Dualement, pour toute partie B de $\mathcal{Q}$, l'ensemble

$$B^\cap \overset{\text{déf}}{=} \{p \in \mathcal{P} \mid (p,q) \in \mathcal{R} \text{ pour tout } q \in B, \ \text{ i.e. } \{p\} \times B \subseteq \mathcal{R}\}$$

est une partie ouverte de $\mathcal{P}$ ayant un plus grand élément $\alpha(B)$, i.e. $B^\cap = \mathcal{P}/\alpha(B)$.

Le plus souvent, $\mathcal{P}$ et $\mathcal{Q}$ seront stables par sup quelconques (donc aussi par inf quelconques). Dans ce cas, (D) équivaut, du côté des $A^\cup$ (pour $A \in \mathfrak{P}(\mathcal{P})$) à ceci :

(D_0) Pour tout $p \in \mathcal{P}$, $\mathcal{R}(p) = \{q \in Q \mid (p,q) \in \mathcal{R}\}$ est une partie ouverte *filtrante* de $\mathcal{Q}$, ou ce qui revient au même, une partie non vide ($\Longleftrightarrow$ contenant le plus petit élément $\emptyset_\mathcal{Q}$ de $\mathcal{Q}$) stable par sup de deux éléments. De plus, $\mathcal{R}(p)$ est stable par sup filtrants, ou ce qui revient au même (étant lui-même filtrant), il contient un plus grand élément. Il revient au même de dire que $\mathcal{R}(p)$ est un *ouvert* de $\mathcal{Q}$ stable par sup quelconques (ce qui implique qu'il contient $\emptyset_\mathcal{Q}$). Dualement, pour tout $q \in \mathcal{Q}$, ${}^s\mathcal{R}(q) = \{p \in \mathcal{P} \mid (p,q) \in \mathcal{R}\}$ est une partie *ouverte* de $\mathcal{P}$, stable par sup quelconques, i.e. une partie ouverte ayant un plus grand élément. [page 70]

Commentary · Exposition [ms. 69]

The relation comes before the order

Grothendieck pauses to isolate the formal mechanism that a successful transporter construction must satisfy. The first part of the section concerns an arbitrary relation, even though the initial presentation starts with ordered sets. Separating those two levels makes the notation more transparent and prevents the later confusion between a closed subset and an element of an ordered set.

For a relation $R \subseteq P \times Q$, put

$$A^{\cup} = \{q \mid (p,q) \in R \text{ for every } p \in A\}, \qquad B^{\cap} = \{p \mid (p,q) \in R \text{ for every } q \in B\}.$$

The decisive equivalence is

$$B \subseteq A^{\cup} \quad \Longleftrightarrow \quad A \times B \subseteq R \quad \Longleftrightarrow \quad A \subseteq B^{\cap}.$$

Both operations reverse inclusions. Every $p \in A$ is related to every member of $A^{\cup}$, so $A \subseteq A^{\cup\cap}$. Applying the inclusion-reversing operation gives $A^{\cup\cap\cup} \subseteq A^{\cup}$; applying extensivity on the other side gives the reverse inclusion. Thus the triple operation equals the single operation, and the double operation is idempotent. This proves (5.5)–(5.7) without any order on P or Q.

The fixed subsets form complete lattices. Arbitrary intersections of fixed subsets are fixed: if $A = \bigcap_i A_i$, monotonicity gives $A^{\cup\cap} \subseteq A_i$ for every i, and extensivity gives the opposite inclusion $A \subseteq A^{\cup\cap}$. Their join is the closure of their union. The two polar operations exchange these closed-set lattices by inverse order-reversing bijections, proving Proposition 5.1 and Corollary 5.2. Empty families cause no exception: the largest closed subset of P is P, while the smallest is $Q^{\cap}$, which need not be empty.

The ordered version asks for more. An "open" subset in this passage is a lower set, and the additional requirement is that each polar lower set be principal. For complete lattices P, Q, this gives maps $\beta_0 : P \to Q$ and $\alpha_0 : Q \to P$ characterized by

$$q \leq \beta_0(p) \quad \Longleftrightarrow \quad p \leq \alpha_0(q).$$

Equivalently, $\alpha_0 : Q \to P^{\mathrm{op}}$ is left adjoint to $\beta_0 : P^{\mathrm{op}} \to Q$. It follows that β_0 sends joins in P to meets in Q, including the empty join. Conversely, if it has this property, set

$$\alpha_0(q) = \bigvee \{p \in P : q \leq \beta_0(p)\}.$$

The set under the join is a lower set and is closed under arbitrary joins, so its join belongs to it; this proves the displayed equivalence and constructs the adjoint. The ensuing fixed-point correspondence is the usual antitone Galois connection. A systematic later account is Ganter and Wille (1999, §0.4, Propositions 7–8 and Theorem 2); the arguments needed here are supplied above, independently of terminology.

En d'autres termes, quand on postule la condition (D) pour A resp. B réduit à un élément, alors elle reste vérifiée pour toute partie. Cela provient des formules

$$\text{(5.2)} \qquad \begin{cases} (\bigcup_i A_i)^{\cup} &= \bigcap_i A_i^{\cup} \\ (\bigcup_j B_j)^{\cap} &= \bigcap_j B_j^{\cap}, \end{cases}$$

et du fait que l'intersection de parties ouvertes de la forme $\mathcal{P}/\alpha_i$ dans $\mathcal{P}$ est de la forme $\mathcal{P}/\alpha$, où $\alpha = \inf_i \alpha_i$, et de même dans $\mathcal{Q}$. Ainsi on trouve

$$\text{(5.3)} \qquad \begin{cases} \beta(\bigcup_i A_i) &= \inf_i \beta(A_i) \\ \alpha(\bigcup_j B_j) &= \inf_j \alpha(B_j). \end{cases}$$

On posera, pour une partie A de $\mathcal{P}$ resp. B de $\mathcal{Q}$

$$\text{(5.4)} \qquad A^{\natural} = (A^{\cup})^{\cap}, \qquad B^{\flat} = (B^{\cap})^{\cup}$$ p. 44

de sorte qu'on aura

$$\text{(5.5)} \qquad A \subseteq A^{\natural}, \qquad B \subseteq B^{\flat}$$

On dira que A est $\mathcal{R}$-*clos* si $A = A^{\natural}$ (ou encore si A est de la forme $B'^{\cap}$ pour $B' \subseteq \mathcal{Q}$, cf. 5.6), que B est $\mathcal{R}$-*clos* si $B = B^{\flat}$. On aura pour tout $A \subseteq \mathcal{P}$, $B \subseteq \mathcal{Q}$ [71]

$$(5.6) \qquad \begin{cases} (A^{\cup})^{\flat} &= A^{\cup}, \quad \text{i.e. } A^{\cup} \text{ est } \mathcal{R}\text{-clos}, \\ (B^{\cap})^{\natural} &= B^{\cap}, \quad \text{i.e. } B^{\cap} \text{ est } \mathcal{R}\text{-clos}. \end{cases}$$

En particulier

$$(5.7) \qquad (A^{\natural})^{\natural} = A^{\natural}, \qquad (B^{\flat})^{\flat} = B^{\flat},$$

i.e. la $\mathcal{R}$-clôture $A^{\natural}$ de $A \subseteq \mathcal{P}$ est $\mathcal{R}$-clos, et de même la $\mathcal{R}$-cloture $B^{\flat}$ de $B \subseteq \mathcal{Q}$.

En fait, je m'aperçois que je suis en train de mélanger deux espèces de faits différents. Les relations (5.2), et (5.4) à (5.7), ne dépendent pas de la donné de relations d'ordre sur $\mathcal{P}$, $\mathcal{Q}$, ni d'axiomes reliant celles-ci à la relation donnée $\mathcal{R}$, mais seulement de cette relation, laquelle n'a pas à être soumise à aucune condition. Notons que

$$(5.8) \qquad \emptyset^{\cup} = \mathcal{Q}, \qquad \emptyset^{\cap} = \mathcal{P},$$

tandis que

$$(5.9) \qquad \emptyset^{\natural} = \mathcal{Q}^{\cap}, \qquad \emptyset^{\flat} = \mathcal{P}^{\cup}$$

sont respectivement la plus petite partie $\mathcal{R}$-close de $\mathcal{P}$ et de $\mathcal{Q}$.

L'application

$$(5.10) \qquad A \longmapsto A^{\natural}$$

est une application *croissante* (et *idempotente*) de $\mathfrak{P}(\mathcal{P})$ dans lui-même, ayant donc la propriété [72]

$$(\bigcup_i A_i)^{\natural} = (\bigcup_i A_i^{\natural})^{\natural}.$$

Pour tout $A \subseteq \mathcal{P}$, $A^{\natural}$ est la plus petite partie $\mathcal{R}$-close de $\mathcal{P}$ contenant A, et de même pour p. 45
tout $B \subseteq \mathcal{Q}$, $B^{\flat}$ est la plus petite partie $\mathcal{R}$-close de Q contentant B. On a de plus (c'était même à dire avant de dire que $A \longmapsto A^{\natural}$ est croissante)

$$(5.11) \qquad \begin{cases} A \subseteq A' &\Longrightarrow A'^{\cup} \subseteq A^{\cup} \\ B \subseteq B' &\Longrightarrow B'^{\cap} \subseteq B^{\cap}, \end{cases}$$

i.e. les applications

$$(5.12) \qquad \mathfrak{P}(\mathcal{P}) \underset{\alpha}{\overset{\beta}{\rightleftarrows}} \mathfrak{P}(\mathcal{Q}) \qquad \begin{matrix} A \longmapsto A^{\cup} \\ B \longmapsto B^{\cap} \end{matrix}$$

sont décroissantes (ce qui implique que les deux composés $\alpha\beta = (A \longmapsto A^{\natural})$ et $\beta\alpha = (B \longmapsto B^{\flat})$ sont croissantes). Leurs restrictions aux sous-ensembles $\mathfrak{P}_{\mathcal{R}}(\mathcal{P})$ et $\mathfrak{P}_{s\mathcal{R}}(\mathcal{Q})$ des parties $\mathcal{R}$-closes de $\mathcal{P}$ resp. de $\mathcal{Q}$, sont, par définition de celles-ci comme

$$\begin{aligned} \mathfrak{P}_{\mathcal{R}}(\mathcal{P}) &= \{A \subseteq \mathcal{P} \mid A^{\natural} \ (\overset{\text{déf}}{=} \alpha\beta(A)) = A\} \\ \mathfrak{P}_{s\mathcal{R}}(\mathcal{Q}) &= \{B \subseteq \mathcal{Q} \mid B^{\flat} \ (\overset{\text{déf}}{=} \beta\alpha(B)) = B\}, \end{aligned}$$

inverse l'une de l'autre. On trouve ainsi

Proposition 5.1. *Soient $\mathcal{P}$, $\mathcal{Q}$ deux ensembles, $\mathcal{R} \subseteq \mathcal{P} \times \mathcal{Q}$ une relation. Alors les applications α, β de (5.12) induisent des bijections inverses l' une de l'autre, entre l'ensemble* [73]

$Cl_{\mathcal{R}}(\mathcal{P})$ des parties $\mathcal{R}$-closes de $\mathcal{P}$, et l'ensemble $Cl_{^s\mathcal{R}}(\mathcal{Q})$ des parties ${}^s\mathcal{R}$-closes (nous dirons $\mathcal{R}$-closes par abus de langage) de $\mathcal{Q}$. Ces bijections sont décroissantes, donc des antiisomorphismes pour les relations d'ordre naturelles (d'inclusion).

Corollaire 5.2. *Soit $(A_i)_i$ une famille de parties $\mathcal{R}$-closes de $\mathcal{P}$. Alors $\bigcap A_i$ est une partie $\mathcal{R}$-close de $\mathcal{P}$, et*

$$(\bigcap_i A_i)^{\cup} = \underbrace{(\bigcup_i A_i^{\cup})^{\flat}}_{\substack{\text{sup des} \\ \text{parties } \mathcal{R}\text{-closes} \\ A_i^{\cup} \text{ de } \mathcal{Q}}} \quad . \tag{5.2.1}$$

Mais la relation $\mathcal{R}$ se 'prolonge' en une relation $\bar{\mathcal{R}}$ entre

$$\bar{\mathcal{P}} = \mathfrak{P}(\mathcal{P}), \qquad \bar{\mathcal{Q}} = \mathfrak{P}(\mathcal{Q}) \tag{5.13}$$

par la prescription

$$\underbrace{\bar{\mathcal{R}}}_{\subseteq \bar{\mathcal{P}} \times \bar{\mathcal{Q}}} = \{(A, B) \in \bar{\mathcal{P}} \times \bar{\mathcal{Q}} \mid B \subseteq A^{\cup}, \text{ i.e. } A \subseteq B^{\cap}, \text{ i.e. } A \times B \subseteq \mathcal{R}\}. \tag{5.14}$$

Les ensembles $\bar{\mathcal{P}}$, $\bar{\mathcal{Q}}$ sont stables par sup quelconques (réunion de parties de $\mathcal{P}$ resp. $\mathcal{Q}$), et la relation $\bar{\mathcal{R}}$ sur ces ensembles ordonnés satisfait à la condition (D_0) ci-dessus (p. 69), de façon évidente : pour A fixé, les B tels que $(A, B) \in \bar{\mathcal{R}}$ sont ceux qui sont contenus dans $A^{\cup}$, donc l'ensemble $\bar{\mathcal{R}}(A)$ n'est autre que $\bar{\mathcal{Q}}/A^{\cup}$, et dualement ${}^s\bar{\mathcal{R}}(B)$ n'est autre que $\bar{\mathcal{P}}/B^{\cap}$. Ainsi p. 46 [74]

$$\beta(A) = A^{\cup}, \qquad \alpha(B) = B^{\cap}. \tag{5.14}$$

Si j'ai songé à introduire l'axiome (D_0), pour un couple d'ensembles ordonnés quelconques, c'est à cause des cas où ceux-ci ne sont *pas* de la forme $\mathfrak{P}(\mathcal{P})$, $\mathfrak{P}(\mathcal{Q})$, et (alors même qu'ils le seraient) où la relation de base n'est pas déduite comme ci-dessus d'une relation quelconque entre ensembles $\mathcal{P}$, $\mathcal{Q}$.

Je reviens donc à l'axiomatique du début, avec $\mathcal{P}$, $\mathcal{Q}$ ordonnés, et $\mathcal{R}$ satisfaisant (D). Dans tous les cas auxquels je peux songer, $\mathcal{P}$ et $\mathcal{Q}$ sont stables par sup quelconques, donc (D) équivaut à (D_0). Notons que l'application

$$\mathcal{P} \longrightarrow \mathfrak{P}(\mathcal{P}), \qquad p \longmapsto \mathcal{P}/p$$

est injective, et de même pour $\mathcal{Q} \longrightarrow \mathfrak{P}(\mathcal{Q})$. Ainsi, la connaisance de $A \longmapsto A^{\cup}$ équivaut à celle de

$$\begin{array}{rcl} A & \longmapsto & \beta(A) \\ \beta : \mathfrak{P}(\mathcal{P}) & \longrightarrow & \mathcal{Q}, \end{array}$$

et de même celle de $B \longmapsto B^{\cap}$ équivaut à celle de [75]

$$\alpha : \mathfrak{P}(\mathcal{Q}) \longrightarrow \mathcal{P}.$$

En fait, il suffit de se donner

$$\begin{array}{rcccl} \beta_0 : & \mathcal{P} & \longrightarrow & \mathcal{Q} & \text{applications} \\ \alpha_0 : & \mathcal{Q} & \longrightarrow & \mathcal{P} & \textit{décroissantes} \end{array} \tag{5.15}$$

définies par

$$\left\{ \begin{array}{rcl} \beta_0(p) & = & \beta(\{p\}) \\ \alpha_0(q) & = & \alpha(\{q\}), \end{array} \right.$$

puisqu'on en déduit β, α par

$$\left\{\begin{array}{lcl}\beta(A) & = & \inf_{p\in A}\beta_0(p)\\ \alpha(B) & = & \inf_{q\in B}\alpha_0(q).\end{array}\right. \tag{5.16}$$

La relation $\mathcal{R}$ se déduit de la donnée de β_0, ou au choix de α_0, par

$$(p,q)\in\mathcal{R} \iff q\leq\beta_0(p) \iff p\leq\alpha_0(q). \tag{5.17}$$

Cela implique donc que α_0, β_0 se déterminent mutuellement, par les formules p. 47

$$\left\{\begin{array}{lcl}\alpha_0(q) & = & \sup\underbrace{\{p\in\mathcal{P}\mid q\leq\beta_0(p)\}}_{\{q\}^\cap}\\ \beta_0(p) & = & \sup\underbrace{\{q\in\mathcal{Q}\mid p\leq\alpha_0(q)\}}_{\{p\}^\cup}.\end{array}\right. \tag{5.18}$$

Reste à se demander quelles sont les applications $\alpha_0:\mathcal{P}\longrightarrow\mathcal{Q}$, ou $\beta_0:\mathcal{Q}\longrightarrow\mathcal{P}$, qui correspondent à une *'relation dualisante'* $\mathcal{R}$ sur $\mathcal{P}\times\mathcal{Q}$. Voici les conditions sur $\beta_0:\mathcal{P}\longrightarrow\mathcal{Q}$: [76]

ⓐ β_0 est *décroissante*,

ce qui implique que la relation

$$\underbrace{\mathcal{R}_{\beta_0}}_{\subseteq\mathcal{P}\times\mathcal{Q}}=\{(p,q)\in\mathcal{P}\times\mathcal{Q}\mid q\leq\beta_0(p)\}$$

satisfait à la condition (D_0) du côté gauche, et il faut encore la vérifier du côté droit, i.e. regarder, pour q fixé, l'ensemble

$$\{q\}^\cap=\{p\in\mathcal{P}\mid q\leq\beta_0(p)\}.$$

Comme β_0 est décroissant, on voit que $p\in\{q\}^\cap$, et $p'\leq p\Longrightarrow p'\in\{q\}^\cap$, i.e. $\{q\}^\cap$ est *ouvert.* On doit vérifier encore (supposant l'existence des sup quelconques dans $\mathcal{P}$) que cet ensemble est stable par sup quelconques - il en résultera qu'il est de la forme $\mathcal{P}/\alpha(q)$. Cela équivaut à la condition

ⓑ β_0 transforme sup quelconques dans $\mathcal{P}$ en inf dans $\mathcal{Q}$.

Si on regarde β_0 comme un foncteur contravariant $\mathcal{P}^o\longrightarrow\mathcal{Q}$, cela signifie qu'il commute aux limites projectives, ou encore qu'il a un adjoint à gauche $\mathcal{Q}\longrightarrow\mathcal{P}^o$, lequel commute aux limites inductives, et correspond à l'application décroissante $\alpha_0:\mathcal{Q}\longrightarrow\mathcal{P}$, transformant sup en inf. [77]

Ici il est commode de considérer $\natural$ et $\flat$ comme des opérations sur $\mathcal{P}$ resp. $\mathcal{Q}$, par

$$p^\natural=\alpha_0\beta_0(p),\qquad q^\flat=\beta_0\alpha_0(q). \tag{5.19}$$

La relation entre ces endomorphismes, et l'opération de même nom sur $\mathfrak{P}(\mathcal{P})$, $\mathfrak{P}(\mathcal{Q})$, est donnée par

$$\left\{\begin{array}{lcl}p^\natural & = & \text{Plus grand élément de } \{p\}^\natural\\ A^\natural & = & \sup_{p\in A}p^\natural,\end{array}\right. \tag{5.20}$$

et symétriquement du côté de $\mathcal{Q}$.

On dit que p est $\mathcal{R}$-*clos,* ou β_0-clos, ou α_0-clos, si $p=p^\natural$, et de même $q\in\mathcal{Q}$ est dit $\mathcal{R}$-*clos* etc. si $q=q^\flat$. Les applications p. 48

$$\left\{\begin{array}{lcl}p\longmapsto p^\natural : \mathcal{P}\longrightarrow\mathcal{P}\\ q\longmapsto q^\flat : \mathcal{Q}\longrightarrow\mathcal{Q}\end{array}\right. \tag{5.21}$$

[78]

sont *croissantes* et *idempotentes.* On peut caractériser $p^\natural$ comme le plus petit élément clos de $\mathcal{P}$ majorant p, et de même pour $q^\flat$. On trouve alors, par (5.19), que α_0 et β_0 induisent des bijections inverses l'une de l'autre, entre l'ensemble des éléments clos de $\mathcal{P}$, et l'ensemble des éléments clos de $\mathcal{Q}$

$$\mathcal{P}^\natural \underset{\bar{\alpha}_0}{\overset{\bar{\beta}_0}{\underset{\sim}{\rightleftarrows}}} \mathcal{Q}^\flat. \tag{5.22}$$

Mais en pratique, les applications α_0, β_0 ne sont pas obtenues directement, mais on dispose de la relation $\mathcal{R}$, satisfaisant la condition (D_0), dont on déduit α_0, β_0. Dans tous les cas auxquels je pense ici, ou bien $\mathcal{P}$, $\mathcal{Q}$ sont de la forme $\mathfrak{P}(P_0)$, $\mathfrak{P}(Q_0)$, et $\mathcal{R}$ se déduit d'une relation $R_0 \subseteq P_0 \times Q_0$ comme ci-dessus (de loin le plus fréquent, il me semble), ou bien $\mathcal{P}$ et $\mathcal{Q}$ apparaissent comme sous-ensembles convenables d'ensembles $\mathfrak{P}(P_0)$, $\mathfrak{P}(Q_0)$, munis de l'ordre induit, et la relation $\mathcal{R}$ sur $\mathcal{P} \times \mathcal{Q}$ s'obtient d'une façon plus complexe.

Commentary · Examples [ms. 77]

A join of closed elements need not be closed

The ordered version allows the closure of a subset to be represented by one element, and Grothendieck wants to pass freely between these descriptions. Formula (5.20) loses a closure in making this passage. The difficulty is mathematical, not a transcription error: the edition prints the second equality exactly as transcribed.

Let $c = \alpha_0\beta_0$ and let $A \subseteq P$. The precise identities are

$$\{p\}^{\cup\cap} = {\downarrow}c(p), \qquad A^{\cup\cap} = {\downarrow}c\left(\bigvee_{p\in A} p\right) = {\downarrow}c\left(\bigvee_{p\in A} c(p)\right).$$

Here $\downarrow x$ denotes the set of elements below x. To prove the middle equality, the polar $A^\cup$ has greatest element $\bigwedge_{p\in A}\beta_0(p) = \beta_0(\bigvee A)$, and its polar has greatest element $\alpha_0\beta_0(\bigvee A)$. For the last equality, $p \le c(p) \le c(\bigvee A)$ for every $p \in A$; apply monotonicity and idempotence to the two resulting inequalities. Thus the supremum can be taken in the *closed-element lattice*, where it means closure of the ambient supremum. It cannot in general be taken unchanged in P.

A small example displays both the omitted operation and its importance. Let $E = \mathbf{F}_2^2$, and take $P = \mathfrak{P}(E)$, $Q = \mathfrak{P}(E^*)$, with the relation that every vector in one subset is annihilated by every functional in the other. Double annihilation sends a subset to its linear span. To check this directly, a linear functional vanishing on a set vanishes on its span; if a vector lies outside that span, extend a basis of the span by that vector and prescribe a functional taking value 1 on it and 0 on the original basis.

Let e_1, e_2 be a basis and put $p_1 = \{0, e_1\}$, $p_2 = \{0, e_2\}$. Each p_i is already closed, but their supremum in P is

$$p_1 \cup p_2 = \{0, e_1, e_2\},$$

which omits $e_1 + e_2$ and is not closed. For the family $A = \{p_1, p_2\} \subseteq P$, the greatest element of $A^{\cup\cap}$ is all of E, whereas the supremum printed in (5.20) is only the three-element union. Moreover, $A^{\cup\cap}$ itself is a subset of P, namely all subsets of E, rather than an element of P. These two distinctions are exactly what the corrected formula records.

This correction does not disturb the subsequent statements that c is monotone, extensive and idempotent, or that the closed elements on the two sides correspond anti-isomorphically. It supplies the correct join operation on those elements and will be needed again when the elements of P are themselves classes of morphisms.

Exemples.

1) Relations d'*orthogonalité* entre parties de deux modules sur un anneau, muni d'un accouplement de dualité. Dans le cas des `[espaces]` vectoriels de dimension finie et d'une vraie dualité, les parties closes sont les sous-espaces vectoriels, dans le cas infini, ce sont les sous-espaces vectoriels fermés pour la 'topologie faible' définie par l'accouplement. [79]

2) Relations d'*orthogonalité* entre parties de deux groupes topologiques commutatifs localement compacts duales l'une de l'autre, au sens de Pontrjagin.

   Les parties closes sont les sous-groupes fermés.

3) Pour deux espaces vectoriels 'en dualité' sur un corps valué complet, tel **R** où **C**, la relation

$$|\langle x, x'\rangle| \leq 1.$$

   Dans le cas réel ou complexe, les parties closes sont les parties convexes cerclées [?] faiblement fermées.

4) Pour les espaces vectoriels réels, la relation de semi-polarité

$$\langle x, x'\rangle \geq -1.$$

   Les parties closes sont les parties convexes faiblement fermées contenant l'origine.

Commentary · Examples [ms. 79]

What the double polar closes

The examples identify the content of a formal closure: the relation supplies tests, and the double polar retains everything that those tests cannot distinguish. The algebraic and analytic identifications require their own separation results; the abstract Galois calculation alone does not prove them.

For a separating dual pair of vector spaces E, F over a field k, the annihilator of $A \subseteq E$ is $A^{\perp} = \{\varphi \in F : \langle a, \varphi\rangle = 0 \text{ for all } a \in A\}$. Its double annihilator is the closure of $\operatorname{span}(A)$ for the weak topology of the pairing, taking k discrete in the purely algebraic formulation. Here is a direct finite-coordinate proof. If x is not in the weak closure of a subspace V, there are $\varphi_1, \ldots, \varphi_n \in F$ for which the vector of values of x is outside the image of V in k^n. A linear functional on k^n vanishes on that image but not on this vector. The corresponding linear combination of the φ_i separates x from V. Conversely every annihilating functional is weakly continuous, so its kernel contains the weak closure of V. For real or complex weak topologies the same argument applies because finite-dimensional linear subspaces are closed. In finite-dimensional perfect duality all subspaces are closed, giving the familiar double-annihilator identity.

For a Pontryagin dual pair $G, \widehat{G}$, the annihilator of $A \subseteq G$ consists of the characters trivial on A. It is unchanged upon replacing A by the closed subgroup it generates. If x lies outside that closed subgroup H, the locally compact abelian quotient G/H has a continuous character nontrivial on xH. Composing it with the quotient map gives a character annihilating A but not x. Thus the double annihilator is $\overline{\langle A\rangle}$. The separation step is the substantive theorem; Morris (1977, Chapter 7, Proposition 38) gives this annihilator statement and its proof from character separation.

For the absolute polar over **R** or **C**, the answer is instead the weakly closed absolutely convex hull of $A \cup \{0\}$. One inclusion follows because each inequality $|\langle -, \varphi\rangle| \leq 1$ defines a weakly closed absolutely convex set containing 0. For the other, separate a point outside that hull by a weakly continuous linear functional; the absolute convexity allows multiplication by a scalar of modulus one, and rescaling gives a functional with absolute value at most 1 on the hull and greater than 1 at the point. The weak continuous dual is precisely the specified testing space. The Hahn–Banach separation theorem therefore supplies the desired test. In the real semi-polar convention $\langle x, \varphi\rangle \geq -1$, negate the separating functional; the double polar is the weakly closed convex hull of $A \cup \{0\}$, without the balancedness condition. These are the two forms of the bipolar theorem; compare Schaefer and Wolff (1999, Chapter IV, §1, Theorem 1.5).

The origin must not disappear from the statement. Under conventions allowing the empty set to count as convex and balanced, the list of absolute-polar closed sets must explicitly exclude it: $\varnothing^{\circ\circ} = \{0\}$ in a separating pair. In $\mathbf{R}^2$, for example, the absolute polar of $\{e_1, e_2\}$ is the square $\{|a| \leq 1, |b| \leq 1\}$, and its polar is the diamond $\{|x_1| + |x_2| \leq 1\}$. The inequality follows by maximizing $ax_1 + bx_2$ over the square; choosing the signs of a, b gives equality. This makes the distinction between linear span, convex hull and absolutely convex hull visible in the same two-dimensional setting.

5) Soit K un corps (pour simplifier), L une extension galoisienne de groupe G. Relation entre L et G

$$\gamma \cdot x = x, \qquad \text{i.e. } x \in L^{\gamma}.$$

Les parties closes de L sont les sous-extensions, les parties closes de G les sous-groupes de G.

Commentary · Examples [ms. 79]

The topology in the Galois example

The fixed-point relation offers another instructive instance of the same issue: the relation always gives a closure, but the description of its fixed subsets changes when the extension becomes infinite. For a Galois extension L/K, the polar of a subset $S \subseteq L$ is the group of automorphisms fixing every element of S. Its double polar is the intermediate field $K(S)$. For a subset $H \subseteq G = \mathrm{Gal}(L/K)$, the double polar is the closure of the subgroup generated by H in the Krull topology. Thus all subgroups are closed when the extension is finite; for an arbitrary Galois extension the manuscript's assertion must read *closed subgroups*. See Milne (2022, Proposition 7.12 and Theorem 7.13), where both directions of this correspondence are proved.

There is a concrete obstruction to omitting that qualification. Take $L = \overline{\mathbf{F}}_p$ and $K = \mathbf{F}_p$. The Galois group is $\widehat{\mathbf{Z}}$, with the Frobenius automorphism corresponding to 1. The cyclic subgroup generated by Frobenius is isomorphic to $\mathbf{Z}$; its image surjects onto every finite quotient $\mathbf{Z}/n$, so it is dense, but it is not all of the uncountable group $\widehat{\mathbf{Z}}$. An element fixed by Frobenius satisfies $x^p = x$, hence lies in $\mathbf{F}_p$. The double polar of this cyclic subgroup is consequently the whole Galois group. It is not a closed subset for the formal polarity, even though it is a subgroup.

This correction is already part of classical infinite Galois theory, rather than a later repair peculiar to derivators. The nearby allusion to inseparable analogues requires a different testing object, such as a suitable restricted Lie algebra in a height-one purely inseparable extension. No precise inseparable theorem is stated here, so the audit records an allusion, not an unrestricted extension of the Galois correspondence.

Il y a des analogues divers dans des cas inséparables (à coups de p-algèbres de Lie par exemple), et des énoncés de descente en tous genres.

Tous ces exemples sont de 1ère espèce, les ensembles ordonnés qui interviennent sont de la [page 80]
forme $\mathfrak{P}(P_0)$, $\mathfrak{P}(Q_0)$, et la relation entre eux est déduite d'une relation R_0 entre P_0 et Q_0. Voici maintenant des exemples plus complexes.

6) Soit $\mathcal{M}$ une catégorie ('grosse', le plus souvent …). On prend

$$\mathcal{P} = \mathcal{Q} = \mathfrak{P}(\mathrm{Fl}(\mathcal{M})).$$

La relation $\mathcal{R} \subseteq \mathcal{P} \times \mathcal{Q}$ est la relation de Quillen, que j'écris, pour $\Phi, \Psi \in \mathfrak{P}$

$$\Psi \subseteq \Phi_*,$$

ou encore de façon équivalente

$$\Phi \subseteq \Psi^*,$$

(Ψ a la LLP `[left lifting property]` pour Ψ, Φ la RLP `[right lifting property]` pour Ψ). Donc les applications α_0, β_0 sont données par

$$\beta_0(\Phi) = \Phi_*, \qquad \alpha_0(\Psi) = \Psi^*.$$

L'idée ici ne viendrait à personne d'introduire $\mathfrak{P}(\mathcal{P})$, $\mathfrak{P}(\mathcal{Q})$ - c'est déjà assez gros comme ça ! La notation pour $\Phi^\natural$ est ici $\tilde{\Phi}$, pour $\Psi^\flat$ c'est $\bar{\Psi}$. Les parties closes sont celles que j'appelle Q-closes à gauche et à droite.

La relation $\mathcal{R}$, que j'écris

$$\Phi \longleftrightarrow \Psi,$$ [page 81]

n'est pas déduite d'une relation entre flèches de $\mathcal{M}$, i.e. d'une partie de $\mathrm{Fl}(\mathcal{M}) \times \mathrm{Fl}(\mathcal{M})$, mais est de nature plus complexe. Pour la décrire, il faut introduire l'ensemble $\mathcal{D}$ des diagrammes carrés commutatifs (traits pleins) de la forme

(∗)
$$\begin{array}{ccc} A & \longrightarrow & X \\ \downarrow{\scriptstyle i} & \overset{f}{\nearrow} & \downarrow{\scriptstyle p} \\ B & \longrightarrow & Y \end{array}$$

(qu'on peut interpréter comme $\mathrm{Fl}(\underline{\mathrm{Fl}}(\mathcal{M}))$, ensemble des flèches dans $\underline{\mathrm{Fl}}(\mathcal{M})$). On a une partie $\mathcal{D}_0$ de $\mathcal{D}$, formée des diagrammes pour lesquels `[il]` existe `[un]` f avec deux triangles commutatifs (c'est donc l'image de $\underbrace{\mathrm{Fl}_3(\mathcal{M})}_{\mathrm{Hom}(\mathbf{\Delta}^3,\mathcal{M})}$ dans $\mathrm{Hom}(\mathbf{\Delta}^1 \times \mathbf{\Delta}^1, \mathcal{M})$, transposée de $\mathbf{\Delta}^1 \times \mathbf{\Delta}^1 \longrightarrow \mathbf{\Delta}^3$ donné par $(0,0) \longmapsto 0$, $(0,1) \longmapsto 1$, $(1,0) \longmapsto 2$, $(1,1) \longmapsto 3$), et une application p. 50

$$\mathcal{D}_0 \subseteq \mathcal{D} \xrightarrow{\varphi} \mathrm{Fl}(\mathcal{M}) \times \mathrm{Fl}(\mathcal{M}),$$

associant à (∗) le couple (i,j) `[plutôt` (i,p)`]` (source et but de (∗), considéré comme flèche dans $\underline{\mathrm{Fl}}(\mathcal{M})$ de i dans p). La relation $\mathcal{R}$ est alors déduite de φ, $\mathcal{D}_0$ par la condition [page 82]

$$\Phi \longleftrightarrow \Psi \qquad \Longleftrightarrow \qquad \varphi^{-1}(\Phi \times \Psi) \subseteq \mathcal{D}_0.$$

Mais à vrai dire, je m'aperçois que c'est quand-même déduit d'une relation entre éléments de $\mathrm{Fl}(\mathcal{M})$, et cette relation entre $i : A \longrightarrow B$ et $p : X \longrightarrow Y$ peut s'écrire ainsi :

(∗∗) pour toutes flèches $A \longrightarrow X$, $B \longrightarrow Y$ rendant commutatif le diagramme (∗), la flèche φ pointillée dans (∗) existe.

Cela me fait penser que si on a une relation $\mathcal{R}$ entre $\mathfrak{P}(P)$ et $\mathfrak{P}(Q)$, satisfaisant (D_0), donc décrite par une application décroissante

$$\mathfrak{P}(P) \longrightarrow \mathfrak{P}(Q)$$

transformant sup en inf, la donné d'une telle application équivaut à celle d'une application quelconque

$$P \longrightarrow \mathfrak{P}(Q),$$

ou ce qui revient au même, d'une relation $\mathcal{R}$ sur $P \times Q$. Donc cette structure doit être regardée comme 'de première espèce'. La situation change à partir du moment où pour décrire la relation $\mathcal{R}$ avec les propriétés voulues, on se trouve contraint de remplacer $\mathfrak{P}(P)$, $\mathfrak{P}(Q)$ par des sous-ensembles convenables - quand on ne regarde que certaines parties de P, Q. C'est ce qu'on va faire au § suivant. Le cas que je vais y traiter est le seul de son espèce que j'ai [page 83] rencontré - un cas de 'dualité formelle' qui s'introduit de façon naturelle, et qui ne soit 'de 1ère espèce'.

Commentary · Later developments [ms. 82]

Lifting gives a polarity before it gives factorization

Grothendieck's second thought about the lifting example is the correct one. A lifting problem involves a square, but the assertion that *every* square with a fixed left edge i and right edge p has a filler is a relation on the pair (i,p). Write $i \,\square\, p$ for that assertion. If Ψ is a class of left maps and Φ a class of right maps, then

$$\Psi \subseteq {}^{\square}\Phi \quad \Longleftrightarrow \quad \Phi \subseteq \Psi^{\square}.$$

The maps are order-reversing and their composites are closure operators by the preceding calculation. The text switches the order of the two factors in the square-based description: if φ records the pair

(i,p), the corresponding condition is $\varphi^{-1}(\Psi\times\Phi)\subseteq\mathcal{D}_0$. This is a notational slip in the printed source, not an obstruction to the construction.

This closure formalism isolates the lifting half of Quillen's framework. A mutually closed pair $(\mathcal{L},\mathcal{R})$ need not supply a factorization of every arrow. That additional existence condition is what makes it a weak factorization system. In the notation used by Riehl (2014, Definition 11.2.1), one requires both $\mathcal{L}={}^{\square}\mathcal{R}$, $\mathcal{R}=\mathcal{L}^{\square}$, and a factorization of every map as a left map followed by a right map. The small object argument supplies factorizations under separate generation and smallness hypotheses; its conclusion is not contained in the order-theoretic anti-isomorphism.

The distinction can be checked in a category with very few arrows. Let $\mathcal{M}$ be the ordered set with objects $0<1$ and its unique nonidentity arrow $a:0\to 1$. A square with both vertical edges a and identity horizontal edges has no filler, so a is not left orthogonal to itself. Identities lift against every map. It follows by checking the only remaining pairs that $(\mathrm{Fl}(\mathcal{M}),\mathrm{Is}(\mathcal{M}))$ and $(\mathrm{Is}(\mathcal{M}),\mathrm{Fl}(\mathcal{M}))$ are mutually closed; their factorizations happen to be the trivial ones. This example illustrates the elementary relation, without using any homotopy theory. In a general category one must still establish factorization independently.

Finally, every map from a powerset to a powerset that turns arbitrary unions into intersections is determined by its values on singletons:

$$\beta(A)=\bigcap_{p\in A}\beta(\{p\}).$$

Defining pRq by $q\in\beta(\{p\})$ recovers the relation. This is the exact reason the lifting example returns to Grothendieck's "first species". The transporter construction differs because its admissible right-hand classes must already be stable under pullback, while its left-hand classes will have to be stable under composition.

p. 51

6 Transporteurs, noyaux, stabiliseurs relatifs à W

Soit $\mathcal{M}$ une catégorie, munie d'une partie

$$W\subseteq\mathrm{Fl}(\mathcal{M}). \tag{6.1}$$

Je pense au cas d'un localiseur, mais n'introduirai d'hypothèse sur W qu'au besoin. Pour simplifier, je suppose $\mathcal{M}$ stable par produits fibrés.

Je pose

$$\text{(6.2)}\qquad \begin{cases} ({}^{4})\mathcal{P} &= \mathfrak{P}(W)=\{A\in\mathfrak{P}(\mathrm{Fl}(\mathcal{M}))\mid A\subseteq W\}\\ \mathcal{Q} &= \{L\in\mathfrak{P}(\mathrm{Fl}(\mathcal{M}))\mid \begin{array}{l}L \textit{ stable} \text{ par changement de}\\ \text{base (par qui je sous-entends aussi,}\\ \text{stable par isomorphie)}\\ \text{et par composition. }\}.\end{array}\end{cases}$$

J'introduis une relation

$$\mathcal{R}\subseteq\mathcal{P}\times\mathcal{Q}$$

de la façon suivante. Pour $A\in\mathcal{P}$, $L\in\mathcal{Q}$, on pose

$$\text{(6.3)}\qquad (A,L)\in\mathcal{R}\iff \text{Pour tout diagramme cartésien}$$
$$\begin{array}{ccc} X & \longleftarrow & X'\\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'}\\ Y & \xleftarrow[p]{} & Y'\end{array}$$
avec $f\in A$, $p\in L$, on a $f'\in W$
(i.e. A est stable par changement de base par $p\in L$).

[page 84]

Quand j'ordonne $\mathcal{P}, \mathcal{Q} \subseteq \mathfrak{P}(\mathrm{Fl}(\mathcal{M}))$ par la relation d'ordre induite par l'inclusion de parties de $\mathrm{Fl}(\mathcal{M})$, on trouve des sous-ensembles ordonnés de $\mathfrak{P}(\mathrm{Fl}(\mathcal{M}))$, stables par réunions quelconques, et aussi par intersections quelconques, avec la seul réserve que dans le cas de $\mathcal{P}$, la famille d'indices doit être $\neq \emptyset$ (puisqu'alors on trouve comme intersection $\mathrm{Fl}(\mathcal{M})$ tout entier, qui n'est pas en général contenu dans W).

Commentary · Exposition [ms. 83]

Why the admissible classes must be corrected

Grothendieck now replaces the moving target A in the stabilizer by the fixed target W. The resulting relation is suitable for a Galois connection, but the first choice of its two domains is too restrictive. Formula (6.2) requires the classes on the right to be closed under both pullback and composition. The transporter constructed on page 85 is closed under pullback, but it need not be closed under composition. The correction at (6.7) therefore removes composition from the definition of the right-hand domain and places it in the left-hand domain.

There is also a smaller order-theoretic point on page 84. Classes closed under composition are not in general closed under unions. In the category $0 < 1 < 2$, let L_1 consist of the identities and $0 \to 1$, and let L_2 consist of the identities and $1 \to 2$. Both classes are closed under pullback and composition, but their union omits $0 \to 2$. Thus the assertion about arbitrary unions is false with the initial definition of $\mathcal{Q}$. Intersections do preserve those properties; the appropriate join is obtained by closing a union under the required operations.

After (6.7), the framework is as follows. Assume W contains isomorphisms and is closed under composition. Let $\mathcal{P}$ consist of the composition-closed classes A with $\mathrm{Is}(\mathcal{M}) \subseteq A \subseteq W$. Let $\mathcal{Q}$ consist of the pullback-stable classes L containing all isomorphisms. Both are complete lattices. Meets are intersections, taking the empty meet to be W in $\mathcal{P}$ and all arrows in $\mathcal{Q}$. A join in $\mathcal{P}$ is the class of finite composites of arrows from the union; it remains in W. A nonempty join in $\mathcal{Q}$ is simply a union, while its empty join is the isomorphisms. These last empty-family conventions are necessary because every admissible class contains the isomorphisms.

For the size of these lattices, fix a universe large enough to contain the chosen collection of arrows, or work in a larger universe than that used for $\mathcal{M}$. The arguments concern classes invariant under isomorphism of arrows and universal quantification over pullback squares. This also explains the footnote on page 85: before invariance of W has been assumed, choosing one representative of each pullback is insufficient. Quantifying over every cartesian square avoids that choice. Once W contains isomorphisms and is composition-closed, invariance follows, and the familiar pullback-functor notation becomes harmless.

On va vérifier la condition (D_0) de la page 69, pour $\mathcal{R}$ et les relations d'ordre. Il y a deux vérifications à faire.

1°) `[où est '2^o' ?]` Donnons nous $A \in \mathcal{P}$, i.e. $A \subseteq W$, et considérons l'ensemble $\mathcal{R}(A)$ des $L \in \mathcal{Q}$ tels que l'on ait $(A, L) \in \mathcal{R}$. Il est clair que c'est un ouvert (et de même, que ${}^s\mathcal{R}(L)$ est un ouvert de $\mathcal{Q}$ pour tout L dans $\mathcal{Q}$) - i.e. $L \in \mathcal{R}(A)$, $L' \subseteq L$ implique $L' \in \mathcal{R}(A)$. Reste p. 52
à trouver un plus grand élément de $\mathcal{R}(A)$. Notons que si $L \in \mathcal{R}(A)$, alors pour tout $p \in L$, $p : Y' \longrightarrow Y$, le changement de base

$$p^* : \mathrm{Cat}/Y \longrightarrow \mathrm{Cat}/Y' : X \longmapsto X \times_Y Y'$$

doit transformer flèches $f \in A$ en flèches $g \in W$, comme il résulte du fait que L est stable par changement de base.

$$\begin{array}{ccc} X_1 & \xleftarrow{q_1} & X_1' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle g} \\ X_2 & \xleftarrow{q_2} & X_2' \\ \downarrow & & \downarrow \\ Y & \xleftarrow{p} & Y'. \end{array}$$

[page 85]

Donc $L \subseteq \mathbf{L}_W(A)$, où on pose

$$\mathbf{L}_W(A) = \{(p : Y' \longrightarrow Y) \in \mathrm{Fl}(\mathcal{M}) \quad | \quad p^* : \mathrm{Cat}/Y \longrightarrow \mathrm{Cat}/Y' \text{ transforme flèches de } A \text{ en flèches } \textit{de } W.\}$$

([5]).

$$\begin{array}{ccc} X_1 & \longleftarrow & X_1' \\ {\scriptstyle f}\downarrow & \text{cart.} & \downarrow{\scriptstyle f'} \\ X_2 & \longleftarrow & X_2' \\ \downarrow & \text{cart.} & \downarrow \\ Y & \xleftarrow{p} & Y' \end{array}$$

$$f \in A \implies f' \in W.$$

Il est clair d'autre part que cette partie de $\mathrm{Fl}(\mathcal{M})$ est stable par changement de base, donc $\mathbf{L}_W(A) \in \mathcal{Q}$, et que $(A, \mathbf{L}_W(A)) \in \mathcal{R}$. Donc $\mathbf{L}_W(A)$ est un plus grand élément de $\mathcal{R}(A)$, donc on trouve

$$\mathcal{R} = \{(A, L) \in \mathcal{P} \times \mathcal{Q} \mid L \subseteq \mathbf{L}_W(A)\}. \tag{6.5}$$

p. 53

$$\begin{array}{ccc} X_1 & \xleftarrow{q_1} & X_1' \\ {\scriptstyle f}\downarrow & \text{cart.} & \downarrow{\scriptstyle f'} \\ X_2 & \xleftarrow{q_2} & X_2' \\ \downarrow & \text{cart.} & \downarrow \\ Y_1 & \xleftarrow{p_1} & Y_1' \\ \downarrow & \text{cart.} & \downarrow \\ Y & \xleftarrow{p} & Y'. \end{array}$$

Inversement, partons de $L \in \mathcal{Q}$, et montrons que l'ouvert ${}^s\mathcal{R}(L)$ de $\mathcal{P}$ a un plus grand élément. Pour ceci, posons

$$\mathbf{A}_W(L) = \{(f : X \longrightarrow Y) \in W \subseteq \mathrm{Fl}(\mathcal{M}) \quad | \quad \forall \quad \begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & \textit{cart.} & \downarrow{\scriptstyle f'} \\ Y & \xleftarrow[p]{} & Y', \end{array} \text{ avec } p \in L, \text{ on a } f' \in W\}. \tag{6.6}$$

(NB Quand L contient les identités, comme c'est le cas notamment s'il est de la forme $\mathbf{L}_W(A)$ - alors il contient les isomorphismes, du moins si A les contient - alors $\mathbf{A}_W(L)$ est l'ensemble de $f \in \mathrm{Fl}(\mathcal{M})$ satisfaisant la condition énoncée après |, sans avoir à spécifier $f \in W$.) On a $\mathbf{A}_W(L) \in \mathcal{P}$, et on vérifie que $(\mathbf{A}_W(L), L) \in \mathcal{R}$ (en utilisant la stabilité de L par composition), enfin il est clair que $(A, L) \in \mathcal{R}$ implique $A \subseteq \mathbf{A}_W(L)$ (en utilisant $A \subseteq W$), donc $\mathbf{A}_W(L)$ est un plus grand élément de ${}^s\mathcal{R}(L)$.

Notons que si W *est stable par composition* (ce que nous allons supposer désormais), il en est de même de $\mathbf{A}_W(L)$ (ce qui utilise encore le fait que L soit stable par changement de [page 86]

4. cf. rectification p. 86.

5. NB le dire plutôt en termes de diagrammes cartésiens, vu qu'on n'a pas fait d'hypothèse de stabilité de W par isomorphismes.

base). De plus, si W *contient les isomorphismes* (ce que nous supposerons également), $\mathbf{A}_W(L)$ les contient aussi. Quant à $\mathbf{L}_W(A)$, il contient les isomorphismes *pourvu que* A soit stable par isomorphismes ; quand A est stable par composition et contient les isomorphismes, cette condition sera automatiquement satisfaite. Nous tenons à cette condition, c'est pourquoi du côté de A, dans la définition de $\mathcal{P}$, je vais introduire cette condition supplémentaire que A soit *stable par isomorphismes.* Donc je pose, en corrigeant (6.2),

$$(6.7)\quad \begin{cases} \mathcal{P} &= \{A \in \mathfrak{P}(\mathrm{Fl}(\mathcal{M})) \quad | \quad \mathrm{Is}(\mathcal{M}) \subseteq A \subseteq W, \quad A \text{ stable par composition}\} \\ \mathcal{Q} &= \{L \in \mathfrak{P}(\mathrm{Fl}(\mathcal{M})) \quad | \quad \mathrm{Is}(\mathcal{M}) \subseteq L, \quad L \text{ stable par changement de base}\}. \end{cases}$$

Commentary · Exposition [ms. 85]

The transporter and its adjoint

The corrected construction works because a larger testing class produces a smaller transporter. It is useful to give the complete argument, including the distinction between testing over one codomain and testing all arrows in a slice.

For $A \in \mathcal{P}$, define $T_W(A)$ to consist of the maps $p : Y' \to Y$ such that every arrow $f : X_1 \to X_2$ in A, equipped with a map $X_2 \to Y$, has $p^*f \in W$. Pullback pasting shows that $T_W(A)$ is stable under arbitrary base change: a test after pulling p back along $Z \to Y$ is already a test for p with its structure map factoring through Z. It contains the isomorphisms because $A \subseteq W$ and W is invariant under isomorphism. Thus $T_W(A) \in \mathcal{Q}$.

For $L \in \mathcal{Q}$, define $N_W(L)$ to consist of the maps $f \in W$ whose pullbacks along all maps of L into their codomain belong to W. The explicit requirement $f \in W$ is redundant here, since identities belong to L. Isomorphisms are in $N_W(L)$. For composable $f, g \in N_W(L)$ and $p \in L$ into the codomain of g, factor $p^*(gf)$ as the pullback of f along g^*p, followed by p^*g. Pullback stability gives $g^*p \in L$, so both factors lie in W. Hence $N_W(L)$ is composition-closed and belongs to $\mathcal{P}$.

The defining relation is now exactly

$$A \subseteq N_W(L) \quad \Longleftrightarrow \quad L \subseteq T_W(A).$$

For the forward direction, test $p \in L$ against $f \in A$ over Y. The base change $X_2 \times_Y Y' \to X_2$ is in L, so the assumption on f applies. Conversely, if p is a map of L into the actual codomain of f, this is a special case of the transporter test. This proves both implications and the maximality assertions on pages 85–86. Closure of L under composition is unnecessary for this adjunction; its appearance in the text's proof of $(N_W(L), L) \in \mathcal{R}$ is redundant.

Both operations reverse inclusions, so the usual polarity argument now applies without qualification. Their composites are monotone, extensive and idempotent; their fixed classes correspond anti-isomorphically. The extreme pairs in (6.9)–(6.10) follow directly: $T_W(\mathrm{Is})$ is all arrows, $N_W(\mathrm{Fl}) = W_{\mathrm{univ}}$, $N_W(\mathrm{Is}) = W$, and $T_W(W) = \mathrm{Fib}_W$. In particular, every closed left class contains all universal W-equivalences, and every closed right class contains Fib_W. This is the relation-theoretic content of §6, established with only the hypotheses actually imposed there.

On est bien sûr intéressé surtout aux éléments clos de $\mathcal{P}$, $\mathcal{Q}$, i.e. les parties A, L de $\mathrm{Fl}(\mathcal{M})$, contenant les isomorphismes, stables par composition (et L stable aussi par changement de base, $A \subseteq W$) telles que l'on ait p. 54

$$(6.8)\qquad A = \mathbf{A}_W(L), \qquad L = \mathbf{L}(A)$$

`[plutôt` $\mathbf{L}_W(A)$`]`.

Je garderai les notations $\natural$, $\flat$ du paragraphe précédent. Quels sont les deux couples extrêmes ? [page 87]

Partant de $A_0 = \mathrm{Is}(\mathcal{M})$ (plus petit des éléments de $\mathcal{P}$), on trouve $\mathbf{L}_W(A_0) = \mathrm{Fl}(\mathcal{M})$ (plus grand élément de $\mathcal{Q}$), et $A_0^\natural = \mathbf{A}_W(\mathrm{Fl}(\mathcal{M})) = W_{\mathrm{univ}}$, ensemble des flèches qui sont dans W et le restent par tout changement de base :

$$(6.9)\quad A_0^\natural = W_{\mathrm{univ}}, \qquad \beta_0(A_0) \overset{\text{déf}}{=} \mathbf{L}_W(A_0) = \mathrm{Fl}(\mathcal{M}), \qquad \text{où } A_0 = \mathrm{Is}(\mathcal{M}) \text{ plus petit élément de } \mathcal{P}.$$

Inversement, partons de $L_0 = \mathrm{Is}(\mathcal{M})$, le plus petit élément de $\mathcal{Q}$. On a $\mathbf{A}_W(L_0) = W$ (W étant stable par composition et contenant les isomorphismes), et $L_0^\flat = \mathbf{L}_W(W) = \mathrm{Fib}_W$, les W-fibrations :

$$L_0^\flat = \mathrm{Fib}_W, \qquad \alpha_0(L_0) = W, \qquad \text{où } L_0 = \mathrm{Is}(\mathcal{M}), \text{ plus petit élément de } \mathcal{Q}. \tag{6.10}$$

Donc les parties $\mathcal{R}$-closes à gauche de $\mathrm{Fl}(\mathcal{M})$ se promènent entre W_{univ} et W, les parties $\mathcal{R}$-closes à droite entre Fib_W et $\mathrm{Fl}(\mathcal{M})$.

Proposition 6.1. *Soient $A \in \mathcal{P}$, $L \in \mathcal{Q}$ tels que $A = \alpha_0(L)$, $L = \beta_0(A)$ (i.e. $A = \mathbf{A}_W(L)$, $L = \mathbf{L}_W(A)$). Pour que L soit stable par composition, il faut et il suffit que A soit stable par changement de base par les flèches $f \in L$. (Plus généralement, si $L \in \mathcal{Q}$ est un élément quelconque de $\mathcal{Q}$, et si on suppose de plus que L est stable par composition, alors $A = \mathbf{A}_W(L)$ est stable par changement de base par L.)* [page 88]

Commentary · Exposition [ms. 87]

When a transporter becomes a stabilizer

Proposition 6.1 identifies the extra condition that makes the formal correspondence compatible with iterated changes of base. Suppose (A, L) is a closed pair, so $A = N_W(L)$ and $L = T_W(A)$. If L is closed under composition, then A is stable under base change along L: for $f \in A$ and $p \in L$, its pullback belongs to W, and each further test along $q \in L$ is a test of f along $pq \in L$. Therefore $p^*f \in A$. When f is an arrow over the target of p, use the pullback of p along its codomain map; it belongs to L by pullback stability. This proves the more general assertion in parentheses, since it uses only $A = N_W(L)$.

Conversely, assume A is stable under base change along L. Given composable maps $q : Z \to Y'$ and $p : Y' \to Y$ in L, and an arrow $f \in A$ over Y, first pull back along p. The result is in A, and its pullback along q is again in $A \subseteq W$. Thus $(pq)^*f \in W$, whence $pq \in T_W(A) = L$. This proves the proposition completely.

For a closed pair one can sharpen its wording without adding a hypothesis:

$$L \text{ is composition-closed} \quad \Longleftrightarrow \quad L = \mathrm{Stab}(A).$$

Indeed, stability of A under L gives $L \subseteq \mathrm{Stab}(A)$, while the reverse inclusion always follows from $A \subseteq W$ and $L = T_W(A)$. Conversely every stabilizer is composition-closed. Thus the two names designate the same class exactly at the closed pairs satisfying Proposition 6.1. Without this extra condition the transporter may contain maps that preserve the W-tests but fail to preserve A itself.

The word "i.e." before (6.8) must accordingly be read with care. Closed pairs do not automatically have a composition-closed right member. Grothendieck is particularly interested in those that do; Proposition 6.1 states the criterion. The following finite example verifies that the distinction is real under the abstract hypotheses of this section.

Commentary · Development (commentators') [ms. 87]

A closed transporter which does not compose

The formal correction of $\mathcal{Q}$ in (6.7) becomes necessary in a four-object category. The example also separates the universal quantifier in a transporter from the stronger demand that it stabilize its source class.

A closed pair with a non-composition-closed right member. [ours] Let $\mathcal{M}$ be the chain $0 < 1 < 2 < 3$, with pullbacks given by minima. Write ij for its unique arrow $i \to j$ and I for its identities. Set

$$W = I \cup \{02, 03\}, \qquad A = I \cup \{03\}.$$

Then W and A contain the isomorphisms and are closed under composition. Moreover,

$$T_W(A) = \mathrm{Fl}(\mathcal{M}) \setminus \{13\}, \qquad N_W(T_W(A)) = A.$$

Thus $(A, T_W(A))$ is a closed pair, but 12 and 23 belong to its right member while their composite 13 does not.

To verify the transporter formula, the only nonidentity arrow of A to test is 03. It can be an arrow over y only when $y = 3$. Pullback along $x3$ gives $0x$, which lies in W precisely for $x = 0, 2, 3$. Therefore 13 is the unique excluded map; all identity tests succeed. This proves the first formula, including all slice tests.

For the kernel formula, the identities and 03 survive by the adjunction. The only remaining member of W is 02. Its pullback along 12, a member of the transporter, is 01, which is not in W. Hence 02 does not survive, and the second formula follows. Finally the right member is closed as well: applying the triple-operation identity for the established Galois connection gives $T_W N_W T_W(A) = T_W(A)$. This completes all the claims.

Here W is an abstract class of arrows with exactly the composition and isomorphism assumptions of §6; it is not asserted to be a fundamental localizer on Cat, or even to satisfy two-out-of-three. We checked the finite calculation exhaustively with the supplied script and proved it above. We did not find this specific example in the checked transporter and smooth-functor sources. It serves to explain the actual generality of Proposition 6.1, without making a claim about the special localizers used elsewhere in the manuscript.

Commentary · Context [ms. 87]

Intrinsic fibrations and sharp maps

Grothendieck wants the admissible changes of base to be determined by the weak equivalences themselves. This is why the extreme pair in (6.10) matters more than an isolated exercise with closure operations. Once W has been fixed, a morphism $p : E \to B$ belongs to Fib_W precisely when

$$p^* : \mathcal{M}/B \longrightarrow \mathcal{M}/E$$

preserves the arrows whose underlying morphisms belong to W. Both the test arrow and its map to B vary. Restricting the test to arrows with target B would omit the further base changes built into the definition.

The letter to Thomason of 2 April 1991 makes this intention explicit. In its first numbered discussion, Grothendieck proposes replacing a suitable proper fibration structure by the class determined by this preservation property; existence of enough such fibrations remains a separate factorization requirement (Grothendieck, 1991a, §1, printed p. 4). Thus the canonical class is available before one knows that it supports a useful model structure. The historical point is the choice of what should be intrinsic, not a rejection of the computational value of lifting and factorization axioms.

In a model category the same preservation property is the definition of a *sharp map* in Rezk (1998, §2). In a right proper model category every model fibration is sharp, and sharpness is equivalent to every strict pullback square along the map being homotopy cartesian (Rezk, 1998, Propositions 2.2 and 2.7). These statements explain both the usefulness and the limitations of the comparison: Grothendieck's Fib_W asks for a property of pullback with respect to W; a chosen Quillen fibration class supplies maps with that property under the additional hypothesis of right properness. An arbitrary transporter $\mathbf{L}_W(A)$ only promises to send the smaller class A into W. A second pullback can therefore leave the class of arrows on which that promise applies. The extra stability in Proposition 6.1 is exactly what permits the second step.

Terminologie : pour $A \in \mathcal{P}$, i.e. A une partie de $\mathrm{Fl}(\mathcal{M})$ contenue dans W contenant les isomorphismes et stable par composition, $\mathbf{L}_W(A)$ s'appelle le *transporteur de A dans W*. (Il y a une notion duale de *cotransporteur*.) C'est un élement de $\mathcal{Q}$, donc une partie de $\mathrm{Fl}(\mathcal{M})$ contenant les isomorphismes et stable par changement de base. D'autre part, pour L dans $\mathcal{Q}$, les $f \in \mathbf{A}_W(L)$ s'appellent flèches *W-L-asphériques,* ou les *W-L-équivalences,* ou les *W-équivalences L-universelles,* et $\mathbf{A}_W(L)$ s'appelle le *L-noyau de W*. On pourrait le noter plus simplement W_L (quand cette notation ne conflicte pas avec $W_S \subseteq \mathrm{Fl}(\mathcal{M}/S)$ pour $S \in \mathrm{Ob}\,\mathcal{M}$). C'est une partie de W qui (comme W lui-même) contient les isomorphismes et est stable par composition.

Enfin, il y a lieu aussi d'introduire le *stabiliseur* $\mathrm{Stab}(A)$, ou transporteur de A dans A, qui ne dépend pas de la donné de W, mais seulement de la partie A de $\mathrm{Fl}(\mathcal{M})$, contenant les isomorphismes et stable par composition. On pourrait aussi le noter Fib_A, et appeler

ses éléments des *A-fibrations* (A jouant à présent le rôle de W). On a $\mathrm{Stab}(A) \subseteq \mathbf{L}_W(A)$, et il semblerait qu'en pratique, ce sont ces stabiliseurs, plus que les transporteurs $\mathbf{L}_W(A)$, qui sont importants (quand les deux ne coïncident pas). C'est ainsi que dans Cat, si W est un localiseur fondamental, les morphismes W-lisses (resp. W-propres) Liss_W (Prop_W), qui sont les stabiliseurs des ensembles W_{as} (W_{coas}) des ensembles de morphismes W-asphériques (resp. W-coasphériques), jouant un rôle essentiel, alors que je ne sais pas caractériser de façon sensible les flèches des transporteurs $\mathbf{L}_W(W_{\mathrm{as}})$, $\mathbf{L}_W(W_{\mathrm{coas}})$, lesquels contiennent, en plus des morphismes W-lisses (resp. W-propres) les W-fibrations Fib_W. Je ne sais pas comment caractériser une classe de morphismes qui apparaît aussi hétéroclite! De même, il y a lieu d'introduire et de caractériser le stabiliseur de W_{bias} (ensemble des flèches W-biasphériques), comme les morphismes 'W-nets' Net_W, par une description similaire à celle des Liss_W, Prop_W, utilisant les bilocalisés $\backslash\underset{u}{X}/$, $\backslash\underset{v}{Y}/$, au lieu des localisés X/x, Y/y ou des colocalisés $x\backslash X$, $y\backslash Y$. Il y a lieu enfin de déterminer le stabiliseur de l'ensemble Equ des Cat-équivalences (ce qui ne dépend pas de la donné d'un W - mais on a $\mathrm{Equ} \subseteq \mathcal{P}(W)$ pour tout W fondamental).

p. 55
[page 89]

Commentary · Present state [ms. 89]

The scope of the remaining transporter questions

The questions at the end of the section ask for usable local tests for classes already defined by universal preservation properties. For smooth maps, that programme was developed explicitly: Maltsiniotis (2005, Definition 4.6, Theorem 4.13, and Example 4.17) defines preservation of asphericity under pullback, gives equivalent local conditions, and compares the result with smoothness for a fundamental localizer. Properness is obtained by opposite categories. This identifies a later theorem corresponding to the stabilizer side of Grothendieck's discussion.

The transporter $T_W(W_{\mathrm{asph}})$ asks only that pullbacks of aspherical maps be W-equivalences; its target condition is weaker than preservation of asphericity. The inclusions on page 89 follow directly: it contains $\mathrm{Stab}(W_{\mathrm{asph}})$ because $W_{\mathrm{asph}} \subseteq W$, and it contains $\mathrm{Stab}(W)$ because the latter preserves every arrow of W. The corresponding statements for coasphericity are dual. They do not identify a union of those classes, nor imply that the transporter is composition-closed.

We checked Maltsiniotis's asphericity paper and searched the literature under the manuscript's transporter, stabilizer and "net" terminology. We did not locate a theorem identifying the general biaspherical stabilizer with precisely the proposed bilocal lifting condition, or a full intrinsic description of both mixed transporters. This is a statement about the scope of our verification, not a claim that those problems remain open in every formulation. The separate question about the stabilizer of categorical equivalences has a definite answer, proved in the block "The stabilizer of categorical equivalences". The history of the intrinsic class Fib_W is discussed in "Intrinsic fibrations and sharp maps".

p. 56
[page 90]

Commentary · Later developments [ms. 89]

The stabilizer of categorical equivalences

The last question on this page has a concrete answer. The obstruction to preserving an equivalence under a strict pullback is an isomorphism of objects in the base which cannot be lifted. The relevant maps are the *isofibrations*, the fibrations of the usual model structure on categories; see Rezk (1996, §2 and Theorem 3.1). We give the argument in the notation of the manuscript, so that the answer also specifies the meaning of its stabilizer.

Proposition. Let Equ be the class of equivalences of small categories. A functor $p : E \to B$ belongs to $\mathrm{Stab}(\mathrm{Equ})$ if and only if, for every $e \in E$ and every isomorphism $\gamma : p(e) \to b$ in B, there are an object e' and an isomorphism $\widetilde{\gamma} : e \to e'$ with $p(e') = b$ and $p(\widetilde{\gamma}) = \gamma$.

Proof. Suppose first that this lifting property holds. Let $F : C \to D$ be an equivalence over B, with structure map $h : D \to B$. The pullback

$$F_E : C \times_B E \longrightarrow D \times_B E$$

is fully faithful: a morphism in either pullback is a pair of morphisms with equal images in B, and full faithfulness of F lifts the first member uniquely without changing that equality. To prove

essential surjectivity, take (d, e) in the target. Choose $c \in C$ and an isomorphism $\theta : F(c) \to d$. Apply the isomorphism-lifting property to $(h\theta)^{-1} : p(e) \to hF(c)$ and invert the resulting lift. This gives an isomorphism $\eta : e' \to e$ with $p(e') = hF(c)$ and $p(\eta) = h\theta$. The pair (θ, η) is an isomorphism $F_E(c, e') \to (d, e)$. Thus F_E is an equivalence, as required for the stabilizer.

Conversely, suppose $p \in \mathrm{Stab}(\mathrm{Equ})$. Let J be the groupoid with two objects $0, 1$ and exactly one morphism between each ordered pair. The data (e, γ) define a functor $J \to B$ taking 0 to $p(e)$, 1 to b, and $0 \to 1$ to γ. The inclusion $\{1\} \to J$ is an equivalence over B. Hence

$$E \times_B \{1\} \longrightarrow E \times_B J$$

is an equivalence. Essential surjectivity at $(e, 0)$ supplies $(e', 1)$ and an isomorphism between it and $(e, 0)$. Orienting that isomorphism from $(e, 0)$ to $(e', 1)$ gives the required $\widetilde{\gamma}$. This proves the converse. □

The proof also explains why the answer is sensitive to strict pullbacks. A point inclusion into J is itself an equivalence, but pulling it back along the inclusion of the other point gives $\emptyset \to e$. An isofibration supplies the missing representatives over isomorphic objects. No assertion about the fundamental localizer W is needed for this calculation. In particular, it answers the question about Equ without identifying the more delicate stabilizer of W-biaspherical maps with a familiar fibration class.

7 Morphismes cofiltrants et localement cofiltrants

Mais je ne veux pas m'attarder à présent sur ces développements, qui ne me paraissent pas urgents, et voudrais revenir aux questions liées à la notion de catégories filtrantes ou cofiltrantes.

Commentary · Exposition [ms. 90]

The conditions that pass through a comma category

Grothendieck returns to filteredness because it supplies concrete conditions under which the cofinality arguments can be repeated after restricting a diagram. The adjective "local" has a precise force here. It does not mean merely that the set of objects in each connected component is directed. The commutativity of the triangles must survive the construction of a common predecessor.

Write $P(C)$ for the following condition: every cospan $a \xrightarrow{r} c \xleftarrow{s} b$ admits arrows $u : d \to a$, $v : d \to b$ such that $ru = sv$. Write $E(C)$ for the equalization condition: every parallel pair $r, s : a \to b$ admits $t : d \to a$ with $rt = st$. Finally, write $I(C)$ for nonemptiness together with the existence of a common predecessor for every pair of objects. These are respectively PS_g1, PS_g2, and PS_g1' in the text. Then C is cofiltered precisely when $I(C)$ and $E(C)$ hold, and locally cofiltered precisely when $P(C)$ and $E(C)$ hold. The latter condition allows the empty category. Equivalently, every connected component is cofiltered; the elementary decomposition underlying this statement is recorded, with the opposite variance, in The Stacks Project Authors (2026e, Lemmas 4.19.6 and 4.19.8).

The weaker terms need an explicit convention. In the working proof, "weakly cofiltered" means $I(C)$, whereas "locally weakly cofiltered" means $P(C)$. Footnote 64 proposes reserving the former term for nonempty connectedness together with $P(C)$. These conditions differ: the category with two parallel arrows $0 \rightrightarrows 1$ satisfies I but fails P. The closing diagrams recognize the distinction and call I irreducibility. We therefore retain I and P in statements where the terminology changes. Proposition 7.3 and its composition corollary hold with either weak convention, provided it is used consistently.

Here is the argument behind the proposition, including its three independent assertions. Suppose first that P holds in Y and in every $y\backslash X$. Given a cospan in X, complete its image in Y to a commutative square with lower vertex y. The three objects of the cospan, equipped with the resulting maps from y, form a cospan in $y\backslash X$. Applying P there gives the required square in X. If instead I holds in Y and in the comma categories, two objects of X first acquire a common predecessor for their images in Y, and then acquire one in the corresponding comma category. Nonemptiness follows by choosing $y \in Y$ and an object of $y\backslash X$.

For equalization, start with $r, s : a \to b$ in X. Choose $v : y \to f(a)$ with $f(r)v = f(s)v$, using $E(Y)$. Then r, s are parallel arrows in $y\backslash X$. An equalizing arrow there equalizes them in X. These arguments prove the cofiltered and locally cofiltered cases as well. For the revised weak convention, $P(Y)$ and connectedness imply $I(Y)$: the relation "has a common predecessor" is transitive by P, and contains every arrow and its reverse. The same observation applies to the comma categories, so the preceding argument also proves connectedness of X.

The composition statement now has a transparent reason. A discrete opfibration $Y' \to Y$ identifies $y'\backslash(X \times_Y Y')$ with $y'_Y\backslash X$, by unique lifting of arrows out of y'. This proves the coétale base-change assertion of Remark 7.2. Apply it to $z\backslash Y \to Y$, and then apply Proposition 7.3 to $z\backslash X \to z\backslash Y$. The printed assertion that *étale* maps are locally "filtrants" has the variance reversed; Lemma 7.5 gives the correct locally cofiltered assertion below.

Definition 7.1. Soit $f : X \longrightarrow Y$ une flèche dans Cat. On dit que f est *cofiltrante* (resp. *localement cofiltrante*, resp. *faiblement cofiltrante* ([64]), resp. *localement faiblement cofiltrante* ou encore *précofiltrante*) si pour tout y dans Y, la catégorie colocalisé $y\backslash X$ est cofiltrante (resp. …). (Dualement, on dit que f est *filtrante*, resp. …, si les catégories X/y sont filtrantes, resp. …, i.e. si $f^o : X^o \longrightarrow Y^o$ est cofiltrante resp. ….)

Remarque 7.2. Notions stables par changement de base coétale. Contient les isomorphismes et même les Cat-équivalences. Les morphismes *étales* sont localement filtrants.

Proposition 7.3. *Soit $f : X \longrightarrow Y$ un morphisme cofiltrant (resp. localement cofiltrant, resp. faiblement cofiltrant, resp. précofiltrant), et supposons que Y soit cofiltrant (resp. localement cofiltrant, resp. faiblement cofiltrant, resp. précofiltrant). Alors X lui-même est cofiltrant (resp. …).*

Démonstration. Il s'agit, dans les quatre cas envisagés, de vérifier pour X la condition $\underbrace{\mathrm{PS}_g1' \,/\, \mathrm{PS}_g1}_{\text{deux derniers cas}} \,/\, \mathrm{PS}_g1' + \mathrm{PS}_g2 \,/\, \mathrm{PS}_g1 + \mathrm{PS}_g2$. Mais pour chacune des trois conditions PS_g1, PS_g1', PS_g2 séparément, on voit immédiatement que si elle est vérifiée pour Y et pour les $y\backslash X$, elle l'est pour X, d'où la proposition. [page 91]

Corollaire 7.3. *Les quatre notions envisagées dans (7.1) sont stables par composition.*

Démonstration immédiate, en utilisant la remarque (7.2).

$$\begin{array}{ccc} X & \longleftarrow & z\backslash X \\ \downarrow & & \downarrow \\ Y & \longleftarrow & z\backslash Y \\ \downarrow & & \downarrow \\ Z & \longleftarrow & z\backslash Z. \end{array}$$

Remarque 7.4. p. 57

1) Notons que la notion de morphisme cofiltrant ou faiblement cofiltrant n'est *pas* stable par changement de base quelconque, ni même par une immersion ouverte. Exemple : $e \longrightarrow \mathbf{\Delta}^1$, appliquant e en 1, est cofiltrant,

$$\begin{array}{ccc} & & e \\ & & \downarrow \\ 0 & \longrightarrow & 1 \end{array}$$

mais sa fibre en 0 est vide, donc n'est ni cofiltrante, ni faiblement cofiltrante. Je n'ai pas vu d'exemple montrant que la notion de flèche *localement* cofiltrante resp. précofiltrante

64. J'ai modifié la terminologie : maintenant faiblement cofiltrant = 0-connexe + localement faiblement cofiltrant, *stable par passage* à X' sur X, X' étale et ∞-connexe. Revoir la terminologie dans le cas faiblement cofiltrant, qui est une notion traîtresse, faute d'être stable par passage [à] un X' étale sur X.

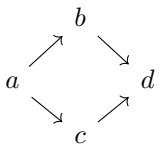
n'est pas stable par changement de base, et ne voudrais pas m'y attarder, n'ayant pas besoin de connaître la réponse.

2) Pour que X soit cofiltrante (resp. …), il faut et il suffit que $X \longrightarrow e$ le soit. Ainsi la notion absolue est ramenée à une notion relative.

3) Si $f : X \longrightarrow Y$ est cofiltrante, elle est W-coasphérique (donc $\in W$) pour tout W satisfaisant l'axiome Loc (8) des limites inductives. En particulier, elle est W_0-asphérique, i.e. un foncteur cofiltrant (et même seulement faiblement cofiltrant) est *cofinal.* [page 92]

La raison principale pour m'intéresser aux flèches cofiltrantes est contenue dans la

Commentary · Development (commentators') [ms. 91]



A finite answer to the base-change question

Grothendieck's example separates cofilteredness from its local form only by making a fibre empty. To answer the question he leaves beside it, the pullback must instead create a connected comma category whose two branches have lost their common predecessor.

A four-object counterexample. [ours]

The class of locally cofiltered functors, and the class of locally weakly cofiltered functors, are not stable under arbitrary base change, even among finite posets.

Proof. Let $f : \{1\} \hookrightarrow [1]$ select the final object of the walking arrow. Both $0\backslash\{1\}$ and $1\backslash\{1\}$ are singleton categories, so f is cofiltered. Let D be the diamond poset

and define $v : D \to [1]$ by $v(a) = 0$ and $v(b) = v(c) = v(d) = 1$. The pullback of f is the full inclusion $j : U \hookrightarrow D$, where $U = \{b, c, d\}$ and $b < d$, $c < d$. Since a is initial in D, there is an isomorphism $a\backslash U \cong U$. This category is connected, but the cospan $b \to d \leftarrow c$ has no common predecessor in U. Thus $P(a\backslash U)$ fails; in particular this comma category is not locally cofiltered. The same pullback disproves both proposed stability assertions. □

This example answers the question for strict categorical pullbacks, which are the pullbacks used in the source. It does not conflict with Remark 7.2: v is not a discrete opfibration, since the arrow $0 \to 1$ has several lifts with source a. Nor does it conflict with Proposition 7.4, which concerns an *étale change of the source* followed by a factorization through an *étale target.*

The same diamond makes the variance slip in Remark 7.2 visible. The lower open subposet $V = \{a, b, c\} \subset D$ defines a discrete fibration. Its comma category V/d is V, which is connected and not filtered: b and c have no common upper bound there. Thus an *étale* functor need not be locally filtered.

We checked the discussions of representable flatness in Tendas (2024, Remark 2.4) and Shulman (2011), and the explicit filteredness criteria in The Stacks Project Authors (2026e, Section 4.19). We did not locate this finite pullback construction there. The label records our supplied answer to the manuscript's question, without claiming priority for the example.

Commentary · Exposition [ms. 92]

The image that belongs in Proposition 7.4

The proposition is intended to compare sections or cosections after passing to an open part of a slice. The target must therefore be the part reached by that open, rather than the part reached by the whole slice. In (c) the printed definition of V omits the restriction to U. Its correct form is

$$V = \{z \in Y/f(x) \mid z\backslash U \neq \varnothing\}.$$

Equivalently, V is the lower open subcategory generated by $(f/x)(U)$. This is already forced by $U = \varnothing$: the desired target is then empty, whereas the target defined in print is all of $Y/f(x)$, because $(f/x)(x) = f(x)$ is its terminal object. More generally, the proof's assertion that $z\backslash U$ is nonempty

"par construction de V" uses exactly the corrected definition. This is a slip in the edition's text, not a mistranscription; the correction is consequently explained here and retained as a recorded slip in the source.

Once this target is specified, the two comparison formulas have their expected variance. With $g : U \to V$, a covariant diagram $G : V \to \mathcal{M}$ has

$$\operatorname*{colim}_U Gg \;\cong\; \operatorname*{colim}_V G,$$

whereas a presheaf $F : V^{\mathrm{op}} \to \mathcal{M}$ has

$$\lim_{V^{\mathrm{op}}} F \;\cong\; \lim_{U^{\mathrm{op}}} Fg^{\mathrm{op}}.$$

Both statements follow from the same nonempty-connected comma criterion for finality. The second does not assert invariance of limits of *covariant* diagrams under a final functor. The needed limits or colimits must exist in $\mathcal{M}$. The letter printed as q in (c) is legible in the edition; it denotes the map called g in the proof and in these formulas.

The homotopical qualification also has a precise scope. The cofiltered comma categories are W-aspherical under the stated axiom Loc (8), so g is W-coaspherical. Weak cofilteredness by itself gives connectedness, hence ordinary finality, but supplies no general assertion of contractibility. Footnote 65 correctly reserves the stronger conclusion for the cofiltered hypothesis. The phrase "W_0-asphérique" in Remark 7.4(3) must read "W_0-coasphérique" in the convention of this chapter.

Proposition 7.4. *Soit $f : X \longrightarrow Y$ dans* Cat *localement cofiltrant (resp. localement faiblement cofiltrant). Alors :*

a) Pour tout X' étale sur X, le composé $f' : X' \longrightarrow X \longrightarrow Y$ est localement cofiltrant (resp. …), et pour toute factorisation de f' en $X' \xrightarrow{g'} Y' \longrightarrow Y$ avec $Y' \longrightarrow Y$ étale, g' est localement cofiltrant (resp. …).

b) $\forall$ x dans X, le morphisme sur les localisés

$$f/x : X/x \longrightarrow Y/x \qquad (y = f(x))$$

est cofiltrant (resp. faiblement cofiltrant).

c) Si x, y comme dans b), et U est un ouvert de X/x, désignant par V l'ouvert de Y/y engendré par l'image de f/x (i.e. l'ouvert formé des z dans Y/y tels que $z\backslash(X/x)$ soit non vide), la flèche induite $q : U \longrightarrow V$ `[est]` *cofiltrante (resp. faiblement cofiltrante), a fortiori cofinale (et même W-coasphérique, pour tout W satisfaisant l'axiome des limites Loc (8))* ([65]).

Donc pout tout cofaisceau *G sur V, à valeurs dans une catégorie $\mathcal{M}$ avec $\varinjlim$, on a* `[un]` *isomorphisme* [page 93]

$$\varinjlim_U g^*(G) \xrightarrow{\sim} \varinjlim_V G,$$

et pour tout préfaisceau F sur V, à valeurs dans une catégorie $\mathcal{M}$ avec $\varprojlim$, on a `[un]` *isomorphisme* p. 58

$$\varprojlim_U g^*(F) \xleftarrow{\sim} \varprojlim_V F.$$

Démonstration. Je vais d'abord expliciter le

Lemme 7.5. *Soit $h : X' \longrightarrow X$ un morphisme étale dans* Cat. *Alors h est localement cofiltrant. De façon plus précise, pour tout x dans X, on a*

$$\pi_0(x\backslash X') \xrightarrow{\sim} \mathrm{Ob}\, X'_x,$$

65. Il suffit ici qu'on soit dans l'hypothèse respée (*f faiblement* localement cofiltrant) sauf pour le NB ici `[`le NB ici' est `(et même ...Loc (8))']`.

toute composante connexe de $x\backslash X'$ contient un élément et un seul de la catégorie discrète $X'_x \subseteq x\backslash X'$. Si x' est dans X'_x (i.e. x' objet de X' tel que $h(x') = x$), c'est un objet initial *de la composante connexe qui le contient. (Donc cette composante est cofiltrante.)*

Ceci prouve (et au delà) la première assertion de 7.4, compte tenu de 7.3 (stabilité par composition), ou parce qu'une catégorie étale (en l'occurrence $y\backslash X'$) au dessus d'une catégorie localement cofiltrante (resp. localement faiblement cofiltrante) (en l'occurrence $y\backslash X$) est itou. [page 94]

$$\begin{array}{ccc} y\backslash X' & \longrightarrow & X' \\ \downarrow{\scriptstyle \text{ét.}} & \text{cart.} & \downarrow{\scriptstyle \text{ét.}} \\ y\backslash X & \longrightarrow & X \\ \downarrow & \text{cart.} & \downarrow \\ y\backslash Y & \longrightarrow & Y. \end{array}$$

Pour la deuxième assertion dans a), on peut maintenant supposer $X' = X$. Il faut prouver que pour tout y' dans Y', $y'\backslash X \overset{\text{déf}}{=} X \times_{Y'} y'\backslash Y'$ est localement cofiltrante (resp. localement faiblement cofiltrante). Soit y dans Y l'image de y', et considérons le diagramme de trois carrés cartésiens ci-contre.

$$\begin{array}{ccccc} y'\backslash X & \longrightarrow & y\backslash X & \longrightarrow & X \\ \downarrow{\scriptstyle \text{ét.}} & \textit{cart.} & \downarrow{\scriptstyle \text{ét.}} & \textit{cart.} & \downarrow{\scriptstyle \text{ét.}} \\ y'\backslash Y' & \longrightarrow & y\backslash Y' & \longrightarrow & Y' \\ & & \downarrow & \textit{cart.} & \downarrow \\ & & y\backslash Y & \longrightarrow & Y \end{array}$$

Le Lemme 7.5 implique que $y'\backslash Y' \longrightarrow y\backslash Y'$ est l'inclusion dans $y\backslash Y'$ d'une composante connexe de $y\backslash Y'$, c'est donc une immersion ouverte. Donc $y'\backslash X \longrightarrow y\backslash X$ est une immersion ouverte. Comme $y\backslash X$ est localement cofiltrant (resp. localement faiblement cofiltrant) par hypothèse, il en est donc de même de $y\backslash X$. Cela prouve d). p. 59

Appliquant a) à la situation $X/x \longrightarrow Y/y$ dans b), on voit que les colocalisés $z\backslash(X/x)$ de X/x sur Y/y ($z \in \mathrm{Ob}\,(Y/y)$) sont localement cofiltrants (resp. faiblement). Mais comme X/x a un objet final au dessus de l'objet final de Y/y, il s'ensuit que $z\backslash(X/x)$ a un objet final, donc est 0-*connexe.* !

Donc ces catégories, étant localement cofiltrantes (resp. faiblement), sont en fait cofiltrantes (resp. faiblement cofiltrantes). [page 95]

Prouvons c). Notons que pour z dans V, $z\backslash U$ s'identifie à l'image inverse, par $z\backslash(X/x) \longrightarrow X/x$, de l'ouvert U de X/x, c'est donc un *ouvert* de $z\backslash(X/x)$, non vide par construction de V. Mais un ouvert non vide d'une catégorie cofiltrante (resp. faiblement cofiltrante) est encore cofiltrant (resp. faiblement cofiltrant). Cela signifie que $g : U \longrightarrow V$ est cofiltrant (resp. faiblement cofiltrant), a fortiori cofinal (et W-coasphérique, pour tout W satisfaisant Loc (8)). Cela achève la démonstration.

Commentary · Exposition [ms. 95]

Why the restriction argument works

The mechanism of Proposition 7.4 is the decomposition in Lemma 7.5, and it is useful to see why that decomposition is canonical. An *étale* functor $h : E \to C$ is a discrete fibration. Given $(e, \alpha : c \to h(e))$ in $c\backslash E$, lift α uniquely to an arrow $e_0 \to e$ with $h(e_0) = c$. This assigns an object e_0 of the discrete fibre to each object of the comma category. Every arrow of the comma

category preserves e_0, by uniqueness of the lift. For each fixed e_0, the object $(e_0, 1_c)$ is initial in the corresponding full subcategory. Thus

$$c\backslash E \;\cong \coprod_{e_0 \in h^{-1}(c)} (e_0\backslash E),$$

and each displayed summand has an initial object. This proves all assertions of the lemma, including the empty-fibre case.

For the first assertion of 7.4(a), $y\backslash X' \to y\backslash X$ is a discrete fibration. Conditions P and E pass to its total category: lift a commutative cone in the base to the prescribed object above its target; uniqueness makes the lifted arrows commute. For E, faithfulness of a discrete fibration makes the lifted equalization an actual equality. This proves preservation of local cofilteredness and its P-only variant.

For the second assertion, let $X \xrightarrow{g} Y' \xrightarrow{h} Y$ be the factorization, with h a discrete fibration. An object $y' \in Y'$ over y determines the summand of $y\backslash Y'$ whose initial object is $(y', 1_y)$. Its inverse image under $y\backslash X \to y\backslash Y'$ is exactly $y'\backslash X$. Hence $y'\backslash X$ is a union of connected components of $y\backslash X$, so it inherits P and E. This argument also explains the second diagram: the labels "ét." on its three vertical arrows are not justified, since $g : X \to Y'$ is arbitrary. The relevant map is the horizontal component inclusion and its pullback. The claimed result does not use those incorrect vertical labels.

Now set $y = f(x)$. The category X/x is *étale* over X, and Y/y is *étale* over Y. Part (a) therefore makes $f/x : X/x \to Y/y$ locally cofiltered. For $z = (z_0 \to y)$, its comma category $z\backslash(X/x)$ has a terminal object: take $(x, 1_x)$ with the specified arrow $z_0 \to y$. Every other object includes its unique morphism to this object as part of its structure. The comma category is consequently nonempty and connected. Combined with local cofilteredness this proves (b), and the same reasoning gives connectedness plus P in the weaker case.

For (c), use the corrected V above. The category $z\backslash U$ is a nonempty lower open full subcategory of $z\backslash(X/x)$. A nonempty lower open subcategory of a cofiltered category is cofiltered: for two objects, any common predecessor still lies in the open, and the same is true of the source of an equalizing arrow. For connectedness plus P, the common-predecessor argument proves connectedness and the square condition restricts. These observations prove (c), and also prove Remark 7.5(1) for an arbitrary cofiltered $f : X \to Y$ and an open $U \subset X$. In that remark the defining condition for V must likewise be $y\backslash U \neq \varnothing$, as its preceding words "engendré par $f(U)$" already require.

Remarque 7.5.

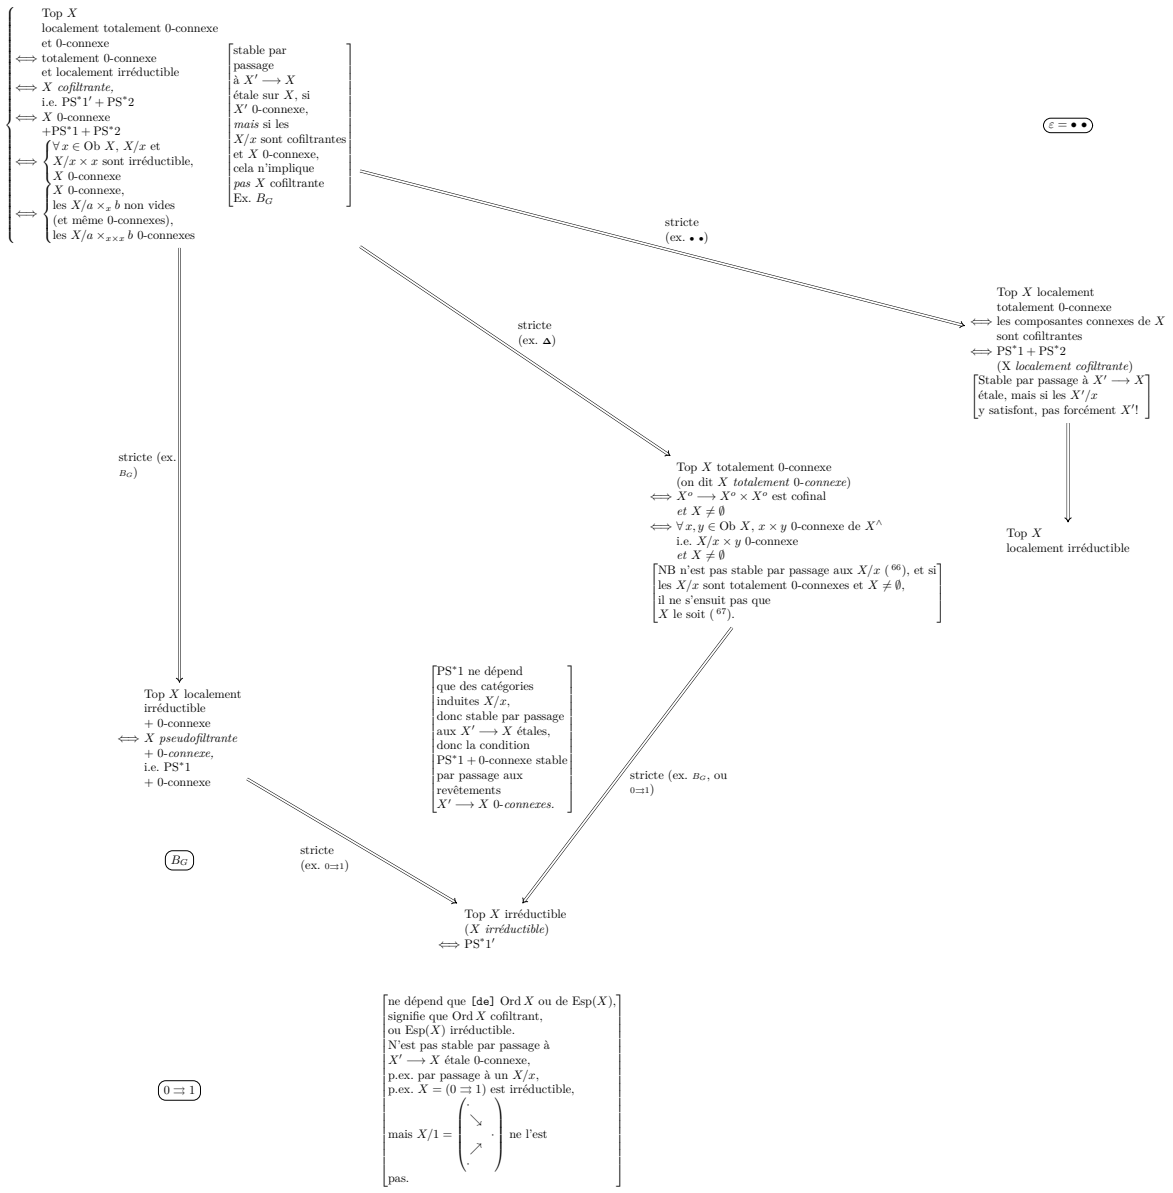
1) Le même argument que dans c) montre que si $f : X \longrightarrow Y$ est cofiltrant (resp. faiblement cofiltrant), alors pour tout ouvert U dans X, si on désigne par V l'ouvert de Y engendré par $f(U)$, i.e. l'ouvert formé des y dans Y tels que $y\backslash X \neq \emptyset$, alors la flèche induite $g : U \longrightarrow V$ est cofiltrante (resp. faiblement cofiltrante), et a fortiori g est cofinal (et plus généralement, si f est cofiltrant, g est W-coasphérique pour tout W satisfaisant la condition Loc (8)).

2) Un cas particulier intéressant de 7.4 est celui où on suppose que les $y\backslash X$ ($y \in \mathrm{Ob}\ Y$) sont sommes directes de catégories ayant chacune un *objet initial.* Alors on voit que cette condition est stable par les opérations de 7.4 a) [?], et par conséquent, les colocalisés $z\backslash(X/x)$ des morphismes localisés en haut $X/x \longrightarrow Y/y$ sont des catégories à objet initial. Ceci implique alors qu'il en est de même des colocalisés $z\backslash U$ ($z \in \mathrm{Ob}\ V$) dans $g : U \longrightarrow V$. Il s'ensuit que g est W-coasphérique pour *tout* localiseur fondamental W (sans avoir à se soucier de l'axiome des limites). [page 96]

   La condition envisagée sur $f : X \longrightarrow Y$ est satisfaite notamment dans les deux cas suivants (qui me paraissent de loin les plus importants) : a) f est étale et b) X est discrète.

Commentary · Exposition [ms. 96] p. 60 [page 97]

Initial objects remove the limit axiom



Grothendieck singles out components with initial objects because here the cofinality argument needs no passage to filtered limits or colimits. The bracketed question in Remark 7.5(2) can be settled directly. Suppose each $y\backslash X$ is a disjoint union of categories with initial objects. If $E \to C$ is a discrete fibration and every component of C has initial object c_0, each object of E receives a unique lift of the arrow from the relevant c_0. The lifts with sources over c_0 partition E into full subcategories, each having its source as an initial object. Consequently the initial-object condition is preserved by the first operation in 7.4(a). The second operation selects a union of components, by the preceding decomposition, and therefore preserves it as well.

For $f/x : X/x \to Y/f(x)$ the comma categories have terminal objects and hence just one component. Their initial-object decomposition therefore consists of a single summand, so they actually have initial objects. Passing to a nonempty lower open $z\backslash U$ preserves this initial object: if an open contains any object, it contains the source of every arrow into that object, in particular the initial object. This proves the strengthened assertion in full.

The examples in the text follow without an additional hypothesis. For a discrete fibration f, Lemma 7.5 supplies the initial objects. If X is discrete, every $y\backslash X$ is discrete, so all of its components are singleton categories. The strengthened conclusion can therefore apply to a functor which is far from final before one restricts to the open image.

For a fundamental localizer W, a category with initial object is W-aspherical. One can justify the initial-object version from the terminal-object axiom: the unique map to the terminal category and its section have composites related to the identity by the natural transformation from the constant initial-object functor. Fundamental localizers identify naturally transformed functors after passage to homotopy, as follows from the interval projection $C \times [1] \to C$ and the terminal-object axiom. Thus all the relevant comma categories are W-aspherical for every fundamental localizer. This is exactly where the appeal to Loc (8) disappears in the manuscript's argument; mere weak cofilteredness would not give this conclusion.

The later theory removes the same qualification from the full cofiltered case. A cofiltered category has weakly contractible nerve: any finite collection of simplices admits a compatible cone after finitely many common-predecessor and equalization operations, giving the required null homotopies. Cisinski (2004, Theorem 2.2.11, p. 136) proves that the weak equivalences detected by nerves form the minimal fundamental localizer. They therefore belong to every fundamental localizer. Consequently every cofiltered comma category is W-aspherical for every fundamental W, and a cofiltered functor is W-coaspherical without an additional Loc (8) assumption. The source's conditional assertion remains correct; the stronger present statement uses this later minimality theorem.

Commentary · Examples [ms. 97] p. 61 [page 98]

Reading the six classes without the changing terminology

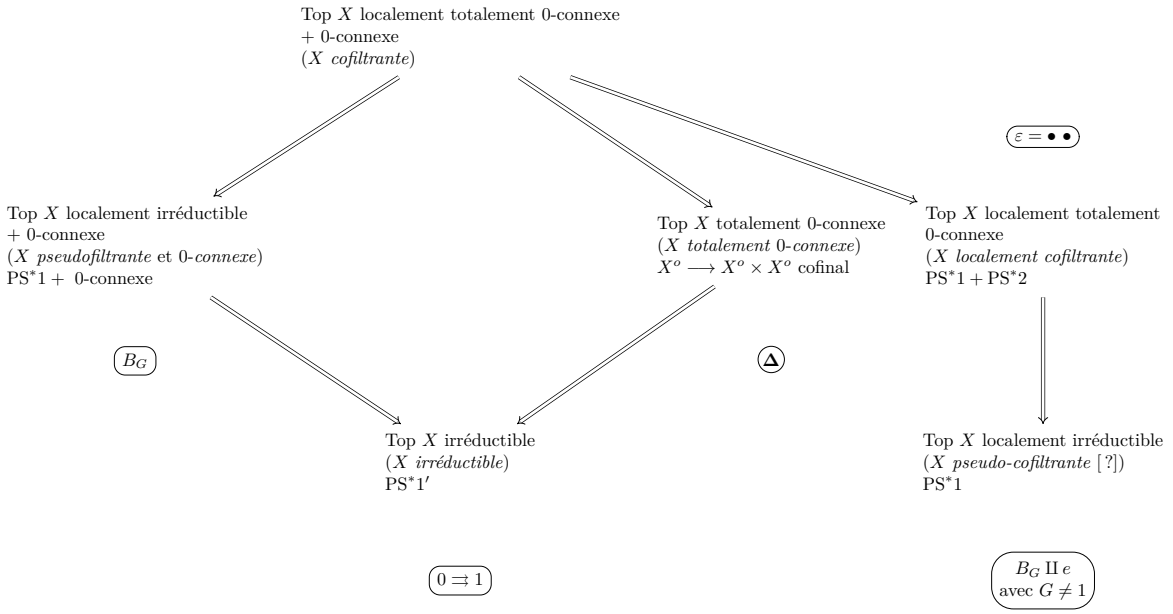
The diagrams collect the distinctions developed earlier in the chapter. Their content is more stable than their terminology: "pseudo-filtrante" and "pseudo-cofiltrante" sometimes omit the direction or change meaning. We use P, E, I as above and write T for the assertion that C^{op} is sifted. Explicitly, T means $C \neq \varnothing$ and the category of cones $c \to a$, $c \to b$ is connected for every a, b. This is Grothendieck's total 0-connectedness, as discussed already in the commentary at manuscript p. 18 ("The ordinary sifted condition and its variance"). The six classes are

C_{cof}	$I + E$ (equivalently $P + E +$ connected, nonempty)
C_{loc}	$P + E$
C_{weak}	$P +$ connected, nonempty
C_{pre}	P
C_{irr}	I
C_{tot}	T.

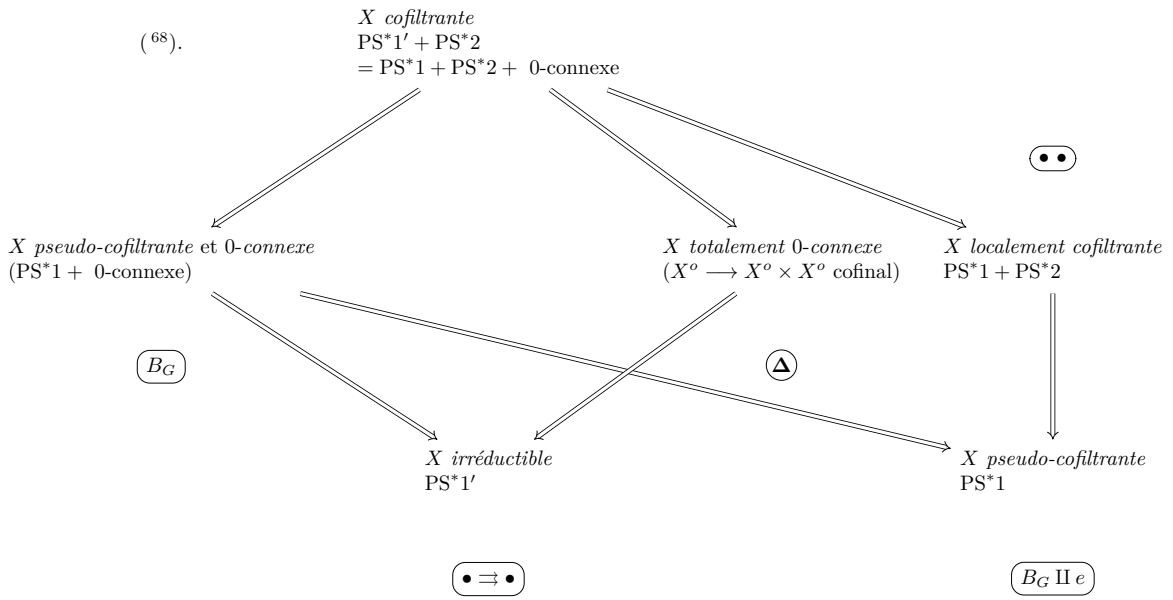
There are inclusions $C_{\mathrm{cof}} \subset C_{\mathrm{loc}}, C_{\mathrm{weak}}, C_{\mathrm{tot}}$, $C_{\mathrm{loc}} \subset C_{\mathrm{pre}}$, $C_{\mathrm{weak}} \subset C_{\mathrm{pre}}, C_{\mathrm{irr}}$, and $C_{\mathrm{tot}} \subset C_{\mathrm{irr}}$. The two middle classes C_{weak} and C_{tot} meet exactly in C_{cof}, by the criterion established earlier in the chapter. The following table makes the five separating examples completely explicit; G is nontrivial and A is the parallel-arrow category.

	C_{cof}	C_{loc}	C_{weak}	C_{pre}	C_{irr}	C_{tot}
B_G	0	0	1	1	1	0
$\mathbf{\Delta}$	0	0	0	0	1	1
$A = (0 \rightrightarrows 1)$	0	0	0	0	1	0
$\varepsilon = \{0, 1\}$	0	1	0	1	0	0
$B_G \amalg e$	0	0	0	1	0	0

For B_G, every cospan can be completed because its arrows are invertible: for $r, s \in G$, use $u = r^{-1}s$ and $v = 1$, obtaining $ru = sv$. Equalization fails for a nonidentity g and 1, since $gt = t$ would imply $g = 1$. The common-cone category of the unique object with itself has objects $(r, s) \in G^2$, with simultaneous right multiplication by $t \in G$ as morphisms. The quantity sr^{-1} labels its connected components, giving $|G|$ components. Thus T fails. This is the same obstruction as the diagonal action on $G \times G$; see The Stacks Project Authors (2026e, Lemma 4.19.4). Every slice $B_G/*$ nevertheless has exactly one arrow between any pair of its objects and is cofiltered. This verifies the diagram's warning that cofiltered slices do not imply a locally cofiltered category.



For A, the object 0 is a common predecessor of any pair of objects, so I holds. The cospan given by the two distinct arrows $r, s : 0 \to 1$ cannot be completed to a commutative square: the only arrow into 0 is its identity. Thus P fails. The cone category for the pair $(0, 1)$ has exactly two objects and no nonidentity arrows, so T fails too. The slice $A/1$ has the shape $r \to 1 \leftarrow s$ and is not irreducible. This simultaneously explains the failure of irreducibility to survive a connected *étale* change of source.

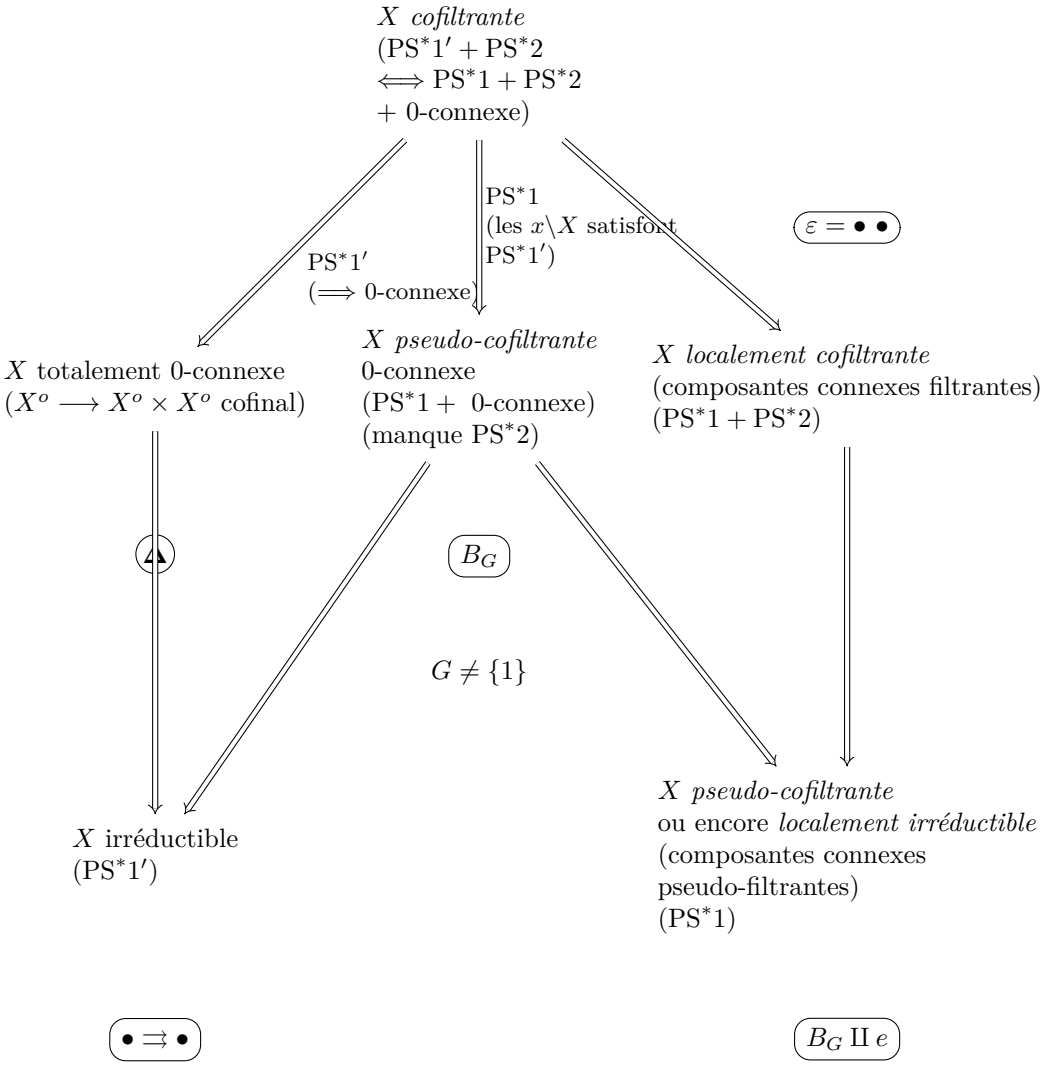


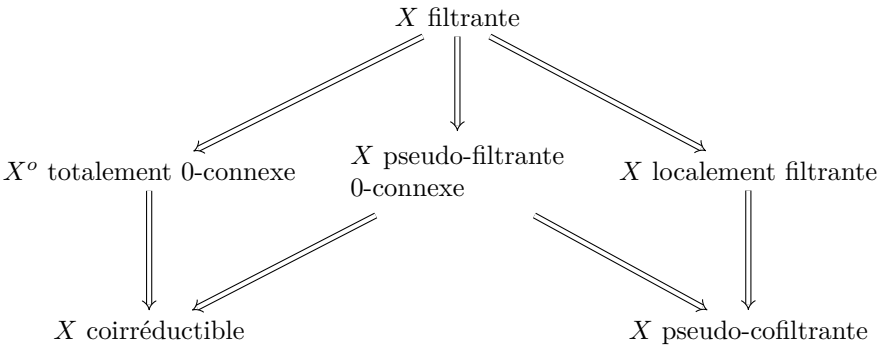
For $\mathbf{\Delta}$, the category of nonempty finite ordinals and monotone maps, every pair admits a common predecessor $[0]$. A cone from $[k]$ to $[m]$ and $[n]$ is a finite monotone string in the rectangular poset $[m] \times [n]$. It is connected, in its cone category, to each of its vertices by the corresponding map $[0] \to [k]$. Any two vertices can be joined by moving horizontally and vertically through the rectangle, each move being represented by a $[1]$-string. Thus the cone category is nonempty and connected, proving T. The two endpoint maps $[0] \rightrightarrows [1]$ cannot be equalized even by two different maps into their sources: every nonempty ordinal has a unique map to $[0]$, and the two resulting maps to $[1]$ remain distinct. Hence P fails. In particular $\Delta/[1]$ is not irreducible: the two endpoint objects have no common predecessor. Total connectedness therefore does not pass to slices.

For ε, the conditions P and E hold separately on each singleton component, while all four classes requiring connectedness fail. For $B_G \amalg e$, P still holds componentwise, E fails in the group component, and connectedness fails globally. These calculations also settle the abbreviated "Itou pour ε" on printed page 62: it can refer to exclusion from the four connected classes, but cannot refer to failure of local cofilteredness, since ε is locally cofiltered.

Finally, the product notation on page 97 takes place in the presheaf category. Thus $C/(a \times_x b)$ means the category of elements of $h_a \times_{h_x} h_b$, and $C/(x \times x)$ means that of $h_x \times h_x$; it is not a product of a slice with an object. The irreducibility of every C/x is P. Together with irreducibility

of every $C/(x \times x)$ it forces E: compare the object defined by $r, s : a \to x$ with $(x, 1_x, 1_x)$ and take a common predecessor. Conversely a cofiltered category provides cones and equalizations for these finite families, so the displayed categories of elements are cofiltered. This explains the strengthened representable tests in the first diagram, without repeating the longer topos arguments of the commentary on the first part of the chapter.





68. **NB** Les cinq catégories typiques B_G ($G \neq 1$), $\mathbf{\Delta}$, $0 \rightrightarrows 1$, $\varepsilon = \bullet\,\bullet$, $B_G \amalg e$ ($G \neq 1$) sont telles qu'elles appartiennent à la classe envisagée C d'objets de Cat, mais à aucune des cinq autres classes sauf celles qui sont reliées à C par $C \Longrightarrow C'$ sur le diagramme d'implications (ou par une implication composée).

$\bullet \rightrightarrows \bullet$	n'est ni pseudo-cofiltrante, ni totalement 0-connexe.	p. 62
B_G	n'est ni localement cofiltrante, ni totalement 0-connexe.	
$\mathbf{\Delta}$	n'est pas pseudo-filtrante.	
$B_G \amalg e$	n'est pas localement cofiltante, car B_G ne l'est pas, ni appartient à une des 4 classes d'objets connexes.	
Itou pour	$\varepsilon = \bullet\ \bullet$	

[page 99]

et dualement on a

X filtrante
X^o totalement 0-connexe
X pseudo-filtrante 0-connexe
X localement filtrante
X coirréductible
X pseudo-cofiltrante

donc on a une terminologie directe sauf pour 'X^o totalement 0-connexe' - je n'ose dire 'X totalement co-connexe'!! p. 63

Commentary · Later developments [ms. 99]

Representable flatness and the pointwise Kan extension

Grothendieck's cofiltered functors have a standard modern name: they are *representably flat*. For each $y \in Y$, the covariant set-valued functor $X \to \mathrm{Set}$, $x \mapsto Y(y, f(x))$, has category of elements $y\backslash X$; requiring this category to be cofiltered is precisely the definition. The adjective matters, since flatness for a functor into a topos has another, internal interpretation. Tendas (2024, Remark 2.4) explicitly distinguishes these notions, following the discussion of Shulman (2011).

One consequence places the closing section directly in the theory of presheaf topoi. For $F : X^{\mathrm{op}} \to \mathrm{Set}$, the left Kan extension along f^{op} is

$$(f_!F)(y) = \operatorname*{colim}_{(y\backslash X)^{\mathrm{op}}} F(x).$$

If f is cofiltered, the indexing category is filtered. Finite limits of presheaves are computed pointwise, and filtered colimits of sets commute with finite limits; hence $f_!$ preserves finite limits. Consequently the adjunction $f_! \dashv f^*$ is a geometric morphism in the direction determined by this inverse-image functor. This is an additional geometric adjunction alongside the usual $f^* \dashv f_*$.

If f is only locally cofiltered, the same formula is a coproduct, indexed by $\pi_0(y\backslash X)$, of filtered colimits. It preserves finite *connected* limits. To check the distinction, a compatible tuple in a connected finite diagram of such coproducts must lie throughout in one summand; within that summand the filtered-colimit argument applies. The terminal presheaf instead has image

$$(f_!1)(y) \cong \pi_0(y\backslash X),$$

which need not be a singleton. This separates the local condition from representable flatness exactly where the manuscript separates local cofilteredness from cofilteredness. The general connected-limit calculation appears in The Stacks Project Authors (2026e, Lemma 4.19.9).

The last diagrams thus organize three different demands on colimits: finite limits, finite connected limits, and finite products. The product condition is the sifted condition on X^{op}, whose later systematic treatment is Adámek et al. (2010, Section 1). The displayed examples show why none of these demands can be substituted for another without its accompanying connectedness or square condition. The missing nonemptiness qualification in the abbreviated diagonal criteria on pages 98–99 should always be read from page 97: the empty category has a final diagonal vacuously, but is not sifted.

Overview · II-b

Reconstruction, preservation, and the geometry of indexing categories.

These pages complete the second chapter by asking how much of a category is visible to its diagram theories. The starting point is the cofinality theorem: a restriction of diagrams preserves a specified limit or colimit when the appropriate comma categories are connected. The next question is more demanding. When does restriction embed the whole category of diagrams fully faithfully? Grothendieck then turns from individual functors to classes of functors. He tries to recover the classes controlling change of base from a chosen class of weak equivalences, and develops the order-theoretic machinery needed to state such a recovery. The closing discussion of cofiltered categories gives concrete tests and counterexamples for this programme. These are successive parts of one investigation: which local tests retain exactly the information that a theory of coefficients can detect?

For ordinary presheaves, the answer to the full-faithfulness question is a two-sided cofinality criterion. Given $u : A \to B$ and an arrow $\gamma : b_0 \to b_1$, form the category of factorizations $b_0 \to u(a) \to b_1$ whose composite is γ. Restriction on set-valued presheaves is fully faithful precisely when every such category is nonempty and connected. The counit evaluated on a representable presheaf has these connected-component sets as its fibres, and representables generate all presheaves by colimits. This is the decisive argument of Proposition 4.1. In later terminology the functors are lax epimorphisms, or absolutely dense functors; the equivalence of these formulations is established by Adámek et al. (2001). The commentary on the first part of the chapter already treats the general criterion. Here the commentary supplies the missing distinction between its two adjunction tests and checks the direction of the comma-category maps.

The right-adjoint unit behaves differently. Its being invertible on every representable says that the restricted Yoneda functor $B \to \mathrm{Set}^{A^{\mathrm{op}}}$ is fully faithful: this is density, in the usual sense (Riehl, n.d., Definition 6.5.11). It does not imply full faithfulness of restriction on all presheaves. The full category of sets on a singleton and a two-element set, with u selecting the singleton, already gives a counterexample. All maps of the original category are recovered from maps of sets of elements, but the identity of the two-element set cannot factor through the singleton. Thus the hesitation on manuscript pages 54–56 concerns a genuine obstruction. The commentary also computes the four-object example on pages 57–58: every factorization category is contractible, while one strict pullback is a disconnected two-point category. The example separates reconstruction of diagrams from universal preservation under strict base change.

For an arbitrary derivator $\mathbf{D}$, one must distinguish full faithfulness for that particular coefficient theory from full faithfulness for every derivator. Modern homotopical epimorphisms impose the latter quantifier. Groth and Šťovíček (2016, Definition 6.1 and Theorem 6.10, arXiv v3) characterize them by weak contractibility of the same factorization categories. Grothendieck's fixed-$\mathbf{D}$ problem is subtler. Global diagrams test only certain diagrams on a slice, and his proof of Proposition 4.4 carefully isolates the additional detection needed to recover all the slice tests. A conservative left Kan extension from the slice suffices; essential surjectivity of restriction to the slice is a stronger sufficient condition. The pointwise Kan-extension and detection axioms of a derivator perform different jobs in this argument (Groth, 2013, Definition 1.5).

The developments in the commentary make two limits of these sufficient conditions explicit. First, in the derivator represented by the complete lattice $\{0 < 1\}$, diagrams on the free category generated by a directed two-cycle are constant. Evaluation at one vertex is therefore fully faithful. Nevertheless, the identity of the other vertex has no factorization through it, and its factorization category is empty. This answers the intended question about $\mathbf{D}$-connectedness versus $\mathbf{D}$-biasphericity. Second, the parenthetical faithfulness assertion in Corollary 4.7 fails for coherent derived diagrams. A discrete fibration from a three-object fork to an interval

sends a nonsplit extension of quiver representations to a split extension. Direct sums in the coefficient derived category are faithful, but the Kan extension is not. The conservativity assertion survives: pointwise detection proves it. Each development is given with a complete proof and a statement of the sources checked, without a claim of priority.

The cancelled passage at the end of §4 must be read with comparable care. Let $S(A)$ be the maps whose pullback functors preserve a class A, and let $N(L)$ be the maps whose pullbacks along a testing class L lie in W. Under the requisite identity and stability hypotheses, the inclusions and the two idempotence calculations in the passage survive. The missing ingredient is order reversal of S: enlarging the preserved class changes both the inputs and the required outputs of a pullback test. It need not give a smaller stabilizer. With W the maximal localizer on categories and A the categorical equivalences, two point inclusions into the walking isomorphism directly refute the stronger identity used in the printed justification. This diagnosis preserves the valid calculations while explaining why they do not constitute a Galois connection.

Section 5 supplies that connection in its proper generality. Any relation between two sets defines two antitone polar operations. The composites are closure operators, and their closed subsets form anti-isomorphic complete lattices. When the sets are ordered, a further condition makes polar lower sets principal and hence represents their closures by elements. Formula (5.20) slips between these levels: a closed subset is not its greatest element, and a join of closed elements need not be closed in the ambient lattice. The corrected formula takes the closure of the join. Double annihilation in $\mathbf{F}_2^2$ gives a short counterexample to the printed equality. The classical examples also require their proper separation or topological hypotheses. In infinite Galois theory the fixed subgroups are the Krull-closed subgroups; the dense cyclic Frobenius subgroup in $\widehat{\mathbf{Z}}$ shows why the qualification cannot be dropped (Milne, 2022, Proposition 7.12 and Theorem 7.13). A lifting relation is another polarity, but a mutually closed pair of lifting classes still requires a separate factorization theorem to become a weak factorization system (Riehl, 2014, Definition 11.2.1).

Section 6 repairs the earlier construction by fixing its target class. The transporter $T_W(A)$ consists of maps whose pullback functors send arrows of A to arrows of W. Testing includes every arrow in the slice, with any structure map from its codomain to the base. It is not enough to test arrows whose codomain happens to equal the base. With A closed under composition and L stable under pullback, both containing isomorphisms, the equivalence

$$A \subseteq N_W(L) \quad \Longleftrightarrow \quad L \subseteq T_W(A)$$

is a genuine antitone adjunction. The correction at (6.7) removes composition closure from the right-hand domain, where it is not automatic. A four-object chain in the commentary exhibits a closed transporter that does not compose, under exactly the abstract assumptions of §6. The example is not claimed to use a fundamental localizer on Cat. Proposition 6.1 then identifies the additional condition: for a closed pair, the right class is composition-closed exactly when it equals the stabilizer of its left class.

This formalism has a direct historical continuation. Grothendieck's letter to Thomason singles out a fibration class defined intrinsically from weak equivalences, while treating factorization as another question (Grothendieck, 1991a, §1, pp. 3–4). Rezk's sharp maps use the same preservation condition. In a right proper model category they characterize the maps all of whose strict pullback squares are homotopy cartesian (Rezk, 1998, Propositions 2.2 and 2.7). Maltsiniotis develops local tests for the corresponding preservation of aspherical maps (Maltsiniotis, 2005, Definition 4.6 and Theorem 4.13). One question on page 89 has a particularly concrete answer: the stabilizer of categorical equivalences is exactly the isofibrations. The commentary gives both directions of the proof, using the walking isomorphism for necessity, and relates the result to the categorical model structure (Rezk, 1996, §2 and Theorem 3.1). For the general mixed transporters and the proposed bilocal description of the

biaspherical stabilizer, what was verified is kept apart from what was not. Failure to find a precise matching theorem is not presented as proof that the questions are open today.

The final section turns the abstract machinery into the geometry of predecessors. A cofiltered functor is tested by cofiltered comma categories; the local version allows several components and asks each to be cofiltered. Over a poset, these conditions become statements about lower open subsets. Proposition 7.4 is essentially sound, but its target lower open must be generated by the image of the chosen open subset: taking the whole principal lower set makes the printed condition false even for the empty subset. The commentary proves the corrected criterion and the initial-object assertion of Remark 7.5. It also exhibits a cofiltered map whose arbitrary base change is not even locally weakly cofiltered, while respecting the stated preservation under co-étale base change. For fundamental localizers, the later minimality theorem removes the extra Loc(8) qualification attached here to the asphericity of cofiltered categories (Cisinski, 2004, Theorem 2.2.11).

The final diagrams distinguish common predecessors, the filling of cospans, equalization of parallel arrows, and connectedness of the categories of cones over every finite family of objects. Their implications become transparent when these requirements are kept separate. Groups, the simplex category, a parallel-arrow category, and disjoint unions give the required separating examples. The modern interpretation of total connectedness is siftedness of the opposite category; cofilteredness adds the equalization needed for commuting with all finite limits, rather than only finite products (Adámek et al., 2010; The Stacks Project Authors, 2026e; Tendas, 2024). In this way the chapter ends where its larger project began: the shape of an indexing category governs which constructions a theory of diagrams can perform and which information restriction can retain. The derived-diagram motivation already appears in *Pursuing Stacks*, §69 (Grothendieck, 1983); here it is being refined into local, verifiable conditions on functors.

1 Relation des dérivateurs avec la catégorie Hot

p. 1
[page 1]

Soit $\mathbf{D}$ un dérivateur, $\mathcal{A}$ sa catégorie fondamentale,

$$\mathcal{A} = \mathbf{D}(e).$$

Je me propose de définir, si faire se peut, des foncteurs

$$(1)\qquad \begin{cases} \mathrm{Hot} \times \mathcal{A} \xrightarrow{\pi_{\mathbf{D}}} \mathcal{A} & (\xi, M) \longmapsto \xi \times M \text{ ou } \xi \otimes M \quad \text{(suivant les cas)} \\ \mathrm{Hot}^o \times \mathcal{A} \xrightarrow{\varpi_{\mathbf{D}}} \mathcal{A} & (\xi, M) \longmapsto \hom(\xi, M). \end{cases}$$

Ces foncteurs doivent s'échanger par dualité : si on prend les foncteurs π^o, ϖ^o sur les catégories opposées, on trouve

$$(1')\qquad \begin{cases} \mathrm{Hot} \times \mathcal{A}^o \xrightarrow{\varpi^o_{\mathbf{D}}} \mathcal{A}^o \\ \mathrm{Hot}^o \times \mathcal{A}^o \xrightarrow{\pi^o_{\mathbf{D}}} \mathcal{A}^o, \end{cases}$$

et on doit avoir

$$\begin{cases} \varpi^o_{\mathbf{D}} = \pi_{\mathbf{D}^o} \\ \pi^o_{\mathbf{D}} = \varpi_{\mathbf{D}^o}. \end{cases}$$

À vrai dire, considérant (1) comme des foncteurs

$$\begin{array}{ll} \mathrm{Hot} & \xrightarrow{\pi_{\mathbf{D}}} \ \underline{\mathrm{Hom}}(\mathcal{A}, \mathcal{A}) \\ \mathrm{Hot}^o & \xrightarrow{\varpi_{\mathbf{D}}} \ \underline{\mathrm{Hom}}(\mathcal{A}, \mathcal{A}), \end{array}$$

on s'attend à ce que ces foncteurs s'étendent en

$$(2)\qquad \begin{cases} \mathrm{Hot} \xrightarrow{\pi_{\mathbf{D}}} \underline{\mathrm{Hom}}(\mathbf{D}, \mathbf{D}) \\ \mathrm{Hot}^o \xrightarrow{\varpi_{\mathbf{D}}} \underline{\mathrm{Hom}}(\mathcal{A}, \mathcal{A}) \end{cases}$$

[plutôt deux fois $\underline{\mathrm{Hom}}(\mathbf{D}, \mathbf{D})$]. Cela signifie, essentiellement, que pour $\xi \in \mathrm{Ob}\,\mathrm{Hot}$ donné, les opérations $\xi \times_{\mathbf{D}} M$ et $\underline{\mathrm{Hom}}_{\mathbf{D}}(\xi, M)$ [plutôt $\hom_{\mathbf{D}}(\xi, M)$] sont définies non seulement dans $\mathcal{A} = \mathbf{D}(e)$, mais dans tous les $\mathbf{D}(I)$, et ceci de façon à commuter aux foncteurs f^* :

Commentary · Exposition [ms. 1]

Spaces acting on coefficients

Grothendieck is looking for the part of ordinary homotopy theory that must act on every theory of coefficients. A space should provide an instruction for assembling copies of an object, while the same space, with the variance reversed, should provide an instruction for taking their limit. This is the reason for placing the two operations together before attempting to construct an external Hom.

Write $BX = |NX|$ for the classifying space of a small category, and temporarily assume that all the categories used below belong to the permitted diagram category. If $p_X : X \to e$, put

$$T_X(M) = (p_X)_! p_X^* M, \qquad C_X(M) = (p_X)_* p_X^* M.$$

These expressions are already defined by the derivator. The problem is to show that they depend on X only through BX, and then to understand their compatibility as X and M vary. In the derivator of spaces they are $BX \times M$ and the derived function space $\mathrm{Map}(BX, M)$. In a derived category they are derived tensor and Hom constructions with the integral chains of BX. The common formalism therefore sees more than the set of components of X.

There are three different Hom constructions in play. The ordinary set $\mathrm{Hom}_{\mathbf{D}(e)}(M, N)$ records morphisms after localization. The cotensor $C_X(N)$ is another coefficient object, hence belongs to $\mathbf{D}(e)$. The proposed external Hom $\hom\mathrm{ext}(M, N)$ is a homotopy type. Its intended property is

$$\mathrm{Hom}_{\mathbf{D}(e)}(T_X M, N) \cong [BX, \hom\mathrm{ext}(M, N)].$$

In a model presentation this last object is the derived mapping space. It is not the internal Hom of a monoidal category of coefficients: no multiplication of two coefficient objects has been assumed. For example, the derived category of modules over a noncommutative ring still has an external mapping space, although a tensor product of two left modules over that ring has no such general meaning.

The extension to every $\mathbf{D}(I)$ is essential. With $p : X \times I \to I$, the same formulas define $T_{X,I} = p_! p^*$ and $C_{X,I} = p_* p^*$. Base change along products supplies their compatibility with restriction f^*. Thus the request in (2) is for morphisms of derivators, including their pseudonaturality isomorphisms, rather than unrelated endofunctors of the individual categories. The passage from $\mathbf{D}(e)$ to the shifted derivator $\mathbf{D}_I$ is the mechanism already used in the commentary on Chapter I, manuscript p. 4 (*From derived coefficients to diagram categories*); here its new role is to make the action itself coherent in the diagram variable.

For a represented derivator, the calculation reduces to an instructive limiting case:

$$T_X(M) = \coprod_{\pi_0 X} M, \qquad C_X(M) = \prod_{\pi_0 X} M.$$

Indeed a cone on a constant ordinary diagram is a family of maps constant on every connected component. The richer dependence on BX belongs to the homotopy theory, not to the notation $p_! p^*$ alone.

[page 2]

Si

$$f : I' \longrightarrow I,$$

alors pour $F \in \mathrm{Ob}\,\mathbf{D}(I)$, on doit avoir des isomorphismes canoniques p. 2

$$(3) \qquad \begin{cases} f^*(\xi \times_{\mathbf{D}} M) & \simeq & \xi \times_{\mathbf{D}} f^*(M) \\ f^* \mathrm{hom}_{\mathbf{D}}(\xi, M) & \simeq & \mathrm{hom}_{\mathbf{D}}(\xi, f^*(M)), \end{cases}$$

avec les compatibilités habituelles pour un composé fg, relatif à $I'' \xrightarrow{g} I' \xrightarrow{f} I$.

Mais je me place de préférence dans $\mathcal{A}$, ce qui devrait impliquer les constructions similaires dans tous les $\mathbf{D}(I)$, quitte à appliquer ce qui a été dit au dérivateur $\mathbf{D}_I$.

L'intuition algébrique fondamentale est celle-ci, en désignant par

$$X \longmapsto \mathrm{hot}(X) : (\mathrm{Cat}) \longrightarrow (\mathrm{Hot})$$

le foncteur de localisation de (Cat) dans (Hot), obtenu en inversant les flèches dans (Cat) qui sont des 'équivalences faibles'. Supposons X dans Diag, soit

$$p : X \longrightarrow e$$

le foncteur à valeurs dans la catégorie ponctuelle. On veut que

$$(4) \qquad \begin{cases} \mathrm{hot}(X) \times_{\mathbf{D}} M & \simeq & p_!(p^*(M)) & = & H^{\mathbf{D}}_{\bullet}(X, M) \\ \mathrm{hom}_{\mathbf{D}}(\mathrm{hot}(X), M) & \simeq & p_*(p^*(M)) & = & H^{\bullet}_{\mathbf{D}}(X, M) \end{cases}$$

(isomorphismes canoniques).

Ceci donnerait un principe de définition pour les opérations cherchées. Une difficulté vient [page 3] du fait qu'en général, Diag n'est pas égal à (Cat), et que les types d'homotopie provenant de Diag ne donnent pas (même à isomorphisme près) *tous* les types d'homotopie. Intuitivement, on ne trouve que des types d'homotopie 'assez petits'. Mais on peut localiser Diag par rapport aux équivalences faibles (il vaut mieux dire 'quasi-isomorphismes'), on trouve alors une catégorie $(\mathrm{Hot})_0$, et un foncteur canonique

$$\mathrm{Hot}_0 \longrightarrow \mathrm{Hot},$$

si on a de la chance, ce foncteur sera pleinement fidèle, et on essayera de décrire les foncteurs (1) ou (2) en y remplaçant Hot par la sous-catégorie pleine des 'petits' types d'homotopie. On

peut aussi oublier (provisoirement!) Hot, et travailler avec Hot_0. C'est ce qu'on va faire pour le moment.

Pour pouvoir définir les foncteurs

$$(5)\qquad \begin{cases} \mathrm{Hot}_0 \times \mathcal{A} \longrightarrow \mathcal{A} \quad (\xi, F) \longmapsto \xi \times_{\mathbf{D}} F \\ \mathrm{Hot}_0^o \times \mathcal{A} \longrightarrow \mathcal{A} \quad (\xi, F) \longmapsto \hom_{\mathbf{D}}(\xi, F), \end{cases}$$

je note que pour F [plutôt M] fixé, X variable dans Diag, les derniers membres dans (4) p. 3 [page 4]

$$(6)\qquad H^{\mathbf{D}}_{\bullet}(X, M), \qquad H^{\bullet}_{\mathbf{D}}(X, M)$$

sont bien, l'un covariant, l'autre contravariant en X. Donc il y a , à isomorphisme unique près, une seule paire de bifoncteurs (5) satisfaisant (bifonctoriellement) les isomorphismes (4), si et seulement si les expressions (6), considérées comme fonctorielles en X, transforment quasi-isomorphismes en isomorphismes. Cela équivaut donc à la validité du

Théorème (?) ([1]). *Soit $f : X' \longrightarrow X$ dans Diag. Si f est un quasi-isomorphisme, c'est une* **D***-équivalence.*

Quand X est la catégorie ponctuelle, ce n'est là autre que l'axiome Der 3 (p. 67). J'ignore si c'est une conséquence des axiomes Der 1 à Der 5 (d). Si ce n'est pas le cas, il faudrait l'ajouter aux axiomes, je crois. Je n'ai pas même prouvé qu'une équivalence de catégories dans Diag (au sens des catégories!) est une **D**-équivalence!

Commentary · Present state [ms. 4]

The descent theorem and its domain

The question marked *Théorème (?)* is precisely the obstruction to making the preceding formulas into operations of homotopy types. It has a positive answer for derivators on all small categories with the usual homotopy Kan extension axioms. The scope of the indexing category matters: that answer must not be silently substituted for a theorem about every restricted Diag occurring in the manuscript.

First, the claimed equivalence with descent is formal. Let W be the nerve weak equivalences in Diag. A bifunctor $(X, M) \mapsto T_X M$ factors through $\mathrm{Diag}[W^{-1}]$ exactly when every natural transformation $T_f : T_{X'} \to T_X$, $f \in W$, is invertible. The localization universal property applies also to natural transformations, giving the factorization with its specified comparison uniquely up to unique compatible isomorphism. The same argument applies contravariantly to C_X. The two conditions are equivalent because $T_X \dashv C_X$, and the comparison transformations are mates: a natural isomorphism between left adjoints has an invertible right mate, and conversely.

The easy case that Grothendieck says he has not yet checked needs no nerve theorem. If $f : X' \to X$ is an equivalence of categories, a quasi-inverse and its invertible unit and counit give, by the prederivator structure, an equivalence $f^* : \mathbf{D}(X) \to \mathbf{D}(X')$. It carries $p_X^* M$ to $p_{X'}^* M$. Hence it induces bijections

$$\mathrm{Hom}_{\mathbf{D}(X)}(p_X^* M, p_X^* N) \longrightarrow \mathrm{Hom}_{\mathbf{D}(X')}(p_{X'}^* M, p_{X'}^* N),$$

which, through the two adjunctions, imply exactly the required comparison isomorphisms. This argument is already available for a prederivator possessing the displayed adjoints.

The passage from categorical equivalences to all nerve weak equivalences is substantial. For a derivator on all small categories, its constant-coefficient equivalences form a fundamental localizer (Cisinski, 2008, Proposition 3.7); Cisinski (2004, Theorem 2.2.11) proves that nerve weak equivalences form the smallest fundamental localizer. Their combination is precisely Cisinski (2008, Corollary 3.10): every nerve weak equivalence is a derivator equivalence. The more structural answer is the same paper's Theorem 3.24 and Corollary 3.26: the derivator of spaces is freely generated under homotopy colimits by a point. Its universal action yields the tensor construction; duality yields the cotensor construction. These results settle the modern full-domain version of the question.

The universal property also identifies the operation, not merely its existence. In its cocontinuous form, evaluation at the point identifies cocontinuous morphisms from the space derivator to **D** with

1. Nouvel axiome ?

objects of $\mathbf{D}(e)$. Let F_M correspond to M. The classifying space BX is the homotopy colimit of the constant point diagram over X. Preservation of that homotopy colimit forces

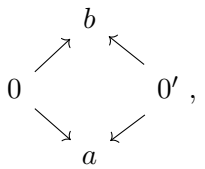
$$F_M(BX) \cong (p_X)_! p_X^* M.$$

The equivalence of categories makes this construction functorial in maps $M \to N$, and the statement for shifted derivators supplies its diagram versions. This explains why the modern theorem answers the particular question on the page: the descended action is constrained to have Grothendieck's formula (4). It also explains why full-domain hypotheses enter the literature. The universal object is the entire space derivator; replacing its diagram domain by an arbitrary subcategory is an additional operation whose effect must be checked.

For a restricted Diag, two further assertions must be kept separate. The internal localization Hot_0 exists under the usual size convention, but its comparison with Hot need not be fully faithful merely by its definition. Even if it is fully faithful, it need not contain all homotopy types. One can work perfectly well with the action of Hot_0 once descent has been established there. What one cannot do is invoke Yoneda with test objects outside that category. This is exactly the limitation that returns on manuscript pages 7–10.

Notons la *formule d'adjonction*

$$\mathrm{Hom}(\xi \times_{\mathbf{D}} M, N) \xrightarrow{\sim} \mathrm{Hom}(M, \mathrm{hom}_D(\xi, N)). \tag{7}$$



Si ξ provient de $X \in \mathrm{Diag}$, alors cela s'écrit

$$\mathrm{Hom}(p_! p^* M, N) \xrightarrow{\sim} \mathrm{Hom}(M, p_* p^* N), \tag{8}$$

or par adjonction les deux membres sont canoniquement isomorphes à [page 5]

$$\mathrm{Hom}_{\mathbf{D}(X)}(p^* M, p^* N).$$

Exemple. Prenant pour ξ le type d'homotopie du cercle standard (représenté p.ex. par l'ensemble ordonné

où on convient de prendre 0 comme origine, et d'orienter de 0 vers a), les deux foncteurs en question sont (sauf erreur) les foncteurs suspension Σ et 'cosuspension' ou foncteur 'espace des lacets' Ω. Sous réserve de vérifier que ΩF coïncide bien avec ce que j'ai décrit ailleurs, à propos des carrés substantiels cartésiens dans $\mathcal{A}$.

Commentary · Examples [ms. 5]

What the circle actually gives

Grothendieck wants the circle action to recover the suspension and loop constructions, thereby linking the abstract action to the elementary squares of the next chapter. The four-object poset drawn here does have the homotopy type of a circle: its nerve has four vertices and four nondegenerate edges and no higher nondegenerate simplices. The difficulty is therefore not a defective model of S^1. It is the distinction between an unpointed tensor and a reduced one, which he himself identifies on page 12.

In spaces,

$$T_{S^1}(M) = S^1 \times M, \qquad C_{S^1}(N) = \mathrm{Map}(S^1, N).$$

The second space is the free loop space. Choosing $s \in S^1$ gives the evaluation map $\mathrm{Map}(S^1, N) \to N$; its homotopy fibre over a chosen point n is $\Omega_n N$. A basepoint in the indexing circle alone does not turn every free loop into a loop based at n.

The algebraic calculation makes the excess term completely visible. With cohomological grading and a chosen orientation,

$$C_*(S^1;\mathbf{Z}) \simeq \mathbf{Z}[0] \oplus \mathbf{Z}[1].$$

Here $\mathbf{Z}[1]$ has its nonzero term in degree -1. Consequently, in $D(k\text{-Mod})$,

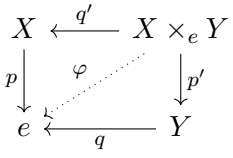
$$T_{S^1}(M) \simeq M \oplus M[1], \qquad C_{S^1}(M) \simeq M \oplus M[-1].$$

The inclusion of the basepoint and the augmentation split off M. Their reduced complements are $M[1]$ and $M[-1]$, the suspension and loop functors of this stable derivator. Taking $M = k \neq 0$, the extra degree-zero copy of k proves that the unqualified identification on the present page is false.

In a pointed homotopy theory the corresponding operation uses the smash tensor with a based circle; its cotensor is the based mapping object. The ordinary unpointed action is recovered by adjoining a disjoint basepoint to the space first. Formula (14) is therefore correct with Σ, Ω understood as the unpointed circle tensor and cotensor, but it is not then the familiar reduced suspension-loop identity. With the reduced meanings, the right side is the loop space of the pointed external Hom at its zero morphism. The explicit Kan extension construction of those reduced functors appears in Groth (2013, Definition 3.16 and Proposition 3.17); Chapter IV is already its essential diagrammatic pattern.

Dans Hot_0 on a une opération produit, en fait ça doit être le produit catégorique dans Hot_0. Mais sur les modèles il est donné par

$$\mathrm{hot}_0(X) \times \mathrm{hot}_0(Y) \;\simeq\; \mathrm{hot}_0(X \times Y) \tag{8}$$



`[deux fois` (8)`]`. Ceci posé, on a les isomorphismes canoniques, pour $\xi, \eta \in \mathrm{Ob}\,\mathrm{Hot}_0$, p. 4

$$\begin{cases} \xi \times_{\mathbf{D}} (\eta \times_{\mathbf{D}} M) \;\simeq\; (\xi \times \eta) \times_{\mathbf{D}} M \\ \hom_{\mathbf{D}}(\xi, \hom_{\mathbf{D}}(\eta, M)) \;\simeq\; \hom_{\mathbf{D}}(\xi \times \eta, M). \end{cases} \tag{9}$$

Si ξ, η sont représentés par X, Y, la première formule p.ex. s'établit en calculant le [page 6] deuxième membre comme

$$\varphi_!(M_{X\times Y}) \simeq p_!(\; \underbrace{q'_!(M_{X\times Y})}_{\substack{\simeq\, q_!(M_Y)_X \\ \text{car } q \text{ est } \mathbf{D}\text{-lisse}}} \;) \simeq \xi \times_{\mathbf{D}} (\eta \times_{\mathbf{D}} M),$$

O.K.

J'ai aussi envie de prouver :

Commentary · Exposition [ms. 6]

Associativity and exactness from product squares

Grothendieck next checks that the action has the algebra expected of an action. The calculation is a Fubini argument for homotopy Kan extensions, and its force is that it works before any mapping-space enrichment has been supplied. We retain his convention that coefficients on I have underlying diagrams of shape I^o.

First, the product on Hot_0 mentioned just above can be justified on the stated models. Assume that Diag is closed under binary products. The nerve preserves those products, and weak equivalences of spaces are preserved by taking a product with a fixed space. Hence the product functor sends a pair of nerve weak equivalences to a nerve weak equivalence and descends to the localization. The diagonal functor descends too. Before localization the diagonal is left adjoint to the binary product; their unit and counit descend as natural transformations, and still satisfy the triangle identities.

The product functor on the localization is therefore right adjoint to its diagonal, which is exactly the universal property of a categorical product. This proves the sentence beginning *en fait ça doit être*, under the required closure assumption, without assuming that $\mathrm{Hot}_0 \to \mathrm{Hot}$ is fully faithful. Existence of this product should not be confused with closure under the right adjoints to products, which becomes relevant to (13).

For $X, Y \in \mathrm{Diag}$, compose the projections $X \times Y \to X \to e$. Pseudofunctoriality of left Kan extension identifies their composite with the extension to e. Base change for the product square identifies the first intermediate extension of a constant coefficient with the constant coefficient $T_Y M$ on X. Thus

$$T_X T_Y M \cong T_{X\times Y} M.$$

The terminal category supplies $T_e \cong \mathrm{id}$. The analogous right Kan calculation gives $C_X C_Y \cong C_{X\times Y}$, with the harmless interchange of X and Y supplied by the product symmetry. The associativity and unit comparisons are canonical mates. Their coherence follows by pasting product squares and using the composition constraints for Kan extension; it is not a second independent choice of associators.

The same argument proves more than preservation of finite colimits or finite limits. Fix X, let $f : I \to J$, and write $p : X \times I \to I$, $q : X \times J \to J$, $f' = 1_X \times f$. The product square is homotopy exact in both directions. Therefore

$$\begin{aligned} f_* C_{X,I} F &= f_* p_* p^* F \\ &\cong q_* f'_* p^* F \\ &\cong q_* q^* f_* F = C_{X,J} f_* F. \end{aligned}$$

The dual calculation gives $f_! T_{X,I} \cong T_{X,J} f_!$. Every Kan extension permitted by Diag is covered. This is the precise content of *exact à gauche* and *exact à droite* here.

For completeness, the decisive product comparison can be checked directly by the pointwise formula. At (x, j), the comma category computing the appropriate Kan extension is a product of the comma category for f with a slice of X having an extremal object. Homotopy Kan extension over the latter factor reduces to evaluation. The resulting isomorphism is the mate of the product square, so its pointwise verification also identifies the comparison that must be used. This is the special case of base change for Grothendieck fibrations and opfibrations formalized in Groth (2013, Proposition 1.24).

Finally,

$$\mathrm{Hom}(T_X M, N) \cong \mathrm{Hom}_{\mathbf{D}(X)}(p_X^* M, p_X^* N) \cong \mathrm{Hom}(M, C_X N)$$

proves the tensor-cotensor adjunction without representability in Hot. This separation is useful: (7), (9), and Proposition 1 are consequences of the Kan formalism once descent is available; the external Hom sought next is an additional representation problem.

Proposition 1. *Soit* $\xi \in \mathrm{Ob}\,\mathrm{Hot}_0$. *Alors* $F \longmapsto \xi \times_{\mathbf{D}} F$, *en tant que morphisme de dérivateurs* $\mathbf{D} \longrightarrow \mathbf{D}$, *est* exact à droite, *et* $F \longmapsto \hom_{\mathbf{D}}(\xi, F)$ *est exact à gauche.*

On peut supposer que ξ est défini par X dans Diag. Soit $f : I \longrightarrow J$, soit F dans $\mathbf{D}(I)$, il faut prouver

$$f_*(\hom_{\mathbf{D}}(\xi, F)) \;\simeq\; \hom_{\mathbf{D}}(\xi, f_*(F)).$$

Considérons donc

$$\begin{array}{ccc} X \times I & \xrightarrow{f'} & X \times J \\ {\scriptstyle p=(x,i)\longmapsto i}\downarrow & & \downarrow{\scriptstyle q=(x,j)\longmapsto j} \\ I & \xrightarrow{\quad f \quad} & J. \end{array}$$

On a

$$\hom_{\mathbf{D}}(\xi, F) = p_*(p^* F),$$

donc

$$f_*(\hom_{\mathbf{D}}(\xi, F)) = \underbrace{f_* p_*}_{(fp)_*}(p^*(F)) = (qf')_* p^*(F) \simeq q_*(f'_* p^*(F)).$$

Mais

$$f'_* p^*(F) \;\simeq\; q^* f_*(F),$$

formule de changement de base des f_*, pour le changement de base q, qui est lisse, car déduit de $X \longrightarrow e$, qui est lisse, par changement de base $J \longrightarrow e$. On trouve donc p. 5 [page 7]

$$f_*(\hom_{\mathbf{D}}(\xi, F)) \simeq q_* q^*(f_*(F)) \overset{\text{déf}}{=} \hom_{\mathbf{D}}(\xi, f_*(F)),$$

q.e.d. L'énoncé pour $F \longmapsto \xi \times_{\mathbf{D}} F$ est dual de celui qu'on vient de prouver.

Reprenons, pour $\xi \in (\mathrm{hot})_0$ [$= \mathrm{Hot}_0$], la formule d'adjonction

$$(*) \qquad \mathrm{Hom}(\xi \times_{\mathbf{D}} M, N) \simeq \mathrm{Hom}(M, \hom_{\mathbf{D}}(\xi, N)) \overset{\text{déf}}{=} \mathrm{Hom}_\xi(M, N).$$

Si ξ est défini par X dans Diag, les deux membres de $(*)$ s'identifient à

$$\mathrm{Hom}_{\mathbf{D}(X)}(p^* M, p^* N),$$

où $p : X \longrightarrow e$ est le foncteur structural.

Fixons M, N, et considérons l'expression $(*)$ comme contrafoncteur

$$(\mathrm{Hot}_0)^o \longrightarrow \mathrm{Ens}.$$

Il semblerait que dans tous les cas connus, ce foncteur soit 'représentable' par un objet, sinon de Hot_0 lui-même, du moins un objet dans Hot. Si on ne peut le définir comme objet H de Hot_0, le fait qu'on ait un isomorphisme canonique

$$(10) \qquad \mathrm{Hom}_\xi(M, N) \simeq \mathrm{Hom}_{\mathrm{Hot}}(\xi, H),$$

fonctoriel en $\xi \in \mathrm{Ob}\,\mathrm{Hot}_0$, ne [le] définit pas forcément à isomorphisme unique près. En fait, quand [page 8]

$$\mathbf{D} = \mathbf{D}_{\mathcal{M},\Sigma}$$

est défini par une catégorie de modèles $(\mathcal{M}, \Sigma)$, alors il y a une définition naturelle d'une opération hom ext (Hom 'externe') à valeurs dans Hot, savoir un foncteur

$$(11) \qquad \begin{cases} \mathcal{A}^o \times \mathcal{A} & \longrightarrow & \mathrm{Hot} \\ (M, N) & \longmapsto & \hom\mathrm{ext}(M, N), \end{cases}$$

où $\mathcal{A} = \mathcal{M}\Sigma^{-1}$ est la catégorie fondamentale de $\mathbf{D} = \mathbf{D}_{\mathcal{M},\Sigma}$. Il est vrai que je n'ai pas vérifié, si p. ex. $(\mathcal{M}, \Sigma)$ est sous-jacente à une catégorie de modèles quillénienne, de sorte que (par Thomason) $\mathbf{D}$ est bien un dérivateur, que cette notion de hom ext satisfait bien à une formule de la forme (10). Ici je vais le poser [?], au besoin, ces données supplémentaires : donnée de (11), et d'un isomorphisme fonctoriel

$$(12) \qquad \underbrace{\mathrm{Hom}_\xi(M, N)}_{\substack{= \mathrm{Hom}(\xi \times_{\mathbf{D}} M, N) \\ = \mathrm{Hom}(M, \hom_{\mathbf{D}}(\xi, N))}} \simeq \mathrm{Hom}_{\mathrm{Hot}}(\xi, \hom\mathrm{ext}(M, N)).$$

Commentary · Later developments [ms. 8]

External Hom as a derived mapping space

Grothendieck is now trying to recover the space of maps from the already available operations on coefficients. In a model category this space had been constructed independently: the hammock localization of Dwyer and Kan (1980b, Corollary 4.2, Proposition 4.4, and Corollary 4.7) supplies mapping complexes, identifies their components with localized morphisms, and compares them with the enrichment of a simplicial model category. This work predates the manuscript. Chapter V will approach the same issue through categories of zigzags.

Here is the verification of (12) in the simplicial case. Choose a cofibrant representative QM and a fibrant representative RN. A simplicial set K representing ξ is cofibrant in the usual model structure. The simplicial tensor-Hom adjunction gives

$$\mathrm{Map}_{\mathcal{M}}(K \otimes QM, RN) \cong \mathrm{Map}_{\mathrm{sSet}}(K, \mathrm{Map}_{\mathcal{M}}(QM, RN)).$$

Taking components identifies the left side with $\mathrm{Hom}_{\mathrm{Ho}(\mathcal{M})}(K \otimes^{\mathbf{L}} M, N)$. The right side is $[K, \mathrm{Map}_{\mathcal{M}}(QM, RN)]$, because the inner mapping complex is fibrant. Moreover $K \otimes^{\mathbf{L}} M$ is the homotopy colimit of the constant M-diagram indexed by the space K. For $K = BX$, the simplicial replacement of the constant X^o-diagram gives exactly that tensor; its simplices are copies of QM indexed by strings of arrows in X^o. Reversal identifies its realized indexing space with BX. This proves the formula with the particular tensor defined in (4).

The cotensor identity follows either from the dual model construction or from the tensor-cotensor adjunction already proved. Derived function complexes and framings give the corresponding statement for a general Quillen model category; the tensor, cotensor, and enrichment compatibilities are treated systematically in Riehl (2014, Sections 10.2–10.3). Thus the extra datum is supplied by the model presentation and is independent, up to homotopy equivalence, of the chosen resolutions.

For a presentable ∞-category $\mathcal{C}$, the same calculation has the particularly transparent form

$$\mathrm{Map}_{\mathcal{C}}\big(\operatorname*{colim}_{K} M, N\big) \simeq \mathrm{Map}_{\mathcal{S}}\big(K, \mathrm{Map}_{\mathcal{C}}(M, N)\big).$$

It is the universal property of the colimit indexed by the space K. Passing to homotopy categories gives (12); no new choice of external Hom is needed once $\mathcal{C}$ is given. The universal role of space-valued presheaves is made precise in Lurie (2009, Theorem 5.1.5.6).

For a completely abstract derivator, one should distinguish an action by spaces from a closed action possessing these Hom objects. Groth and Shulman (2017, Section 1, pp. 3–4, and Definition 4.2) explicitly distinguish the two structures. The cited results settle the model and presentable ∞-categorical cases; they do not justify erasing Grothendieck's representability hypothesis for every restricted diagram domain considered here.

Si maintenant η est un deuxième élément de Hot_0, on a envie d'écrire p. 6 [page 9]

$$(13) \qquad \begin{cases} \hom \mathrm{ext}(\eta \times_{\mathbf{D}} M, N) \simeq \hom \mathrm{ext}(M, \hom_{\mathbf{D}}(\eta, N)) \\ \qquad\qquad\qquad\quad \simeq \hom_{\mathrm{HOT}}(\eta, \hom \mathrm{ext}(M, N)), \end{cases}$$

où dans le deuxième membre, $\hom_{\mathrm{HOT}}$ est l'opération (1) dans le cas où $\mathbf{D} = \mathrm{HOT}$, et qui est défini aussi en termes du produit cartésien $\xi \times \eta$ dans Hot, par

$$\mathrm{Hom}_{\mathrm{Hot}}(\xi, \hom_{\mathrm{HOT}}(\eta, \zeta)) \simeq \mathrm{Hom}_{\mathrm{Hot}}(\xi \times \eta, \zeta),$$

en d'autres termes, pour η fixé, le foncteur

$$\zeta \longmapsto \hom_{\mathrm{HOT}}(\eta, \zeta)$$

est défini comme le foncteur adjoint à droite du foncteur

$$\xi \longmapsto \xi \times \eta.$$

Pour vérifier heuristiquement la formule (13) (vérification valable 'en forme' si les trois objets envisagés sont en fait définis comme objets de Hot_0 ...), on prend $\mathrm{Hom}_{\mathrm{Hot}}(\xi, -)$ à valeurs dans les trois membres, pour ξ donné dans Hot_0. Pour le premier, on trouve

$$\begin{aligned} \mathrm{Hom}_{\xi}(\eta \times_{\mathbf{D}} M, N) &= \mathrm{Hom}(\xi \times_{\mathbf{D}} (\eta \times_{\mathbf{D}} M), N) \\ &= \mathrm{Hom}((\xi \times \eta) \times_{\mathbf{D}} M, N). \end{aligned}$$

Pour le deuxième

$$\begin{aligned} \mathrm{Hom}_{\xi}(M, \hom_{\mathbf{D}}(\eta, N)) &= \mathrm{Hom}_{\mathcal{A}}(\xi \times_{\mathbf{D}} M, \hom_{\mathbf{D}}(\eta, N)) \\ &\simeq \mathrm{Hom}_{\mathcal{A}}(\eta \times_{\mathbf{D}} (\xi \times_{\mathbf{D}} M), N) \\ &\simeq \mathrm{Hom}_{\mathcal{A}}((\eta \times \xi) \times_{\mathbf{D}} M, N), \end{aligned}$$

[page 10]

et enfin pour le troisième

$$\begin{aligned}\mathrm{Hom}_{\mathrm{Hot}}(\xi \times \eta, \hom\mathrm{ext}(M,N)) &\simeq \mathrm{Hom}_{\xi\times\eta}(M,N)\\ &\simeq \mathrm{Hom}((\xi\times\eta)\times_{\mathbf{D}} M, N),\end{aligned}$$

donc toujours la même chose ! Pas de doute, ça doit marcher.

S'il faut se donner le hom ext (11) comme donnée supplémentaire, avec de plus un isomorphisme trifonctoriel (12), il faut aussi se donner les isomorphismes trifonctoriels (13), '*compatibles*' avec l'isomorphisme (12) au sens du calcul précédent.

Commentary · Exposition [ms. 10]

What the Yoneda calculation proves

Grothendieck's three calculations are intended to identify the external Hom of a tensor with the cotensor of an external Hom. The calculation is correct. His qualification about the test category is also correct, and is part of the argument rather than an unnecessary hesitation.

Suppose the external Hom represents (12), and suppose that all three candidate objects in (13) belong to Hot_0. For every $\xi \in \mathrm{Hot}_0$, tensor associativity and the tensor-cotensor adjunction give natural identifications of their represented functors with

$$\xi \longmapsto \mathrm{Hom}_{\mathcal{A}}((\xi\times\eta)\times_{\mathbf{D}} M, N).$$

Yoneda in Hot_0 then gives a unique isomorphism respecting these identifications. Naturality in η, M, N follows from the same uniqueness. The last candidate additionally requires the relevant function object to exist in Hot_0; closure under products alone does not imply that closure under function objects.

If the candidates lie only in Hot, the calculation instead identifies their *restricted* represented functors. Such an identification need not determine the objects. For a concrete example, take Hot_0 to be the full subcategory of discrete spaces. For any discrete set S and any nonempty connected space H, the set $[S,H]$ has one element: a map is a choice of a component for each element of S, and there is only one component. Consequently the point and S^1 define isomorphic functors on this test category, although they are not isomorphic homotopy types. This example isolates the exact logical failure that would result from applying unrestricted Yoneda here.

There are two legitimate completions. One may assume the restricted Yoneda functor is fully faithful on the particular objects under consideration, and then the displayed calculation suffices. Alternatively, a model or ∞-categorical construction gives the actual comparison of mapping spaces before passage to homotopy types, proving (13) directly. The manuscript follows the first course conditionally and otherwise proposes to retain the comparisons as part of the additional structure. No gap should be charged to a proof that explicitly states this restriction.

Par exemple, prenant $\eta =$ type d'homotopie du cercle S^1, les formules (13) se spécialisent en p. 7

$$\begin{aligned}\hom\mathrm{ext}(\Sigma M, N) &\simeq \hom\mathrm{ext}(M, \Omega N)\\ &\simeq \Omega\hom\mathrm{ext}(M,N)\\ &\overset{\text{déf}}{=} \hom_{\mathrm{HOT}}(S^1, \hom\mathrm{ext}(M,N)).\end{aligned} \tag{14}$$

Mais cette formule dans Hot n'est sans doute pas tout à fait la bonne, car le bon formalisme de Ω, Σ se fait dans les catégories *ponctuées,* et en particulier dans la catégorie homotopique ponctué $\mathrm{Hot}_\bullet$.

Je vais expliciter un exemple, en prenant le dérivateur

$$\mathrm{Dér}(A)$$

'dérivé' d'une catégorie abélienne A. Donc $\mathbf{D}(e) =$ catégorie dérivée de A. Pour éviter des difficultés accessoires ici, je vais supposer que A est la catégorie des k-modules, k un anneau [page 11]

quelconque.

À tout $\xi \in \operatorname{Ob}\mathrm{Hot}$ est associé un 'abélianisé'

$$\xi_{\mathrm{ab}} \overset{\text{déf}}{=} H_\bullet(\xi) \in \underbrace{D(\mathrm{Ab})}_{\text{ou } \mathbf{D}(\mathbf{Z}\text{-Mod})}, \qquad \text{catégorie dérivée des groupes abéliens,}$$

objet qui n'a de cohomologie qu'en degré ≤ 0. Ceci dit, si M est dans $D(k\text{-Mod})$, on aura

$$\begin{cases} \xi \times_{\mathbf{D}} M \;\simeq\; \xi_{\mathrm{ab}} \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} M \\ \hom_{\mathbf{D}}(\xi, M) \;\simeq\; \mathbf{R}\mathrm{Hom}_{\mathbf{Z}}(\xi_{\mathrm{ab}}, M), \end{cases} \tag{15}$$

formule qui est en cheville avec la formule de Künneth pour l'homologie

$$(\xi \times \eta)_{\mathrm{ab}} \simeq \xi_{\mathrm{ab}} \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} \eta_{\mathrm{ab}}, \tag{16}$$

ce qui redonne un aspect familier aux formules (9), qui se réduisent à

$$\begin{cases} \xi_{\mathrm{ab}} \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} (\eta_{\mathrm{ab}} \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} M) \;\simeq\; (\xi_{\mathrm{ab}} \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} \eta_{\mathrm{ab}}) \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} M \\ \mathbf{R}\mathrm{Hom}_{\mathbf{Z}}(\xi_{\mathrm{ab}}, \mathbf{R}\mathrm{Hom}_{\mathbf{Z}}(\eta_{\mathrm{ab}}, M)) \;\simeq\; \mathbf{R}\mathrm{Hom}_{\mathbf{Z}}(\xi_{\mathrm{ab}} \overset{\mathbf{L}}{\otimes}_{\mathbf{Z}} \eta_{\mathrm{ab}}, M). \end{cases} \qquad ([2])$$

D'autre part, existe-t-il bien un $\hom\operatorname{ext}(M, N)$, si M, N dans $D(k\text{-Mod})$? On pense à $\mathbf{R}\mathrm{Hom}_k(M, N)$, mais pour en faire un type d'homotopie, on doit 'tronquer en degrés > 0'. On pourrait donc prendre

$$\hom\operatorname{ext}(M, N) \;\simeq\; \tau_{\leq 0}(\mathbf{R}\mathrm{Hom}_k(M, N)).$$

Commentary · Examples [ms. 11]

Integral chains and the truncation of derived Hom

Grothendieck turns to complexes because they make the external Hom computable. We can verify every part of the proposed formula, provided that *abélianisation* means the derived free abelian-group construction and that the truncation is the canonical one.

For a simplicial set K, let

$$A_K = N\mathbf{Z}[K]$$

be its normalized free chain complex, written cohomologically in degrees at most zero. This is the object denoted $H_\bullet(\xi)$ in the manuscript. It is a chain complex up to quasi-isomorphism, not merely its graded homology groups. The free simplicial abelian-group functor is left adjoint to the forgetful functor. After deriving and applying the Dold–Kan equivalence, it gives

$$[K, U\,\mathrm{DK}(B)] \cong \mathrm{Hom}_{D(\mathbf{Z})}(A_K, B), \qquad B \in D(\mathbf{Z})^{\leq 0}.$$

Here DK means denormalization with the change from cohomological to homological grading, and U forgets the abelian-group structure. The underlying equivalence is The Stacks Project Authors (2026c, Theorem 14.24.3). It is this derived adjunction that answers the question in footnote 3; being only an abelian-group object in the ordinary homotopy category would not by itself specify the requisite strict or coherent abelian structure.

Put $R = \mathbf{R}\mathrm{Hom}_k(M, N)$, viewed as an object of $D(\mathbf{Z})$. For a noncommutative k, this target is still correct: there is generally no left k-module structure on this Hom complex. Since $A_K \in D(\mathbf{Z})^{\leq 0}$, the truncation adjunction gives

$$\begin{aligned} [K, U\,\mathrm{DK}(\tau_{\leq 0}R)] &\cong \mathrm{Hom}_{D(\mathbf{Z})}(A_K, \tau_{\leq 0}R) \\ &\cong \mathrm{Hom}_{D(\mathbf{Z})}(A_K, R) \\ &\cong \mathrm{Hom}_{D(k)}(A_K \otimes^{\mathbf{L}}_{\mathbf{Z}} M, N). \end{aligned}$$

2. Expliciter aussi la formule d'adjonction (7) (p. 4).

The final equality is the derived tensor-Hom adjunction; k acts on the factor M. This proves (10) and (12) for the claimed external Hom, with the otherwise suppressed Dold–Kan and forgetful functors restored.

The truncation is the smart truncation: its degree-zero term is $\ker(d : R^0 \to R^1)$, and its negative terms are those of R. Simply deleting the positive degrees would replace degree-zero cocycles by all of R^0, generally giving a wrong set of components. The homotopy groups of the resulting simplicial abelian group are

$$\pi_n \hom\operatorname{ext}(M,N) \cong H^{-n}R \cong \operatorname{Hom}_{D(k)}(M, N[-n]), \qquad n \geq 0.$$

For instance, with $k = \mathbf{Z}$, $M = \mathbf{Z}$, and $N = \mathbf{Z}[r]$, $r \geq 0$, one obtains $K(\mathbf{Z}, r)$. The adjunction then reads $[K, K(\mathbf{Z}, r)] \cong H^r(K; \mathbf{Z})$, including degree zero with its usual unreduced interpretation.

The other formula in (15) follows from the same adjunction:

$$T_K M = A_K \otimes^{\mathbf{L}}_{\mathbf{Z}} M, \qquad C_K M = \mathbf{R}\operatorname{Hom}_{\mathbf{Z}}(A_K, M).$$

The Eilenberg–Zilber comparison identifies $A_{K\times L}$ with $A_K \otimes^{\mathbf{L}}_{\mathbf{Z}} A_L$ (Eilenberg and Zilber, 1953, Section 1, theorem, pp. 200–201); normalized free chains are bounded above complexes of free abelian groups in this grading, so the ordinary tensor already computes the derived tensor. Formula (16) is this chain-level equivalence. A formula involving only the tensor product of homology groups would lose the Tor terms and would not suffice for Grothendieck's argument.

p. 8
[page 12]

La formule fondamentale (10) est-elle alors valable ? Le deuxième membre est en effet

$$\operatorname{Hom}_{\mathrm{Hot}}(\xi, H) \;\simeq\; \operatorname{Hom}_{\mathrm{Hotab}}(\xi_{\mathrm{ab}}, H) \qquad ({}^{3})$$

car H est un objet abélien de Hot (cf. le tapis sur l'abélianisation …), à partir de là c'est gagné :

$$\operatorname{Hom}_{\underbrace{\mathrm{Hotab}}_{\substack{\approx\, D(\mathbf{Z}\text{-Mod})^{\leq 0},\\ \text{sous-catégorie } \textit{pleine}\\ \text{de } D(\mathbf{Z}\text{-Mod})}}}(\xi_{\mathrm{ab}}, \tau_{\leq 0}\mathbf{R}\operatorname{Hom}_k(M,N)) \;\simeq\; \operatorname{Hom}_{D(\mathbf{Z}\text{-Mod})}(\xi_{\mathrm{ab}}, \mathbf{R}\operatorname{Hom}_k(M,N))$$

$$\simeq\; \operatorname{Hom}_{D(k\text{-Mod})}(\xi_{\mathrm{ab}} \times M, N),$$

O.K.

D'autre part, le bifoncteur

$$(M,N) \;\longmapsto\; \hom\operatorname{ext}(M,N) \;=\; \tau_{\leq 0}\mathbf{R}\operatorname{Hom}_k(M,N)$$

se factorise canoniquement par Hotab et a fortiori par $\mathrm{Hot}_{\bullet}$. Le 'bon' $\hom\operatorname{ext}(M,N)$ serait ici plutôt celui dans Hotab, voire même dans la catégorie $D^-(\mathbf{Z}\text{-Mod})$, déduite de celle là 'en rendant le foncteur translation inversible'. Il est évident d'ailleurs qu'ici le $\xi_{\mathrm{ab}} \times_{\mathbf{D}} M$, où $\xi = S^1$, n'est pas 'la bonne' suspension, qui doit être le décalage des degrés – ξ_{ab} ne devrait avoir de la cohomologie qu'en degré -1, et non aussi en degré 0.

Commentary · Present state [ms. 12]

Keeping all degrees of the mapping complex

Grothendieck's last suggestion seeks an external Hom that remembers the linear structure and the information restored by suspension. That is the correct direction, but the proposed bounded-above target requires a qualification when the coefficient category is the unbounded derived category.

The homotopy category of simplicial abelian groups is equivalent to $D(\mathbf{Z})^{\leq 0}$. Allowing finite shifts of its objects produces $D^-(\mathbf{Z})$: an object in the union has cohomology bounded above, and conversely any bounded-above complex can be shifted into nonpositive degrees. This observation

3. ? ? est-ce vrai ? ? ?

correctly describes the stated formal inversion of translation at the level of objects and morphisms. It does not imply that every derived Hom complex belongs to this union.

A two-term algebra already shows the difficulty. Let F be a field, let $k = F[\epsilon]/(\epsilon^2)$, and let $L = k/(\epsilon)$. A projective resolution of L is

$$\cdots \xrightarrow{\epsilon} k \xrightarrow{\epsilon} k \xrightarrow{\epsilon} k \longrightarrow L \longrightarrow 0.$$

It is exact because the kernel and image of multiplication by ϵ are both the ideal (ϵ). Applying $\mathrm{Hom}_k(-, L)$ gives one copy of F in every nonnegative cohomological degree and zero differentials. Thus

$$H^n \mathbf{R}\mathrm{Hom}_k(L, L) = \mathrm{Ext}^n_k(L, L) \cong F \qquad (n \geq 0).$$

The full derived Hom is not in $D^-(\mathbf{Z})$. The present external mapping space is nevertheless well defined: its nonpositive truncation is the discrete group F. The omitted extension groups reappear as $\pi_0 \mathrm{hom}\,\mathrm{ext}(L, L[n])$, for every $n \geq 0$. This example explains why a single mapping space and the whole stable mapping object are different levels of information.

For complexes, the full enhancement is by the unbounded complex $\mathbf{R}\mathrm{Hom}_k(M, N)$; in a general stable homotopy theory it is by a mapping spectrum. The classical differential graded formulation and its relation to triangulated categories are discussed by Keller (2006, Sections 2–3). The modern theory of monoidal and enriched derivators distinguishes the unpointed, pointed, and stable actions and the existence of their right adjoints (Groth et al., 2014b, Sections 3 and 8–9).

The correction here concerns the generality of a tentative proposal, not a theorem whose proof has collapsed. The formulas involving $\tau_{\leq 0}\mathbf{R}\mathrm{Hom}$ are valid. The earlier circle identification is repaired by reduced chains. An additional boundedness hypothesis, such as suitable finite projective dimension and boundedness on the inputs, is needed only if one insists that the entire linear external Hom take values in $D^-(\mathbf{Z})$.

[page 73]

Construction de diagrammes substantiels pour un dérivateur.

Soit $\mathbf{D}$ un prédérivateur, I dans Diag, considérons
$\varphi_I : \mathcal{D}(I) \longrightarrow \underline{\mathrm{Hom}}(I^o, \mathcal{A})$, où $\mathcal{A} = \mathbf{D}(e)$ est la catégorie fondamentale des coefficients.

Les objets de $\underline{\mathrm{Hom}}(I^o, \mathcal{A})$ s'interprètent comme des *diagrammes de type* I^o dans $\mathcal{A}$. Ce langage est surtout commode si I est ordonnée. Notons, pour $F \in \mathrm{Ob}\,\mathbf{D}(I)$, par $(F_i)_{i\in \mathrm{Ob}\, I}$ le I^o-diagramme associé dans $\mathcal{A}$. Par l'axiome Dér 2, le foncteur

$$\varphi : F \longmapsto (F_i)_{i\in \mathrm{Ob}\, I}$$

est conservatif. Mais il n'a aucune envie d'être fidèle, encore moins pleinement fidèle. Quand on connaît le diagramme $(F_i)_i$, on est loin de connaître F, pas même à isomorphisme non unique près, je présume. Il n'est nullement clair que si F, F' dans $\mathbf{D}(I)$ sont tels que les diagrammes associés soient isomorphes, ils soient eux-mêmes isomorphes.

Commentary · Context [ms. 73]

Why the skeleton is insufficient

Grothendieck's term *diagramme substantiel* names the information on which the whole project depends: a diagram before its coherent relations have been discarded. The point is not that an ordinary commutative diagram has been drawn inaccurately. It is that several different homotopies and compatibilities can produce the same drawing in the homotopy category.

In the model example,

$$\mathbf{D}(I) = \mathcal{M}^{I^o}[(W^{I^o})^{-1}], \qquad \varphi_I : \mathbf{D}(I) \longrightarrow (\mathrm{Ho}\mathcal{M})^{I^o}.$$

Localization is performed on the category of whole diagrams. The target instead localizes the values first and subsequently records arrows and their equations. These operations need not commute. Axiom Der 2 says that a morphism of coherent diagrams which is an isomorphism at every vertex is invertible. It says neither that every skeletal morphism lifts nor that two lifts agree. The distinction was illustrated in the commentary on Chapter I, manuscript p. 11 (*Conservative is not faithful*); there is no need to repeat that counterexample here.

For the walking arrow one can make a useful positive statement. A *strong* derivator satisfies fullness and essential surjectivity of

$$\mathbf{D}(I \times [1]) \longrightarrow \mathbf{D}(I)^{[1]^o}$$

for every I. This is the usual modern Der 5, not an identification of the numbered axioms appearing earlier in the manuscript (Groth, 2013, Definition 1.8). Fullness together with conservativity implies that two coherent arrows whose skeletal arrows are isomorphic are themselves isomorphic: lift the skeletal isomorphism by fullness, then use its invertibility at both endpoints. It does not imply a unique lift of that isomorphism. Thus Grothendieck's question about objects with isomorphic skeletons has a different answer for a single arrow in a strong derivator than for an unrestricted diagram shape.

The historical motivation is particularly close to the present construction. In *Pursuing Stacks*, Grothendieck (1983, Section 69, pp. 1–2 of the edited extract) recalls the need, arising around SGA 5, to supplement a derived category by derived categories of triangles and filtered complexes. Here he seeks a procedure that constructs the supplements and their maps from Kan extension itself. Heller's parallel treatment packages homotopy theories as systems of diagram categories (Heller, 1988, Introduction and Chapter I). Neither perspective asks one to manufacture a functorial cone on the bare homotopy category.

The two examples pursued below are deliberately chosen to retain a universal property throughout the construction. The loop square is determined by a zero extension followed by a right Kan extension. The unit and counit arrows are determined by a category that encodes the functor f. This is why canonical coherent versions of these particular arrows can be obtained even though a general skeletal arrow has no specified canonical lift.

Pour insister sur ce point, les objets de $\mathbf{D}(I)$ s'appelleront les '*diagrammes substantiels* de type I^o dans $\mathcal{A}$' (ou $\mathbf{D}$-substantiel, s'il y a risque de confusion). Pour étayer l'intuition et simplifier les explications, un objet F de $\mathbf{D}(I)$ ($\mathbf{D}$-coefficients sur I) sera représenté graphiquement par le diagramme 'faible' ou 'squelettique' correspondant – on le regarde comme une sorte de (pâle) 'squelette' du diagramme substantiel dont il provient. P. ex. si [page 74] $I = \mathbf{\Delta}_0 : 0 \longrightarrow 1$ `[plutôt` $\mathbf{\Delta}_1$`]`, on note un diagramme substantiel de type $(\mathbf{\Delta}_0)^o$ `[plutôt` $(\mathbf{\Delta}_1)^o$`]` par le même graphisme, que le diagramme ordinaire :

$$F_0 \longleftarrow F_1.$$

Si

$$I = \begin{array}{ccc} a & \longrightarrow & c \\ \uparrow & & \uparrow \\ 0 & \longrightarrow & b, \end{array}$$

les diagrammes substantiels de type I se notent

$$\begin{array}{ccc} F_a & \longleftarrow & F_c \\ \downarrow & & \downarrow \\ F_0 & \longleftarrow & F_b. \end{array}$$

Il faudra bien sûr préciser chaque fois si ce graphisme désigne un diagramme squelettique, ou substantiel. Souvent on part d'un squelette, et on essaye de 'l'étoffer' avec un peu de chair, pour en faire un diagramme substantiel – si possible, de façon canonique. C'est là un point de philosophie dérivatique essentiel pour la pratique. On procédera souvent de proche en proche, en 'substantifiant' des sous-diagrammes correspondants à une suite strictement croissante $I_0 \subset I_1 \subset \cdots \subset I_n = I$ de I, au mieux de la situation particulière. p. 2

En voici un exemple typique, en supposant $\mathbf{D}$ un dérivateur *ponctué* (les $\mathbf{D}(I)$ sont ponctuées, et les f^* transforment objets nuls en objets nuls). Il s'agit de la définition du foncteur 'cosuspension' ou 'espace de lacets' dans $\mathcal{A}$, [page 75]

$$\Omega : \mathcal{A} \longrightarrow \mathcal{A}.$$

Il est entendu que pour M dans $\mathcal{A}$, $\Omega(M)$ doit s'insérer dans un carré commutatif

(C)
$$\begin{array}{ccc} e & \longleftarrow & \Omega M \\ \downarrow & & \downarrow \\ M & \longleftarrow & e, \end{array}$$

où e désigne les éléments unités. Ce carré cependant devrait être substantiel, plus précisément, être un carré substantiel '$\mathbf{D}$-*cartésien*'. Étant entendu qu'un objet de $\mathbf{D}(I)$ (carré substantiel dans $\mathcal{A}$) est dit $\mathbf{D}$-cartésien, s'il est dans l'image essentielle de $\mathbf{D}(I_1)$ par i_{1*}, où

$$i_1 : I_1 \hookrightarrow I,$$

I_1 étant la sous-catégorie ouverte de I définie par

$$I_1 = \begin{array}{ccc} & & a \\ & & \uparrow \\ 0 & \longrightarrow & b. \end{array}$$

Commentary · Exposition [ms. 75]

Constructing the loop square without choosing homotopies

Grothendieck wants to obtain a functor Ω, not merely an object which happens to have the expected homotopy type. The two successive Kan extensions supply that functoriality. The direction of the arrows is governed by the presheaf convention: the indexing square has initial vertex 0 and final vertex c, while its coefficient diagram has arrows pointing toward 0.

Let $I_0 = \{0\}$, let $I_1 = \{0, a, b\}$ with $0 \to a, 0 \to b$, and let I be the completed square. Denote the inclusions by $i_0 : I_0 \to I_1$ and $i_1 : I_1 \to I$, as in the text. Since I_0 is a sieve in I_1, the *left* Kan extension in the presheaf convention is extension by the initial object outside I_0. Pointedness identifies this initial object with zero. Hence

$$(i_0)_! M|_0 = M, \qquad (i_0)_! M|_a = (i_0)_! M|_b = 0.$$

The pointwise assertion follows from empty comma categories at a, b, and the assertion at 0 follows from full faithfulness of the inclusion. Thus the cospan $0 \to M \leftarrow 0$ has been made coherent without choosing representatives or nullhomotopies.

Apply the right Kan extension $(i_1)_*$. Its value at c is the homotopy limit of that cospan. Set

$$\Omega M = c^*(i_1)_*(i_0)_! M.$$

The object $(i_1)_*(i_0)_! M$ carries, at once, the two maps from ΩM to zero and the specified coherent commutativity with the two zero maps to M. It is cartesian by construction. Every morphism $M \to N$ induces a morphism of these squares by the functoriality of the composite, so the construction really produces an endofunctor.

The stronger equivalence stated on page 77 follows with little extra work. Let $\mathcal{Q} \subset \mathbf{D}(I)$ be the full subcategory of cartesian squares with values zero at a, b. The functor

$$L = (i_1)_*(i_0)_! : \mathbf{D}(e) \longrightarrow \mathcal{Q}$$

is fully faithful, since both Kan extensions are. It is essentially surjective as well. If $Q \in \mathcal{Q}$, cartesianness gives $Q \cong (i_1)_* i_1^* Q$. The counit $(i_0)_! i_0^* i_1^* Q \to i_1^* Q$ is an isomorphism at 0, and at a, b both sides are zero. Der 2 therefore makes it an isomorphism. Substitution gives $Q \cong L(Q_0)$, and restriction to 0 is a quasi-inverse.

The phrase *unique à isomorphisme unique près* has its usual universal-property meaning: after specifying the identification of the input with M, a comparison is unique when required to induce that identification. A square may have automorphisms induced by automorphisms of M. Also, one should not add a requirement that the induced comparison fix an independently chosen identification of the fourth vertex. The theorem determines that vertex as part of the construction.

For complexes, the homotopy fibre of $0 \to M$ is $M[-1]$, so this recovers the reduced loop functor, with no unwanted summand M. This is the construction needed to repair the circle calculation of Chapter III.

[page 76]

La restriction du carré substantiel cherché (C) à la sous-catégorie I_1 est donc un diagramme substantiel de squelette

(Sq)
$$\begin{array}{ccc} & & e \\ & & \downarrow \\ M & \longleftarrow & e, \end{array}$$

dont il se déduit (à isomorphisme canonique près) en appliquant i_* à ce dernier, de façon p. 3
à le compléter en $\begin{array}{ccc} e & \leftarrow & \Omega M \\ \downarrow & & \vdots \\ M & \longleftarrow & e \end{array}$. Il reste donc à décrire une substantiation canonique du squelette (Sq), en termes de M. Cela nous conduit à regarder la sous-catégorie ouverte

$$I_0 = \{0\} : \quad \begin{array}{ccc} & \cdots\cdots\rightarrow & \\ \uparrow & & \uparrow \\ 0 & \cdots\cdots\rightarrow & \end{array}$$

de I_1 (donc aussi de I) réduite à l'objet initial, et l'inclusion

$$I_0 \overset{i_0}{\hookrightarrow} I_1,$$

et de substantifier le squelette (Sq) par $(i_0)_!(M)$.

On peut dire a posteriori que, si on connaissait le carré substantiel, il n'y a, à isomorphisme unique près, qu'une seule façon de l'obtenir comme un $i_{1*}i_{0!}(?)$, avec ? dans $\mathbf{D}(I_0) \simeq \mathcal{A}$, car $i_{0!}$ et i_{1*} étant pleinement fidèles, il en est de même de leur composé.

En fait, on voit que le foncteur [page 77]

$$i_{1*}i_{0!} : \ \mathcal{A} \simeq \mathbf{D}(I_0) \longrightarrow \mathbf{D}(I)$$

induit une équivalence de $\mathcal{A}$ avec la sous-catégorie pleine de $\mathbf{D}(I)$ formée des carrés **D**-cartésiens dont les fibres en a et b sont nulles. (Le foncteur quasi-inverse évident est i^*, où $i : U_0 \hookrightarrow I$ `[plutôt` $I_0 \hookrightarrow I$`]`.) Cela signifie donc que dans ce cas, la donnée du squelette de nature très particulière ($F_a \simeq F_b \simeq 0_{\mathcal{A}}$), plus la contrainte supplémentaire **D**-cartésienne, sur le carré cherché, détermine celui-ci à isomorphisme unique près en termes de son squelette : il y a une substantiation non seulement 'canonique' de celui-ci, mais même unique à isomorphisme unique près, à cause de la contrainte **D**-cartésienne.

Je voudrais commencer par regarder le cas plus simple encore où $I = \mathbf{\Delta}_1 = (0 \longrightarrow 1)$, donc les squelettes envisagés sont simplement les flèches

$$F_1 \longrightarrow F_0 \qquad \text{dans } \mathcal{A}.$$

La philosophie nous oblige, pour les flèches les plus fondamentales dans la théorie des dérivateurs $\mathbf{D}$ (flèches dans $\mathcal{A}$, ou par extension dans une $\mathbf{D}(I) \simeq \mathcal{A}_{\mathbf{D}_I}$, catégorie fondamentale du dérivateur induit $\mathbf{D}_I$) de se demander s'il n'y a pas

une façon 'canonique', 'naturelle', 'voulue par Dieu', de le 'remplumer' en un diagramme substantiel. Les flèches les plus évidentes qui se présentent sont relatives à un foncteur p. 4 [page 78]

$$f : I \longrightarrow J$$

dans Diag, et aux deux morphismes d'adjonction pour le couple (f^*, f_*), savoir

$$\begin{aligned} G &\longrightarrow f_* f^* G \quad \text{dans } D(J) \\ f^* f_* F &\longrightarrow F \qquad \text{dans } D(I). \quad (^2) \end{aligned}$$

Je vais essayer de remplumer ces deux flèches, et vais généraliser en envisageant la situation ci-contre `[ci-dessous]`

$$\begin{array}{ccc} I & & F \\ {\scriptstyle f}\downarrow & & \uparrow{\scriptstyle u} \\ J & & G, \end{array}$$

où

$$\mathrm{Hom}^f(G, F) \overset{\text{déf}}{=} \mathrm{Hom}(f^*G, F) \overset{\text{adj.}}{\simeq} \mathrm{Hom}(G, f_*F).$$

Donc le même u s'interprète par *deux* flèches squelettiques

$$\text{(1)} \qquad \begin{cases} f^*(G) \longrightarrow F & \text{dans } \mathbf{D}(I) \\ G \longrightarrow f_*(F) & \text{dans } \mathbf{D}(J). \end{cases}$$

Les remplumer, c'est les interpréter (si faire se peut) en termes de deux objets (si possible canoniques) dans $\mathbf{D}(I \times \mathbf{\Delta}_1)$ et $\mathbf{D}(J \times \mathbf{\Delta}_1)$ respectivement.

Je vais me guider sur le cas particulier d'un dérivateur trivial

$$\mathbf{D} = \mathbf{D}_{\mathcal{M}},$$

où $\mathcal{M}$ est une catégorie de modèles 'nue' ($\Sigma = \emptyset$).

Pour f fixé, on va construire une catégorie auxiliaire $K(f)$, de telle façon que pour toute catégorie $\mathcal{M}$, les systèmes (G, F, u) d'un $\mathcal{M}$-préfaisceau G sur J, d'un autre F sur I, et d'un f-homomorphisme $G \longrightarrow F$, s'identifient (fonctoriellement) aux $\mathcal{M}$-préfaisceaux sur $K(f)$. Ceci dit, on va essayer d'interpréter les flèches (1) squelettiques, mais peu importe ici – tous les $\mathbf{D}$-squelettes sont maintenant remplumés) en termes de la géométrie de $K(f)$. [page 79] p. 5

$$\begin{cases} \mathrm{Ob}\, K(f) = \mathrm{Ob}\, K(I) \amalg \mathrm{Ob}\, K(J) \qquad \texttt{[plutôt Ob } I \amalg \mathrm{Ob}\, J \texttt{]} \\ I,\ J \text{ s'identifiant à des sous-catégories pleines de } K(f), \\ \text{il n'y a pas des flèches d'un } j \in J \text{ dans un } i \in I. \\ \text{(Donc } I \text{ est ouverte dans } K(f),\ J \text{ son complémentaire fermé.)} \\ \text{Pour } i \in \mathrm{Ob}\, I,\ j \in \mathrm{Ob}\, J, \text{ on pose } \mathrm{Hom}_{K(f)}(i, j) = \mathrm{Hom}_J(f(i), j). \end{cases}$$

2. Bien sûr, problème dual pour $(f_!, f^*)$.

La composition des flèches dans $K(f)$ est évidente. On va définir une rétraction canonique

$$\bar{f} : K(f) \longrightarrow J$$

de $K(f)$ sur sa sous-catégorie fermée J. Donc $\bar{f}$ est connu sur $\operatorname{Ob} J$, et sur $\operatorname{Ob} I$ ce sera f :

$$\begin{cases} \bar{f}(j) = j & \text{si } j \in \operatorname{Ob} J \\ \bar{f}(i) = f(i) & \text{si } i \in \operatorname{Ob} I. \end{cases}$$

Il reste à définir, pour $x, y \in \operatorname{Ob} K(f)$, [page 80]

$$\operatorname{Hom}_{K(f)}(x, y) \longrightarrow \operatorname{Hom}_J(\bar{f}(x), \bar{f}(y)).$$

Si $x, y \in \operatorname{Ob} J$, c'est l'identité, si $x, y \in I$, c'est f. Si $x \in I$, $y \in J$, on doit définir une flèche

$$\operatorname{Hom}(f(x), y) \longrightarrow \operatorname{Hom}(f(x), y),$$

et on prend encore l'identité. On a

$$\begin{array}{ccccc} J & \xrightarrow{\ j\ } & K(f) & \xleftarrow{\ i\ } & I \\ & \searrow & \downarrow{\scriptstyle \bar{f}} & & \\ & & J & & \end{array}$$

$$\begin{cases} \bar{f} \circ j = \mathrm{id}_J \\ j \circ \bar{f} = \begin{cases} j & \text{sur } J \\ jf & \text{sur } I, \end{cases} \end{cases} \qquad \text{i.e.} \quad \boxed{\begin{array}{ll} j\bar{f}j = j & \text{sur } J \\ j\bar{f}i = jf & \text{sur } I \end{array}},$$

et on a $[K = K(f)]$

$$\begin{aligned} \alpha :\ & \mathrm{id}_K \longrightarrow j\bar{f} \qquad\qquad \text{i.e. homomorphisme fonctoriel} \\ & x \xrightarrow{\alpha(x)} j(\bar{f}(x)), \quad x \in \operatorname{Ob} K, \end{aligned}$$

défini ainsi :

p. 6

$$\begin{cases} \text{Si } x \in J,\ \alpha(x) = \mathrm{id}_x \ :\ x \xrightarrow{\sim} j(\bar{f}(x)) = j(x) = x \\ \text{Si } x \in I,\ \alpha(x) : \underbrace{x \longrightarrow f(x)}_{\text{dans } K(f)},\ \text{ou } \underbrace{f(x) \longrightarrow f(x)}_{\text{dans } J},\ \alpha(x) = \mathrm{id}_{f(x)}. \end{cases}$$

On doit vérifier la fonctorialité pour x variable dans K …

Commentary · Exposition [ms. 79]

The collage records a relative morphism

Grothendieck introduces $K(f)$ to turn a morphism between coefficients on two different bases into an ordinary diagram on one base. This is a categorical form of the mapping cylinder, or more precisely the collage of the profunctor $\operatorname{Hom}_J(f(-), -)$. The construction encodes the direction of the relative morphism in its mixed arrows.

For clarity, distinguish the copy of I from the copy of J, even when they have the same objects. Internal arrows are those of I and J; a mixed arrow $x \to y$, with $x \in I, y \in J$, is an arrow $f(x) \to y$ in J; there are no mixed arrows in the other direction. If $a : x' \to x$ lies in I, $b : y \to y'$ lies in J, and $\beta : f(x) \to y$ represents a mixed arrow, composition is

$$\beta \circ a = \beta \circ f(a), \qquad b \circ \beta = b\beta$$

in J. Associativity follows directly from associativity in I, J and functoriality of f. These formulas also prove that I is a sieve and J is its complementary cosieve.

Here is the universal property in full. Given presheaves $F : I^o \to \mathcal{M}$, $G : J^o \to \mathcal{M}$, and a natural transformation $u : f^*G \to F$, define $\Phi : K(f)^o \to \mathcal{M}$ to equal F and G on the two pieces. On the mixed arrow represented by $\beta : f(x) \to y$, set

$$\Phi(\beta) = \big(G(y) \xrightarrow{G(\beta)} G(f(x)) \xrightarrow{u_x} F(x)\big).$$

Naturality of u proves compatibility with composition on the I-side; functoriality of G proves compatibility on the J-side. Conversely, restriction gives F, G, and evaluation on the mixed arrow $x \to f(x)$ represented by $\mathrm{id}_{f(x)}$ gives u_x. The two constructions are inverse.

A morphism between triples is a pair $r : F \to F'$, $s : G \to G'$ with $r\,u = u'\,f^*s$. This equation is precisely naturality on the distinguished mixed arrows, and hence on every mixed arrow by the formula above. We have therefore obtained an isomorphism of categories, natural in $\mathcal{M}$:

$$\mathrm{Fun}(K(f)^o, \mathcal{M}) \cong \{(F, G, u : f^*G \to F)\}.$$

The isolated superscript o on the category of triples on manuscript page 82 is inconsistent with the preceding displayed universal property if the same variance is retained. One may either omit it in the modern formulation or dualize both sides. The printed reading is preserved in the transcription and recorded in the corrections table.

The retraction $\bar f : K(f) \to J$ and transformation $\alpha : \mathrm{id} \to j\bar f$ need no additional coherence data. In fact $\bar f \dashv j$: for $x \in K(f), y \in J$, the equality $\mathrm{Hom}_K(x, jy) = \mathrm{Hom}_J(\bar f x, y)$ follows from the defining cases. Its unit is precisely α, and its counit is the identity. This proves the naturality left for verification on page 80 and explains why the identities involving $\bar f$ fit together.

Soit Φ un $\mathcal{M}$-préfaisceau sur K. Il définit

$$\begin{aligned} F &= i^*(\Phi) \quad \in \mathrm{Ob}\,\mathbf{D}_{\mathcal{M}}(I) \\ G &= j^*(\Phi) \quad \in \mathrm{Ob}\,\mathbf{D}_{\mathcal{M}}(J). \end{aligned}$$

D'autre part $f^*(G)$ s'interprète comme $(j\bar f)^*(\Phi)|I$, car

$$\begin{aligned} f^*(G)(i) &= G(\underbrace{f(i)}_{=\bar f(i) \in J}) \\ &= j^*(\Phi)(\bar f(i)) \\ &= \Phi(j\bar f(i)) \\ &= (j\bar f)^*(\Phi)(i). \end{aligned}$$

Donc

$$f^*(G) \simeq (j\bar f)^*(\Phi)|I. \qquad \text{[page 81]}$$

Or la flèche

$$\alpha : \mathrm{id}_K \longrightarrow j\bar f$$

donne

$$\underbrace{\mathrm{id}_K(\Phi)}_{=\Phi} \xleftarrow{\Phi(\alpha)} (j\bar f)^*(\Phi), \qquad \text{fonctoriel en } \Phi,$$

d'où, en prenant les restrictions à I,

$$i^*(\Phi) \overset{\text{déf}}{=} F \xleftarrow{u} f^*G.$$

En fait, sans tellement se tortiller, on devrait pouvoir montrer que pour toute catégorie $\mathcal{M}$, la catégorie $\underline{\mathrm{Hom}}(K^o, \mathcal{M})$ des $\mathcal{M}$-préfaisceaux sur K est isomorphe à celle des triples (F, G, u), avec $F \in \mathrm{Ob}\,\underline{\mathrm{Hom}}(I^o, \mathcal{M})$, $G \in \underline{\mathrm{Hom}}(J^o, \mathcal{M})$, et $u : f^*(G) \longrightarrow F$. Ainsi, K apparaît comme solution d'un problème universel

$$\underline{\mathrm{Hom}}(K^o, \mathcal{M}) \longrightarrow \{F,\ G,\ u \text{ comme dessus}\}(\mathcal{M}).$$

Mais pour y préciser la flèche $\longrightarrow$ de façon conceptuelle simple, il est bon de se donner K avec les structures supplémentaires $I \underset{\bar{f}}{\overset{j}{\rightleftarrows}} K \xleftarrow{\ i\ } I$, $\bar{f}j = \mathrm{id}_J$, $\mathrm{id}_K \xrightarrow{\alpha} j\bar{f}$. Et ce système p. 7
$\{K,\ i,\ j,\ \bar{f},\ \alpha\}$ est (sauf erreur) défini à isomorphisme canonique près par la condition de [page 82]
représenter le foncteur $\mathcal{M} \longmapsto \{F,\ G,\ u\}^o(\mathcal{M})$ …

En particulier, le système défini par $G \in \mathrm{Ob}\,\mathbf{D}_{\mathcal{M}}(J)$

$$(f^*(G),\ G,\ \mathrm{id} : f^*(G) \longrightarrow f^*(G))$$

est défini sauf erreur par $\bar{f}^*(G)$ sur $K(f)$. On se propose [?] de trouver une interprétation similaire pour

$$(F,\ f_*(F),\ f^*f_*F \longrightarrow F)$$

($F \in \mathrm{Ob}\,\mathbf{D}(I)$). Le candidat naturel serait ici $\Phi = i_*(F)$. Admettons ce point (i.e. surtout la vérification du fait que $j^*(i_*(F)) \simeq f_*(F)$). Tout ceci montre que si $\mathbf{D}$ est à nouveau un dérivateur quelconque, on peut, par les formules précédentes, trouver un objet canonique Φ de $\mathbf{D}(K)$, en termes soit d'un $\mathbf{D}$-coefficient F sur I (en prenant $\Phi = i_*(F)$), soit d'un $\mathbf{D}$-coefficient G sur J (en prenant $\Phi = \bar{f}^*(G)$). D'autre part, on peut espérer définir canoniquement

$$\mathbf{D}(K) \longrightarrow \mathbf{D}(I \times \mathbf{\Delta}_1)$$
$$\mathbf{D}(K) \longrightarrow \mathbf{D}(J \times \mathbf{\Delta}_1)$$

dont les composés avec les foncteurs 'squelettes'

$$\mathbf{D}(I \times \mathbf{\Delta}_1) \longrightarrow \underline{\mathrm{Hom}}(\mathbf{\Delta}_1^o, \mathbf{D}(I))$$
$$\mathbf{D}(J \times \mathbf{\Delta}_1) \longrightarrow \underline{\mathrm{Hom}}(\mathbf{\Delta}_1^o, \mathbf{D}(J))$$

redonnent (pour $\Phi \in \mathrm{Ob}\,\mathbf{D}(K)$) les flèches squelettiques [page 83]

$$\begin{cases} f^*(G) \xrightarrow{u} F \\ G \xrightarrow{v} f_*F \end{cases}$$

associées à (F, G, u). De façon précise, $f^*(G) \longrightarrow F$ se définit en termes de $\mathbf{D}$, et $\Phi \in \mathrm{Ob}\,\mathbf{D}(K)$, comme ci-dessus, et v s'en déduit par adjonction.

Commentary · Exposition [ms. 82]

The missing Kan extension comparison

Grothendieck's candidate i_*F is correct, and the comparison $j^*i_*F \cong f_*F$ follows directly from the geometry of the mixed arrows. This is the point at which the collage begins to do mathematical work: a right Kan extension along an arbitrary functor is recovered from one along an inclusion.

For $y \in J$, the comma category (i/jy) has objects $x \in I$ together with arrows $i(x) \to j(y)$ in $K(f)$. By definition, such an arrow is an arrow $f(x) \to y$ in J. Morphisms are the same commuting triangles in both descriptions. Hence there is a canonical isomorphism

$$(i/jy) \cong (f/y)$$

commuting with the projections to I, naturally in y. The pointwise right Kan extension axiom in the presheaf convention computes both $(i_*F)_{j(y)}$ and $(f_*F)_y$ as the homotopy limit of F over $(f/y)^o$. The comparison is therefore an isomorphism at every y, and Der 2 makes it an isomorphism in $\mathbf{D}(J)$.

There is a precise canonical map behind this pointwise calculation. The transformation $i \to jf$ induced by α yields

$$f^*j^*i_*F \longrightarrow i^*i_*F \cong F.$$

Its mate is $j^*i_*F \to f_*F$. The comma-category identification proves that this mate is the isomorphism just computed. Consequently the displayed arrow on I, after that identification, is exactly the counit

$f^*f_*F \to F$; agreement on objects is not being used as a substitute for agreement of the relevant natural transformations.

The other candidate is immediate but equally canonical. If $\Phi = \bar{f}^*G$, then $j^*\Phi = G$, $i^*\Phi = f^*G$, and the transformation on I is the identity, since $\bar{f}(\alpha_x) = \mathrm{id}_{\bar{f}(x)}$. These assertions hold for a derivator whenever the required indexing shapes are permitted. They use only restriction, right Kan extension, and the prederivator action on natural transformations.

In modern language the comma square expressing this argument is homotopy exact. The general calculus of such squares, with the comparison specified as a mate, is developed in Groth (2013, Proposition 1.26); the relevant earlier convention was fixed in the commentary on Chapter I, manuscript p. 31 (*The base-change map as a mate*). The argument above completes the local proof rather than appealing to a stronger base-change statement with unchecked hypotheses.

Commentary · Development (commentators') [ms. 83]

Completing both coherent adjunction arrows

Grothendieck leaves the chapter just after finding the characteristic map $K(f) \to [1]$. His construction can be completed explicitly. The point is to use that map together with the retraction to J, rather than to select a coherent representative of an arbitrary arrow in a homotopy category. We give the completion because it explains why both members of an adjoint pair can be treated by the same category.

Collage completion. [ours] Let $\mathbf{D}$ be a derivator in the presheaf convention, and let $f : I \to J$. Assume its diagram category contains $K = K(f)$, the products $I \times [1]$, $J \times [1]$, and the comma categories needed for the indicated right Kan extensions. There are functors

$$H : \mathbf{D}(K) \longrightarrow \mathbf{D}(I \times [1]), \qquad V : \mathbf{D}(K) \longrightarrow \mathbf{D}(J \times [1])$$

whose skeletal arrows are, respectively, $u : f^*G \to F$ and its adjoint $v : G \to f_*F$, for $F = i^*\Phi$, $G = j^*\Phi$, and u induced by α.

Proof. Define $h : I \times [1] \to K$ by

$$h(x,0) = i(x), \qquad h(x,1) = j(f(x)).$$

On an arrow $a : x \to x'$ at level 0 use $i(a)$, and at level 1 use $j(f(a))$. A mixed arrow $(x,0) \to (x',1)$, determined by a, is sent to the mixed arrow represented by $f(a)$. The definition of composition in the collage shows that this is a functor. Its vertical arrow at x is $\alpha_{i(x)}$. Therefore $H = h^*$ has restrictions F, f^*G, and its arrow in the presheaf direction is exactly $u : f^*G \to F$. This proves the first assertion without any Kan extension.

To construct the adjoint arrow, let $\chi : K \to [1]$ be 0 on I and 1 on J, and set

$$q = (\bar{f}, \chi) : K \longrightarrow J \times [1], \qquad V = q_*.$$

For $y \in J$, the category $(q/(y,0))$ contains only objects from I; its definition identifies it with (f/y). Thus

$$(q_*\Phi)|_{J\times\{0\}} \cong f_*F.$$

The category $(q/(y,1))$ has the terminal object given by $j(y)$ and the identity of $(y,1)$. Indeed every object of that comma category specifies precisely one arrow to $j(y)$, either an internal arrow of J or the mixed arrow represented by its J-component. In the presheaf convention the right Kan formula takes a homotopy limit over the opposite of this comma category, so the terminal object becomes an initial object and the limit is evaluation there. Consequently

$$(q_*\Phi)|_{J\times\{1\}} \cong G.$$

These comparisons are natural, and their pointwise invertibility implies invertibility as coefficient diagrams.

It remains to identify the arrow, since its two endpoints alone would not determine it. Put $E = q_*\Phi$, let $t : E_1 \to E_0$ be its skeletal arrow, and use the counit $\varepsilon : q^*E \to \Phi$. Its restriction to J gives an isomorphism $\lambda : E_1 \to G$. Its restriction to I gives $f^*E_0 \to F$; let $\theta : E_0 \to f_*F$ be its

mate. The preceding comma calculations say exactly that θ is an isomorphism. Naturality of ε with respect to the mixed arrows $x \to f(x)$ gives

$$(f^{*}E_{0} \longrightarrow F) \circ f^{*}t = u \circ f^{*}\lambda.$$

After substituting the definitions of θ and the counit of $f^{*} \dashv f_{*}$, this says that $\theta\, t\, \lambda^{-1} : G \to f_{*}F$ has adjoint u. The adjunction bijection identifies it with v. This proves the second assertion and the proposition. □

Taking $\Phi = \bar{f}^{*}G$, the first arrow is the identity on $f^{*}G$, so the second is the unit $G \to f_{*}f^{*}G$. Taking $\Phi = i_{*}F$, the first is the counit $f^{*}f_{*}F \to F$, while the second is the identity on $f_{*}F$. Hence both adjunction transformations have canonical coherent realizations, natural in their coefficients. Applying the construction after a shift by A gives the corresponding statement in every $\mathbf{D}(A)$; the compatibility with restriction in A follows from the product-square base change already used in Chapter III.

No strongness axiom was used. The input was the coherent Φ, and for the unit and counit that input was itself constructed by a specified Kan extension or restriction. The result does not supply a canonical section of the skeleton functor on all arrows.

The collage and the mate calculus are standard constructions. We checked the treatments of homotopy exact squares in Groth (2013, Section 1), enriched derivator adjunctions in Groth et al. (2014b, Sections 8–9), and pointwise Kan extension through modules in Riehl and Verity (2017, Section 5). We did not find in these sources the precise pair h^{*}, q_{*} written as a completion of this unfinished chapter. The marker above identifies our explicit completion and proof; it makes no claim of priority.

L'idée naturelle ici, serait de ramener le problème de l'étoffement des flèches d'adjonction sqelettiques, au cas des immersions ouvertes ou fermées. Notons que les sous-catégories ouvertes de K correspondent justement aux foncteurs $K \longrightarrow \mathbf{\Delta}_1$, en prenant les images inverses de l'ouvert générique. Il y a donc un unique

$$\varphi :\ K(f) \longrightarrow \mathbf{\Delta}_1$$

avec $I = \varphi^{-1}(\{0\})$. Donc `[fin du chapitre]`

Commentary · Examples [ms. 83]

A diagonal and its two projections

Grothendieck's geometric construction can be seen completely in the case where $I = \{a, b\}$ is discrete, $J = e$, and f is the unique functor. Here $K(f)$ is the cospan $a \to * \leftarrow b$. Its presheaf coefficients have the opposite shape: an object Φ is a coherent pair of arrows from G to F_a, F_b.

The right Kan extension $f_{*}F$ is the product $F_a \times F_b$ in $\mathbf{D}(e)$. Indeed Der 1 identifies $\mathbf{D}(I)$ with $\mathbf{D}(e) \times \mathbf{D}(e)$; the right adjoint to the diagonal restriction is the categorical product. The map $q : K(f) \to [1]$ sends a, b to 0 and $*$ to 1. Its right Kan extension sends the coherent pair to the single coherent arrow

$$G \longrightarrow F_a \times F_b$$

whose two components are the original arrows. This proves directly, in this example, that the second construction is the adjoint of the first.

For $\Phi = \bar{f}^{*}G$, both original arrows are identities. The output is the diagonal $G \to G \times G$, as a specified object of $\mathbf{D}([1])$. For $\Phi = i_{*}F$, the value at $*$ is $F_a \times F_b$, and restriction along h gives the two projection arrows. The same collage has therefore produced the unit and counit of the diagonal-product adjunction, including their coherent representatives.

The empty case checks the direction of every construction. If $I = \varnothing$, then $K(f) = J$, q is the level-1 inclusion, and $q_{*}\Phi$ has value Φ at level 1 and the terminal coefficient at level 0. Its presheaf arrow is $\Phi \to 1$, the unit of the adjunction between restriction to the empty category and its right Kan extension. Interchanging the two endpoints would give the wrong arrow even in this simplest case.

1 La catégorie des chemins

p. 1
[page 1]

Soit Φ la catégorie suivante :

$$\begin{cases} \operatorname{Ob}\Phi &= \mathbf{Z} \\ \operatorname{Fl}\Phi &= \operatorname{Ob}\Phi \sqcup \mathbf{Z} \qquad (\operatorname{Ob}\Phi \leftrightarrow \text{identités}) \end{cases}$$

On note $\{\alpha\}$, ou simplement α, l'objet qui correspond à $\alpha \in \mathbf{Z}$. On note u_α la flèche qui correspond à l'entier $\alpha \in \mathbf{Z}$.

$$\begin{aligned} s(u_\alpha) &= \alpha \qquad \text{si } \alpha \text{ pair}, \quad \alpha+1 \quad \text{si } \alpha \text{ impair} \\ b(u_\alpha) &= \alpha+1 \qquad \text{si } \alpha \text{ pair}, \quad \alpha-1 \quad \text{si } \alpha \text{ impair} \end{aligned}$$

[plutôt $b(u_\alpha) = \alpha+1$ si α pair, α si α impair]

Il n'y pas à définir de compositions, car si deux flèches sont composables, elles sont l'identité. En fait, Φ est une catégorie *ordonnée*, $\{\alpha\} < \{\beta\}$ si et seulement si α pair, $\beta = \alpha+1$ [plutôt $\beta = \alpha+1$ ou $\beta = \alpha-1$].

On note, pour $n \in \mathbf{N}$,

$$\Phi_n \subseteq \Phi, \quad \operatorname{Ob}\Phi_n = \{\alpha \in \operatorname{Ob}\Phi \mid -n \le \alpha \le +n\},$$

la sous-catégorie pleine de Φ dont les objets sont les $\{\alpha\}$ avec $-n \le \alpha \le +n$. Ainsi

$$\Phi_1 = \{-1 \longleftarrow 0 \longrightarrow 1\},$$

la duale est

$$\Psi_1 = \Phi_1^o = \{-1 \longrightarrow 0 \longleftarrow 1\}.$$

On peut considérer Φ comme somme amalgamée d'une suite ordonnée infinie (de deux côtés) de copies de Φ_1, ou aussi d'une suite similaire de copies de Ψ_1.

$$\cdots \quad \overbrace{\longleftarrow -4 \longrightarrow -3 \longleftarrow -2 \longrightarrow -1 \longleftarrow 0 \longrightarrow 1 \longleftarrow 2 \longrightarrow 3 \longleftarrow 4 \longrightarrow}^{\Phi_1 \quad \Phi_1 \quad \Phi_1 \quad \Phi_1 \quad \Phi_1} \quad \cdots$$
$$\underbrace{\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad}_{\Psi_1 \quad \Psi_1 \quad \Psi_1 \quad \Psi_1}$$

Commentary · Exposition [ms. 1]

A path remembers the arrows that will be inverted

Grothendieck is preparing a geometric description of localization. A morphism in a category of fractions is represented by a finite word of arrows, some traversed in their original direction and some traversed backwards. The alternation imposed here is a way of giving all such words a common shape. Inserting identity arrows makes any finite zigzag alternating; adding identities at its ends gives an interval symmetric about zero. The identities are bookkeeping, whereas the arrows traversed backwards carry the mathematical restriction imposed by the chosen class of denominators.

After the edition's correction of the target of u_α, the category Φ is the poset on $\mathbf{Z}$ whose only strict relations are

$$2i < 2i-1, \qquad 2i < 2i+1.$$

Every even vertex is a source and every odd vertex a sink. There is no composite of two nonidentity arrows. The sentence saying that two composable arrows "sont l'identité" must therefore mean that at least one of them is an identity. Composing an identity with an arbitrary arrow supplies the elementary exception to its literal wording.

The subcategory Φ_n has $2n$ edges, not n. Thus the manuscript's later references to the parity of a path concern the index n, or half its number of edges. This distinction explains the repair on manuscript page 14. A path of index 1 has shape $\cdot \leftarrow \cdot \rightarrow \cdot$; two such paths joined end to end have

the opposite orientation from Φ_2. The correct assertion at the end of the present page is that Φ_n, for even $n > 0$, is assembled from copies of $\Psi_1 = \Phi_1^o$. The printed Ψ_n has the wrong orientation. We keep that reading in the source and use the corrected statement in the mathematics.

The nerve of every finite Φ_n is an ordinary subdivided interval. Nevertheless the category itself, including the directions of its arrows, matters: a functor from it to X is an actual zigzag in X, and its natural transformations are actual commutative ladders. Passing immediately to the geometric interval would discard precisely the information needed to distinguish denominators from the other arrows.

Les Φ_n, pour n impair, sont de même somme de copies de Φ_1 mises bout à bout, et les Ψ_n, pour n pair > 0, somme de copies de Ψ_1.

Les Φ_n forment un système inductif avec foncteurs de transition pleinement fidèles, dont Φ est la limite inductive p. 2

$$\Phi = \varinjlim_n \Phi_n.$$

Mais pour la suite on va faire des Φ_n un système *projectif*, en définissant pour tout $n \leq m$ une *rétraction* $\varphi_{n,m}$ de Φ_m sur Φ_n, par

[page 2]

$$\left\{\begin{array}{l} \varphi_{n,m} : \Phi_m \longrightarrow \Phi_n \subset \Phi_m \\ \varphi_{n,m}(\{\alpha_i\}) = \left\{\begin{array}{lcll} \alpha_i & = & i & \in \operatorname{Ob}\Phi_n, \quad \text{i.e.} \quad -n \leq i \leq n \\ \alpha_i & = & n & \text{si} \quad n \leq i \leq m \\ \alpha_i & = & -n & \text{si} \quad -m \leq i \leq -n \end{array}\right. \end{array}\right.$$

[plutôt

$$\begin{array}{rcl} \varphi_{n,m} : \Phi_m & \longrightarrow & \Phi_n \subset \Phi_m \\ \varphi_{n,m}(\{i\}) & = & \left\{\begin{array}{lll} \{i\} & \texttt{si } i \in \operatorname{Ob}\Phi_n, & \texttt{i.e} \quad -n \leq i \leq n \\ \{n\} & & \texttt{si} \quad n \leq i \leq m \\ \{-n\} & & \texttt{si} \quad -m \leq i \leq -n \texttt{]} \end{array}\right. \end{array}$$

On note le système projectif d'ensembles ordonnés ainsi obtenu par

$$\boldsymbol{\Phi} = (\Phi_n)_{n \in \mathbf{N}} \in \operatorname{Pro}(\mathrm{Cat}).$$

Soit X une catégorie, alors pour $n \in \mathbf{N}$

$$\underline{\mathrm{Ch}}_n(X) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(\Phi_n, X)$$

est la catégorie des diagrammes de X de la forme

$$(*) \qquad A_{-n} \cdots \longleftarrow A_{-2} \xrightarrow{u_{-2}} A_{-1} \xleftarrow{u_{-1}} A_0 \xrightarrow{u_0} A_1 \xleftarrow{u_1} A_2 \xrightarrow{u_2} A_3 \longleftarrow \cdots A_n$$

avec $2n$ flèches bout à bout u_i $(-n \leq i \leq n)$ [plutôt $(-n \leq i \leq n-1)$], deux flèches consécutives allant toujours en sens opposé,

$$\text{soit} \ \cdot \longrightarrow \cdot \longleftarrow \cdot, \quad \text{soit} \ \cdot \longleftarrow \cdot \longrightarrow \cdot.$$

Le foncteur canonique déduit de $\varphi_{n,m} : \Phi_m \longrightarrow \Phi_n$

$$\varphi_X^{m,n} : \underline{\mathrm{Ch}}_n(X) \longrightarrow \underline{\mathrm{Ch}}_m(Y), \qquad n \leq m,$$

[plutôt $\underline{\mathrm{Ch}}_m(X)$] est le 'foncteur de dégénérescence', consistant à compléter un diagramme $(*)$, par $m-n$ termes A_{-n} avec des identités à gauche, et par $m-n$ termes $[A_n]$ avec des identités à droite, donc pour n pair on trouve p. 3

$$\underbrace{A_{-n} \cdots \xrightarrow{\mathrm{id}} A_{-n}}_{m-n \text{ termes}} \xleftarrow{\mathrm{id}} A_{-n} \longrightarrow A_{-(n-1)} \cdots\cdots A_{n-1} \longleftarrow A_n \xrightarrow{\mathrm{id}} \underbrace{A_n \xleftarrow{\mathrm{id}} A_n \longrightarrow \cdots A_n}_{m-n \text{ termes}}.$$

C'est un foncteur pleinement fidèle (ce qui correspond au fait que $\varphi_{n,m}$ est surjectif sur les objets et sur les flèches.

On pose

[page 3]

$$\underbrace{\underline{\mathrm{Ch}}_\infty(X)}_{\text{ou simplement } \underline{\mathrm{Ch}}(X)} = \underline{\mathrm{Hom}}(\boldsymbol{\Phi}, X) \overset{\text{déf}}{=} \varinjlim_n \underline{\mathrm{Ch}}_n(X)$$

([3]) ([4]). On a une inclusion pleinement fidèle

$$\underline{\mathrm{Ch}}_\infty(X) \hookrightarrow \underline{\mathrm{Hom}}(\Phi, X),$$

où la deuxième catégorie est celle des diagrammes infinis (dans les deux directions)

$$\cdots \longleftarrow A_{-2} \xrightarrow{u_{-2}} A_{-1} \xleftarrow{u_{-1}} A_0 \xrightarrow{u_0} A_1 \xleftarrow{u_1} A_2 \xrightarrow{u_2} \cdots$$

et où $\underline{\mathrm{Ch}}_\infty(X)$ s'identifie à la sous-catégorie pleine formées des objets pour lesquels les flèches u_i sont des identités, pour $|i|$ assez grand.

On appellera $\underline{\mathrm{Ch}}_\infty(X)$ la *catégorie des chemins* dans X, ses objets seront les chemins dans X. Ceux qui proviennent de $\underline{\mathrm{Ch}}_n(X)$ seront appelés *chemins standards de longueur* $2n$. (Le terme 'standard' s'applique ici à nos conventions de notations. Ainsi nous ne considérons que des chemins de longueur paire, et pour une longueur déterminée, nous choisissons l'une parmi les deux espèces raisonnables, par exemple pour les chemins de longueur 2 nous avons pris seulement

$$A_{-1} \longleftarrow A_0 \longrightarrow A_1$$

et non pas

$$A_{-1} \longrightarrow A_0 \longleftarrow A_1.)$$

Commentary · Exposition [ms. 3]

The pro-interval and the eventually constant diagram

Grothendieck wants paths of arbitrary finite length without making their length part of the final object. He obtains them by extending a finite diagram with identity arrows at both ends. The projective system of intervals and the inductive system of path categories describe the same operation from opposite sides.

Write $r_{n,m} : \Phi_m \to \Phi_n$ for the numerical clamping map

$$r_{n,m}(i) = \max(-n, \min(i, n)), \qquad n \le m.$$

It is a functor: an edge inside $[-n, n]$ is unchanged, and every other edge is sent to an identity. The equality $r_{n,m} r_{m,l} = r_{n,l}$ is literal, so precomposition gives a strict inductive system. Its transition functors are fully faithful, for a reason slightly more precise than mere surjectivity on objects and arrows. If $F, G : \Phi_n \to X$ and $\eta : F r_{n,m} \to G r_{n,m}$, naturality on each collapsed edge says that the two adjacent components of η agree. They therefore agree throughout either constant tail. Restriction to Φ_n determines η uniquely and yields an arbitrary natural transformation $F \to G$. This proves the required bijection on Hom sets.

Surjectivity alone would not prove this assertion for an arbitrary functor. The map from a discrete two-point category to the point is surjective on objects and arrows, while precomposition gives the diagonal $X \to X \times X$, which need not be full. What makes clamping work is the chain of edges sent to identities inside each fibre.

The filtered colimit is consequently realized as the full subcategory of $\mathrm{Fun}(\Phi, X)$ consisting of diagrams whose edges are identities outside a finite interval. A natural transformation between two such diagrams also becomes constant in both tails: choose one interval containing the nonidentity edges of both diagrams and apply naturality to the identity edges beyond it. Thus both objects and morphisms descend to a common finite stage. No assertion about commuting an arbitrary functor category with filtered colimits is being used here.

The notation $\mathrm{Fun}(\mathbf{\Phi}, X)$ is a convenient enriched version of the usual pro-object formula: it means $\mathrm{colim}_n \mathrm{Fun}(\Phi_n, X)$ as a category. Its set of objects is not a space of arbitrary infinite paths. The eventual identity condition is essential, and differs even from eventual invertibility.

Reflection $i \mapsto -i$ is the unique nonidentity automorphism of Φ_n when $n > 0$, since an automorphism of the underlying finite path is either the identity or reflection and both preserve the alternating orientation. For $n = 0$ the automorphism group is trivial. This harmless boundary case will also matter when the two endpoints coincide.

Je me rends compte que mes notations u_i ne sont pas commodes pour la dualité, je vais les changer, en u_i pour les flèches entre objets $\{i\}$ avec $i \geq 0$, et v_i la flèche symétrique de u_i par rapport à l'origine. (Le groupe des automorphismes des Φ_n est réduit au groupe à deux éléments, le seul automorphisme non trivial étant la symétrie $\{i\} \longrightarrow \{-i\}$. Donc nos chemins seront notés désormais

$$(*) \qquad A_{-2} \xrightarrow{v_1} A_{-1} \xleftarrow{v_0} A_0 \xrightarrow{u_0} A_1 \xleftarrow{u_1} A_2 \longrightarrow \cdots .$$

(Ce n'est pas non plus enthousiasmant …) p. 4

Soit

$$\varepsilon = \{-1, +1\}$$

l'ensemble ordonné *discret,* réduit aux deux éléments -1, $+1$, et définissons des foncteurs d'inclusion (pleinement fidèles)

$$\alpha_n : \varepsilon \longrightarrow \Phi_n \quad \alpha_n(-1) = -n \qquad \alpha_n(1) = n,$$

ces foncteurs sont compatible avec les $\varphi_{n,m}$, d'où

$$\alpha_\infty : \varepsilon \longrightarrow \mathbf{\Phi} \in \mathrm{ProCat},$$

d'où pour tout X un foncteur

$$\kappa : \underline{\mathrm{Hom}}(\mathbf{\Phi}, X) \longrightarrow \underline{\mathrm{Hom}}(\varepsilon, X) \simeq X \times X$$

i.e.

[page 5]

$$\underline{\mathrm{Ch}}(X) \longrightarrow X \times X \qquad c \longrightarrow (\sigma(x), \beta(x)).$$

[plutôt $(\sigma(c), \beta(c))$] Pour tout chemin c dans X i.e. un diagramme $(*)$ (satisfaisant à la condition de dégénérescence à l'infini), on a une source ou origine du chemin, et un but ou une *extrémité*

$$\begin{cases} \sigma(x) = A_i & \text{pour } i \leq -\mathrm{long}(x) \\ \beta(x) = A_i & \text{pour } i \geq \mathrm{long}(x) \end{cases}$$

[remplacer x par c; pour long(c) défini convenablement]. La fibre du foncteur précédent en x, y sera notée

$$\underline{\mathrm{Ch}}(X; x, y) \qquad \text{ou simplement } \underline{\mathrm{Ch}}(x, y),$$

catégorie des chemins de x à y.

Commentary · Examples [ms. 5]

Fixing the endpoints also fixes the vertical arrows

Grothendieck's source–target functor allows a path to become a candidate morphism from a specified object to another. Its fibre over (x, y) is a strict categorical fibre. An object is an eventually constant zigzag with tails x and y; a morphism is a natural transformation whose two tail components are 1_x and 1_y. This last condition is indispensable for the interpretation by a Hom set.

There are two different full-subcategory statements in these pages. The category of Σ-paths is full in the category of all paths, because it imposes a condition only on the objects. Likewise its fixed-endpoint fibre is full in the fixed-endpoint fibre of all paths. But a fixed-endpoint fibre is generally not full in the entire functor category. On pages 15–16 and 24 the expressions "sous-catégorie pleine"

3. L'ensemble des objets de cette catégorie se notera $\mathrm{Ch}_\infty(X)$ ou $\mathrm{Ch}(X)$, de même on définit les $\mathrm{Ch}_n(X)$.
4. dans cette formule: $\mathbf{\Phi}$ procatégorie

must be read with this correction: the endpoint components of a natural transformation are required to be identities.

For a concrete test take the one-object category BG of a nontrivial group G, and let Σ contain only the identity. The paths representing 1 and $g \neq 1$ may be written, at index 2,

$$(1,1,1,1), \qquad (g,1,1,1),$$

where the entries label the four alternating arrows. There is a natural transformation from the first diagram to the second with vertex components $(1,g,g,g,g)$. It satisfies all four naturality squares, but its final component is g, not the identity. Thus it is not a morphism in the strict fibre. If one used the full subcategory on objects with the prescribed endpoints, this transformation would identify 1 with g on connected components, although localization at identities leaves BG unchanged.

For an ordinary arrow category, the same convention makes the fibre over (x,y) discrete: a morphism from $f : x \to y$ to $g : x \to y$ with both vertical sides identities exists precisely when $f = g$, and is then unique. This is the precise assertion used on page 8.

The map $\varepsilon \to \Phi_n$ is fully faithful for $n > 0$. At $n = 0$ it sends both endpoint labels to the same object and is not fully faithful. It still defines the source–target functor, whose index-zero stage is the diagonal $X \to X \times X$. Consequently a path of index zero occurs in the fibre only when $x = y$, exactly as the identity construction requires.

p. 5

2 Calcul d'une catégorie de fractions $X\Sigma^{-1}$

Avant de continuer le formalisme des chemins (composition etc.), je vais tester l'utilité de la notion de catégorie des chemins, pour le 'calcul' des $X\Sigma^{-1}$, où

$$\Sigma \subset \mathrm{Fl}(X), \qquad \Sigma \text{ contient les identités}$$

est une partie autrement *quelconque* de $\mathrm{Fl}(X)$. On sait que $\mathrm{Ob}\, X\Sigma^{-1} = \mathrm{Ob}\, X$, et tout revient à définir les

$$\mathrm{Hom}_{X\Sigma^{-1}}(x,y), \qquad x,y \in \mathrm{Ob}\, X,$$

et pour $x,y,z \in \mathrm{Ob}\, X$ la composition [page 6]

$$\mathrm{Hom}_\Sigma(x,y) \times \mathrm{Hom}_\Sigma(y,z) \xrightarrow{(u,v)\mapsto vu} \mathrm{Hom}_\Sigma(x,z),$$

(où on note Hom_Σ au lieu de $\mathrm{Hom}_{X\Sigma^{-1}}$, pour alléger les notations).

Grâce à Σ, on définit une sous-catégorie pleine

$$\underline{\mathrm{Ch}}_\Sigma(X) \hookrightarrow \underline{\mathrm{Ch}}(X),$$

([3]) par la condition sur $c \in \mathrm{Ch}(X)$: Pour i impair, `[plutôt pair]` i.e. $i-1 \xleftarrow{u_i} i$ (u_i est dite 'rétrograde'), $c(u_i) \in \Sigma$, i.e. les 'tronçons' rétrogrades dans le chemin c doivent être dans Σ. On définit de même les sous-catégories pleines

$$\underline{\mathrm{Ch}}_\Sigma(X;x,y) = \{c \in \underline{\mathrm{Ch}}(X;x,y) \mid c \in \underline{\mathrm{Ch}}_\Sigma(X)\},$$

ou encore la fibre en (x,y) du foncteur source-but pour $\underline{\mathrm{Ch}}_\Sigma(X)$

$$\underline{\mathrm{Ch}}_\Sigma(X) \longrightarrow X \times X.$$

3. L'ensemble de ses objets est noté $\mathrm{Ch}(X)$. Ses éléments sont les Σ-chemins de x à y `[de x à y?]`.

Commentary · Exposition [ms. 6]

Why a commutative ladder gives equality after localization

Grothendieck places no calculus-of-fractions hypothesis on Σ: it is any set of arrows containing the identities. Its closure under composition is unnecessary for the path construction. The hypothesis concerns only the backwards horizontal arrows; the vertical arrows of a morphism of paths may be arbitrary arrows of X.

To see why this is sufficient, let $Q : X \to X[\Sigma^{-1}]$ be the localization and consider a square around a backwards edge,

$$\begin{array}{ccc} A_{i-1} & \xleftarrow{\ s\ } & A_i \\ {\scriptstyle a_{i-1}}\downarrow & & \downarrow{\scriptstyle a_i} \\ B_{i-1} & \xleftarrow{\ t\ } & B_i \end{array} \qquad s, t \in \Sigma.$$

Its commutativity gives $Q(a_{i-1})Q(s) = Q(t)Q(a_i)$, hence

$$Q(a_i)Q(s)^{-1} = Q(t)^{-1}Q(a_{i-1}).$$

The square therefore remains commutative after reversing its horizontal arrows. Apply this to every backwards edge and then compose the resulting forward squares. The endpoint components give a commutative square between the two composite arrows in the localization. In a strict endpoint fibre those components are identities, so the two composites are equal.

This proves the functor to the arrow category and the induced function on π_0 without assuming that any vertical arrow becomes invertible. It also explains the deliberate use of connected components: an equality may be witnessed by a finite zigzag of natural transformations rather than a single transformation. The later reparametrization argument is designed to produce just such zigzags.

The parity notation changes during the construction. It is safest to number the edges consecutively from the left whenever discussing a fixed even-index interval; its even-numbered edges are then the backwards ones. This numerical convention must not be confused with the original label u_α on the doubly infinite interval, or with the symmetric u_i, v_i notation introduced on page 4. The invariant definition is simply that an edge traversed right-to-left belongs to Σ.

On définit une application canonique

$$\mathrm{Ch}_\Sigma(X, x, y) \longrightarrow \mathrm{Hom}_\Sigma(x, y),$$

en associant 'a tout chemin de x dans y le Σ-homomorphisme de x dans y obtenu en *inversant* (dans $X\Sigma^{-1}$) les tronçons rétrogrades (ce qui est possible, puisqu'ils sont dans Σ), de sorte qu'on trouve dans $X\Sigma^{-1}$ un 'chemin direct' [page 7]

$$x = A_{-n} \longrightarrow \cdots \longrightarrow A_{-1} \longrightarrow A_0 \longrightarrow A_1 \longrightarrow A_2 \cdots A_n = A_{n+1} = \cdots = y.$$

et on compose tous ces morphismes.

En fait, on trouve aussitôt que l'on définit ainsi un *foncteur*

$$\underline{\mathrm{Ch}}_\Sigma(X) \longrightarrow \underline{\mathrm{Fl}}(X\Sigma^{-1}),$$

[Fl catégorie des flèches] du fait que si on a un diagramme

$$\begin{array}{ccc} A_{i-1} & \xleftarrow{u_i} & A_i \\ \downarrow{\scriptstyle f_{i-1}} & & \downarrow{\scriptstyle f_i} \\ A'_{i-1} & \xleftarrow{u'_i} & A'_i \end{array} \qquad (i \text{ pair}) \qquad \text{p. 6}$$

avec u_i, u'_i dans Σ, ce diagramme, en tant que diagramme dans $X\Sigma^{-1}$, est commutatif avec flèches horizontales des *isomorphismes,* et reste donc commutatif en inversant lesdites flèches. D'où un foncteur induit

$$\underline{\mathrm{Ch}}_\Sigma(X; x, y) \longrightarrow \underline{\mathrm{Fl}}(\underbrace{X\Sigma^{-1}}_{X'}; x, y). \qquad [\text{page 8}]$$

Mais pour toute catégorie X', et des objets x, y dans X', la catégorie $\underline{\mathrm{Fl}}(X', x, y)$ est une catégorie *discrète,* ayant comme ensemble d'objets $\mathrm{Hom}_{X'}(x, y)$. Ainsi le foncteur précédant définit en fait une application canonique

$$\boxed{\pi_0 \underline{\mathrm{Ch}}_\Sigma(X; x, y) \longrightarrow \mathrm{Hom}_\Sigma(x, y).}$$

Je dis que cette application est toujours bijective. Pour le voir, nous allons *constuire* 'from scratch' la catégorie $X\Sigma^{-1}$, en prenant comme objets ceux de X, et en *définissant*

$$\boxed{\mathrm{Hom}_\Sigma(x, y) = \pi_0 \underline{\mathrm{Ch}}_\Sigma(X; x, y).}$$

Il faut donc définir la composition

$$\mathrm{Hom}_\Sigma(x, y) \times \mathrm{Hom}_\Sigma(y, z) \longrightarrow \mathrm{Hom}_\Sigma(x, z).$$

Pour ceci, on va définir des foncteurs 'composition de chemins'

$$\begin{aligned} \underline{\mathrm{Ch}}_m(X; x, y) \times \underline{\mathrm{Ch}}_n(X; y, z) &\longrightarrow \underline{\mathrm{Ch}}_{m+n}(X; x, z) \\ (c, c') &\longmapsto c' \circ c, \end{aligned}$$

mais en nous bornant pour simplifier au cas où m, n ont *la même parité,* de telle façon qu'en 'mettant bout à bout' c et c' (dans cet ordre), on trouve bien un chemin de type $n + m$.

Commentary · Context [ms. 8]

Localization without a short-fraction hypothesis

Grothendieck now proposes to recover the ordinary localization directly from categories of paths. The basic localization by composable words and inverse symbols is classical; compare Gabriel and Zisman (1967, Chapter I, pp. 6–21) and the explicit word formulation in Dwyer and Kan (1980c, §3.1–3.3). His additional object of study is the category of presentations of a morphism, whose connected components recover those words modulo relations.

A short fraction such as $x \leftarrow x' \rightarrow y$ need not represent every localized morphism unless one imposes extra hypotheses. Arbitrary finite zigzags do. The use of all indices thus avoids an Ore condition, a model structure, and any saturation assumption on the original set Σ. Enlarging Σ to the subcategory it generates changes neither the ordinary localization nor the final set of components, but the unlocalized path categories can change. They should not be silently identified.

There are three tasks in the proposed proof. First, concatenation must descend from particular finite representatives to their classes. Second, the original arrows of X must determine a functor to those classes, and arrows in Σ must become invertible. Finally, every functor inverting Σ must factor uniquely by evaluating zigzags. The first task occupies most of the combinatorics. The second is where a generalized interval lemma is temporarily assumed. We supply its relative version below and also give direct witnesses for the particular identities needed here. The universal property then follows by an explicit argument at the end of the section.

Cette opération est 'transposée' du couple de foncteurs [page 9]

$$\begin{aligned} \Phi_n &\xrightarrow{\alpha} \Phi_{n+m} \quad i \longmapsto (i - m) \\ \Phi_m &\xrightarrow{\beta} \Phi_{n+m} \quad i \longmapsto (i + n), \end{aligned}$$

où on aura

$$\alpha(\{n\}) = \beta(\{-m\}) = n - m, \qquad \text{p. 7}$$

et on aura

$$\Phi_{n+m} \simeq \Phi_n \sqcup_e \Phi_m,$$

i.e. Φ_{n+m} est la 'somme amalgamée' dans (Cat), obtenue en 'recollant' Φ_n et Φ_m, par identification de l''élément but' de Φ_n avec l''élément source' de Φ_m. Le foncteur composition

de chemins induit [dans ce qui précède, à partir du début de la page 9, il faut inverser m et n]

$$\underline{\mathrm{Ch}}_{m,\Sigma}(x,y) \times \underline{\mathrm{Ch}}_{n,\Sigma}(y,z) \longrightarrow \underline{\mathrm{Ch}}_{m+n,\Sigma}(x,z),$$

d'où en passant aux π_0

$$\mathrm{Hom}_{\Sigma,m}(x,y) \times \mathrm{Hom}_{\Sigma,n}(y,z) \longrightarrow \mathrm{Hom}_{\Sigma,m+n}(x,z),$$

où on dénote, pour $a, b \in \mathrm{Ob}\, X$, par

$$\mathrm{Hom}_{\Sigma,n}(a,b) \overset{\text{déf}}{=} \pi_0(\underline{\mathrm{Ch}}_{m,\Sigma}(a,b)).$$

[plutôt $\underline{\mathrm{Ch}}_{n,\Sigma}$]
Pour en déduire une application sur les $\varinjlim$ [page 10]

$$\underbrace{\mathrm{Hom}_\Sigma(x,y)}_{=\varinjlim \mathrm{Hom}_{\Sigma,m}(x,y)} \times \underbrace{\mathrm{Hom}_\Sigma(y,z)}_{=\varinjlim \mathrm{Hom}_{\Sigma,n}(y,z)} \longrightarrow \underbrace{\mathrm{Hom}_\Sigma(x,z)}_{=\varinjlim \mathrm{Hom}_{\Sigma,n+m}(x,z)}$$

il faut prouver, pour $n \le n'$, $m \le m'$, la commutativité dans

$$\begin{array}{ccc} \mathrm{Hom}_{\Sigma,m}(x,y) \times \mathrm{Hom}_{\Sigma,n}(y,z) & \longrightarrow & \mathrm{Hom}_{\Sigma,m+n}(x,y) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\Sigma,m'}(x,y) \times \mathrm{Hom}_{\Sigma,n'}(y,z) & \longrightarrow & \mathrm{Hom}_{\Sigma,m'+n'}(x,y) \end{array}$$

[plutôt $\mathrm{Hom}_{\Sigma,m+n}(x,z)$, $\mathrm{Hom}_{\Sigma,m'+n'}(x,z)$] En d'autres termes, que pour $c : x \longrightarrow y$ et $c' : y \longrightarrow z$ deux Σ-chemins composables de longueur m et n respectivement, le composé $c'c : x \longrightarrow z$ ne change pas, 'à homotopie près' dans $\underline{\mathrm{Ch}}_\Sigma(x,z)$, quand on remplace c, c' par des chemins $\bar{c}$, $\bar{c}'$ de longueur m', n' déduits de c et c' par 'dégénérescence aux bouts'.

Plus précisement,

$$\bar{c}'\bar{c} \sim \overline{c'c},$$

le chemin composé est homotope à celui déduit de $c'c$ par 'dégénérescence aux bouts'.

Je viens de regarder pour $n = m = 1$, $n' = m' = 2$, et de constater qu'il n'y a pas de flèche naturelle entre $\bar{c}'\bar{c}$ et $\overline{c'c}$ - l'homotopie cherchée doit se définir à l'aide d'un 'chemin' dans $\underline{\mathrm{Ch}}_{\Sigma,m',n'}(X;x,z)$. Dans le cas général, on va en fait trouver une homotopie p. 8 [page 11]

$$h = h_{(n,m),(n',m')}$$

'rendant commutatif' le diagramme de foncteurs

$$\begin{array}{ccc} \mathcal{A} = \underline{\mathrm{Ch}}_{\Sigma,m}(X;x,y) \times \underline{\mathrm{Ch}}_{\Sigma,n}(X;y,z) & \xrightarrow{*_{m,n}} & \underline{\mathrm{Ch}}_{\Sigma,m+n}(X;x,z) \\ \downarrow{\scriptstyle i_{m,m'} \times j_{n,n'}} & \overset{h}{\swarrow} & \downarrow{\scriptstyle k_{m+n,m'+n'}} \\ \underline{\mathrm{Ch}}_{\Sigma,m'}(X;x,y) \times \underline{\mathrm{Ch}}_{\Sigma,n'}(X;y,z) & \xrightarrow{*_{m',n'}} & \underline{\mathrm{Ch}}_{\Sigma,m'+n'}(X;x,z) = \mathcal{B}, \end{array}$$

où les $i_{\alpha,\beta}$, $j_{\alpha,\beta}$, $k_{\alpha,\beta}$ sont les foncteurs de transition

$$\underline{\mathrm{Ch}}_{\Sigma,\alpha}(X;a,b) \longrightarrow \underline{\mathrm{Ch}}_{\Sigma,\beta}(X;a,b)$$

($\alpha \le \beta$) pour les (x,y), (y,z) et (x,z) (en guise de (a,b)) respectivement. L'homotopie h sera un chemin dans la catégorie $\underline{\mathrm{Hom}}(\mathcal{A},\mathcal{B})$, allant de

$$k_{m+n,m'+n'} \circ *_{m+n} \longrightarrow *_{m'+n'} \circ (i_{m,m'} \times j_{n,n'}).$$ [page 12]

L'existence d'une telle homotopie signifie ni plus ni moins que le diagramme carré ci-dessus est commutatif, en tant que diagramme dans la catégorie (Cat hot) des 'catégories à homotopie près,' dont les objets sont les (petites) catégories, et où on définit

$$\mathrm{Hom}_{\mathrm{Cat\,hot}}(\mathcal{A},\mathcal{B}) \overset{\text{déf}}{=} \underbrace{\pi_0(\underline{\mathrm{Hom}}(\mathcal{A},\mathcal{B}))}_{\substack{\text{classes d'homotopie}\\ \text{de foncteurs de } \mathcal{A}\\ \text{dans } \mathcal{B}}} .$$

C'est cette conclusion qui sera pour nous utile, et non la description explicite du chemin h. Cette existence admise (cf. ci-dessous la preuve), on voit donc que si on regarde, pour $a, b \in \mathrm{Ob}\, X$, le système des catégories $\underline{\mathrm{Ch}}_{\Sigma,r}(X; a, b)$ ($r \in \mathbf{N}$) comme un *ind-objet de* Cat hot, qu'on désigne par

$$\underline{\mathrm{Ch}}^{\mathrm{ind}}_{\Sigma}(X; a, b) \in \mathrm{Ob}\,\mathrm{Ind}(\mathrm{Cat\,hot}),$$

on aura un morphisme canonique dans Ind(Cat hot)

$$\underline{\mathrm{Ch}}^{\mathrm{ind}}_{\Sigma}(X; x, y) \times \underline{\mathrm{Ch}}^{\mathrm{ind}}_{\Sigma}(X; y, z) \xrightarrow{*} \underline{\mathrm{Ch}}^{\mathrm{ind}}_{\Sigma}(X; x, z),$$

appelé *'ind-morphisme de composition de chemins.'* On aurait aimé le déduire d'un honnête *foncteur* 'composition de chemins'

$$\underline{\mathrm{Ch}}_{\Sigma}(X; x, y) \times \underline{\mathrm{Ch}}_{\Sigma}(X; y, z) \xrightarrow{?} \underline{\mathrm{Ch}}_{\Sigma}(X; x, z),$$
$$\text{qu'on noterait } (c, c') \longmapsto c' \circ c \text{ ou } c' \cdot c,$$

mais je doute qu'un tel foncteur existe,

Commentary · Present state [ms. 12]

What composition in an ind-category actually asserts

Grothendieck has reached a useful level of coherence before obtaining a single composition functor on the eventual path categories. For even indices m, n, concatenation gives an actual functor at a finite stage. Increasing either index changes its comparison with the larger-stage concatenation by a finite zigzag of natural transformations. This is exactly the relation imposed in Cat hot, where

$$\mathrm{Hom}_{\mathrm{Cat\,hot}}(A, B) = \pi_0\,\mathrm{Fun}(A, B).$$

Products descend to this category because one can multiply each natural transformation in a zigzag by an identity transformation.

For ind-objects the assertion is governed by the formula

$$\mathrm{Hom}_{\mathrm{Ind}(C)}((A_i), (B_j)) = \lim_i \operatorname*{colim}_j \mathrm{Hom}_C(A_i, B_j).$$

Take $A_{m,n} = \mathrm{Ch}_{\Sigma,m}(x, y) \times \mathrm{Ch}_{\Sigma,n}(y, z)$ and $B_r = \mathrm{Ch}_{\Sigma,r}(x, z)$, with all indices even. The stagewise concatenation maps land in B_{m+n}. Their compatibility as elements of the displayed inverse limit is precisely what the reparametrization lemma proves. The passage to components then gives an ordinary associative composition law.

A functor between the ordinary filtered unions would be additional data. Even if such a functor exists, its restriction to one source stage need not land in a bounded target stage: the source stage can have infinitely many objects. The parenthesis on page 13 explicitly adds the necessary boundedness condition. The equivalence asserted there is therefore conditional on this extra factorization, not a formal property of every functor between filtered colimits.

We do not infer a negative theorem from Grothendieck's doubt. The strict composition demanded on his particular category with symmetric end-padding is not constructed in these pages, and we did not locate a resolution of that exact requirement in the localization sources consulted. Other choices of path presentations do support strict composition. Their existence does not by itself provide the requested functor on this fixed category. The distinction is comparable to the one already emphasized in the commentary on Chapter I, manuscript p. 7 ("Coherent squares and what the axioms remember"): an equality after passage to a homotopy category does not specify its coherent witness.

p. 9
[page 13]

qui par passage aux ind-objets redonne le morphisme précédent, ou, ce qui revient au même, tel que pour tout $m, n \in \mathbf{N}$ (de même parité), il existe un $N \geq m+n$ assez grand tel que l'on ait un diagramme

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{\Sigma,m}(X;x,y) \times \underline{\mathrm{Ch}}_{\Sigma,n}(X;y,z) & \xrightarrow{*_{m,n}} & \underline{\mathrm{Ch}}_{\Sigma,m+n}(X;x,z) \\ \downarrow & \searrow & \downarrow \\ & & \underline{\mathrm{Ch}}_{\Sigma,N}(X;x,z) \\ & & \downarrow \\ \underline{\mathrm{Ch}}_{\Sigma}(X;x,y) \times \underline{\mathrm{Ch}}_{\Sigma}(X;y,z) & \xrightarrow{?} & \underline{\mathrm{Ch}}_{\Sigma}(X;x,z) \end{array}$$

et où le triangle supérieur est *commutatif dans* Cat hot. (Il faut supposer que pour N assez grand, le composé $\downarrow\!\!\!\rightarrow$ se factorise par $\underline{\mathrm{Ch}}_{\Sigma,N}(X;x,z)$ …) Pour voir que les foncteurs composition $*_{m,n}$ définissent un homomorphisme des ind-objets dans (Cat hot), il suffit de le prouver dans les cas particuliers $(m',n') = (m+1, n+1)$. On va faire la figure en supposant m, n *impairs.*

Je m'aperçois ici que je me suis canulé stupidement, la composition de deux chemins de longueur *impaire* m, n *n'est*

pas un chemin de longueur $m+n$, i.e. un diagramme de type Φ_n, mais un diagramme de type *dual* $\Phi_n^o = \Psi_n$. Par exemple, pour $m = n = 1$ [page 14]

$$\underbrace{A_0 \longleftarrow A_1 \longrightarrow A_2}_{c} = \underbrace{B_0 \longleftarrow B_1 \longrightarrow B_2}_{c'}$$

est de type Φ_2^o! Donc pour ne pas trop compliquer la vie, on va dans les développements précédents se borner à m, n *pairs,* donc des chemins de longueur au moins 4. C'est un peu ridicule! On est ramené à prouver la commutativité à homotopie près dans le cas où on laisse c' fixé et où on envoie $\underline{\mathrm{Ch}}_{\Sigma,m}(X;x,y)$ dans $\underline{\mathrm{Ch}}_{\Sigma,m+2}(X;x,y)$, ou inversement c fixe et $\underline{\mathrm{Ch}}_{\Sigma,n}(X;y,z)$ dans $\underline{\mathrm{Ch}}_{\Sigma,n+2}$ `[lire:`$\underline{\mathrm{Ch}}_{\Sigma,n+2}(X;y,z)$`]`. Prenons le premier cas, et notons un chemin c sans indices négatifs (ce n'est pas une notation bien heureuse!)

$$A_0 \longrightarrow A_1 \longleftarrow A_2 \cdots \longleftarrow A_{2m}$$

(NB à cause de la condition n pair, tous nos chemins commencent désormais par une flèche de A_0 dans A_1, jamais en sens inverse).

Je vois que l'explicitation de l'homotopie, sans offrir de difficulté, est très fastidieuse à expliquer. Je vais essayer de donner une démonstration conceptuelle, sans 'calcul' fastidieux.

Commentary · Exposition [ms. 14]

Even indices and reparametrization relative to the ends

Grothendieck's correction on this page is part of the proof. The earlier statement that equal parity suffices for concatenation is false for two odd indices. Translation by an odd integer reverses the source–sink parity in Φ, so the proposed embeddings of the two odd intervals into Φ_{m+n} are not functors with the advertised orientation. Restricting to even indices repairs the construction and loses no path, since every finite index is bounded by an even one.

For even m, n use the embeddings

$$\Phi_m \longrightarrow \Phi_{m+n}, \quad i \longmapsto i-n, \qquad \Phi_n \longrightarrow \Phi_{m+n}, \quad j \longmapsto j+m.$$

They identify the final vertex of the first interval with the initial vertex of the second. At the join both incident arrows have the same source–sink type, so no new composite of two nonidentity arrows appears. Consequently the resulting pushout in categories is Φ_{m+n}. Restricting a functor on that pushout is the same as giving the two composable diagrams with their common object literally

identified. Natural transformations with identity components at the exterior endpoints concatenate as well.

To compare padding before concatenation with padding afterwards, regard the two resulting diagrams as precompositions with maps from a larger interval to a smaller one. Both maps are nondecreasing in the ordinary numerical order of the vertices and fix the two endpoint labels. Their categorical orders are still the alternating orders. This second monotonicity condition, explicitly restored in the edition's footnote on page 17, prevents a backwards source edge from travelling forwards in the smaller interval.

The boundary equation is $h\alpha' = \alpha$, with α' the endpoint map into the larger interval and α the endpoint map into the smaller one. The corrected Hom expression on page 16 fixes the order of those intervals, but its description of the restriction as α' still has the wrong codomain; the displayed equation is the precise interpretation.

The intermediate maps in a homotopy must have that same property. If c is a Σ-path and h is a numerically nondecreasing functor between alternating intervals, each backwards edge is sent either to a backwards edge or to an identity. Hence ch remains a Σ-path. Every natural transformation between such h's induces a ladder with identity endpoint components. The forthcoming connectedness argument therefore proves compatibility inside the required path category, with the denominator condition intact.

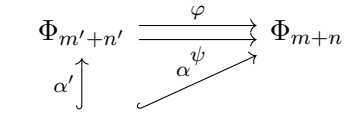
The reduction to simultaneous increments $(m, n) \mapsto (m + 1, n + 1)$ before the correction is insufficient for arbitrary independent changes of the two indices. After restriction to even indices, separate increments by two in the first or second variable generate all transitions. Grothendieck's revised formulation on this page makes exactly this repair.

p. 10
[page 15]

Les deux foncteurs composés

$$f = k \circ *_{m,n} \ , \quad g = *_{m',n'} \circ (i \times j)$$

dans le carré page 11, dont il faut prouver qu'ils sont homotopes dans $\underline{\mathrm{Hom}}(\mathcal{A}, \mathcal{B})$, peuvent être vus comme obtenus de la façon suivante, en termes de deux foncteurs



$$\varphi, \psi : \Phi_{m'+n'} \rightrightarrows \Phi_{m+n}, \tag{1}$$

d'où deux foncteurs 'transposés'

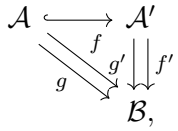
$$\underline{\mathrm{Hom}}(\Phi_{m,n}, X) \underset{G}{\overset{F}{\rightrightarrows}} \underline{\mathrm{Hom}}(\Phi_{m',n'}, X) \tag{2}$$

[plutôt Φ_{m+n}, $\Phi_{m'+n'}$] lesquels foncteurs 'induisent' f et g. De façon précise, désignant par a, b les objets source et but de Φ_{m+n}, par c l'objet qui correspond au but du chemin c de longueur m [trop de c's], à la source du chemin c' de longueur n qu'il s'agit de composer, enfin par a_0, b_0 les éléments source et but de $\Phi_{m'+n'}$, les foncteurs envisagés (1) appliquent a_0 dans a, b_0 dans b, donc définissent un diagramme commutatif

(3)

$\varepsilon = \{a_0, b_0\}$.
catégorie discrète

Ceci dit, la catégorie but $\mathcal{B}$ pour f, g, à savoir $\underline{\mathrm{Ch}}_{\Sigma,m'+n'}(X; x, z)$, s'interprète comme la sous-catégorie pleine de $\underline{\mathrm{Hom}}(\Phi_{m+n}, X)$ formée



des foncteurs $c' : \Phi_{m'+n'} \longrightarrow X$ dont le composé avec α' est le foncteur [page 16]

$$\beta : \varepsilon \longrightarrow X \qquad \begin{matrix} a_0 \longrightarrow x \\ b_0 \longrightarrow z, \end{matrix} \tag{$*$}$$

et de même la catégorie source $\mathcal{A}$ s'interprète comme la sous-catégorie pleine de $\underline{\mathrm{Hom}}(\Phi_{m+n}, X)$ formée des $c : \Phi_{m+n} \longrightarrow X$ dont la restriction à $\{a, b, c\}$ est le foncteur

$$a \longrightarrow x,\ b \longrightarrow y,\ c \longrightarrow z.$$

[plutôt $b \longrightarrow z$, $c \longrightarrow y$] Elle est contenue dans la sous-catégorie pleine $\mathcal{A}'$ des foncteurs dont la restriction à $\{a, b\}$ soit $a \longrightarrow x,\ b \longrightarrow z$, i.e. dont le composé avec α soit le foncteur $\beta : \varepsilon \longrightarrow X$ déjà envisagé ci-dessus. Ainsi les foncteurs $f, g : \mathcal{A} \rightrightarrows \mathcal{B}$ se factorisent par $\mathcal{A}'$ p. 11

foncteurs déduits de φ, ψ ci-dessus, donnant lieu aux triangles commutatifs (3), et du foncteur $\beta : \varepsilon \longrightarrow X$, de la façon dite. Pour prouver que f et g sont homotopes, il suffit de le prouver pour f', g'. Et pour ceci, il suffit de montrer que φ et ψ sont homotopes en tant qu'objets de la catégorie $\underline{\mathrm{Hom}}(\Phi_{m+n}, \Phi_{m'+n'}; \alpha)$ formée des foncteurs dont la restriction à ε est α [plutôt de la catégorie $\underline{\mathrm{Hom}}(\Phi_{m'+n'}, \Phi_{m+n}; \alpha')$ formée des foncteurs dont la restriction à ε est α'].

D'ailleurs, les deux assertions (sur f', g', quels que soient X, x, y, z, [plutôt x, z] et sur φ, ψ, α [plutôt α']) sont en fait équivalentes comme on voit en faisant $X = \Phi_{m+n}$, $x = a$, $y = c$, $z = b$ [plutôt $x = a$, $z = b$]. Ceci sera contenu dans le lemme plus général. ([4]) [page 17]

Lemme. *Soient k et l deux entiers. Alors la sous-catégorie pleine de $\underline{\mathrm{Hom}}(\Phi_k, \Phi_l)$ formée des foncteurs $\Phi_k \longrightarrow \Phi_l$ appliquant source en source, but en but, est connexe.* (NB Elle est non vide si et seulement si $k \geq l$.)

On va décrire entièrement ces foncteurs (= applications croissantes) $\Phi_k \xrightarrow{\varphi} \Phi_l$, en identifiant $\mathrm{Fl}(\Phi_k)$ [plutôt l'ensemble des flèches non identiques de Φ_k] à l'intervalle d'entiers $[1, 2k]$, et en associant à φ la partie

$$E_\varphi \subset \mathrm{Fl}(\Phi_k) = [1, 2k] \qquad E_\varphi = \{u \in \mathrm{Fl}(\Phi_k) \mid \varphi(u) \text{ une identité}\}$$

formée des $u \in \mathrm{Fl}(\Phi_k)$ qui sont 'contractées' par φ en une identité. Si E est un ensemble d'entiers, on y introduit la notion de composantes connexes (par la relation d'équivalence dans E engendrée par la relation de succession $y = x + 1$). On voit aussitôt que les composantes connnexes de E_φ qui ne contiennent ni la première ni la dernière flèche de Φ_k sont paires, et que

$$\underbrace{\mathrm{card}\,\mathrm{Fl}(\Phi_k)}_{2k} = \mathrm{card}\,(E_\varphi) + \underbrace{\mathrm{card}\,\mathrm{Fl}(\Phi_l)}_{2l},$$

Commentary · Exposition [ms. 17]

A contraction is determined by the edges it erases

Grothendieck reduces a diagrammatic homotopy problem to finite combinatorics. Number the vertices of Φ_k from 0 to $2k$, preserving their numerical order; the vertex numbered t is the original vertex $t - k$. Number the edges from 1 to $2k$. For a numerically nondecreasing endpoint-preserving functor $f : \Phi_k \to \Phi_l$, adjacent values differ by zero or one: the target has no nonidentity arrow joining nonadjacent vertices. Every noncollapsed edge advances the numerical position once. Therefore

$$f_E(t) = -l + t - \big|E \cap [1, t]\big|, \qquad 0 \leq t \leq 2k,$$

where the values are written in the original target numbering and E is the set of collapsed edges. This formula both proves uniqueness and makes the prefix and suffix observations on page 20 transparent.

4. Dans les considérations qui suivent, on considère en fait tacitement que les foncteurs envisagés sont *croissants* sur les sommets pour l'ordre de leur numérotation. Donc il faudrait écrire $\underline{\mathrm{Hom}}_{cr}$ au lieu de $\underline{\mathrm{Hom}}$, dans les énoncés qui suivent, y compris dans le lemme de connexité ci-contre.

When $l > 0$, the admissibility conditions have a direct explanation. Exactly $2l$ edges survive, so $|E| = 2(k - l)$. Between successive surviving edges, an even number of erased edges is necessary and sufficient for their alternating orientations to agree. The same condition holds at an endpoint when the initial orientations agree. If k and l have opposite parity, the initial and terminal erased runs must both be odd. The parity of the terminal run follows from the total cardinality together with the parity of all interior runs; the edition rightly inserts both conditions (a) and (b) at that point.

Conversely, these conditions make each consecutive pair $f_E(t-1), f_E(t)$ either equal or the endpoints of the correctly oriented target edge. They thus define a functor. It is surjective on objects and nonidentity arrows, because it starts at $-l$, ends at l, and advances by steps of at most one. Its only identifications are the consecutive strings of vertices joined by edges of E, so it is the stated quotient. This establishes necessity and sufficiency, not merely the numerical count.

For $l = 0$ there is one constant functor and $E = [1, 2k]$. No initial target direction exists, so the parity condition must be omitted in that case. For $k = l = 0$ the same convention gives $E = \varnothing$. Endpoint-preserving functors exist exactly when $k \geq l$: necessity follows from counting surviving edges, while sufficiency follows from the clamping functor $\Phi_k \to \Phi_l$.

The footnote's restriction to numerical monotonicity is essential for the description by E. A general functor can retrace a target edge, and its noncollapsed edges need not number $2l$. Later we prove contractibility also for the full endpoint fibre, but that stronger statement does not make the intervening classification of contractions valid without its hypothesis.

For instance, number the source vertices of Φ_3 from 0 to 6, and retain the target numbering $-1, 0, 1$ for Φ_1. The row

$$(-1, 0, -1, 0, -1, 0, 1)$$

defines an endpoint-preserving functor. At the odd-numbered source vertices, which are sources in this numbering, its value is 0; every generating arrow is therefore sent to one of the two nonidentity arrows leaving 0 in Φ_1. No edge is erased. Nevertheless the difference in the indices is $3 - 1 = 2$, so the proposed cardinality would be four. This example isolates the precise role of the footnote: endpoint preservation is sufficient for the later contractibility theorem, but it is insufficient for this particular description by a set of contractions.

i.e. [page 18]

$$\operatorname{card}(E_\varphi) = 2(k - l).$$

Il est immédiat qu'un foncteur φ est surjectif sur les objets et sur les flèches, donc identifie p. 12
Φ_l à une catégorie quotient de Φ_k - et la relation d'équivalence dans Φ_k définie par φ est celle obtenue en identifiant tous les objets qui sont source ou but de flèches d'une même composante connexe I de E_φ

$$\cdots \longleftarrow \underbrace{\longrightarrow \longleftarrow \longrightarrow \longleftarrow}_{I} \longrightarrow \cdots$$

et les flèches dans cette composante à l'identité correspondante. Les conditions énoncées sur E (indépendamment d'un φ qui lui donnerait naissance assurent que la catégorie quotient est isomorphe (avec *préservation* de source et de but) soit à Φ_l, soit à la duale $\Psi_l = \Phi_l^o$, suivant la direction de la première flèche de $\bar{\Phi}_k$ (quotient de Φ_k). Cette 'direction initiale' est la même que celle pour Φ_k si la première flèche de Φ_k n'appartient pas à E, ou bien si elle y appartient et sa composante connexe dans E est de cardinal pair. Dans le cas inverse ($u \in E$ et sa composante connnexe dans E est de cardinal impair), la direction initiale de $\bar{\Phi}_k$ est opposée à celle de Φ_k.

On voit donc que E doit satisfaire encore à une condition supplémentaire, pour que le [page 19]
$\bar{\Phi}_k$ correspondant soit isomorphe à Φ_l, i.e. pour que E provienne d'un foncteur φ. Je résume toutes les conditions

a) $\operatorname{card} E = 2(k - l)$.

b) Les composantes connexes de E qui ne contiennent pas de flèche initiale ou finale sont de cardinal pair.

c) Si Φ_k et Φ_l ont même direction initiale (k et l de même parité), alors l'éventuelle composante de E contenant la flèche initiale doit être elle aussi de cardinal pair (ce

qui, à cause de a) [plutôt a) et b)], équivaut à la même condition pour l'éventuelle composante connexe contenant la flèche finale de Φ_k). Si Φ_k et Φ_l ont des directions initiales différentes, il faut que la flèche initiale de Φ_k appartienne à une composante connexe de cardinal *impair* de E (ce qui équivaut à itou pour la flèche finale).

D'autre part, le foncteur φ est uniquement déterminé par la connaissance de E, car il y a un *unique* isomorphisme $\bar{\Phi}_k \xrightarrow{\sim} \Phi_l$ compatible avec sources et buts, à cause du

Lemme (immédiat) : *Un automorphisme de Φ_l qui est l'identité sur l'objet source (ou sur l'objet but) est l'identité partout.*

Les foncteurs φ, ψ de tantôt correspondaient au choix, l'un de $E_\varphi = \{1, 2, k-1, k\}$ [plutôt $E_\varphi = \{1, 2, 2k-1, 2k\}$], l'autre de $E_\psi = \{1, 2, i, i+1\}$, 2 composantes connexes dans un cas, trois [plutôt deux] dans l'autre.) [page 20]

Dans le cas général, il y a lieu d'expliciter la relation d'ordre de l'ensemble $\underline{\mathrm{Hom}}^!(\Phi_k, \Phi_l)$ p. 13 (! signifie : compatible avec source et but), en termes des ensembles représentatifs E_φ, E_ψ. Je ne vais pas expliciter cette relation d'ordre, mais seulement une propriété de celle-ci qui nous sera suffisante. Soit φ_E le foncteur défini par une partie $E \subset [1, 2k]$. Tout d'abord :

Lemme 1 (immédiat) : *Soient $E, E' \subset [1, 2k]$ admissibles, et soit $j \in [1, 2k]$ tel que $E \cap [1, j] = E' \cap [1, j]$. Alors φ_E et $\varphi_{E'}$ coïncident sur le but de u_j (j une flèche de Φ_k) et sur tous les objets de Φ_k antérieurs à celle-ci (au sens de la numérotation des objets, et non de la relation d'ordre de la catégorie Φ_k bien sûr.) Dualement, si $E \cap [j, 2k] = E' \cap [j, 2k]$, alors φ_E et $\varphi_{E'}$ coïncident sur la source de y, et sur tous les objets de Φ_k postérieurs à celui-ci.*

Considérons maintenant une partie connexe I de E (pas forcément une composante connexe), $I = [r, s] \subset [1, 2k]$ (r le plus petit élément de I, s son plus grand élément) et supposons que

a) card$I$ est pair (i.e. $s - r$ est pair) [plutôt $s - r$ impair]

b) $r \neq 1$, et $r - 1 \notin E$ (i.e. $r - 1 \in [1, 2k] \backslash E$)

et soit

$$E' = (E \backslash \{s\}) \cup \{r-1\} = E \backslash I \cup \overbrace{[r-1, s-1]}^{I'}$$

déduit de I en 'translatant' sur la gauche d'un cran.

Il est immédiat que si E est admissible, E' aussi (et inversement). Ceci dit, on a le [page 21]

Lemme 2. *E et E' étant comme ci-dessus, il existe une homomorphisme de foncteurs entre φ_E et $\varphi_{E'}$* (je ne dis pas dans quel sens va la flèche!).

Corollaire. Énoncé dual, quand E' est déduit de E en translatant à droite d'un cran un intervalle connexe de longueur paire $I = [r, s]$ de E, $s \neq 2k$ et $s + 1 \notin E$.

En effet, dans ce cas E est déduit de E' par une opération du type explicité dans le lemme 2.

La connexité de la catégorie $\underline{\mathrm{Hom}}^!(\Phi_k, \Phi_l)$ est maintenant claire. Si k et l ont même parité, en poussant les composantes connexes de E vers la gauche, on écrit E sous la forme 'normale'

$$E_0 = [1, 2(k-l)].$$

Si k et l sont de parité inverse, on ne peut pousser toute la composante connexe de E qui contient l'élément dernier $2k$, car elle est de cardinal impair. Il faut laisser $2k$ dans E et pousser le reste, et on ramène E à la forme normale

$$E_0 = [1, 2(k-l)-1] \cup \{2k\}.$$

Commentary · Exposition [ms. 21]

Sliding an even block gives a natural transformation

Grothendieck's elementary move explains why different padding conventions become equivalent. The formula just obtained gives a short proof of the move, including the natural transformation he leaves implicit. Suppose $I = [r, s] \subset E$ has even cardinality, $r > 1$, and $r - 1 \notin E$, and put $E' = (E \setminus \{s\}) \cup \{r - 1\}$. Then

$$|E' \cap [1, t]| - |E \cap [1, t]| = \begin{cases} 1, & r - 1 \le t \le s - 1, \\ 0, & \text{otherwise.} \end{cases}$$

The map f_E is constant, say equal to a, on the vertices $r - 1, \dots, s$, because all intervening edges belong to E. Thus $f_{E'}$ differs from f_E only by replacing a with $a - 1$ at the vertices $r - 1, \dots, s - 1$. These two target vertices are joined by one arrow. Its orientation determines a natural transformation in one direction between the two functors; outside the displayed interval its components are identities. Naturality is automatic in a poset once the component inequalities hold.

The endpoints are unchanged, since $r - 1 > 0$ and $s - 1 < 2k$. Admissibility is preserved: removing an even initial block from a collapsed run preserves the parity of its remainder, and translating that even block preserves the parity of every run it meets. The initial and terminal parity conditions are therefore unchanged. This also proves the right-moving version by reversing the move.

Repeated left-moving operations terminate: the sum of the indices in E strictly decreases at each move. If the endpoint orientations agree, every collapsed run is even and all runs can be joined to the leftmost one, yielding $[1, 2(k - l)]$. If they disagree, the initial and terminal runs are odd. Keep the final edge $2k$ in place and move the remaining even part of the final run, together with the interior runs, to the left. The normal form is

$$[1, 2(k - l) - 1] \cup \{2k\}.$$

Each move is a morphism in one of the two directions, so every object is connected to the same normal form. This is a proof of connectedness, which is all the composition argument needs.

For example, with $k = 4, l = 2$, the set $E = \{1, 2, 7, 8\}$ successively becomes $\{1, 2, 6, 7\}$, $\{1, 2, 5, 6\}$, $\{1, 2, 4, 5\}$, and $\{1, 2, 3, 4\}$. The associated functors form a zigzag of four natural transformations relative to the endpoints. This gives a visible instance of the homotopy comparing padding at an exterior end with padding near a join. The proof does not assert that there is always one natural transformation between the original two functors.

cqfd!

Ce qui précède justifie notre raisonnement, qui donnait par composition des chemins des p. 14
applications de composition bien définies

$$\underbrace{\mathrm{Hom}_\Sigma(x,y)}_{=\pi_0\underline{\mathrm{Ch}}_\Sigma(x,y)} \times \underbrace{\mathrm{Hom}_\Sigma(y,z)}_{=\pi_0\underline{\mathrm{Ch}}_\Sigma(y,z)} \longrightarrow \underbrace{\mathrm{Hom}_\Sigma(x,z)}_{=\pi_0\underline{\mathrm{Ch}}_\Sigma(x,z)}.$$

Je dis que cette composition est associative. Ceci résulte du fait que si on a trois chemins [page 22]
(d'indices *pairs*!)

$$x \xrightarrow{c} y \xrightarrow{c'} z \xrightarrow{c''} t,$$

on a (sans avoir à effectuer des homotopies …) associativité stricte

$$c''(c'c) = (c''c')c.$$

Je dis qu'il y a des identités. On définit

$$1_x \in \mathrm{Hom}_\Sigma(x, x)$$

par le chemin d'indice 0 (qui est pair!), i.e. par le diagramme réduit à x, sans flèche (ou si on veut interpréter le diagramme comme un foncteur $e \longrightarrow X$, il y a la flèche identique sous-entendue). Nos raisonnements n'excluaient pas le cas $n = 0$ ou $m = 0$, et il est tautologique

que pour un chemin

$$x \xrightarrow{c} y$$

on a

$$c \cdot 1_x = 1_y \cdot c = c.$$

Donc on a bien défini une catégorie, que je vais appeler X_Σ. Ja vais définir un foncteur canonique

$$\theta : X \longrightarrow X_\Sigma$$

qui sera l'identité sur les objets, il faut le définir sur les flèches

$$\mathrm{Hom}_X(x, y) \longrightarrow \mathrm{Hom}_{X_\Sigma}(x, y) = \pi_0 \mathrm{Ch}_\Sigma(x, y)$$

[plutôt $\pi_0 \underline{\mathrm{Ch}}_\Sigma(x, y)$]. Malheureusement, une flèche

$$x \xrightarrow{u} y$$

ne peut s'interpréter directement comme un chemin à notre sens, il faut payer nos fuites! Mais on va à une telle flèche associer le chemin [page 23]

$$x \longrightarrow y \xleftarrow{\mathrm{id}} y \xrightarrow{\mathrm{id}} y \xleftarrow{\mathrm{id}} y,$$

élément de $\underline{\mathrm{Ch}}_{\Sigma,2}(x, y)$, ce qui définit l'application cherchée. Il faut vérifier la compatibilité avec les identités et sous la composition. À la flèche $1_x : x \longrightarrow x$ est associé l'élément de p. 15
$\Phi_2(x, x)$

$$x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x,$$

il faut prouver que dans $\pi_0(\underline{\mathrm{Ch}}_{\Sigma,2}(x, x))$ il devient égal à l'élément déduit de $1_x \in \Phi_{\Sigma,0}(x, x)$, par le foncteur de transition. Mais cet élément n'est autre justement que

$$x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x,$$

c'est le même (sans avoir même à passer au π_0)!

Commentary · Examples [ms. 22]

A denominator set need not be closed under composition

Grothendieck's use of arbitrarily long paths is already visible in the simplest one-object example. Let X have one object and endomorphism monoid $(\mathbf{N}, +)$, writing its generator multiplicatively as t. Take

$$\Sigma = \{1, t\}.$$

This contains the identity but is not closed under composition: $t^2 \notin \Sigma$. A backwards edge may carry t, but not t^2. For a path c, let $a(c)$ be the sum of the exponents on its forward edges and let $b(c)$ count the backwards edges labelled t. Its evaluation is determined by the integer

$$\nu(c) = a(c) - b(c).$$

A commutative ladder with identity endpoints preserves this integer. Indeed, write each vertical component as t^{h_i} with $h_0 = h_{2n} = 0$. For a forward edge of exponent a_i, naturality gives $h_i + a_i = a_i' + h_{i-1}$; for a backwards edge the analogous equality has the horizontal exponents reversed. Summing the signed equalities cancels all the h_i, leaving $\nu(c) = \nu(c')$.

Conversely, every integer is represented. A nonnegative integer r is represented by the ordinary arrow t^r with identity padding. For $-r < 0$, concatenate r backwards copies of t, separating them by identities, then pad to an even index. The cancellation ladders below show that a forward t followed by a backwards t represents the identity, in either order. Splitting a forward t^a into a successive copies of t is allowed by the functoriality calculation for ordinary arrows. These two operations reduce any path to the representative of its signed exponent. Thus

$$\pi_0 \, \mathrm{Ch}_\Sigma(X; *, *) \cong \mathbf{Z},$$

with concatenation corresponding to addition.

The resulting localization is the one-object category of the group $\mathbf{Z}$. Its universal property says exactly that a chosen endomorphism T becomes invertible: the image of the integer r must be T^r. Negative integers require arbitrarily many backwards edges when the denominator set is the original $\{1, t\}$. Replacing it by all powers of t permits a single backwards edge to represent them, but this changes the categories of presentations. The agreement after passage to connected components is the invariant conclusion.

Pour la compatibilité avec la composition

$$x \xrightarrow{u} y \xrightarrow{v} z,$$

on a d'une part

$$x \xrightarrow{vu} z \xleftarrow{\mathrm{id}} z \xrightarrow{\mathrm{id}} z \xleftarrow{\mathrm{id}} z,$$

d'autre part

$$x \xrightarrow{u} y \xleftarrow{\mathrm{id}} y \xrightarrow{\mathrm{id}} y \xleftarrow{\mathrm{id}} y \xrightarrow{v} z \xleftarrow{\mathrm{id}} z \xrightarrow{\mathrm{id}} z \xleftarrow{\mathrm{id}} z.$$

On complète le premier chemin par dégénérescence aux deux bouts, pour le comparer au deuxième en tant qu'élément de $\underline{\mathrm{Ch}}_4(x, z)$,

$$x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x \xrightarrow{vu} z \xleftarrow{\mathrm{id}} z \xrightarrow{\mathrm{id}} z \xleftarrow{\mathrm{id}} z \xrightarrow{\mathrm{id}} z \xleftarrow{\mathrm{id}} z.$$

Commentary · Examples [ms. 23]

Two ordinary arrows and one comparison diagram

Grothendieck needs to show that sending an ordinary arrow to its padded path respects composition. This particular comparison is smaller than the general interval problem and can be completed explicitly. Let $x \xrightarrow{u} y \xrightarrow{v} z$, and regard it as a functor $T : [2] \to X$ with $T(0) = x$, $T(1) = y$, and $T(2) = z$.

Number the nine vertices of Φ_4 from 0 to 8. The concatenated path for u and v, and the padded path for vu, arise from the following functors to the ordered category [2]:

i	0	1	2	3	4	5	6	7	8
$f(i)$	0	1	1	1	1	2	2	2	2
$g(i)$	0	0	0	2	2	2	2	2	2
$h(i)$	0	0	0	1	1	2	2	2	2.

Here $h(i) = \min(f(i), g(i))$. Every row is a functor: along each forward edge its values are nondecreasing, while the values on the two ends of every backwards edge are equal. Pointwise inequalities give natural transformations

$$f \longleftarrow h \longrightarrow g.$$

Their endpoint components are identities, because all three rows take the values 0 and 2 at the two ends. Applying T produces the desired two-step ladder in $\mathrm{Ch}_{\Sigma,4}(X; x, z)$. No nonidentity arrow is placed on a backwards edge, so the proof works for any Σ containing the identities.

This calculation establishes $\theta(v)\theta(u) = \theta(vu)$ after passage to components. For identities the two diagrams already agree at the finite stage, as Grothendieck observes. Hence θ is a functor without assuming the general lemma. The display $\Delta_1 \sqcup \Delta_1 \simeq \Delta_2$ on the following manuscript page must mean amalgamation over the common object, $[1] \sqcup_{[0]} [1] \cong [2]$; the ordinary disjoint union has four objects.

The table also records why an unqualified homotopy in a functor category would be insufficient. An arbitrary map $\Phi_4 \to [2]$ may send a backwards edge to a nonidentity arrow. Its image under T would then require u, v, or vu to lie in Σ, which has not been assumed. Our three rows avoid that problem by making every backwards edge constant.

Il faut prouver que les deux sont homotopes. On a donc deux foncteurs

$$(*) \qquad f,g : \underbrace{\overbrace{\underline{\mathrm{Fl}}(X;x,y)}^{\text{catégorie discrète}} \times \overbrace{\underline{\mathrm{Fl}}(X;y,z)}^{\text{catégorie discrète}}}_{\mathcal{A}} \overset{f}{\underset{g}{\rightrightarrows}} \underbrace{\underline{\mathrm{Ch}}_{4,\Sigma}(X;x,z)}_{\mathcal{B}},$$

on veut prouver qu'ils sont homotopes. Pour ceci, on les regarde (comme tantôt) comme 'transposés' des deux foncteurs

$$\begin{array}{ccc} \mathbf{\Delta}_1 \sqcup \mathbf{\Delta}_1 \simeq \mathbf{\Delta}_2 & \underset{\psi}{\overset{\varphi}{\leftleftarrows}} & \Phi_4 \\ & \overset{\alpha}{\nwarrow} & \uparrow \alpha' \\ & & \varepsilon, \end{array}$$

vu que les catégories $\mathcal{A}$, $\mathcal{B}$ des deux membres de (*) s'interprètent comme des sous-catégories pleines de $\underline{\mathrm{Hom}}(\mathbf{\Delta}_2, X)$ et $\underline{\mathrm{Hom}}(\Phi_4, X)$ respectivement; à savoir les sous-catégories pleines formées des foncteurs dont le composé avec α resp. α' est donné par x et par z, et de plus (pour $\mathcal{A}$) dont la valeur en l'objet médian de $\mathbf{\Delta}_2$ soit y. On peut encore remplacer $\mathcal{A}$ par la sous-catégorie pleine plus grande $\mathcal{A}'$ de $\underline{\mathrm{Hom}}(\mathbf{\Delta}_2, X)$, obtenue en ignorant cette dernière condition, et il suffit de prouver que les deux foncteurs 'plus gros' p. 16

$$\mathcal{A}' \overset{f'}{\underset{g'}{\rightrightarrows}} \mathcal{B}'$$

sont homotopes. Et pour ceci, il suffit de voir encore que φ et ψ sont homotopes dans la [page 25] catégories des foncteurs $\Phi_4 \longrightarrow \mathbf{\Delta}_2$ qui sont compatibles avec la source, et le but. On voit donc que notre lemme d'homotopie de tantôt n'était pas assez général. Il faudrait définir les *catégories intervalles généralisés,* de longueur n quelconque (n = nombre de flèches bout à bout), une catégorie intervalle généralisé *standard* de longueur n a pour ensemble d'objets l'intervalle d'entiers

$$[0,n],$$

et pour tout couple d'entiers consécutifs $i-1$, i parmi les objets ($1 \leq i \leq n$), il y a exactement une flèche qui relie i, $i+1$ `[plutôt i − 1, i]`. On affecte l'intervalle $[i, i+1]$ du signe $+$ si $i \longrightarrow i+1$ (flèche en sens direct), du signe i `[plutôt −]` si $i \longleftarrow i+1$ (flèche en sens rétrograde) - donc les catégories standards sont définies, pour n fixé, par un système de signes $+$ ou $-$, dont on affecte les n 'tronçons' consécutifs $A_i := [i-1, i]$ ($1 \leq i \leq n$) de l'intervalle d'entiers $[0,n]$. Il y en a donc exactement 2^n.

On s'attend à ce que l'énoncé suivant soit vrai :

Commentary · Development (commentators') [ms. 25]

Contracting relative functor categories into an interval

Grothendieck's question asks whether the choices used to change a path's parametrization form a contractible category. We can prove a slightly more flexible statement that also accommodates the cancellation diagrams on page 27, where both endpoints have the same image. The proof uses the numerical order of an interval only to define minimum and maximum; the categorical order retains the prescribed directions of all its edges.

Relative interval contraction. [ours] Let J be the free category on an oriented path with vertices $0, \ldots, r$. Let $j : B \to A$ be a functor and $b : B \to J$ a fixed diagram. The strict fibre

$$\mathcal{F}_b = \{f : A \to J \mid fj = b\}$$

of restriction, with transformations restricting to 1_b, is either empty or categorically contractible: if $g \in \mathcal{F}_b$, its identity endofunctor is joined to the constant endofunctor at g by a finite zigzag of natural transformations. If A is itself an oriented interval and the fibre is restricted to functors

nondecreasing in the numerical vertex orders, the same assertion holds whenever that restricted fibre is nonempty.

Proof. The category J is a poset. Its order relation $a \leq_J a'$ means that the unique numerical segment between a and a' is oriented all the way from a to a'. For fixed c, each of the numerical clamping maps

$$a \longmapsto \min(a, c), \qquad a \longmapsto \max(a, c)$$

is a functor $J \to J$: the image of a directed segment is either a point or a directed subsegment with the same orientation. Consequently numerical minimum and maximum are functors $J \times J \to J$. Indeed they are order preserving in either variable separately, and a product-order comparison factors into one comparison in each variable.

Assume that $g \in \mathcal{F}_b$. For each vertex t of J define endofunctors of $\mathcal{F}_b$ by pointwise operations

$$F_t(f) = \min\bigl(f, \max(g, t)\bigr), \qquad G_t(f) = \min\bigl(g, \max(f, t)\bigr),$$

where t denotes the constant functor $A \to J$. These are functors on diagrams and on natural transformations because minimum and maximum are functors. They preserve the prescribed restriction: at an object of B, both f and g have the same value a, and

$$\min(a, \max(a, t)) = a.$$

Since J is a poset, the component of any resulting transformation at such an object is the identity. Thus the construction really stays inside the strict fibre.

Each generating arrow $t \to t'$ of J induces natural transformations $F_t \to F_{t'}$ and $G_t \to G_{t'}$. If an edge points in the opposite direction, both induced transformations point in that opposite direction. We therefore obtain finite zigzags as t runs numerically from 0 to r. At the ends,

$$F_r = 1_{\mathcal{F}_b}, \qquad F_0 = \min(-, g) = G_0, \qquad G_r = \mathrm{const}_g\,.$$

Traversing the F zigzag backwards and the G zigzag forwards contracts the identity to g. Every functor in the zigzag fixes g itself. On taking nerves and geometric realizations, natural transformations give homotopies, so $|N\mathcal{F}_b|$ is contractible as well. If $r = 0$, the nonempty fibre has one object and the conclusion is immediate.

For the numerical-monotonicity variant, the pointwise minimum or maximum of two nondecreasing numerical functions is nondecreasing, and constant functions are nondecreasing. Hence all F_t and G_t preserve the indicated full subcategory. Their restrictions give the same contraction. This completes the proof. □

The construction gives a uniform bound on the length of the contracting zigzag: there are r comparisons in the F family and r in the G family. This bound depends only on the target interval, not on the number of objects or arrows of A. In particular, no finite-source hypothesis was concealed in the proof. When $r = 1$, the contraction has the particularly transparent form

$$1_{\mathcal{F}_b} \longleftarrow \min(-, g) \longrightarrow \mathrm{const}_g$$

if the target edge points from 0 to 1; both arrows reverse if it points from 1 to 0. The fixed-boundary identity used above makes this a contraction inside the fibre even when j identifies several boundary labels. That includes the two coincident endpoint labels of an excursion.

Taking B to be the two endpoint labels proves both the proposed connectedness and the stronger contractibility of the generalized-interval functor category. Taking a fixed pair of equal endpoint values gives the version needed for an excursion followed by its return. For alternating intervals, the numerically monotone version strengthens the contraction-set argument on pages 17–21 and preserves the condition on backwards arrows when used for reparametrization.

The minimum–maximum preservation property is familiar in the theory of ordered digraphs; compare the definition of a Min–Max ordering in Hell and Rafiey (2012, p. 1577). We checked that account and the localization sources cited in this section, together with searches for relative functor categories of oriented intervals. We did not locate this fixed-restriction contraction in those sources. The result is presented as a direct continuation of the manuscript, with its full proof, and carries no claim of priority.

Lemme. *Soient I, I' deux intervalles généralisés, munis d'objets source et objet but*

(de sorte que I, I' soient canoniquement *isomorphes aux intervalles genéralisés standards correspondants). Soit* $\underline{\mathrm{Hom}}^!(I, I')$ *la catégorie des foncteurs de I dans I', compatibles avec source et but. Si cette catégorie est $\neq \emptyset$, elle est* 0*-connexe* (et, je présume, même contractile?). [page 26]

Je vais admettre provisoirement qu'il en est ainsi, du moins dans le cas particulier de Φ_4 (intervalle généralisé de longueur 8) et $\mathbf{\Delta}_2$. Cela donne donc un foncteur

$$\theta : X \longrightarrow X_\Sigma.$$

On a gagné, car la propriété universelle de ce foncteur est pratiquement évidente. Mais j'ai oublié de vérifier que θ transforme éléments de Σ en flèches inversibles. Soit donc

$$x \xrightarrow{u} y$$

avec $u \in \Sigma$, on va définir un chemin en sens inverse

$$y \xrightarrow{c} x$$

qui définira dans X_Σ une flèche inverse de u. L'idée naturelle est de prendre le 'chemin'

$$y \xleftarrow{u} x$$

de y dans x, mais ce n'est pas un chemin au sens de nos définitions, on va le compléter en

$$c : y \xrightarrow{\mathrm{id}} y \xleftarrow{u} x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x. \qquad \text{p. 17}$$

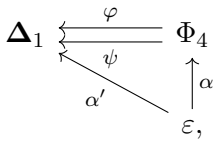
Je dis que c fait l'affaire. On doit prouver deux relations d'homotopie, de $c \cdot \bar{u}$ et de $\bar{u} \cdot c$ avec les chemins identiques en x `[resp. en` y`]` de longueur 8 (indice 4, i.e. dans $\underline{\mathrm{Ch}}_{\Sigma,4}(X; x, x)$ resp. $\underline{\mathrm{Ch}}_{\Sigma,4}(X; y, y)$), où $\bar{u}$ est le chemin associé à u

$$x \xrightarrow{u} y \xleftarrow{\mathrm{id}} y \xrightarrow{\mathrm{id}} y \xleftarrow{\mathrm{id}} y.$$

[page 27]

On a donc à regarder

$$x \xrightarrow{u} y \xleftarrow{\mathrm{id}} y \xrightarrow{\mathrm{id}} y \xleftarrow{\mathrm{id}} y \xrightarrow{\mathrm{id}} y \xleftarrow{u} x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x$$



et voir qu'il est homotope au chemin trivial

$$x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} \cdots x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x$$

(des identités partout), et itou pour

$$y \xrightarrow{\mathrm{id}} y \xleftarrow{u} x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x \xrightarrow{u} y \xleftarrow{\mathrm{id}} y \xrightarrow{\mathrm{id}} y \xleftarrow{\mathrm{id}} y$$

et le chemin trivial en y. Cette fois, on a encore deux foncteurs

compatibles avec objets sources et objets buts, et on doit prouver qu'ils sont homotopes dans $\underline{\mathrm{Hom}}^!(\Phi_4, \mathbf{\Delta}_1)$. Cela doit donc résulter du même lemme général. On a gagné - par une interprétation simple de $X\Sigma^{-1}$, et en particulier des $\mathrm{Hom}_{X\Sigma^{-1}}(x, y)$ et de leur composition, en termes de la géométrie des espaces de chemins :

$$\begin{cases} \mathrm{Hom}_{X\Sigma^{-1}} \simeq \pi_0(\underline{\mathrm{Ch}}_\Sigma(X; x, y)) \\ \text{Composition des homomorphismes dans } X\Sigma^{-1} \text{ correspond à} \\ \text{la composition des } \Sigma\text{-chemins dans } X \end{cases}$$

Commentary · Examples [ms. 27]

Cancellation uses the same endpoint twice

Grothendieck has written down the correct inverse path. The only remaining work is to make its two cancellation witnesses explicit. Let $u : x \to y$ belong to Σ, and write $T : [1] \to X$ for the corresponding functor. In the numerical ordering $0 < 1$, the first eight-edge excursion on the page is the image of the row

$$a = (0, 1, 1, 1, 1, 1, 0, 0, 0),$$

whereas the second is the image of

$$b = (1, 1, 0, 0, 0, 1, 1, 1, 1).$$

The source is Φ_4, numbered from 0 to 8. Both rows are functors: on a forward source edge the value can increase, and on a backwards edge it can decrease. Their endpoint values are respectively $(0, 0)$ and $(1, 1)$.

There are pointwise natural transformations

$$(0, 0, 0, 0, 0, 0, 0, 0, 0) \longrightarrow a, \qquad b \longrightarrow (1, 1, 1, 1, 1, 1, 1, 1, 1).$$

Applying T gives a transformation from the constant path at x to the first excursion, and one from the second excursion to the constant path at y. Their endpoint components are identities. Each horizontal backwards edge in these diagrams is either an identity or u, so it belongs to Σ. Thus both transformations are morphisms in the required Σ-path fibres, and the two cancellation identities follow immediately on π_0.

There is a small mismatch in the manuscript's invocation of the general lemma. That lemma is worded for maps taking the initial endpoint to the initial endpoint and the final endpoint to the final endpoint. These cancellation diagrams instead take both endpoints to 0, or both to 1. The relative-fibre theorem above includes them, but the two displayed transformations already prove exactly what is needed. This is a missing specification of the boundary condition, with an elementary repair, rather than a failure of localization.

Commentary · Exposition [ms. 27]

Completing the universal property

Grothendieck's path category now gives the promised localization. We record the complete conclusion because the construction uses less structure than many familiar fraction calculi.

Path presentation of ordinary localization. Let X be a small category and let Σ contain all its identity arrows. There is a canonical isomorphism of categories over X

$$X[\Sigma^{-1}] \cong X_\Sigma, \qquad \mathrm{Hom}_{X_\Sigma}(x, y) = \pi_0 \,\mathrm{Ch}_\Sigma(X; x, y),$$

where the path categories use strict endpoint fibres and composition is induced by concatenation at even indices.

Proof. The reparametrization argument proves independence of padding. More explicitly, the maps that compare padding before and after concatenation are numerically monotone endpoint-preserving functors between alternating intervals. The connectedness proved by even-block slides supplies a zigzag between them. After precomposition with a Σ-path, every backwards edge is still a backwards edge of that path or an identity. Thus the comparison is a zigzag inside the specified path category. Morphisms of the factors concatenate to morphisms of the result, so the product descends to components. Associativity follows from strict associativity of finite concatenation, after choosing common even indices; the zero-length paths give identities.

The preceding table proves that $\theta : X \to X_\Sigma$ preserves composition, and the cancellation ladders prove that it inverts Σ. Let $F : X \to Y$ invert Σ. Evaluate each finite path in Y by using F on forward arrows and inverses of $F(s)$ on backwards arrows. Identity padding leaves the result unchanged. Naturality squares, with the backwards ones inverted as above, show that endpoint-fixed ladders give equal arrows of Y. Evaluation therefore defines maps on the proposed Hom sets. It takes concatenation to composition and constant paths to identities, so it defines a functor $\overline{F} : X_\Sigma \to Y$ with $\overline{F}\theta = F$.

To prove uniqueness, one must know that a path class is the composite of its elementary arrows and inverse arrows. Pad the original path to an even index. Replace each forward arrow by its four-edge representative under θ, and each backwards arrow by the four-edge inverse representative. Concatenating these representatives gives the original list of nonidentity edges with additional identities inserted. It is the pullback of the original path by a numerically monotone contraction from a larger alternating interval. The usual end-padding is another such pullback. The two contractions belong to the same connected endpoint-preserving category, so the two paths have the same component. Hence every path class is the required composite, and any extension of F must evaluate it as $\overline{F}$ does.

Thus θ has the defining universal property of localization. Applying the two universal properties gives inverse functors between X_Σ and $X[\Sigma^{-1}]$ that agree with the identity on X. Their composites are identities by uniqueness. □

The proof explains the exact status of the manuscript: its principal theorem is correct, and its proof becomes complete after the endpoint-fibre convention, the even-index repair already made by the author, and the supplied interval comparisons. No Ore condition or closure of Σ under composition has entered.

Commentary · Later developments [ms. 27]

From components of path categories to mapping spaces

Grothendieck has recovered a set of morphisms by taking connected components of a category of presentations. The next question is whether one can retain higher homotopy information and compose it coherently. The relevant historical comparison already existed before these notes: the two papers of Dwyer and Kan appeared in 1980.

Their standard simplicial localization has the ordinary localization as its category of components (Dwyer and Kan, 1980c, §4.2). The hammock construction gives a more diagrammatic model: its simplices are commutative ladders of variable length, with all vertical arrows and all leftward horizontal arrows in the chosen subcategory of weak equivalences. Composition is concatenation followed by reduction (Dwyer and Kan, 1980a, Definition 2.1 and Proposition 3.1). These are close relatives of the present paths, but the vertical-arrow requirement is different: Grothendieck permits arbitrary vertical arrows. Therefore the formula for π_0 proved here does not itself identify the nerve of his path category with a derived mapping space.

There is also a preliminary distinction in the input data. The classical Dwyer–Kan construction starts with a subcategory W containing all objects, whereas the present Σ need contain only identities. To compare the two ordinary localizations one may take W to be the subcategory generated by Σ: every functor inverting Σ inverts its finite composites, and the converse is immediate. This proves equality of their universal properties. It does not identify the intervening categories of paths. The example with $\Sigma = \{1, t\}$ above shows concretely how adjoining composite denominators changes the allowed horizontal presentations before any homotopy comparison is proved.

The comparison becomes sharper under additional hypotheses. A homotopy calculus of fractions allows certain short zigzag categories to compute hammock mapping spaces; the exact reduction results are Dwyer and Kan (1980a, Proposition 6.2). Their hypotheses concern the homotopy types of diagram categories, not just the existence of short ordinary fractions. Consequently a reduction that is sufficient for Hom sets need not preserve all higher homotopy groups.

One elementary check shows the difference in what is being sought. If every arrow of a category X is inverted, the ordinary localization records only its groupoid completion. A higher localization retains the homotopy type of the classifying space: in the connected case the mapping spaces have the homotopy type of its loop space (Dwyer and Kan, 1980c, §5.5). Take the poset of nonempty proper faces of a tetrahedron: its nerve is the barycentric subdivision of the boundary sphere S^2. Its groupoid completion is equivalent to the terminal groupoid, since the sphere is connected and simply connected, while the higher endomorphism space has the nontrivial homotopy type ΩS^2. This example does not decide the homotopy type of Grothendieck's particular path category; it explains why agreement on its components is only the first comparison one would require.

The later development of simplicial and higher localizations gives a precise home for the ambition of retaining those spaces of presentations. It does not retroactively turn every category of zigzags into the same model. The admissible horizontal arrows, the vertical arrows, the allowed reparametrizations, and the endpoint conditions are part of the theorem to be proved.

p. 18

[page 28]

3 Passage aux catégories de diagrammes

Nous aurions dû noter la catégorie $X\ \mathcal{M}$, car par la suite elle jouera le rôle d'une 'catégorie de modèles'. On désignera par contre par X les 'catégories d'indices' sur lesquelles on veut construire les 'catégories de diagrammes' de type X

$$\mathcal{M}(X) = \underline{\mathrm{Hom}}(X, \mathcal{M}).$$

On se donne donc

$$\underbrace{\Sigma}_{\text{quasi-isomorphismes}} \subseteq \mathrm{Fl}(\mathcal{M}), \qquad \Sigma \supset \text{ensemble des flèches identiques},$$

et pour toute catégorie X on définit

$$\Sigma_X \subset \mathrm{Fl}\,\mathcal{M}(X)$$

ainsi: si $F, G \in \mathrm{Ob}\,\mathcal{M}(X)$ $(F, G : X \rightrightarrows \mathcal{M})$, une flèche $u : F \longrightarrow G$ (homomorphisme de foncteurs) est dans Σ_X si et seulement si $\forall x \in X$, $u(x) : F(x) \longrightarrow G(x)$ est dans Σ ('critère de quasi-isomorphie fibre par fibre', pour l'homomophisme entre les copréfaisceaux F, G envisagés).

Commentary · Exposition [ms. 28]

The parameter is a diagram shape

Grothendieck now asks the path construction to do more than compute a single localized Hom-set. He wants the same calculation after replacing the coefficient category by every category of diagrams. This is the point at which a category of paths begins to behave like an external Hom: its test objects are the indexing categories themselves. The change of letters is deliberate. In this section $\mathcal{M}$ supplies coefficients, whereas X is allowed to vary as a parameter.

There is no model-category structure in the hypotheses. We have a category $\mathcal{M}$ and a class Σ containing the identities; for the localization calculation even closure of Σ under composition is unnecessary. One may enlarge Σ to the subcategory it generates without changing the localization. We work in fixed universes, so that the localizations and the Hom-sets under discussion exist in the chosen larger universe. The designation "quasi-isomorphism" means membership in this specified class, rather than a statement about chain complexes.

Write $\mathcal{M}^X = \mathrm{Fun}(X, \mathcal{M})$ and let Σ_X consist of natural transformations whose components belong to Σ. Restriction along $f : X \to Y$ preserves these transformations and therefore induces

$$f^* : \mathcal{M}^Y[\Sigma_Y^{-1}] \longrightarrow \mathcal{M}^X[\Sigma_X^{-1}].$$

The two objects of special interest are the constant diagrams a_X, b_X. Thus the functor to be understood is

$$H_{a,b}(X) = \mathrm{Hom}_{\mathcal{M}^X[\Sigma_X^{-1}]}(a_X, b_X), \qquad H_{a,b} : \mathrm{Cat}^{\mathrm{op}} \to \mathrm{Ens}.$$

These are constant diagrams before localization. We are not replacing an arbitrary diagram by its values in $\mathcal{M}[\Sigma^{-1}]$; that would discard precisely the coherent information retained in Chapters I and II. See the commentary on Chapter I, manuscript p. 13 ("Localizing diagrams and deriving their Kan extensions") for that distinction.

For a fixed finite path shape Φ_n, the elementary exponential law

$$\mathrm{Fun}(\Phi_n, \mathrm{Fun}(X, \mathcal{M})) \cong \mathrm{Fun}(X, \mathrm{Fun}(\Phi_n, \mathcal{M}))$$

already contains the calculation. Its objects agree because both sides are functors $X \times \Phi_n \to \mathcal{M}$; its arrows agree because both sides are natural transformations of such functors. The restrictions on backward arrows are checked at each object of X, and the restrictions on the endpoints are also objectwise. The difficulty is therefore not the exponential law. It is the passage from one finite path shape to all path lengths, where one must retain a uniform bound.

Soient

$$a, b \in \mathrm{Ob}\,\mathcal{M}$$

et considérons les foncteurs constants correspondants sur X

$$a_X, b_X \in \mathrm{Ob}\,\mathcal{M}(X).$$

On se propose d'appliquer la théorie du §2 au 'calcul' de [page 29]

$$\mathrm{Hom}_{\Sigma_X}(a_X, b_X),$$

on a donc une bijection canonique

$$\boxed{\mathrm{Hom}_{\Sigma_X}(a_X, b_X) \simeq \pi_0 \underline{\mathrm{Ch}}_{\Sigma_X}(\mathcal{M}(X); a_x, b_x).}$$

On se propose d'expliciter la catégorie de chemins du second membre. On a, abstraction faite des données de Σ, a, b dans $\mathcal{M}$, l'expression pour la catégorie de *tous* les chemins dans $\mathcal{M}(X)$ p. 19

$$\begin{aligned}
\underline{\mathrm{Ch}}(\mathcal{M}(X)) &\simeq \underline{\mathrm{Hom}}\Big(\underbrace{\mathbf{\Phi}}_{\substack{\text{pro-catégorie}\\(\Phi_n)_{n\in\mathbf{N}}}}, \underbrace{\mathcal{M}(X)}_{\underline{\mathrm{Hom}}(X,M)}\Big) \\
&\overset{\text{déf}}{=} \varinjlim_n \underline{\mathrm{Hom}}(\Phi_n, \mathcal{M}(X)) \\
&\simeq \varinjlim_n \underline{\mathrm{Hom}}(\Phi_n \times X, \mathcal{M}) \\
&\simeq \varinjlim_n \underline{\mathrm{Hom}}(X, \underline{\mathrm{Hom}}(\Phi_n, \mathcal{M})) \\
&\overset{\text{déf}}{=} \varinjlim_n \underline{\mathrm{Hom}}(X, \underline{\mathrm{Ch}}_n(\mathcal{M})) \\
&\simeq \underline{\mathrm{Hom}}^!(X, \underline{\mathrm{Ch}}(\mathcal{M})),
\end{aligned}$$

où le signe ! signifie qu'on prend la sous-catégorie pleine des foncteurs

$$X \longrightarrow \underline{\mathrm{Ch}}(\mathcal{M}),$$

qui se factorisent par une des sous-catégories pleines $\underline{\mathrm{Ch}}_n(\mathcal{M})$. On peut dire aussi que si on [page 30] considère le système inductif des catégories $\underline{\mathrm{Ch}}_n(\mathcal{M})$ comme un ind-objet de Cat, qu'on va noter

$$\underline{\underline{\mathrm{Ch}}}(\mathcal{M}) \qquad\qquad \text{ind-objet de Cat,}$$

on a

$$\underline{\mathrm{Ch}}(\mathcal{M}(X)) \xrightarrow{\sim} \underline{\mathrm{Hom}}(X, \underline{\underline{\mathrm{Ch}}}(\mathcal{M})).$$

Si on en vient à Σ, Σ_X, on trouve aussitôt qu'un chemin dans $\mathcal{M}(X)$ est un Σ_X-chemin, si et seulement si le foncteur correspondant $X \longrightarrow \underline{\mathrm{Ch}}(\mathcal{M})$ se factorise par $\underline{\mathrm{Ch}}_\Sigma(\mathcal{M})$. Ainsi on trouve

$$\underline{\mathrm{Ch}}_{\Sigma_X}(\mathcal{M}(X)) \simeq \underline{\mathrm{Hom}}^!(X, \underline{\mathrm{Ch}}_\Sigma(\mathcal{M})),$$

où le signe ! a le même sens que plus haut. Si on introduit le ind-objet $\underline{\underline{\mathrm{Ch}}}_\Sigma(\mathcal{M})$ défini par les $\underline{\mathrm{Ch}}_{\Sigma,n}(\mathcal{M})$, on trouve donc aussi

$$\underline{\mathrm{Ch}}_{\Sigma_X}(\mathcal{M}(X)) \xrightarrow{\sim} \underline{\mathrm{Hom}}(X, \underline{\underline{\mathrm{Ch}}}_\Sigma(\mathcal{M})).$$

Commentary · Exposition [ms. 30]

Why the exclamation mark is necessary

Grothendieck introduces the exclamation mark to remember that a path of diagrams has one length for the entire diagram. An object of $\mathrm{Fun}(X, \mathrm{Ch}_\Sigma(\mathcal{M}))$ may assign a finite path to every $x \in X$ without these lengths being bounded as x varies. Such a functor need not come from a path in $\mathcal{M}^X$. This is a genuine distinction even before taking connected components or weak equivalences.

Let K_n denote the fixed-endpoint path category at stage n, using the fully faithful identity-padding inclusions, and put $K_\infty = \bigcup_n K_n$. Then

$$\mathrm{Fun}^!(X, K_\infty) = \bigcup_n \mathrm{Fun}(X, K_n)$$

is the full subcategory on bounded functors. Fullness deserves a verification. If F and G factor through K_n, every component of a natural transformation $F \Rightarrow G$ lies in K_n, because $K_n \subseteq K_\infty$ is full. Its naturality equations are the same equations in either category. Thus no additional bound is needed for arrows between already bounded objects.

The failure for an infinite source can be seen without any homotopy theory. Take K_n to be the discrete category on $\{0, \dots, n\}$ and X the discrete category on $\mathbf{N}$. The functor $x \mapsto x$ from X to K_∞ lies in no $\mathrm{Fun}(X, K_n)$. It cannot even be isomorphic to a bounded functor, since the target is discrete. The ind-object (K_n) records a uniform finite stage which the ordinary union has forgotten.

Connected components do commute with the filtered union used here. A component of the union has a representative object at some stage. If two objects become connected, a finite zigzag of arrows witnesses this, and all its objects and arrows occur at one sufficiently large stage. This proves directly that

$$\varinjlim_n \pi_0 \,\mathrm{Fun}(X, K_n) \xrightarrow{\sim} \pi_0 \left(\varinjlim_n \mathrm{Fun}(X, K_n) \right).$$

Nothing in this argument permits one to replace the category inside the final parentheses by the unrestricted functor category. The exclamation mark and the double underline serve the same purpose: the first describes bounded functors, while the second retains the system of bounds as an ind-object.

[page 31]

Soit c un chemin dans $\mathcal{M}(X)$, et

$$X \longrightarrow \underline{\mathrm{Ch}}(\mathcal{M})$$

le foncteur qu'il définit, composons-le avec les foncteurs source-but

$$\underline{\mathrm{Ch}}(\mathcal{M}) \longrightarrow \mathcal{M} \times \mathcal{M},$$

on trouve un foncteur

$$X \longrightarrow \mathcal{M} \times \mathcal{M},$$

i.e. un objet (F_0, F_1) de $\mathcal{M}(X) \times \mathcal{M}(X)$. Je dis que F_0 et F_1 sont respectivement la source et le but du chemin c. De façon un peu plus précise, on a commutativité (stricte) dans le diagramme de foncteurs p. 20

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{\Sigma_X}(\mathcal{M}(X)) & \xrightarrow{\sim} & \underline{\mathrm{Hom}}^!(X, \underline{\mathrm{Ch}}_\Sigma(\mathcal{M})) \\ \downarrow{\scriptstyle \sigma_{\mathcal{M}(X)}, \beta_{\mathcal{M}(X)}} & & \downarrow{\scriptstyle \text{déduit de } \sigma_{\mathcal{M}}, \beta_{\mathcal{M}}} \\ \mathcal{M}(X) \times \mathcal{M}(X) & \xrightarrow{\sim} & \underline{\mathrm{Hom}}(X, \mathcal{M} \times \mathcal{M}), \end{array}$$

où les foncteurs σ sont les foncteurs source, les foncteurs β les foncteurs but.

Si on se donne arbitrairement les objets F_0, F_1 dans $\mathcal{M}(X)$, donc un foncteur

[page 32 vide]

$$X \longrightarrow \mathcal{M} \times \mathcal{M},$$ [page 33]

$\underline{\mathrm{Ch}}_{\Sigma_X}(F_0, F_1)$ s'identifie donc à la catégorie des foncteurs 'admissibles' (i.e. se factorisant par un $\underline{\mathrm{Ch}}_{\Sigma,n}(\mathcal{M})$) $X \xrightarrow{C} \underline{\mathrm{Ch}}_{\Sigma}(\mathcal{M})$ qui *relèvent* le foncteur $(\sigma_{\mathcal{M}}, \beta_{\mathcal{M}})$ `[plutôt` (F_0, F_1)`]` précédent, i.e. qui donnent lieu à un triangle commutatif (strict)

$$\begin{array}{ccc} & & \underline{\mathrm{Ch}}_{\Sigma}(\mathcal{M}) \\ & \overset{C}{\nearrow} & \big\downarrow {\scriptstyle (\sigma_{\mathcal{M}}, \beta_{\mathcal{M}})} \\ X & \xrightarrow[(F_0,F_1)]{} & \mathcal{M} \times \mathcal{M}. \end{array}$$

Mais si les foncteurs F_0, F_1 sont constants, de valeur a, b comme tantôt, i.e. (F_0, F_1) constant de valeur (a, b), alors la catégorie des foncteurs C en question est tautologiquement isomorphe à celle des foncteurs de X dans la fibre de $(\sigma_{\mathcal{M}}, \beta_{\mathcal{M}})$ en (a, b), d'où l'isomorphisme de catégories fondamental

$$\boxed{\underline{\mathrm{Ch}}_{\Sigma_X}(X; a_X, b_X) \simeq \underline{\mathrm{Hom}}^{!}(X, \underline{\mathrm{Ch}}_{\Sigma}(\mathcal{M}; a, b)).}$$

On va expliciter le contenu essentiel de cette formule en une

Commentary · Exposition [ms. 33]

The precise meaning of ind-representation

The scholium isolates what survives every arbitrary choice in the path calculation. If Cat hot denotes the category with small categories as objects and

$$\mathrm{Hom}_{\mathrm{Cat\,hot}}(X, Y) = \pi_0 \,\mathrm{Fun}(X, Y),$$

then the result says that $H_{a,b}$ is a filtered colimit of representable presheaves on Cat hot. The homotopy relation in this formula is generated by natural transformations, with arrows in either direction. Composition is well defined because whiskering preserves natural transformations.

For clarity, the fully faithful embedding of ind-objects in presheaves can be proved in the notation needed here. To an ind-object $K = (K_i)$ of a locally small category C associate

$$h_K(X) = \varinjlim_i \mathrm{Hom}_C(X, K_i).$$

If $L = (L_j)$ is another ind-object, Yoneda and the universal property of a colimit give

$$\mathrm{Nat}(h_K, h_L) \cong \varprojlim_i \mathrm{Nat}(h_{K_i}, h_L) \cong \varprojlim_i \varinjlim_j \mathrm{Hom}_C(K_i, L_j) = \mathrm{Hom}_{\mathrm{Ind}(C)}(K, L).$$

The limits and colimits occur in that order. No interchange theorem has been used. A natural isomorphism of the presheaves consequently gives a unique isomorphism of the corresponding ind-objects, compatible with the specified representations. This is the exact sense of the uniqueness statement on manuscript p. 34.

To obtain the scholium, apply the preceding path-localization theorem inside $\mathcal{M}^X$, then apply the exponential law with fixed endpoints, and finally commute π_0 with the filtered union. This yields

$$H_{a,b}(X) \cong \varinjlim_n \mathrm{Hom}_{\mathrm{Cat\,hot}}(X, K_n) = h_{(K_n)}(X).$$

The notation in the boxed formula just before the scholium has X where the ambient path category should be $\mathcal{M}(X)$; the edition prints this slip. The preceding endpoint square determines the intended meaning unambiguously.

The result has a useful limit. It gives uniqueness in Ind(Cat hot), not uniqueness of the ordinary union K_∞ in Cat hot. A colimit of a chosen sequence of actual categories contains information about the representatives and their compatibility which an ind-object in a homotopy category need not retain. The questions at the end of the chapter begin exactly at this boundary.

Scholie. Soient $\mathcal{M}$ une catégorie avec un ensemble Σ de flèches de localisation, $a, b \in \mathrm{Ob}\,\mathcal{M}$. Alors on peut trouver un objet $\underline{\underline{K}} = K(a, b)$, $K = (K_n)$, de Ind Cat (indexé par $\mathbf{N}$ mais

peu importe ce fait), et un isomorphisme canonique pour toute catégorie X (isomorphisme fonctoriel en X)

$$\begin{aligned}\mathrm{Hom}_{\Sigma_X}(a_X, b_X) &\simeq \pi_0(\underline{\mathrm{Hom}}(X, \underline{\underline{K}}))\\ &\overset{\text{déf}}{=} \pi_0(\varinjlim \underline{\mathrm{Hom}}(X, K_n))\\ &\simeq \varinjlim \pi_0(\underline{\mathrm{Hom}}(X, K_n)).\end{aligned}$$

Je vais épiloguer sur ce résultat, sans me soucier pour l'instant de la façon particulière dont la ind-catégorie K [plutôt $\underline{\underline{K}}$] a été obtenue en termes de $\mathcal{M}$, Σ, a, b. p. 21 [page 34]

Comme les $\pi_0\underline{\mathrm{Hom}}(X, K_n) = \mathrm{Hom}_{\mathrm{Cat\,hot}}(X, K_n)$ ne dépendent que de X et de K_n en tant qu'objets de Cat hot, je vais interpréter $\underline{\underline{K}}$ comme un ind-objet de Cat hot, et écrire la formule fondamentale sous la forme

$$\mathrm{Hom}_{\Sigma_X}(a_X, b_X) \simeq \mathrm{Hom}_{\mathrm{Ind\,Cat\,hot}}(X, \underline{\underline{K}}).$$

Ainsi, l'énoncé du scholie implique deux choses :

a) Le contrafoncteur $X \longmapsto \mathrm{Hom}_{\Sigma_X}(a_X, b_X)$ sur Cat se factorise canoniquement par Cat hot, via un foncteur canonique

$$\mathrm{Cat\,hot}^o \xrightarrow{H = H^{\mathcal{M},\Sigma}_{a,b}} \mathrm{Ens}\ ;$$

b) Ce dernier contrafoncteur sur Cat hot est *ind-représentable* par un ind-objet $\underline{\underline{K}}$ de Cat hot.

C'est cet ind-objet de Cat hot qui est défini à isomorphisme unique près par $\mathcal{M}$, Σ, a, b, indépendamment de tout artifice de calcul pour expliciter les $\mathrm{Hom}_{\Sigma_X}(a_X, b_X)$.

Notons aussi la conclusion suivante, nullement évidente à priori :

Notons d'abord (ceci étant implicite dans le scholie) que toute flèche dans Cat [page 35]

$$X \xrightarrow{f} Y$$

définit

$$\mathcal{M}(Y) \xrightarrow{\mathcal{M}(f)} \mathcal{M}(X) \qquad \text{appliquant } \Sigma_Y \text{ dans } \Sigma_X,$$

d'où

$$\mathcal{M}(Y)\Sigma_Y^{-1} \overset{\text{déf}}{=} \mathbf{D}_{\mathcal{M},\Sigma}(Y) \longrightarrow \mathcal{M}_X\Sigma_X^{-1} = \mathbf{D}_{\mathcal{M},\Sigma}(X),$$

[plutôt $\mathcal{M}(X)$] d'où, pour tout $a, b \in \mathrm{Ob}\,\mathcal{M}$, vu que $\mathcal{M}(f)$ transforme a_Y, b_Y en a_X, b_X :

$$\boxed{\mathrm{Hom}_{\Sigma_Y}(a_Y, b_Y) \longrightarrow \mathrm{Hom}_{\Sigma_X}(a_X, b_X).}$$

Ceci posé, on a :

Corollaire : *Si f est un homotopisme, alors quelque soient $a, b \in \mathcal{M}$, la flèche précédente est un isomorphisme.*

La question naturelle, c'est de savoir si la même conclusion est encore valable, en supposant seulement que f soit un '*quasi-isomorphisme*' (ou 'équivalence faible'), ici que f définisse un isomorphisme dans la catégorie de fractions Hot de Cat. (À ne pas confondre avec Cat hot, nettement plus fine). S'il en était ainsi, le contrafoncteur p. 22 [page 36]

$$X \longmapsto \mathrm{Hom}_{\Sigma_X}(a_X, b_X)$$

se factoriserait non seulement par Cat hot, mais même par la catégorie de fractions plus grossière Hot. Et dès lors se poserait la question si ce contrafoncteur hypothétique

$$\mathrm{Hot}^o \longrightarrow \mathrm{Ens}$$

est encore ind-représentable; et de préférence ([5]) ind-représentable par le ind-objet image de $\underline{\underline{K}}$ dans Ind Hot par

$$\mathrm{Ind}(\mathrm{Cat}\,\mathrm{hot}) \longrightarrow \mathrm{Ind}(\mathrm{Hot}),$$

déduit du foncteur de localisation Cat hot $\longrightarrow$ Hot. (Car cet ind-objet est un candidat tout trouvé.)

Commentary · Exposition [ms. 35]

Two homotopy invariance questions

Grothendieck has proved invariance under categorical homotopy equivalence, and now asks for invariance under weak equivalence of nerves. The first assertion is immediate from the ind-representation. A natural transformation $f \Rightarrow g$ induces, by precomposition, a natural transformation between the two functors on each $\mathrm{Fun}(Y, K_n)$. These functors therefore induce the same map on π_0. A finite zigzag gives the same conclusion, and a homotopy inverse to f gives inverse maps on $H_{a,b}$.

The second assertion has additional content. A weak equivalence Nf need not admit an inverse represented by a functor and a finite zigzag of natural transformations. Nor does the construction of $H_{a,b}$, for an arbitrary class Σ, supply a derived mapping space. Thus the corollary proves factorization through Cat hot; it does not prove factorization through Hot. This is the same difference that appeared in the commentary on Chapter I, manuscript p. 102 ("What the completion requires"), now applied to a particular family of coefficients.

Once that factorization is established, however, the subsequent question about ind-representability has a formal affirmative answer. It does not require the proposed right adjoint to Cat hot $\to$ Hot. More generally let $\varphi : C \to D$ be a localization, let $H = \varinjlim_i h_{K_i}$ on C, and suppose $H = \varphi^* H'$ for a presheaf H' on D. Restriction φ^* is fully faithful by the universal property of localization. Put $L = \varinjlim_i h_{\varphi K_i}$ on D. For every presheaf F on D, Yoneda gives natural bijections

$$\mathrm{Nat}(L, F) \cong \varprojlim_i F(\varphi K_i) \cong \mathrm{Nat}(H, \varphi^* F) \cong \mathrm{Nat}(H', F).$$

Yoneda, now in the presheaf category, proves $L \cong H'$. Equivalently, left Kan extension along φ^{op} sends h_K to $h_{\varphi K}$, preserves the filtered colimit, and recovers a descended presheaf; this is the usual Kan-extension formalism (Riehl, 2014, §§1.1–1.4). Thus, conditional only on weak-equivalence invariance, the image of (K_i) in Ind(Hot) represents the descended functor. What remains conditional on the later right adjoint is the characterization by a Thomason–Kan envelope, not this descent of ind-representability.

A useful sufficient hypothesis is that localization of the strict diagram categories presents the expected infinity-categories of diagrams. More explicitly, suppose a homotopy theory $\mathcal{C}$ satisfies, naturally in small X,

$$\mathcal{M}^X[\Sigma_X^{-1}] \simeq h\,\mathrm{Fun}(NX, \mathcal{C}).$$

If $Z = \mathrm{Map}_{\mathcal{C}}(a, b)$, the space of natural transformations between constant diagrams is

$$\mathrm{Map}_{\mathrm{Fun}(NX,\mathcal{C})}(a_X, b_X) \simeq \mathrm{Map}_{\mathcal{S}}(|NX|, Z).$$

Indeed, a coherent transformation chooses a point of Z at each object, a path for each arrow, and the compatible higher homotopies for composable strings; these are exactly the simplices of a map from NX into Z. Taking π_0 proves $H_{a,b}(X) \cong [|NX|, Z]$. Under this hypothesis the functor is represented on Hot, rather than merely ind-represented there.

Combinatorial simplicial model categories provide a familiar setting for this statement. The mapping space must be derived, using a cofibrant source and a fibrant target. The model-independent function-complex construction is due to Dwyer and Kan; their comparison theorem explains why the resulting homotopy type is independent of auxiliary model structures (Dwyer and Kan, 1980b, §4). The displayed hypothesis is stated explicitly here because it is not a consequence of an arbitrary choice of Σ.

5. ce sera automatique si on a ind-représentabilité comme foncteur sur Hot, cf. ci-dessous.

Commentary · Examples [ms. 36]

An external Hom that is an ordinary homotopy type

Grothendieck's candidate can be made completely concrete for simplicial sets with their usual weak equivalences. Take $a = \Delta^0$ and let $b = Z$ be a Kan complex. For a small category X, a projectively cofibrant replacement of the constant point diagram is supplied by the usual bar construction. At $x \in X$ its value is $N(X/x)$; this is contractible because X/x has the terminal object id_x. The diagram is assembled from the covariant representables by attaching simplices along their boundaries, so it is projectively cofibrant. The constant diagram Z_X is projectively fibrant.

A natural transformation from this resolution to Z_X is equivalent to a simplicial map from its colimit to Z. The colimit of the diagram $x \mapsto N(X/x)$ is NX: a simplex represented by a string ending in an arrow to x is identified with the same string at its last vertex. Consequently the derived simplicial mapping space between the two constant diagrams is Z^{NX}. Since the source simplicial set is cofibrant and Z is Kan,

$$\mathrm{Hom}_{\mathrm{Ho}(\mathbf{sSet}^X)}(*_X, Z_X) = \pi_0 Z^{NX} = [NX, Z].$$

This is the bar-construction calculation underlying the abstract assertion in the preceding block; see Riehl (2014, §§4.4–4.5 and 5.1) for the construction and its homotopical justification.

For $Z = K(A, m)$ with $m \geq 1$ and A abelian, it gives $H_{*,Z}(X) = H^m(NX; A)$, with constant coefficients. If X is the one-object category attached to the cyclic group C_r, the familiar periodic resolution has alternating differentials $g - 1$ and $1 + g + \cdots + g^{r-1}$. After applying $\mathrm{Hom}_{\mathbf{Z}[C_r]}(-, A)$ for the trivial action, these differentials become 0 and multiplication by r. Hence

$$H^{2q}(BC_r; A) = A/rA \quad (q \geq 1), \qquad H^{2q+1}(BC_r; A) = A[r] \quad (q \geq 0).$$

The category BC_r has finitely many objects and arrows, but its nerve has nondegenerate simplices in arbitrarily high dimensions. Thus "finite category" in the closing question must not be silently replaced by "finite CW complex". The same example also shows that successful homotopy-theoretic coefficients often produce an actually representable functor on Hot. This is distinct from essential constancy in Ind(Cat hot), the subject of the pessimistic parenthesis on manuscript p. 46. Passing from the first assertion to the second would require precisely the right adjoint discussed next.

Je vais faire quelques rappels catégoriques, généralisant la situation du foncteur canonique [page 37]
de localisation

$$\mathrm{Cat\,hot} \xrightarrow{\varphi} \mathrm{Hot},$$

dont on sait qu'il admet un adjoint à droite `[si un lecteur a une démonstration de ce fait, prière de contacter G. Maltsiniotis : [e-mail address removed]]`

$$\mathrm{Cat\,hot} \xleftarrow{\psi} \mathrm{Hot}, \qquad \mathrm{Hom}_{\mathrm{Hot}}(\varphi X, Y) \simeq \mathrm{Hom}_{\mathrm{Cat\,hot}}(X, \psi Y),$$

où ψ est le foncteur 'enveloppe de Kan' ou 'représentant de Kan'. On va donc considérer la situation plus générale

$$C \underset{\varphi}{\overset{\psi}{\leftrightarrows}} C' \qquad \mathrm{Hom}_{C'}(\varphi X, X') \simeq \mathrm{Hom}_C(X, \psi X')$$

i.e.

$$\varphi, \psi \text{ couple de foncteurs adjoints.}$$

On suppose de plus

$$\begin{cases} \varphi \text{ un foncteur localisation, i.e. } \psi \text{ pleinement fidèle,} \\ \text{i.e. } \varphi\psi \xrightarrow[\sim]{\mathrm{adj}} \mathrm{id}_{C'} \quad . \end{cases}$$

Soit $W = W_\varphi \subset \mathrm{Fl}\, C$, défini par $\varphi : W_\varphi = \{u \in \mathrm{Fl}\, C \mid \varphi(u) \text{ isomorphisme}\}$. Voici la proposition que j'avais oubliée, et que j'ai eu du mal à reconstituer, hélas!

Commentary · Development (commentators') [ms. 37]

The reflection does not exist

Grothendieck wants to convert homotopy invariance of a represented functor into a condition on its representing object. For a reflective localization this is an elementary and powerful argument, and Propositions 1 and 2 below are correct formal statements about any reflective localization. The edition questions the right adjoint to $\varphi : \mathrm{Cat\,hot} \to \mathrm{Hot}$ on which their application rests. It does not exist.

Theorem. [ours] *The functor $\varphi : \mathrm{Cat\,hot} \to \mathrm{Hot}$ has no right adjoint. More precisely, there is no small category K with bijections $\pi_0 \mathrm{Fun}(X, K) \cong [BX, K(\mathbf{Z}/2, 2)]$ natural in the small category X.*

Proof. A right adjoint ψ would give such a K, namely ψ of the homotopy type $Y = K(\mathbf{Z}/2, 2)$, since morphisms $X \to K$ in $\mathrm{Cat\,hot}$ are the connected components of $\mathrm{Fun}(X, K)$. Suppose K is given. Taking $X = e$ shows that $\pi_0 K = [\mathrm{pt}, Y]$ is one point.

Let Ω be an infinite set of cardinality greater than that of the set of arrows of K, and G the group of even permutations of Ω with finite support. It is the union of the alternating groups of the finite subsets of Ω, so it is simple, and its cardinality is that of Ω. A functor from the one-object category $\mathsf{B}G$ to K is an object k with a homomorphism $G \to \mathrm{Aut}(k)$. Its kernel is a normal subgroup; it is not trivial because $\mathrm{Aut}(k)$ has fewer elements than G; so the homomorphism is trivial. A natural transformation between two such constant functors is a single arrow of K. Hence $\mathrm{Fun}(\mathsf{B}G, K) \cong K$ and $\pi_0 \mathrm{Fun}(\mathsf{B}G, K)$ is one point.

On the other side $[BG, K(\mathbf{Z}/2, 2)] = H^2(G; \mathbf{Z}/2)$ classifies the central extensions of G by $\mathbf{Z}/2$, and one of them does not split. Let V be the real vector space with orthonormal basis $(e_\omega)_{\omega \in \Omega}$ and $\mathrm{Cl}(V)$ its Clifford algebra, with $v^2 = -|v|^2$. For $\omega \neq \omega'$ the unit vector $\tau = (e_\omega - e_{\omega'})/\sqrt{2}$ is invertible in $\mathrm{Cl}(V)$ and $v \mapsto -\tau v \tau^{-1}$ is the reflection of V that exchanges e_ω and $e_{\omega'}$. Let $\widehat{G}$ be the group of products of an even number of such vectors. Sending such a product to the corresponding product of transpositions is a surjective homomorphism $\widehat{G} \to G$; its kernel is contained in $\{\pm 1\}$, the kernel of the map from the Pin group to the orthogonal group, and $-1 = (\tau\tau')^2 \in \widehat{G}$ for two orthogonal such vectors τ, τ'. So $\widehat{G}$ is a central extension of G by $\mathbf{Z}/2$. The element $g = (\omega_1\, \omega_2)(\omega_3\, \omega_4)$ has order two, and its two lifts $\pm\tau\tau'$ have square -1; a splitting would lift g to an element of order two. So $H^2(G; \mathbf{Z}/2) \neq 0$, and the two sets cannot be in bijection. □

The argument shows more than the statement: a category K represents on $\mathrm{Cat\,hot}$ only what homomorphisms into its automorphism groups and its arrows can see, and a group that is large and simple is invisible to it. The functors $X \mapsto [BX, Y]$ that are representable on all of $\mathrm{Cat\,hot}$ are those with Y a 1-type, represented by a groupoid (the proof for a general Y, which replaces G by large simple groups with the homology of spheres, is not reproduced here); the fundamental groupoid $X \mapsto \Pi_1 X$ is a reflection of $\mathrm{Cat\,hot}$ onto groupoids modulo natural isomorphism, and it inverts the functors that are bijective on π_0 and on all π_1, a larger class than the weak equivalences. Propositions 1 and 2 apply to that reflection.

Thomason's model structure gives a fibrant replacement $K \to RK$ and an equivalence between its homotopy category and Hot (Thomason, 1980, Theorem 4.9 and Corollary 5.5). It does not identify $\pi_0 \mathrm{Fun}(X, RK)$ with $[NX, NK]$ for every X: mapping formulas in a model category need a cofibrant source, and the cofibrant objects of that structure are posets. Below, references to an envelope or to a reflective localization of $\mathrm{Cat\,hot}$ onto homotopy types are to be read as hypotheses that cannot be met; references to Thomason fibrant replacements mean the model-category construction and carry only its conclusions.

Proposition 1. *Soit $K \in Ob C$. Les conditions suivantes sur K sont équivalentes :*

(i) *Le foncteur* p. 23

$$X \longmapsto K(X) \overset{\text{déf}}{=} \mathrm{Hom}_C(X, K) \qquad C^o \longrightarrow \mathrm{Ens}$$

transforme flèches de W ('quasi-isomorphismes') en bijections.

(i′) *Même condition pour les flèches d'adjonction*

$$X \longrightarrow \psi\varphi X \qquad (\forall X \in \mathrm{Ob\ C})$$

(i″) *Même condition pour la flèche d'adjonction* ([6])

$$K \longrightarrow \psi\varphi K.$$

6. N.B. Il suffit même que l'élément id_K de $F_K(K)$ provienne de $F_K(\psi\varphi K)$ [où $F_K = K(-) = \mathrm{Hom}(-, K)$],

(ii) *K appartient à l'image essentielle de ψ*

(ii′) *$K \longrightarrow \psi\varphi K$ (adjonction) est un isomorphisme.*

(ii″) *L'homomorphisme fonctoriel en X*

$$\mathrm{Hom}_C(X,K) \longrightarrow \mathrm{Hom}_{C'}(\varphi X, \varphi K)$$

est un isomorphisme.

Démonstration. On a d'abord comme quasi-tautologies (ii′)$\Longrightarrow$ (ii)$\Longrightarrow$ (ii″)$\Longrightarrow$ (ii′), i.e. l'équivalence des trois dernières conditions. En effet, (ii′)$\Longrightarrow$ (ii) tautologique, (ii)$\Longrightarrow$ (ii″) car si $K = \psi(K')$ on a par adjonction [page 38]

$$\mathrm{Hom}_C(X,K) = \mathrm{Hom}_C(X,\psi(K')) \overset{\mathrm{adj}}{\simeq} \mathrm{Hom}_{C'}(\varphi X, K'),$$

or $\varphi(K) = \varphi\psi(K') \xrightarrow{\sim} K'$ (adjonction, et ψ pleinement fidèle).

$$\begin{array}{ccc} \mathrm{Hom}_C(X,K) & \xrightarrow{\quad\sim\quad} & \mathrm{Hom}_C(\varphi X, K') \\ & {\scriptstyle\varphi_{X,K}}\searrow \quad \nearrow{\scriptstyle\sim}\ \mathrm{adj} & \\ & \mathrm{Hom}_{C'}(\varphi X, \underbrace{\varphi K}_{=\varphi\psi(K')}) & \end{array} \qquad \text{qui se complète en}$$

ce qui prouve que $\varphi_{X,K}$ est un isomorphisme.

(ii″) $\Longrightarrow$ (ii′). Car la flèche

p. 24

$$\begin{array}{ccc} \mathrm{Hom}_C(X,K) & \xrightarrow{\alpha_X} & \mathrm{Hom}_{C'}(\varphi X, \varphi K) \\ & \searrow & \wr \Big| \mathrm{adj} \\ & & \mathrm{Hom}_C(X, \psi\varphi K) \end{array}$$

est déduite de la flèche d'adjonction

$$K \longrightarrow \psi\varphi K$$

en prenant $\mathrm{Hom}_C(X,-)$, donc α_X est un isomorphisme pour tout X si et seulement si cette flèche d'adjonction est un isomorphisme. Donc

$$\text{(ii)} \Longleftrightarrow \text{(ii′)} \Longleftrightarrow \text{(ii″)}.$$

D'autre part,

$$\text{(ii″)} \Longrightarrow \text{(i)} \Longrightarrow \text{(i′)} \Longrightarrow \text{(i″)}$$

sont tautologiques, en tenant compte pour (i) $\Longrightarrow$ (i) `[probablement (i) ⟹ (i′)]` que les flèches d'adjonction

$$X \xrightarrow{u} \psi\varphi X \qquad\qquad \text{dans } C$$

sont bien dans W, car on a un triangle commutatif

$$\begin{array}{ccc} \varphi(X) & \xrightarrow{\varphi(u)} & \varphi(\psi\varphi X) = (\varphi\psi)(\varphi X) \\ & \searrow^{\mathrm{id}_{\varphi(X)}} & \Big\downarrow \wr \text{ adj } \varphi\psi \longrightarrow 1, \text{ qui est un} \\ & & \text{isomorphisme car } \psi \text{ est pleinement fidèle} \\ & & \varphi(X), \end{array}$$

donc $\varphi(u)$ est bien un isomorphisme.

Reste à prouver (i″) $\Longrightarrow$ (ii′), i.e. on suppose [page 39]

que le foncteur $X \longrightarrow \mathrm{Hom}(X, K)$ transforme le morphisme d'adjonction particulier

$$K \xrightarrow{i} \psi\varphi K$$

en

$$\begin{array}{ccc} u & \longrightarrow & u \circ i \\ \mathrm{Hom}(\psi\varphi(K), K) & \longrightarrow & \mathrm{Hom}(K, K), \end{array}$$

qui est une bijection. Donc id_K est dans l'image, soit p un élément du premier membre qui lui donne naissance

p. 25

$$K \underset{p}{\overset{i}{\leftrightarrows}} \psi \underbrace{\varphi(K)}_{K'} \qquad \text{donc } p\circ i = \mathrm{id}_K$$

Considérons

$$ip = q : \psi(K') \longrightarrow \psi(K') \qquad (\text{NB } q^2 = q),$$

comme ψ est pleinement fidèle, il existe un unique

$$q_0 : K' \longrightarrow K' \qquad (K' \overset{\text{déf}}{=} \varphi(K))$$

tel que l'on ait

$$q = \psi(q_0).$$

La relation $pi = \mathrm{id}_K$ donne, en appliquant φ,

$$\varphi(p)\varphi(i) = \mathrm{id},$$

donc comme $\varphi(i)$ est un isomorphisme (c'est

$$\begin{array}{ccc} \varphi(K) & \xrightarrow{\sim} & \varphi(\psi\varphi)(K) = (\varphi\psi)(\varphi K) \\ & \overset{\sim}{\searrow}{}^{\mathrm{id}} & \wr \downarrow \mathrm{adj} \\ & & \varphi(K), \end{array}$$

rendant commutatif le triangle ci-contre), $\varphi(p)$ l'est. Donc $\varphi(q) = \varphi(i)\varphi(p)$ l'est, puisque $\varphi(i)$ et $\varphi(i)$ `[plutôt` $\varphi(p)$`]` le sont. Mais

$$\varphi(q) = \varphi\psi(q_0) \qquad \underbrace{\overset{\sim}{\longrightarrow}}_{\text{adj } \varphi\psi \overset{\sim}{\to} \mathrm{id}} \qquad q_0,$$

donc q_0 est un isomorphisme, donc aussi $q = \psi q_0$. Comme $q^2 = q$, cela implique $q = \mathrm{id}$. Donc i et p sont des isomorphismes inverses l'un de l'autre, ce qui établit (ii″) `[plutôt (ii′)]` et achève la démonstration.

Commentary · Exposition [ms. 39]

A retract of a local object is local

Grothendieck's proof of Proposition 1 identifies the precise amount of surjectivity needed: the identity of K must lift across its unit. This is stronger than a convenient trick. It says that the full subcategory of local objects is closed under retracts, and explains why checking every weak equivalence can be reduced to one particular map.

Let $\varphi : C \rightleftarrows C' : \psi$ be an adjunction with fully faithful right adjoint, and write $T = \psi\varphi$ and $\eta : 1 \to T$ for its idempotent localization monad. An object K is local exactly when η_K is invertible.

i.e.

(i‴) Il existe une rétraction de $\psi\varphi X$ sur X `[plutôt` $\psi\varphi K$ `sur` K`]` (NB Celle-ci sera même un isomorphisme).

Local objects invert W_φ under $\mathrm{Hom}_C(-,K)$ by adjunction. Conversely, if precomposition with η_K is surjective at the identity of K, choose $p : TK \to K$ with $p\eta_K = 1_K$.

Here is a short verification of the remaining step. Since $\varphi\eta_K$ is invertible by the triangle identity, φp is its inverse. Thus $\varphi(\eta_K p) = 1_{\varphi TK}$. The functor φ is faithful on the full subcategory of local objects: on that subcategory it is quasi-inverse to ψ. Both source and target of $\eta_K p$ are the local object TK, so $\eta_K p = 1_{TK}$. Hence η_K and p are inverse isomorphisms. This proves the implication from the weakest condition in the footnote and therefore all the equivalences in the proposition.

The representability corollary is then exact. If $H = H'\varphi$, every W_φ is sent to a bijection. When $H \cong \mathrm{Hom}_C(-,K)$, the proposition makes K local, and adjunction identifies H' with $\mathrm{Hom}_{C'}(-,\varphi K)$. In the other direction, a representative K' for H' pulls back to the representative $\psi K'$. Essential surjectivity of φ onto C' ensures that the resulting natural isomorphisms are determined by the original factorization. The repeated X in the footnote's first formulation is a printed slip; the object at this step is K, as the edition itself corrects.

Corollaire : *Considérons des foncteurs* $C^o \xrightarrow{H}$ Ens, *et* $C'^o \xrightarrow{H'}$ Ens, *tels que* $H \simeq H' \circ \varphi$. *Pour que* H *soit représentable, il faut et il suffit que* H' *le soit, et dans ce cas, l'objet* K *de* C *qui représente* H *satisfait aux conditions équivalentes de la proposition. Si* K, K' *les représentent, on a des isomorphismes canoniques* $K' \simeq \varphi K$, $K \simeq \psi K'$. [page 40]

Si H' est représentable par $K' \in \mathrm{Ob}\, C'$, on aura donc

$$H' \circ \varphi(X) \simeq \mathrm{Hom}_{C'}(\varphi X, K') \overset{\mathrm{adj}}{\simeq} \mathrm{Hom}_C(X, \psi(K'))$$

donc H est représentable par $K = \psi(K')$, satisfaisant la condition (ii) de la proposition. p. 26
Inversement, si H est représentable par un objet K, alors K satisfait à la condition (i), donc par (ii″) on a

$$\mathrm{Hom}_C(X,K) \xrightarrow{\sim} \mathrm{Hom}_{C'}(\varphi X, \varphi K),$$

donc le foncteur $H' : C^o \longrightarrow$ Ens qui factorise H s'explicite comme $X' \longmapsto \mathrm{Hom}_{C'}(X', \varphi K)$, donc est représentable par φK.

Passons aux ind-objets. Les foncteurs φ, ψ passent aux ind-objets, d'où des foncteurs

$$\mathrm{Ind}\, C \underset{\Phi=\mathrm{Ind}\,\varphi}{\overset{\Psi=\mathrm{Ind}\,\psi}{\rightrightarrows}} \mathrm{Ind}\, C'.$$

On aura encore la formule d'adjonction pour $X = (X_i)_{i\in I}$ dans $\mathrm{Ind}\, C$, $X' = (X'_{i'})_{i'\in I'}$ dans $\mathrm{Ind}\, C'$, car

$$\begin{aligned}\mathrm{Hom}(X, \Psi X') &= \varprojlim_i \varinjlim_{i'} \mathrm{Hom}(X_i, \psi(X'_{i'})) \\ &= \varprojlim_i \varinjlim_{i'} \mathrm{Hom}(\varphi X_i, X'_{i'}) \\ &= \mathrm{Hom}(\Phi X, X').\end{aligned}$$

On prouve de même que Ψ est pleinement fidèle, car si $X' = (X'_i)_{i\in I}$, $Y' = (Y'_j)_{j\in J}$ sont des [page 41]
objets de $\mathrm{Ind}\, C'$, on aura

$$\begin{array}{ccc} \mathrm{Hom}(X',Y') & \simeq \varprojlim_i \varinjlim_j & \mathrm{Hom}_{C'}(X'_i, Y'_j) \\ \downarrow{\scriptstyle \Psi_{X',Y'}} & & \downarrow{\scriptstyle \psi_{X'_i,Y'_j}} \\ \mathrm{Hom}(\Psi X', \Psi Y') & \simeq \varprojlim_i \varinjlim_j & \mathrm{Hom}_C(\psi(X'_i), \psi(Y'_j)), \end{array}$$

donc $\Psi_{X',Y'}$ est un isomorphisme si les $\psi_{X'_i,Y'_j}$ le sont.

Donc la proposition 1 peut s'appliquer à la situation Φ, Ψ entre ind-objets. Je vais l'expliciter sous la forme la plus commode :

Proposition 2. *Soit $K = (K_i)_{i\in I}$ un ind-objet de C, et soit H le foncteur*

$$\begin{cases} H : X & \longmapsto & \underbrace{\mathrm{Hom}_C(X,K)}_{K(X)} \overset{\text{déf}}{=} \varinjlim_i \mathrm{Hom}_C(X,K_i) \\ C^o & \longrightarrow & \mathrm{Ens} \end{cases}$$

qu'il ind-représente. Conditions équivalentes

(i) *Le foncteur H se factorise (à isomorphisme près) par C' via φ, i.e. transforme les $u \in W_\varphi$ en isomorphismes.* p. 27

(i′) *Même condition pour les flèches d'adjonction $X \longrightarrow \psi\varphi(X)$ (lesquelles sont dans W).*

(i″) *Même condition pour la flèche d'adjonction $K \longrightarrow \psi\varphi(K)$.*

(ii) *K appartient à l'image essentielle de* $\mathrm{Ind}\, C'$ *par Ψ.*

(ii′) *$K \longrightarrow \Psi\Phi(K)$ est un* isomorphisme *dans* $\mathrm{Ind}\, C$.)

(ii″) *L'homomorphisme fonctoriel*

$$K(X) = \mathrm{Hom}_C(X,K) \longrightarrow \mathrm{Hom}_{C'}(\varphi(X),\varphi(K))$$

`[plutôt` $\mathrm{Hom}_{\mathrm{Ind}(C)}(X,K) \longrightarrow \mathrm{Hom}_{\mathrm{Ind}(C')}(\Phi(X),\Phi(K))$`, en identifiant l'objet` X `de` C `à son image dans` $\mathrm{Ind}(C)$`]` *est un isomorphisme.*

Démonstration. L'équivalence de (ii), (ii′), (ii″) est la proposition 1 appliquée à Φ et Ψ, à cela près qu'il faut noter que (ii″) reste évidemment valable si on y remplace X par un ind-objet $(X_j)_{j\in J}$ quelconque. On a [page 42]

$$(\mathrm{ii}'') \Longrightarrow (\mathrm{i}) \Longrightarrow (\mathrm{i}')$$

tautologiquement, il reste à prouver que (i′) implique (i″) et (i″) (ii′). On ne peut pas appliquer directement la proposition 1, car l'hypothèse (i′) ici ne porte que sur les objets de $\mathrm{Ind}\, C$ qui proviennent de C, et il n'est pas évident à priori qu'elle passe aux objets quelconques. Mais cela l'est dans le cas d'un homomorphisme de ind-objets (X_i), (Y_i) sur le même ensemble d'indices, donné par un homomorphisme ordinaire (terme à terme) de systèmes inductifs sur I, $X_i \longrightarrow Y_i$: si les $X_i \longrightarrow Y_i$ sont dans W, l'hypothèse (i) implique que $H(Y) \longrightarrow H(X)$ est un isomorphisme, et de même pour (i′) pour $\underbrace{X}_{=(X_i)_i} \longrightarrow \underbrace{\Psi\Phi(X)}_{=(\psi\varphi(X_i))_i}$, où l'homomorphisme d'adjonction est donné terme à terme par les homomorphismes d'adjonction $X_i \longrightarrow \psi\varphi(X_i)$. Donc l'hypothèse (i′) ici implique l'hypothèse (i′) de la proposition 1 pour Φ et Ψ, donc aussi (ii′) (par la proposition 1), et on gagne.

Commentary · Exposition [ms. 42]

Why the argument passes to ind-objects

Grothendieck is careful at the one point where the extension to ind-objects is not a formal substitution. The hypothesis tests units on objects of C, whereas Proposition 1, applied to $\mathrm{Ind}(C)$, would test units on all ind-objects. The missing bridge is a limit, and it needs no exactness assumption.

Put $\Phi = \mathrm{Ind}(\varphi)$ and $\Psi = \mathrm{Ind}(\psi)$. For filtered systems $X = (X_i)$ and $Y' = (Y'_j)$,

$$\mathrm{Hom}(X, \Psi Y') = \varprojlim_i \varinjlim_j \mathrm{Hom}_C(X_i, \psi Y'_j) \cong \varprojlim_i \varinjlim_j \mathrm{Hom}_{C'}(\varphi X_i, Y'_j).$$

This proves $\Phi \dashv \Psi$. Applying the same formula to two systems from C' proves that Ψ is fully faithful. The upper arrow in the edition's displayed pair of ind-functors points the wrong way; these types determine its direction.

For a fixed ind-object K, write $\widehat{H}(X) = \mathrm{Hom}_{\mathrm{Ind}(C)}(X, K)$. Its restriction to C is the functor H of the proposition. Suppose each unit $X_i \to \psi\varphi X_i$ induces a bijection under H. The unit of an arbitrary system X is represented term by term by these maps. Therefore

$$\widehat{H}(\Psi\Phi X) = \varprojlim_i H(\psi\varphi X_i) \xrightarrow{\sim} \varprojlim_i H(X_i) = \widehat{H}(X).$$

A limit of a natural diagram of bijections is a bijection: its inverse is obtained by taking the componentwise inverses, which remain compatible. There is no interchange of a filtered colimit with an inverse limit here. Proposition 1 now applies in $\mathrm{Ind}(C)$ and gives $K \cong \Psi\Phi K$.

Condition (i″) needs this extension $\widehat{H}$ to have a meaning, because K is not in general an object of C. The text uses $\psi\varphi K$ as shorthand for $\Psi\Phi K$; the corrected statement is a test at the unit of an ind-object. Likewise condition (ii″), when tested only on $X \in C$, extends to arbitrary ind-objects by the displayed limit formula. These are not extra hypotheses or repairs to the argument. They make explicit the conventions under which its proof is complete.

Revenons à la situation où $C = \mathrm{Cat}\,\mathrm{hot}$, $C' = \mathrm{Hot}$, φ le foncteur `[de]` localisation. Si $K \in \mathrm{Ob}\,\mathrm{Cat}\,\mathrm{hot}$, alors $\psi\varphi(K)$ s'appelle *l'enveloppe de Thomason-Kan* de K - si K est une catégorie, son enveloppe $\bar{K}$ et la flèche $K \longrightarrow \bar{K}$ ne sont définis que dans la catégorie $\mathrm{Cat}\,\mathrm{hot}$, i.e. $\bar{K}$ n'est défini qu'à 'homotopisme près'.
Mais on peut toujours *choisir* un objet $\bar{K}$ de Cat, et une flèche [page 43]

$$i : K \longrightarrow \bar{K} \qquad\qquad \textit{dans } \mathrm{Cat},$$

pas seulement dans $\mathrm{Cat}\,\mathrm{hot}$, de telle façon de plus que i soit une '*cofibration* de Thomason' p. 28
(et en particulier une immersion ouverte?). Il en résulte que si on a un système inductif

$$K = (K_n)_{n \in \mathbf{N}}$$

indexé par $\mathbf{N}$, et si on choisit pour chaque n une enveloppe de Thomason-Kan

$$K_n \overset{\alpha_n}{\hookrightarrow} \bar{K}_n$$

de cette façon, on peut trouver des foncteurs de transition

$$\bar{K}_n \xrightarrow{\bar{i}_n} \bar{K}_{n+1}$$

tels que les carrés

$$\begin{array}{ccc} K_n & \xhookrightarrow{\alpha_n} & \bar{K}_n \\ {\scriptstyle i_n}\downarrow & & \downarrow{\scriptstyle \bar{i}_n} \\ K_{n+1} & \xhookrightarrow{\alpha_{n+1}} & \bar{K}_{n+1} \end{array}$$

soient commutatifs, de telle sorte que l'on ait donc un homomorphisme de *systèmes inductifs de* Cat

$$K \longrightarrow \bar{K}$$

et a fortiori un homomorphisme de ind-objets de Cat. Ceci posé, les conditions (i), (ii′) de la proposition 2 montrent que le foncteur ind-représenté par K *dans* $C = \mathrm{Cat}\,\mathrm{hot}$ transforme quasi-isomorphismes

Commentary · Later developments [ms. 43]

What Thomason replacement supplies

Grothendieck needs replacements which can be chosen together with the transition maps, so that he still has a sequence of actual categories. This part of the argument has a direct model-category realization. Given a sequence $K_n \to K_{n+1}$, choose trivial cofibrations $\alpha_n : K_n \to R_n$ with R_n

Thomason fibrant. The square with top map α_n, bottom object R_{n+1} and right map $R_{n+1} \to *$ admits a lift. It gives $R_n \to R_{n+1}$ extending $\alpha_{n+1} i_n$. Since the indexing category is the freely generated chain, no relations beyond these adjacent squares need to be imposed.

The parenthetical question about open immersions also has a precise answer. Thomason cofibrations are sieves, hence full inclusions with no arrows from outside to inside. A technical correction matters here: Thomason originally asserted that retracts of Dwyer maps remain Dwyer maps. Cisinski (1999) gives a counterexample and proves that every cofibration is instead a pseudo-Dwyer map; the corrected assertion retains the sieve property and the proper model structure. This repairs that specific later proof, not a gap in Grothendieck's formal Propositions 1–2.

One can also replace any sequence of fibrant objects by a sequence of fibrant objects with cofibration transitions, up to a levelwise weak equivalence. Start with $T_0 = R_0$. If $g_n : T_n \to R_n$ has been constructed, factor the composite $T_n \to R_n \to R_{n+1}$ as

$$T_n \hookrightarrow T_{n+1} \xrightarrow[\sim]{g_{n+1}} R_{n+1},$$

where the first map is a cofibration and the second a trivial fibration. Then T_{n+1} is fibrant and the g_n form a strict map of sequences. The transition inclusions are fully faithful. This proves a useful model-theoretic version of the rearrangement proposed on manuscript p. 46. It gives a levelwise weak equivalence and therefore an isomorphism of ind-objects in Hot. Calling it an isomorphism in Ind(Cat hot) requires a further comparison; that conclusion is not supplied by the factorization axiom.

ordinaires (équivalences faibles) en bijections, *si et seulement si* l'homomorphisme précédent est un isomorphisme de ind-objets de Ind Cat hot. [page 44]

Ce sera donc cela la condition naturelle à imposer aux ind-catégories de chemins

$$\underline{\underline{\mathrm{Ch}}}_{\Sigma}(\mathcal{M}; a, b) \qquad\qquad (a, b \in \mathrm{ob}\,\mathcal{M})$$

provenant d'une 'catégorie de modèles' $\mathcal{M}$, Σ.

Bien sûr, disposant d'un système inductif explicite de catégories (pas seulement d'objets de Cat hot)

$$K_n = \underline{\mathrm{Ch}}_{\Sigma,n}(\mathcal{M}; a, b),$$

il est tentant de passer à la limite inductive

$$K_\infty = \varinjlim_n \underline{\mathrm{Ch}}_{\Sigma,n}(\mathcal{M}; a, b) \overset{\text{déf}}{=} \underline{\mathrm{Ch}}_{\Sigma}(\mathcal{M}; a, b),$$

et ceci d'autant plus que les foncteurs de transition sont des monomorphismes et pleinement fidèles, de sorte que les K_n s'identifient à une suite de sous-catégories pleines de

K_∞, dont la réunion est K_∞. Mais d'autre part je ne sais donner aucune interprétation convaincante de K_∞, comme de celle du ind-objet de Cat hot defini par $\underline{\underline{K}} = (K_n)_{n\in\mathbf{N}}$, qui ind-représente le foncteur remarquable p. 29

$$H = H_{\mathcal{M};x,y} : \mathrm{Cat\,hot}^o \longrightarrow \mathrm{Ens}$$

factorisant le foncteur

$$X \longmapsto H_{\mathcal{M};x,y}(X) \overset{\text{déf}}{=} \mathrm{Hom}_{\mathcal{M}(X)\Sigma_X^{-1}}(x_X, y_X), \qquad \text{[page 45]}$$

par la formule donc

$$H(X) = \varinjlim_n \underbrace{\pi_0 \underline{\mathrm{Hom}}(X, K_n)}_{\mathrm{Hom}_{\mathrm{Cat\,hot}}(X, K_n)}.$$

Je ne sais donner d'interprétation de ce type ni de la catégorie K_∞ elle-même, ni de son image dans Cat hot, ni de son image dans Hot. Il est vrai que si je restreins le foncteur H à la sous-catégorie pleine de (Cat) formée des catégories *finies* (Ob X et Fl X finis), alors on aura

$$\underline{\mathrm{Hom}}^!(X, K_\infty) = \underline{\mathrm{Hom}}(X, K_\infty),$$

et l'isomorphisme précédant s'interprète comme

$$\mathrm{Hom}_{\mathcal{M}(X)\Sigma_X^{-1}}(a_X, b_Y) \overset{\text{déf}}{=} H(X) \simeq \pi_0 \underline{\mathrm{Hom}}(X, K_\infty) \overset{\text{déf}}{=} \mathrm{Hom}_{\mathrm{Cat\,hot}}(X, K_\infty).$$

[plutôt (a_X, b_X)] Cela prouve du moins que la connaissance de K_∞ est utile. Mais cette formule, pour X restreint aux catégories *finies,* ne définira pas K_∞ comme objet de Cat hot, à isomorphisme unique près dans cette catégorie - *sauf* dans le cas où K_∞ est elle-même homotope à une catégorie finie. (Je ne me rends pas bien compte si ça arrive très souvent … Mais on ne peut fonder une théorie générale des dérivateurs et des catégories de modèles 'dérivables' sur une hypothèse de ce genre.) [page 46]

Commentary · Development (commentators') [ms. 45]

Finitely many objects already give a uniform stage

Grothendieck uses finite categories to remove the exclamation mark. The proof is controlled by the number of objects, because fullness has already supplied every arrow between objects that have appeared. We record the resulting refinement to make this source of finiteness explicit.

Finite-object factorization. [ours] Let $K_0 \subseteq K_1 \subseteq \cdots$ be full subcategories, let K_∞ be their union, and let X have finitely many objects, with no restriction on its sets of arrows. Then the canonical functor

$$\varinjlim_n \mathrm{Fun}(X, K_n) \longrightarrow \mathrm{Fun}(X, K_\infty)$$

is an isomorphism of categories. In particular, the path-localization formula on manuscript p. 45 holds for such X.

Proof. Given $F : X \to K_\infty$, choose a stage containing each of its finitely many object-values, and take the largest of these stages. Every arrow of X has endpoints whose images lie in that stage, so fullness supplies its image arrow there. The composition and identity equations hold because inclusion is faithful. Thus F factors through this one stage. If F, G are two functors represented at possibly different stages, put them in a common stage. All components of every transformation $F \Rightarrow G$ then belong to that stage by fullness; its naturality equations are unchanged. Conversely, inclusions of stages introduce no identifications between different transformations. This proves both bijectivity on objects and bijectivity on every Hom-set. □

There is a version invariant under equivalence of the source. If X has only finitely many isomorphism classes of objects, choose a finite-object skeleton S and an equivalence $S \to X$. Precomposition gives equivalences of functor categories into every K_n and into K_∞. Passing to π_0 therefore proves

$$\varinjlim_n \pi_0 \,\mathrm{Fun}(X, K_n) \cong \pi_0 \,\mathrm{Fun}(X, K_\infty).$$

The strict equality of bounded and unrestricted functor categories need not hold for this larger class: an actual functor may send infinitely many isomorphic source objects to different target objects appearing at unbounded stages. The statement on components is the appropriate invariant one.

The qualification at the end of manuscript p. 45 also needs its domain of comparison. Ordinary Yoneda gives uniqueness among objects of Cat hot homotopy equivalent to finite categories. It does not give uniqueness among all objects merely because one candidate is finite. The same elementary fence which will make the later length obstruction visible already separates these assertions.

Failure of unrestricted uniqueness from finite tests. [ours] Let B be the poset $0 \to 1 \leftarrow 2 \to 3 \leftarrow \cdots$, and let B_n be its full subcategory on $\{0, \ldots, n\}$. The restrictions of $\mathrm{Hom}_{\mathrm{Cat\,hot}}(-, B)$ and $\mathrm{Hom}_{\mathrm{Cat\,hot}}(-, *)$ to finite categories are naturally isomorphic, although B and $*$ are not isomorphic in Cat hot.

Proof. The maps $r_j(i) = \min(i, j)$, for $0 \leq j \leq n$, are endofunctors of B_n: they preserve every fence arrow below j and collapse every arrow above it to an identity. For even j there is a transformation $r_j \Rightarrow r_{j+1}$; for odd j there is a transformation in the reverse direction. Thus r_0, the constant functor at 0, and $r_n = 1_{B_n}$ are joined by a zigzag. Postcomposition contracts $\mathrm{Fun}(X, B_n)$ for every X. When X is finite, the preceding factorization lemma places each functor $X \to B$ in some B_n. It is therefore homotopic to the constant functor at 0, and $\pi_0 \,\mathrm{Fun}(X, B)$ is a singleton. These singleton identifications are natural in X.

If 1_B were joined to the constant functor at 0 by L transformations, evaluation at $L+1$ would give a zigzag of L arrows connecting $L+1$ to 0. Each fence arrow changes the index by at most one, which is impossible. Hence B is not categorically contractible. □

The nerve of B realizes to an infinite ray and is contractible. This counterexample concerns Cat hot; the last-page obstruction in Hot will require a different example. It gives a precise reason to restrict the finite-object exception to comparisons within the finite subcategory, if that is the intended reading of the parenthesis.

We checked the general filtered-colimit and functor-category framework in Riehl (2014, Chapters 1 and 7) and the specific argument in the chapter. We did not find this exact refinement stated there. It is an elementary continuation of the printed proof, with no claim of priority. Its relevance is practical: a one-object category with infinitely many endomorphisms still satisfies the lemma, even though it is not a finite category in the author's stated sense.

Mais supposons que le foncteur H envisagé se factorise même par Hot, i.e. qu'il transforme quasi-isomorphismes en bijections. On a vu que cela équivaut à la condition qu'il puisse se représenter par un système inductif sur $\mathbf{N}$ formé de catégories de Thomason-Kan. Il doit être facile de plus, si on y tient, de s'arranger pour que les foncteurs de transition soient des monomorphismes et pleinement fidèles, pour avoir une $\varinjlim$ sympathique. Ce sera bien sûr une catégorie de Thomason-Kan. Cette catégorie est-elle déterminée par le foncteur $H : \mathrm{Cat\,hot}^o \longrightarrow \mathrm{Ens}$ à isomorphisme unique près dans Cat hot? Bien sûr, il n'est pas question qu'elle représente le foncteur H, sauf `[si]` celui-ci est bel et bien représentable, i.e. si le ind-objet $\underline{\underline{K}}$ de Cat hot est essentiellement constant (ce qui ne doit pratiquement jamais être le cas). Notons déjà que si u est un homomorphimse de ind-objets *dans* Cat, ou, ce qui revient p. 30 maintenant au même, un homomorphisme dans Cat [page 47]

$$K_\infty \xrightarrow{u_\infty} K'_\infty$$

tel que $\forall n$, $u_\infty(K_n) \subseteq K'_{n'}$ pour $n' = \tau(n)$ convenable, et si on suppose que l'homomorphisme de ind-objets induit un isomorphisme pour les foncteurs ind-représentables *sur* Cat hot (par exemple, si $\underline{\underline{K}}$ et $\underline{\underline{K}}'$ ind-représentent le même foncteur H, et l'homomorphisme de ind-objets est celui qui correspond à id_H), alors u_∞ est forcément un isomorphisme *dans* Hot, donc aussi (sauf erreur) dans Cat hot puisque K_∞, K'_∞ sont des catégories de Thomason-Kan. Mais ce qui n'est pas évident, c'est l'existence d'un homomorphisme u_∞ comme `[ci-]`dessus, et s'il existe, qu'il soit unique (ou du moins canonique?) comme flèche de Cat hot.

Commentary · Exposition [ms. 46]

Fibrancy passes to the union

Grothendieck expects the union of his replacement categories to remain a good representative of a homotopy type. For Thomason fibrancy this expectation is correct and has a finite combinatorial proof. A category K is Thomason fibrant when $\mathrm{Ex}^2 NK$ is a Kan complex. For a filtered system (K_i), the nerve commutes with its colimit: an n-simplex is a finite composable string, and both the string and the finitely many equations expressing a morphism of such strings occur at one stage. Moreover

$$(\mathrm{Ex}^2 S)_n = \mathrm{Hom}_{\mathbf{sSet}}(\mathrm{Sd}^2 \Delta^n, S)$$

commutes with filtered colimits, since $\mathrm{Sd}^2 \Delta^n$ is a finite simplicial set. Finally, a horn in a filtered colimit of Kan complexes lies in one stage, and has a filler at that stage. Consequently

$$\mathrm{Ex}^2 N(\varinjlim_i K_i) \cong \varinjlim_i \mathrm{Ex}^2 NK_i$$

is Kan whenever all the terms are Kan. This proof even dispenses with fully faithful transition maps.

Fibrancy does not answer the next uniqueness question. There are three different conclusions available from three different kinds of information. A presheaf determines its representing ind-object in Ind(Cat hot). A coherent map of strict diagrams which is a weak equivalence at every stage gives a weak equivalence on the appropriate homotopy colimits. A specified categorical homotopy

between maps of unions requires actual natural transformations, with a finite common length. These conclusions are not interchangeable.

In particular, an isomorphism in the ind-category of a homotopy category is only eventual equality of homotopy classes at each stage. It does not come with compatible choices of the homotopies. The claim on manuscript p. 47 that a corresponding union map must be a weak equivalence is false, even for full inclusions of finite fibrant stages with fibrant union; the example is in the commentary at ms. 49. The verified model-category replacement construction in the preceding block avoids this difficulty by giving actual coherent maps and levelwise weak equivalences. The raw categorical-homotopy strictification questions remain separately recorded in the audit.

Pour l'existence d'un u_∞, on est ramené à prouver que si on a un diagramme à flèches pleines

$$\begin{array}{ccc} K_n & \xrightarrow[\text{cofib.}]{i_n} & K_{n+1} \\ \downarrow{\scriptstyle u_n} & & \searrow \\ K'_{\tau(n)} & \xrightarrow[\text{transition}]{} & K'_N, \end{array}$$

et si une flèche u_{n+1} est donnée 'en pointillés' *dans* Cat hot, de façon à rendre le carré commutatif, alors on peut la réaliser par une flèche *dans* Cat qui rende le diagramme [page 48] commutatif pour de bon (dans Cat). On est ramené au même problème dans une situation

$$X \underset{i}{\overset{p}{\leftrightarrows}} Y,$$

où X est une catégorie de Thomason, i une cofibration de Thomason, p une rétraction de Y dans X *dans* Cat hot, on veut la réaliser par une vraie rétraction ([7]).

En admettant que ça soit le cas, donc que tout homomorphisme des ind-objets $\underline{\underline{K}}$, $\underline{\underline{K}}'$ *dans* Cat hot se représente par un homomorphisme entre les ind-objets *dans* Cat, donc aussi par un foncteur $K_\infty \longrightarrow K'_\infty$, reste la question si l'homomorphisme correspondant dans Cat hot est unique. Donc si on a deux foncteurs f, g qui induisent le même homomorphisme sur les foncteurs ind-représentés sur Cat hot, si f et g sont homotopes. Donc

Question. Deux foncteurs $f, g : K_\infty \longrightarrow K'_\infty$ tels que pour tout $n \in \mathbf{N}$, f_n, g_n qui s'en déduisent par restriction à K_n sont homotopes (et même homotopes en tant que foncteurs de K_n dans un K'_N convenable), sont-ils homotopes? ([8])

Je présume que non - qu'il peut arriver que la longueur minimum requise $l(n)$ pour un p. 31 chemin dans $\underline{\mathrm{Hom}}(K_n, K'_{\tau(n)})$ reliant f_n et g_n, tende vers l'infini si $n \longrightarrow \infty$. L'hypothèse que [page 49] les K'_n sont des catégories de Thomason y change-t-il quelque chose (deux objets homotopes dans $\underline{\mathrm{Hom}}(X, K')$, si K' est de Thomason, sont-ils reliés par une flèche?)

Commentary · Development (commentators') [ms. 49]

A complete instance of the length obstruction

Grothendieck identifies a concrete mechanism by which stagewise homotopies could fail to assemble: their lengths may become unbounded. The following example realizes that mechanism with full inclusions at every stage. It deliberately leaves the additional target-fibrancy condition aside, so that the obstruction itself can be seen without a model-category comparison.

Unbounded categorical homotopies. [ours] There are full filtrations $A_0 \subset A_1 \subset \cdots$ and $B_0 \subset B_1 \subset \cdots$, and functors $f, g : A_\infty \to B_\infty$, such that $f|_{A_n}$ and $g|_{A_n}$ are homotopic in $\mathrm{Fun}(A_n, B_n)$ for every n, but f and g are not homotopic in $\mathrm{Fun}(A_\infty, B_\infty)$.

Proof. Take A_n to be discrete on $\{0, \ldots, n\}$. Take B_n to be the full subcategory on the same vertices of the infinite alternating fence

$$0 \longrightarrow 1 \longleftarrow 2 \longrightarrow 3 \longleftarrow 4 \longrightarrow \cdots .$$

7. [un ? dans la marge]
8. K, K' catégories de Thomason, les K_n, K'_n aussi.

There are no nonidentity composites, so this is a poset. Define $f(i) = 0$ and $g(i) = i$. For $0 \le j \le n$, put $h_j(i) = \min(i, j)$ on A_n. Since the source is discrete, these assignments are functors. If j is even there is a transformation $h_j \Rightarrow h_{j+1}$, and if j is odd there is a transformation $h_{j+1} \Rightarrow h_j$: each component is either the identity or the indicated fence arrow. Hence

$$h_0 = f|_{A_n}, \quad h_1, \quad \dots, \quad h_n = g|_{A_n}$$

is a categorical homotopy of length n, contained in B_n.

Suppose a zigzag of L natural transformations connected f and g globally. Evaluate it at the object $L + 1$ of A_∞. Each nonidentity arrow in B_∞ changes the vertex by exactly one, so a zigzag of L arrows cannot connect 0 to $L + 1$. This contradiction proves the assertion; it also proves that the displayed stagewise length n is minimal. □

Both filtrations consist of full subcategories, and the source stages are discrete, hence Thomason fibrant. We have not shown that the target stages or their union are Thomason fibrant; this construction therefore does not answer the stronger question with that additional hypothesis. The next commentary does. It proves exactly the length mechanism suggested in the first sentence of manuscript p. 49. The argument was developed directly from that sentence. We checked the surrounding categorical-homotopy and model-category references cited in this section and did not find this exact fence formulation; it is presented as an elementary illustration, not a priority claim.

Commentary · Development (commentators') [ms. 49]

The same ind-morphism, two different maps of the unions

With Thomason fibrancy imposed on every stage and on the unions, the questions of ms. 47–49 still have negative answers. The example is a strict form of the symmetric-group shift used at ms. 52.

Proposition. [ours] *There are a sequence $T_0 \subset T_1 \subset \cdots$ of full inclusions of finite categories, each T_n Thomason fibrant and isomorphic in* Cat hot *to a group, with Thomason-fibrant union T, and a functor $s : T \to T$ with $s(T_n) \subseteq T_{n+1}$, such that:*

(a) *for every n, the functor $s|_{T_n}$ and the inclusion $T_n \to T_{n+1}$ are joined by a zigzag of three natural transformations, so s and* id_T *induce the same endomorphism of the ind-object (T_n) of* Cat hot*;*

(b) *Bs is not a weak equivalence; in particular s and* id_T *are not homotopic;*

(c) *there is a weak equivalence $r : T \to \mathsf{B}G$ onto a group, between Thomason-fibrant categories, that is not an isomorphism in* Cat hot*.*

Proof. Let G_j be the group of permutations of $\{0, \dots, j\}$, with $G_j \subset G_{j+1}$ by fixing $j + 1$, and $G = \bigcup G_j$. Let T_n have the objects $0, \dots, n$, with $\mathrm{Hom}(i, j) = G_j$ if $i \le j$ and empty otherwise, and composition by multiplication in the group of the target. The inclusions $T_n \subset T_{n+1}$ are full. The functor $r_n : T_n \to \mathsf{B}G_n$ that forgets the objects and the functor $j_n : \mathsf{B}G_n \to T_n$ onto the object n satisfy $r_n j_n = \mathrm{id}$, and the arrows $i \to n$ labelled by the unit form a natural transformation $\mathrm{id} \Rightarrow j_n r_n$. So $T_n \cong \mathsf{B}G_n$ in Cat hot.

Fibrancy. A category is Thomason fibrant when it has the right lifting property for the functors $c\,\mathrm{Sd}^2\Lambda \to c\,\mathrm{Sd}^2\Delta$ associated with the horn inclusions, and these are sieves (Thomason, 1980, Proposition 4.2). Let $F : A \to T_n$ be given on such a sieve $A \subset B$. The functor $r_n F$ extends to B, because the nerve of a groupoid is a Kan complex. Extend F by sending every object of B outside A to n and every arrow that meets the complement of A to the arrow with the label given by the extension of $r_n F$. No arrow leads from the complement into A, and $\mathrm{Hom}(i, n) = G_n$ for all i, so this is defined, and it is a functor because composition in T_n multiplies labels. So T_n is fibrant, and the union T is fibrant by the preceding commentary on ms. 46.

The shift. For $g \in G_j$ let $\sigma(g) \in G_{j+1}$ fix 0 and act on $\{1, \dots, j + 1\}$ as g does on $\{0, \dots, j\}$; let $s : T \to T$ send i to $i + 1$ and the arrow labelled g to the arrow labelled $\sigma(g)$. On T_n both s and the inclusion into T_{n+1} map, by the arrows labelled by the unit, to the functors with the same labels and constant value $n + 1$ on objects, and these two are isomorphic by the cycle $c = (0\,1 \cdots n + 1)$, since $cgc^{-1} = \sigma(g)$ for $g \in G_n$. This is (a).

The functors r_n are compatible and give $r : T \to \mathsf{B}G$; the nerve and homotopy groups commute with the union, so Br is a weak equivalence and BT is a $K(G, 1)$. Under this identification s induces $\sigma : G \to G$ on π_1, which is not surjective (its image fixes 0). This is (b). For (c): if r were

invertible in Cat hot, there would be a functor $j : \mathsf{B}G \to T$ with rj joined to the identity by natural transformations, that is, with $rj : G \to G$ an inner automorphism. But j sends the object to some i and G into $\mathrm{Hom}(i,i) = G_i$, so the image of rj lies in $G_i \neq G$. □

Consequences for these pages. The assertion of ms. 47, that a morphism of such systems inducing an isomorphism of ind-objects induces a weak equivalence of the unions, is false: s induces the identity of the ind-object. The question of ms. 48, whether two maps of unions that are homotopic on every stage inside a later stage are homotopic, has the answer no, with homotopies of length three at every stage; what fails is their compatibility, not the growth of their length as in the fence example above. The union of fibrant stages is fibrant, but the union T of stages each isomorphic in Cat hot to a groupoid is not isomorphic to one, by (c). And a weak equivalence between Thomason-fibrant categories need not be an isomorphism in Cat hot (ms. 47, "sauf erreur"): fibrancy is not the envelope property.

Commentary · Examples [ms. 49]

Fibrancy does not reduce every homotopy to one arrow

The parenthetical question asks a sharper thing than a uniform bound: for a Thomason fibrant target, must two homotopic functors already be joined by a single natural transformation? A three-object category gives a negative answer, and the fibrancy can be checked directly against the generating horns.

Every category C with a terminal object t is Thomason fibrant. Indeed, Thomason (1980, Propositions 2.5 and 4.2) identify the lifting test with inclusions

$$c\,\mathrm{Sd}^2\,\Lambda^k[n] \hookrightarrow c\,\mathrm{Sd}^2\,\Delta[n],$$

which are sieves. More generally, if $A \subseteq D$ is a sieve and $F : A \to C$ is a functor, extend F by assigning t to every object outside A. There are no arrows from an outside object to an object of A. Send arrows between outside objects to 1_t, and each arrow from inside to outside to the unique map into t. Composition is respected by uniqueness of maps to the terminal object. This constructs the required lift against every displayed horn, so $C \to *$ is a Thomason fibration.

Now take C to be $0 \to 1 \leftarrow 2$, whose terminal object is 1, and take $X = *$. The functors selecting 0 and 2 lie in the same component of $\mathrm{Fun}(*, C) = C$, connected by the two-arrow zigzag through 1. There is no arrow $0 \to 2$ or $2 \to 0$, so there is no single transformation in either direction between them. The target is fibrant by the preceding proof.

This answers the exact one-arrow question. It does not say that minimal lengths can grow without bound for a fixed fibrant target, and it does not establish a counterexample to the preceding question with fibrant full filtrations. A claim of bounded shortening, or of compatibility of stagewise homotopies, has different quantifiers and needs a separate argument.

Bien sûr, on peut prétendre que les catégories $\underline{\mathrm{Ch}}_{\Sigma,n}(\mathcal{M}; a, b)$ ont été définies 'canoniquement', et leur limite inductive $\underline{\mathrm{Ch}}_{\Sigma}(\mathcal{M}; a, b)$ aussi. Mais la définition était assez arbitraire et abracadabrante - je suis convaincu que dix mathématiciens, se proposant de développer cette même idée des catégories de chemins, dans le même but que moi, arriveraient à dix définitions différentes! Pourtant, il n'est pas exclu que l'on finisse par trouver un système transitif d'isomorphismes dans Cat hot, entre les catégories de chemins 'infinis' (i.e. de longueur non précisée) $K_\infty = K_\infty(\mathcal{M}; a, b)$ que nous aurons construites, dans le but principal (disons) [page 50] de représenter le foncteur H *sur les catégories finies.* Et que les isomorphismes obtenus seront, bien entendu, des homomorphismes dans Ind(Cat hot). J'ai l'impression de ne pas avoir encore axiomatisé à fond la notion même de chemins, qui après tout a un sens géométrique assez évident et important par lui-même. Donc par ce qu'il faut entendre par '*une* théorie des chemins dans une catégorie'. Une telle théorie $\mathcal{T}$ associerait donc à $\mathcal{M}$, Σ, a, b un système inductif de catégories $\underline{\mathrm{Ch}}^{\mathcal{T}}_{n,\Sigma}(\mathcal{M}; a, b)$. Et les contraintes géométriques naturelles à imposer à de telles théories, en vue aussi de leur utilisation pour expliciter

$$\mathrm{Hom}_{\mathcal{M}(X)\Sigma_X^{-1}}(a_X, b_X) \xrightarrow{\sim} \pi_0 \underline{\mathrm{Hom}}(X, \underline{\underline{\mathrm{Ch}}}^{\mathcal{T}}(\mathcal{M}; a, b))$$

donnerait un système transitif d'isomorphismes non seulement entre les ind-objets de Cat hot, mais peut-être aussi entre les $\underline{\mathrm{Ch}}^{\mathcal{T}}_{\infty,\Sigma}(\mathcal{M}; a, b)$, pour des théories differentes. Si on dispose d'un tel énoncé, la catégorie $\underline{\mathrm{Ch}}_{\infty,\Sigma}(\mathcal{M}; a, b)$, ou plus exactement ses images dans Cat hot et Hot, prendraient un sens convaincant. [page 51]

Commentary · Later developments [ms. 51]

What a canonical mapping space requires

Grothendieck wants a theory of paths whose result is independent of its combinatorial presentation. The preceding scholium already supplies such independence at the level it actually computes: different constructions representing the same $H_{a,b}$ give uniquely isomorphic ind-objects in Cat hot. To obtain a canonical homotopy type of paths, one needs information beyond the connected-component calculation.

Dwyer and Kan's simplicial localization provides the standard stronger construction. For a relative category $(\mathcal{M}, W)$ it gives simplicial mapping objects with the localized Hom-sets as their connected components (Dwyer and Kan, 1980a, §2 and Proposition 3.1). Their hammock construction uses diagrams of zigzags and coherent higher comparisons; in a model category its mapping objects recover the usual derived function complexes (Dwyer and Kan, 1980b, Proposition 4.4 and Corollary 4.7). Thus composition and its higher compatibility are retained while allowing different presentations of the same homotopy theory.

There is a precise caution in comparing it with these pages. Grothendieck's K_∞ is the ordinary union of full categories of fixed-endpoint paths, and the morphisms of those categories are the transformations specified in sections 1–2. The theorem proved here identifies π_0 of bounded diagram categories with an ordinary localized Hom-set. That theorem alone is not a weak-equivalence comparison between NK_∞ and a Dwyer–Kan function complex. Replacing vertical morphisms, changing allowed zigzags, or using a homotopy colimit may change the higher homotopy type while leaving this π_0 calculation intact.

Accordingly, the modern theory answers the demand for an invariant mapping-space object, but does not automatically verify each proposed comparison between the particular unbounded path categories in the manuscript. In the favorable model case discussed above, the desired functor $H_{a,b}$ is represented on Hot by the derived mapping space. A direct identification of a chosen K_∞ with that object is a separate theorem to be proved under stated assumptions. This distinction explains both the force of the scholium and the legitimacy of the questions which follow it.

Il y a d'autre part un autre point de vue, qui peut-être pourrait 'canonifier' les catégories $\underline{\mathrm{Ch}}_\infty$ en tant qu'objet de Cat hot et surtout de Hot (on passerait à Cat hot en appliquant le foncteur ψ, enveloppe de Thomason-Kan …). En effet, on est intéressé à construire, en termes de $\mathcal{M}$, Σ, un 'dérivateur' (ou un prédérivateur) $\mathbf{D}_{\mathcal{M},\Sigma}$ surtout sur le 'domaine' des catégories finies. L'étendre à un domaine plus large est peut-être important dans un 'deuxième souffle', mais peut être considéré comme du luxe dans le premier mouvement de fondation d'une théorie des dérivateurs. Ceci dit, on peut se poser des questions du type suivant.

Soit

$$\mathrm{Hot}_0 \subset \mathrm{Hot}$$

la sous-catégorie pleine de Hot, définie par les catégories finies ([9]) - appelons les types d'homotopie 'de type fini' (ou de *présentation* finie?). On a un foncteur évident p. 32 [page 52]

$$\begin{aligned} \mathrm{Hot} &\longrightarrow \mathrm{Hot}_0^\wedge = \underline{\mathrm{Hom}}(\mathrm{Hot}_0^o, (\mathrm{Ens}))\,, \\ X &\longmapsto \tilde{X} = (\xi \longmapsto \mathrm{Hom}_{\mathrm{Hot}}(\xi, X)). \end{aligned}$$

Ce foncteur est *conservatif* `[cela semble faux]`, puisque un homomorphisme $X \longrightarrow X'$ dans Hot est un isomorphisme s'il induit des isomorphismes pour les foncteurs $\tilde{X} \longrightarrow \tilde{X}'$, et même seulement pour leurs valeurs pour les sphères S^n $(n \geq 0)$. (Sauf erreur. Y a-t-il des canulars, parce que le critère d'équivalence faible par les π_i ne s'applique pas directement,

9. *NB* Hot_0 est équivalente à une petite catégorie.

en l'absence de points bases. Ça ne doit pas être très sérieux … [cela semble en fait sérieux]). Mais est-il peut-être même *pleinement fidèle* ([10])? De sorte que Hot se réaliserait comme sous-catégorie pleine de $\mathrm{Hot}_0^{\wedge}$, contenant les foncteurs représentables?

Commentary · Examples [ms. 52]

Finite unbased tests miss a symmetric-group shift

Grothendieck's final question concerns a specific restricted Yoneda functor, and here a concrete counterexample settles both the conservativity assertion and the stronger full-faithfulness question. The mechanism is that every finite test sees a conjugating element, but no one element works globally. The finite-support symmetric-group example is the classical case recorded in Matumoto et al. (1984, Proposition 4.1); the attribution and its relation to the later general result are confirmed by Arlin and Christensen (2023, Remark 2.3). We give the elementary verification in the exact form needed for these pages.

Let G be the group of permutations of $\mathbf{N} = \{0, 1, \dots\}$ with finite support. Define a homomorphism $s : G \to G$ by

$$s(\sigma)(0) = 0, \qquad s(\sigma)(n+1) = \sigma(n) + 1.$$

It is injective but is not surjective, since every image permutation fixes 0, whereas the transposition $(0\ 1)$ belongs to G. Therefore $Bs : BG \to BG$ is not a weak homotopy equivalence: on fundamental groups it is s.

Now let P be any finitely generated group and $\rho : P \to G$ a homomorphism. Choose a finite generating set. The union of the supports of the images of those generators is finite, so every element of $\rho(P)$ fixes all integers greater than some m. Let $c = (0\ 1\ \cdots\ m+1)$. Conjugation by c carries the action on $\{0, \dots, m\}$ to the shifted action on $\{1, \dots, m+1\}$ and fixes 0. Directly, for every $p \in P$,

$$c\rho(p)c^{-1} = s(\rho(p)).$$

Hence $s\rho$ and ρ are conjugate homomorphisms.

For a connected CW complex T, homotopy classes of maps to $BG = K(G, 1)$ correspond to homomorphisms $\pi_1 T \to G$ modulo conjugation. One way to verify this description is to choose a vertex, extend a chosen group homomorphism across the 2-skeleton, and then use the vanishing higher homotopy groups of BG for existence and uniqueness of further extensions. Forgetting the chosen basepoint changes the homomorphism by conjugation. If T is the realization of the nerve of a finite category, each component has finitely presented fundamental group: its finite 2-skeleton gives generators and relations. Applying the preceding conjugacy calculation on each component therefore shows

$$(Bs)_* : [T, BG] \longrightarrow [T, BG] \quad \text{is the identity}$$

for every $T \in \mathrm{Hot}_0$. The same holds for every sphere. This proves that the restricted Yoneda functor is not conservative.

It is also not faithful. The maps 1_{BG} and Bs are distinct in Hot, since the latter is not an equivalence and the former is. Nevertheless they induce the same natural endomorphism of the presheaf $T \mapsto [T, BG]$ on Hot_0: both are the identity at each test object. Thus the proposed full faithfulness fails even at injectivity on morphisms. The two editorial warnings at the end of the chapter are justified; the missing basepoint information cannot be recovered merely by adding more finite unbased tests.

Commentary · Present state [ms. 52]

The modern scope of the final obstruction

The counterexample above addresses exactly the finite-category tests in the manuscript. A much stronger theorem is now available: Arlin and Christensen (2023, Theorem 2.1) prove that no set of objects of the unpointed homotopy category jointly reflects isomorphisms. Their proof enlarges the symmetric-group construction to a sufficiently large regular cardinal. Consequently the obstruction is not removed by choosing a different small family of unbased tests. The same paper distinguishes this theorem from an earlier argument of Heller whose asserted boundedness property had a gap.

10. [un ? dans la marge]

> The loss occurs at the passage to sets of homotopy classes. Retaining more structure changes the answer: Arlin and Christensen (2023, Theorem 4.3) show that spheres jointly detect equivalences in the homotopy 2-category of spaces, whose Hom-categories are fundamental groupoids of mapping spaces. Already the automorphisms in the mapping groupoid out of a point retain the fundamental group which a set of unbased components forgets. At the infinity-categorical level, mapping spaces provide the full Yoneda data. These results give a precise modern reason for the insistence, throughout these chapters, on keeping coherent diagrams and their transformations together.

Overview · III-V

These chapters study how a homotopy theory can retain operations that ordinary homotopy classes conceal. They approach the problem from three directions. Chapter III asks for an action of homotopy types on coefficients and for an external Hom that represents the resulting families of morphisms. Chapter IV constructs coherent diagrams by extending coefficients along carefully chosen inclusions. Chapter V returns to the elementary presentation of a localization by zigzags, then asks how much of its homotopy theory those zigzags remember. The order matters. The external Hom is a desired object; coherent diagrams provide a way to construct operations on it; the categories of paths are a candidate model. What is established at each stage must be distinguished from what the next stage would require.

These chapters have three independent manuscript numberings. Chapter III contains manuscript pages 1–12, Chapter IV contains 73–83 (the edition explicitly says that pages 1–72 are absent), and Chapter V contains 1–52, with page 32 marked blank. We therefore cite manuscript locations with a chapter numeral. In the edition, the mathematical text occupies forty-seven pages, besides titles and editorial notices. The inserted comments preserve the edition's corrections in square brackets. The corrections to the transcription restore what that edition actually prints; mathematical repairs are stated in the commentary instead of being silently substituted for the historical text.

Chapter III begins with a concrete requirement. If $p : X \to e$ and M is a coefficient, a tensor by the homotopy type of X should be $p_!p^*M$, and a cotensor should be p_*p^*M. Their adjunction follows directly from the two adjunctions involving p^*:

$$\mathrm{Hom}(p_!p^*M, N) \cong \mathrm{Hom}_{\mathbf{D}(X)}(p^*M, p^*N) \cong \mathrm{Hom}(M, p_*p^*N).$$

The issue is descent in X: a weak homotopy equivalence of indexing categories must induce an isomorphism on constant-coefficient homology and cohomology. There is also a size issue. A derivator defined on a restricted class of shapes cannot be presumed to see every homotopy type. These are separate questions, and neither is settled by the formal adjunction alone.

The modern action of spaces on derivators gives a precise setting for the first construction, while model presentations provide derived mapping spaces. The distinction between an action and a closed enrichment remains essential: the former is not, by itself, a representability theorem for the external Hom. We relate the discussion to the universal property of the derivator of spaces and to the later account of homotopy-theoretic module structures (Cisinski, 2008; Groth and Shulman, 2017). For familiar derived categories one can see all the operations explicitly. With cohomological grading,

$$K \otimes M = C_*(K; \mathbf{Z}) \otimes^{\mathbf{L}}_{\mathbf{Z}} M, \qquad M^K = \mathbf{R}\mathrm{Hom}_{\mathbf{Z}}(C_*(K; \mathbf{Z}), M).$$

The mapping space from M to N is obtained from the good truncation $\tau_{\leq 0}\mathbf{R}\mathrm{Hom}_k(M, N)$ by the Dold–Kan construction and forgetting the abelian structure. Thus its nth homotopy group at zero is $\mathrm{Hom}_{D(k)}(M, N[-n])$. A positive Ext group appears as a higher homotopy group after the corresponding shift of the target; it is not a positive homotopy group of this unshifted mapping space merely because it is an Ext group.

The circle calculation explains why pointedness enters the manuscript. Unreduced chains on S^1 give $\mathbf{Z} \oplus \mathbf{Z}[1]$, hence $S^1 \otimes M \simeq M \oplus M[1]$ in the derived category. The suspension is the reduced summand. Grothendieck's first identification of the tensor with suspension is therefore corrected by his own closing observation; it should not be reported as an unresolved defect of his final construction. His suggestion of a bounded-above enhancement, however, requires a boundedness hypothesis on derived Hom. An elementary example over the dual numbers shows why arbitrary coefficients do not supply one.

Chapter IV explains why these operations must be constructed on coherent diagrams. The underlying-diagram functor is conservative, but it discards information about coherent

compositions and homotopies. The commentary on Chapter I already examines this failure in detail. Here the new point is constructive: Kan extension along a suitable sequence of inclusions supplies the coherence that a diagram drawn in the fundamental category does not specify. The loop object is obtained by extending a single coefficient by zero to a punctured square and then taking its right Kan extension to the whole square. Full faithfulness of these extensions explains both the existence and the correctly qualified uniqueness of the resulting cartesian square. This is the pattern developed systematically for pointed and stable derivators in Groth (2013).

The same method makes the adjunction maps visible. For $f : I \to J$, Grothendieck forms the collage $K(f)$ with mixed morphisms $\mathrm{Hom}_{K(f)}(i, j) = \mathrm{Hom}_J(f(i), j)$. A presheaf on $K(f)$ is exactly a pair of presheaves together with a map $f^*G \to F$. The elementary description identifies the required units and counits before the derived case is attempted. We complete the construction by giving the indexing functors and checking the pointwise Kan-extension comparison. The benefit is a canonical coherent realization of these particular adjunction maps. It does not assert a canonical lift of every arrow drawn in a homotopy category.

Chapter V begins with alternating finite paths, extended by identities at their two ends. A backward segment is required to belong to Σ; the connected components of the resulting category with fixed endpoints then give the morphisms of $\mathcal{M}[\Sigma^{-1}]$. Here "fixed" includes the morphisms: transformations in the fibre have identity components at the two endpoints. Replacing this fibre by the full subcategory on paths with those endpoint objects would change the construction. We give the quotient and composition argument with this convention throughout.

The manuscript's parity correction is also substantive. Concatenating two of the initially chosen odd-indexed standard paths reverses the standard orientation. Passing to the cofinal subsystem of even indices repairs the problem. Grothendieck's analysis of admissible contractions establishes the necessary compatibility with padding. His more general interval lemma is left as an assumption, with contractibility proposed as a strengthening. The development supplied here proves that strengthening: for a finite oriented path as target, every nonempty category of functors with a prescribed restriction is categorically contractible. Numerical minimum and maximum give explicit endofunctors and a zigzag between the identity and a constant functor. The fixed-restriction version also covers the cancellation diagrams whose two endpoints have the same image. We give the full argument and state the extent of the literature search; the label *ours* records responsibility for this proof, not a claim of priority.

Passing to diagrams exposes a uniformity condition that a bare union of path categories forgets. A path in $\mathcal{M}^X$ has one finite length bound valid at every object of X. Consequently the natural representing object is an ind-category (K_n), with

$$\mathrm{Hom}_{\mathcal{M}^X[\Sigma_X^{-1}]}(a_X, b_X) \cong \operatorname*{colim}_n \pi_0 \,\mathrm{Fun}(X, K_n).$$

This is an unconditional statement about ordinary localizations. It is not yet an identification of NK_∞ with a derived mapping space. The later simplicial-localization theory supplies canonical mapping spaces and comparison theorems under their stated hypotheses; the commentary keeps those theorems separate from what this particular path model proves.

The formal propositions on reflective localizations and their ind-categories can be preceded by a simpler affirmative result. If $H_{a,b}$ inverts nerve weak equivalences, the image of its representing ind-object already ind-represents the descended functor on Hot. Indeed, left Kan extension along the opposite of a localization carries representable presheaves to representable presheaves and preserves filtered colimits; restriction along the localization is fully faithful. This conclusion needs no right adjoint between the original categories.

The stronger formal propositions on reflective localizations and their ind-categories are sound when the fully faithful right adjoint is supplied. Their application to $\mathrm{Cat}\,\mathrm{hot} \to \mathrm{Hot}$ needs that additional premise. Here $\mathrm{Cat}\,\mathrm{hot}$ means categories and functors modulo finite

zigzags of natural transformations, whereas Hot inverts weak equivalences of nerves. The editorial request for a proof of the right adjoint is consequently material. Thomason's model structure does not alone establish the asserted adjunction with this particular source category. We leave that premise unresolved in this audit and explain the valid replacement-based conclusions without promoting an unsuccessful search to a claim that the problem is open.

The last page admits a definite answer. Testing an unpointed homotopy type by every finite category does not give a conservative or a faithful restricted Yoneda functor. Let G be the group of permutations of $\mathbf{N}$ with finite support, and let $s : G \to G$ shift a permutation one place to the right while fixing zero. The induced Bs is not an equivalence. Every map from a finite category's nerve into BG, however, uses a finitely generated fundamental group and hence only finitely many permutation supports. On those supports the shift is conjugation by one finite permutation. Thus Bs induces the identity on all the proposed tests. The same example separates Bs from the identity despite their identical restricted Yoneda transformations. The modern general theorem says that no set of unpointed spaces jointly reflects isomorphisms in Hot (Arlin and Christensen, 2023, Theorem 2.1 and Remark 2.3). Retaining mapping groupoids changes this conclusion: the sphere tests do reflect equivalences in the homotopy 2-category, as their Theorem 4.3 proves. The obstruction on the closing page is precisely information discarded by passing too early to sets of unpointed homotopy classes.

Le dérivateur HOT

14.11.90

(Les premières feuilles, d'il y a deux semaines, ont été larguées, dépassées par VII)

Je définis Hot à partir de la catégorie de modèles

$$\mathcal{M} = \mathrm{Cat},\ W \subseteq \mathrm{Fl}(\mathrm{Cat}),$$

W étant en principe les Hot-équivalences. Mais je vais dans la mesure du possible axiomatiser plus, en supposant donné un ensemble W plus général, appelé 'localisateur fondamental' (basic localiser), p. ex. $W = W_{\mathbf{D}}$, où $\mathbf{D}$ est un dérivateur déjà donné (mais en supposant que son domaine soit (Cat) tout entier). Nous allons noter au fur et à mesure de quelles propriétés de W nous aurons besoin. Aux fins de référence ultérieure, je vais rappeler ici celles que j'ai dégagées dans Pursuing Stacks.

L1 Saturation de W

a) *Les identités* `[sont]` *dans* W.

b) *Si deux parmi* gf, f, g `[sont]` *dans* W, *le troisième aussi,* $X \xrightarrow{f} Y \xrightarrow{g} Z$.

c) *Si* gf *et* fg *sont dans* W, *alors* f *et* g *aussi,* $X \underset{g}{\overset{f}{\rightleftarrows}} Y$.

L2 $\mathbf{\Delta}^1$ *est universellement* W*-asphérique, i.e.* $\mathbf{\Delta}^1 \times X \longrightarrow X$ *est dans* W *pour tout* X *dans* Cat. Cela implique

L2 bis $\mathbf{\Delta}^1$ *est* W*-asphérique.* (C'était L3′ dans Pursuing Stacks.)

L3 *Si* X *a un objet final,* X *est* W*-asphérique.* ([1])

Je note ici `[des]` variantes renforcées.

L3 bis *Si* X *est* Hot-*asphérique, il est* W*-asphérique.*

L3 ter *Si* X *est* Hot-*asphérique, il est universellement* W*-asphérique, i.e.* $X \times Y \xrightarrow{\mathrm{pr}_2} Y$ *est dans* W *pour tout* Y *dans* Cat. ([2])

1. Il y a un L3′ dual de L3.
2. Suffit pour entraîner L2, L3.

L3 quater *Toute* Hot-*équivalence est dans* W. p. 2
L3 quater $\Longrightarrow$ L3 ter $\Longrightarrow$ L3 bis $\Longrightarrow$ L3.
L3 ter $\Longrightarrow$ L2 $\Longrightarrow$ L2 bis.

[page 2]

Commentary · Context [ms. 1]

The axioms are being found

Grothendieck wants to construct the homotopy theory of diagrams from categories themselves. The expression "catégorie de modèles" here initially means a category supplied with distinguished weak equivalences; no classes of Quillen cofibrations and fibrations have yet been specified. We write W∞ for functors inducing weak homotopy equivalences of nerves, and Q : Cat $\to$Cat[W -1] for ordinary localization. Categories and localizations are understood in fixed, sufficiently large universes. This avoids mistaking the construction of Q for a smallness theorem about its hom sets.

The changing list of axioms is part of the argument. In particular, the L4 of manuscript page 2 is the absolute assertion that an aspherical functor is a weak equivalence. The relative assertion for a map X $\to$Y over an arbitrary third category S appears only as L4 bis on page 44. Later proofs require this stronger formulation. The modern definition uses the relative statement from the outset; compare Cisinski (2004, Definition 1.1.3 and Remark 1.1.4). Similarly, the L5 on page 2 concerns descent of fibrewise equivalences, whereas the L5 on page 43 concerns recovery of fibrewise equivalences from a total equivalence. They are different assertions, with different strength. The interval [1] explains why these axioms can remember homotopy. A natural transformation F $\Rightarrow$G is a functor A $\times$ [1] $\to$B with prescribed endpoint restrictions. L2 makes both endpoints inverse to the projection after localization. Thus a natural transformation becomes an equality between the induced maps of localized categories. This observation will repeatedly turn an elementary adjunction into a weak equivalence without requiring a model structure.

The optional L3 quater also has a precise later history. Under the modern relative axioms, the inclusion W$\infty\subseteq$W is a theorem, established by Cisinski (2004, Theorem 2.2.11). That theorem does not license replacing the initial absolute L4 by its relative form without explanation. In these pages the additional hypothesis is explicitly adopted at manuscript page 7, and we retain the distinction when tracing the proofs.

L4 *Si* $f : X \longrightarrow Y$ *est* W*-asphérique (i.e. les* $X/y \longrightarrow Y/y$ *dans* W*, i.e. (si on a L3) si les* X/y *sont* W*-asphériques), alors* f *aussi.* (Axiome de localisation.) ([3]) `[`aussi' = dans` $W$`]`

L5 (Axiome de fibration). *Si*

$$\begin{array}{ccc} X & \xrightarrow{\ f\ } & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

avec X *et* Y *fibrées sur* S *et* f *cartésien, si pour tout* $s \in S$ $f_s : X_s \longrightarrow Y_s$ *est dans* W*,* f *aussi.*

Dans Pursuing Stacks j'ai supposé toujours $\boxed{\text{L1, L3, L4}}$ (impliquant L2) - c'étaient ces conditions qui définissaient la notion de 'localisateur' (fondamental) dans Cat. ([4]) D'autre part, $\boxed{\text{L1, L2 bis, L5}}$ impliquent L1,2,3,4,5.
On va supposer ici aussi qu'on ait au moins L1, L3, L4 (i.e. W un localisateur). En appliquant la construction de I, p. 72-**75,** on voit que $f : X \longrightarrow Y$ est dans W si et seulement si $f^o : X^o \longrightarrow Y^o$ l'est. Donc L1, L3, L4 impliquent L3′, L4′ (axiomes duaux de L3, L4).
Il y avait des axiomes complémentaires

La $f \in W \Longrightarrow \pi_0(f)$ *bijectif.*

3. il y a un L4′ dual de L4.

4. Si W `[est]` un localisateur, alors les catégories contractiles sont W-asphériques, les homotopismes sont dans W, les applications homotopes sont égales dans $(\mathrm{Cat})W^{-1} \overset{\text{déf}}{=} \mathrm{Hot}_W$.

Lb *Le foncteur canonique de localisation*

$$\mathrm{Cat} \longrightarrow (\mathrm{Cat})W^{-1} \overset{\text{déf}}{=} \mathrm{Hot}_W$$

commute aux sommes finies.

Lc *Itou pour produits finis.*

Il faudrait quand même dégager des conditions concrètes sur W pour la validité de Lb, Lc. p. 3
Les conditions L3 quater et La s'écrivent respectivement

$$W_\infty \subseteq W, \quad W \subseteq W_0.$$

[page 3]

Commentary · Exposition [ms. 2]

What the first fibration axiom already gives

Grothendieck's short implication from L1, L2 bis and the original L5 can be expanded into a useful collection of elementary arguments. It also clarifies why that first L5 becomes dispensable after relative descent has been imposed. First apply L5 to the cartesian functor [1] × A →A between fibrations over A. Its fibre map is [1] →{∗}, so L2 follows. For the projection p : A × [1] →A and its sections e0, e1, two-out-of-three gives e0, e1 ∈W. If H : A × [1] →B is a natural transformation between F and G, it follows that F ∈W if and only if G ∈W: both are equivalent to H ∈W. Moreover, Qe0 = Qp−1 = Qe1, whence QF = QG. An adjoint pair F ⊣G has GF and FG connected to the corresponding identities by its unit and counit. Both composites belong to W, and L1(c) gives F, G ∈W. Applying this to the terminal-object adjunction proves L3, and the initial-object case follows as well.

There is a particularly concrete way to obtain invariance under opposites without assuming it. Let T(A) have objects the arrows a →b of A, with a morphism from a →b to a′ →b′ given by a′ →a and b →b′ making the evident rectangle commute. The two projections

T(A)op −→A,

T(A)op −→Aop are fibrations. Their fibres are respectively (a\A)op and A/b, each with a terminal object. L5, applied to each projection as a cartesian functor to the identity fibration, makes both projections elements of W. Their naturality in A and two-out-of-three now imply

T(f)op ∈W

f op ∈W. f ∈W ⇐⇒ ⇐⇒ Here the fibration assertion can be checked directly: a change of the first endpoint is made by precomposition before taking opposites, and a change of the second endpoint by postcomposition. These are the specified cartesian lifts after reversal.

Now let f : X →Y be a map over S such that every f/s : X/s →Y/s belongs to W. The construction Ψ on manuscript pages 17–20 produces split opfibrations with these maps as their fibre maps, and Ψ(f) preserves the chosen cocartesian lifts. After taking opposites, L5 applies, so Ψ(f) ∈W. The natural maps X →Ψ(X) and Y →Ψ(Y) are homotopy equivalences by the adjunction exhibited below; hence two-out-of-three gives f ∈W. This proves even L4 bis, and therefore L4. Each ingredient is independent of the later, much stronger L5. The argument verifies the implication recorded here while anticipating only constructions that Grothendieck gives explicitly in the next few pages.

Leur conjonction est l'axiome des plus raisonnables

$$W_\infty \subseteq W \subseteq W_0.$$

Bien sûr, l'axiome L5 a maintenant l'air un peu étriqué, i.e. faiblard. On va voir très vite de quoi on aura besoin!
On veut donc définir un dérivateur

$$\mathrm{HOT}_W$$

à partir de la catégorie de modèles

$$(\mathrm{Cat}, W \subseteq \mathrm{Fl}(\mathrm{Cat})).$$

Donc pour définir

$$\mathrm{HOT}_W(S) \qquad\qquad (S \in \mathrm{Ob}\,\mathrm{Cat}),$$

la récette générale est de prendre la catégorie

$$\mathcal{M}(S) = \mathrm{Cat}(S) = \underline{\mathrm{Hom}}(S^o, (\mathrm{Cat})),$$

d'y introduire l'ensemble de flèches

$$\begin{cases} W_S \subseteq \mathrm{Fl}(\mathcal{M}(S)) \\ u \in W_S \iff u_s \in W \quad \forall\, s \in \mathrm{Ob}\, S. \end{cases}$$

On doit poser

$$\mathrm{HOT}_W(S) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(S^o, \mathrm{Cat}) W_S^{-1}.$$

Mais la catégorie $\underline{\mathrm{Hom}}(S^o, \mathrm{Cat})$ s'interprète, à isomorphisme canonique près, comme celle

$$\underline{\mathrm{Fibsc}}\, S$$

des catégories X Cat-fibrées sur S, munies d'un 'scindage', i.e. d'un choix de foncteurs changement de base $u^* : X_t \longrightarrow X_s$ (pour $t \overset{u}{\to} s$ dans S) [plutôt $u^* : X_s \longrightarrow X_t$], avec de plus *transitivité stricte*

$$(vu)^* = u^* v^* \qquad \text{si } \; t \overset{u}{\to} s \overset{v}{\to} r \;\text{ dans } S$$

[page 4]

Commentary · Exposition [ms. 3]

Products and sums survive the localization

Grothendieck asks for concrete conditions ensuring Lb and Lc because a homotopy theory should still allow objects to be assembled and compared. A useful answer is available as soon as relative L4 bis is admitted. We give the argument, including the passage from closure of weak equivalences to the universal property of products and coproducts.

Suppose W satisfies L1, L2 and L4 bis. If f : A →B lies in W, then f × idC lies in W for every C. View this map over C. Its comma map at c is f × idC/c. Since C/c has a terminal object, the two projections A × (C/c) →A and B × (C/c) →B are homotopy equivalences: the terminal object defines sections and a contraction natural transformation. They are in W by the preceding block. Two-out-of-three makes the comma map a weak equivalence, and L4 bis gives the assertion. The same axiom, applied over a discrete indexing category I, shows that ‘ i fi ∈W whenever every fi ∈W. The latter closure is also Cisinski (2004, Proposition 1.1.5).

For completeness, localization of a product of relative categories is the product of their localizations. One can see this directly from the generators: (w, id) and (id, w′) become invertible, their commutation squares still commute after inversion, and a pair of finite zigzags can be interleaved to give a zigzag in the product. Consequently both the diagonal and the binary product functor descend. The adjunction Δ⊣× descends with its original unit and counit, since those are natural transformations between relative functors and the triangle identities remain identities. Its descended right adjoint is therefore a binary product in Cat[W −1]. The same argument with ‘ ⊣Δgives binary coproducts. The adjunctions defining the initial and terminal objects descend without any closure hypothesis beyond identities belonging to W.

Thus finite products and coproducts are preserved by Q under these concrete assumptions. This is an ordinary localization argument, not a claim that arbitrary homotopy limits or colimits agree with ordinary ones. In particular, it does not supply the derived Kan extensions needed for the derivator. Those require the diagram categories whose construction begins here.

et non seulement transitivité à isomorphisme canonique près. Ainsi on peut écrire aussi p. 4

$$(*) \qquad \mathrm{HOT}_W(S) \xrightarrow{\sim} (\underline{\mathrm{Fibsc}}\, S) W_S^{-1},$$

où cette fois W_S est interprété comme

$$W_S \subseteq \mathrm{Fl}(\underline{\mathrm{Fibsc}}\, S),$$

savoir

$$W_S = \{u \in \mathrm{Fl}(\underline{\mathrm{Fibsc}}\, S) \mid u_s \in W \text{ pour tout } s \in \mathrm{Ob}\, S\}$$

(foncteurs strictement cartésiens, i.e. commutant aux scindages, qui induisent des W-équivalences entre les catégories fibres).

La flèche dans $(*)$ est bel et bien un isomorphisme de catégories, pas seulement une équivalence. Mais on va définir d'autres catégories, plus commodes à certains égards, qui seront *équivalentes* (on l'espère), mais sûrement pas isomorphes, à $\mathrm{HOT}_W(S)$. (On s'occupera plus tard de la variance de $\mathrm{HOT}_W(S)$ en S.)

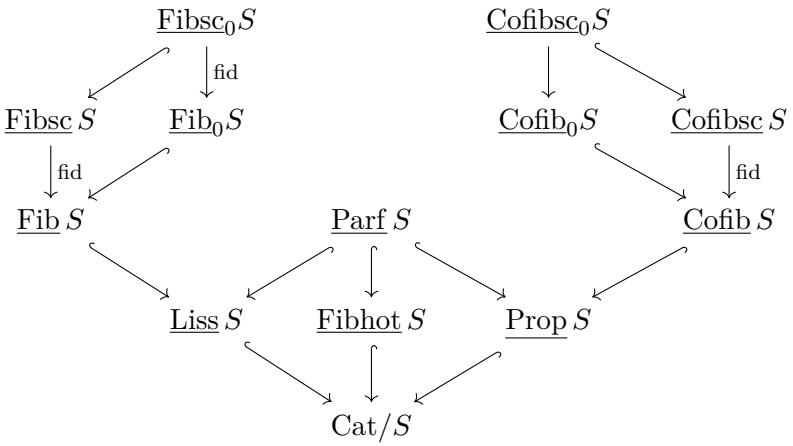
Les catégories $\underline{\mathrm{Hom}}(S^o, \mathrm{Cat})$, $\underline{\mathrm{Fibsc}}\, S$, ainsi que les variantes que nous allons introduire maintenant, sont en fait des 2-catégories. Mais pour décrire $\mathrm{HOT}_W(S)$, seule les structures de 1-catégories sont utilisées. On a l'impression que c'est bien grossier, qu'on perd quelque [page 5]
chose ce faisant. Mais ce qui est perdu va se retrouver, et surabondamment, dans la structure des $\underline{\mathrm{Hom}}$ internes dans les $\mathrm{HOT}(S)$, si on se 'rappelle' que ces $\underline{\mathrm{Hom}}$ internes, donnant lieu à des 'types d'homotopie relatifs' $\underline{\mathrm{Hom}}_{\mathrm{HOT}_W}(S; \xi, \eta)$ (si ξ, η en sont), peuvent s'interpréter en termes de ∞-champs en groupoïdes sur S, avec toute la richesse de structure qui leur appartient. Mais ceci est une autre histoire…

Commentary · Exposition [ms. 4]

A diagram written as its category of elements

Grothendieck passes to fibrations in order to replace an externally indexed diagram by one category carrying a projection to its index. This is the same organizing construction used in descent; the relevant background is Grothendieck (1971, Exposé VI, §§8–9). It is useful to write out the variance because both directions of the construction will soon be needed.

For F : Sop →Cat, its Grothendieck construction has objects (s, x) with x ∈F(s). An arrow (s, x) →(t, y) consists of u : s →t and a : x →F(u)y in F(s). Composition is



(v, b) ∘(u, a) = (vu, F(u)(b) ∘a).

The chosen cartesian lift of u at (t, y) is (u, id) : (s, F(u)y) →(t, y). The strict functoriality of F makes these choices compose strictly. Conversely, a normalized splitting of a fibration gives strict pullback functors u∗, with (vu)∗= u∗v∗and identity pullbacks equal to identities. These equations, rather than the existence of unspecified isomorphisms, are what is meant by a splitting.

A natural transformation F →G induces a functor of the total categories that preserves the specified lifts. Conversely, such a functor restricts to the components of a strict natural transformation. Therefore the weak equivalences in the diagram category correspond exactly to fibrewise weak equivalences among splitting-preserving functors. With fibrations encoded by their fibre families, this is the identification Grothendieck calls an isomorphism. If arbitrary underlying object sets for total categories are allowed, the usual construction and reconstruction are canonically isomorphic over S, and the comparison is expressed as an equivalence. No homotopical argument depends on this bookkeeping convention.

The subsequent forgetful functor to Fib S changes the morphisms: there one allows all functors over S. Forgetting a splitting is therefore not merely forgetting redundant labels. The natural comparison maps used later must be checked in the category whose morphisms they actually preserve. This is the source of the obstruction on manuscript pages 32–39, and of the strictification work beginning on page 52.

En fait, je vois un diagramme de 13 catégories de 'categories sur S', à examiner à présent

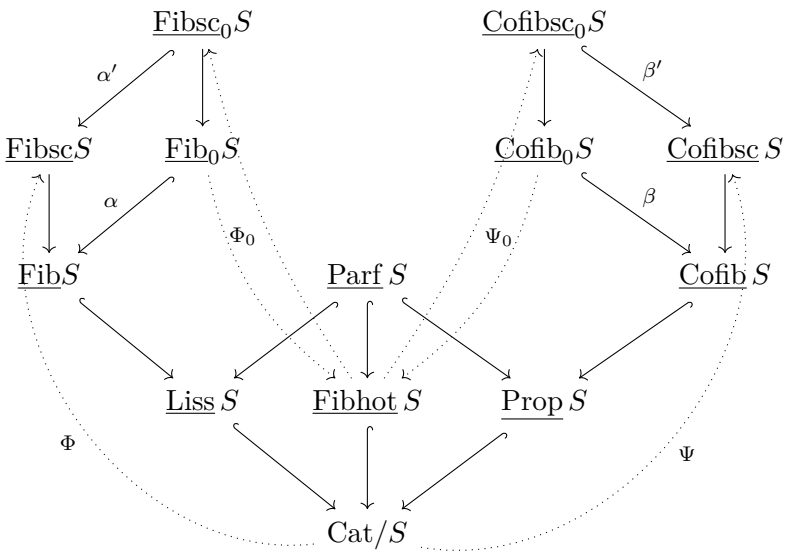
où Fib, Cofib désignent les catégories Cat-fibrées, Cat-cofibrées sur S, Liss et Prop les catégories lisses resp. propres sur S, Parf celles qui sont à la fois lisses et propres (fibrations parfaites), enfin Fibhot les catégories Hot-fibrées sur S. Toutes les flèches sont des foncteurs strictement pleinement fidèles, à l'exception des deux (plutôt quatre) flèches verticales supérieures, qui sont fidèles sans plus. Je viens d'en rajouter encore 4, de catégories : Fibsc$_0$, Fib$_0$, Cofibsc$_0$, Cofib$_0$ sont les sous-catégories pleines des catégories correspondantes sans indice, formées des catégories fibrées resp. cofibrées X sur S, pour lesquelles les foncteurs changement de base resp. cochangement de base p. 5 [page 6]

$$u^* : X_t \longrightarrow X_s, \qquad \text{resp.} \qquad u_* : X_s \longrightarrow X_t,$$

pour $s \xrightarrow{u} t$ dans S, sont des Hot-équivalences. En termes de foncteurs

$$S^o \xrightarrow{F} \mathrm{Cat} \qquad \text{resp.} \qquad S \xrightarrow{F'} \mathrm{Cat},$$

cela signifie que ce foncteur transforme flèches quelconques dans S en éléments de W dans Cat, i.e. qu'on a un diagramme commutatif



$$\begin{array}{ccc} S^o & \xrightarrow{\qquad F \qquad} & \mathrm{Cat} \\ {\scriptstyle \mathrm{can}}\downarrow & & \downarrow{\scriptstyle \mathrm{can}} \\ \Pi(S^o) \simeq (\Pi S)^o = S^o(\mathrm{Fl}\, S^o)^{-1} & \xrightarrow[\bar F]{} & \mathrm{Hot}_W = (\mathrm{Cat})W^{-1} \end{array}$$

(et de même pour F'), i.e. qu'on a un 'système local' $\bar F$ sur S, à valeurs dans Hot$_W$, défini à l'aide de F. Je rappelle qu'on trouve également un tel système local dans le cas d'une catégorie Hot-fibrée sur S (et même un système local à valeurs dans Hot lui-même, au lieu de Hot$_W$ - on utilise ici tacitement que $W_\infty \subseteq W$, i.e. L3 quater ([5])). Et il en est de même a fortiori pour les objets de Parf S. Pour Liss S resp. Prop S, on trouve simplement un foncteur [page 7]

$$S^o \xrightarrow{\bar F} \mathrm{Hot} \qquad \text{resp.} \qquad S \xrightarrow{\bar F'} \mathrm{Hot},$$

d'où, en composant avec Hot $\longrightarrow$ Hot$_W$, des foncteurs à valeurs dans Hot$_W$.

Dans chacune de ces 14 [13?] catégories, on introduit un ensemble de flèches, qui serviront à localiser, et on le désignera toujours par la même notation W_S. Dans toutes ces catégories sauf seulement Cat/S, W_S désigne la W-équivalence 'fibre par fibre'. Dans Cat/S d'autre part, ce sera la W-équivalence sans plus. Toutes les flèches du diagramme sont compatibles avec les ensembles localisants de flèches. p. 6 [page 8]

Commentary · Examples [ms. 7]

A local system in the homotopy category misses twisting

Grothendieck's passage from F to F$^-$: Π(Sop) →HotW records monodromy, but he also signals on page 5 that richer coherence remains. A familiar pair of bundles makes the difference visible. We use ordinary spaces to display the phenomenon; replacing spaces by their simplex categories gives categorical models with the same homotopy information.

Consider the trivial circle bundle S2 × S1 →S2 and the Hopf bundle (Hatcher, 2002, Examples 4.45 and 4.51)

S3 = {(z0, z1) ∈C2 : |z0|2 + |z1|2 = 1} −→CP1 ∼= S2, (z0, z1) 7−→[z0 : z1]. On the chart z0 = 0, with coordinate w = z1/z0, a trivialization is

λ

λ ∈S1. (w, λ) 7−→ 1 + |w|2 (1, w), p The other chart is analogous. Thus both maps are locally trivial bundles with fibre S1, and hence fibrations. Since the base is simply connected, their parallel transport determines the same functor from the fundamental groupoid to the homotopy category: a constant local system with value S1. Nevertheless they are not fibre homotopy equivalent. Such an equivalence would induce a weak equivalence of total spaces by the homotopy exact sequences, whereas

H1(S2 × S1; Z) = Z.

H1(S3; Z) = 0, The missing information is the coherence of transport around two-dimensional homotopies, not an additional choice of monodromy around loops.

In contemporary language the appropriate datum is a functor from the entire homotopy type of the base, considered as an ∞-groupoid, to spaces. Passing to the fundamental groupoid of the base and the ordinary homotopy category of spaces discards part of that datum. Straightening and unstraightening provide the relevant modern comparison; Lurie (2009, Theorems 2.2.1.2 and 3.2.0.1) treat respectively space-valued and category-valued versions. Here this explains the direction of Grothendieck's remark about ∞-groupoid stacks, without asserting that a single ordinary category HOTW (S) already determines every higher structure he envisages. The commentary on the earlier chapters, on what a diagram theory remembers, remains applicable.

There is also a small logical distinction in the definition on page 6. If the subscript 0 means that all transition functors lie in W∞, their images lie in W once W∞⊆W. The converse need not hold for a larger W. A W-locally constant diagram and an ordinarily homotopically locally constant diagram must therefore be distinguished whenever W is still variable.

`[Dans ce diagramme, il y a aussi` Liss$_0$ `et` Prop$_0$ `mais sans connexion aux autres objets.]`

5. On va le supposer vrai dans toute la suite.

Je suis quasiment sûr du

Theorème. ([6]) *Tous les foncteurs précédents induisent des équivalences entre les catégories localisées.*

Comme il y a 16 foncteurs, ça a l'air d'un exercise de patience. Le principe général, c'est qu'on arrive à définir des foncteurs en sens inverse, compatibles avec les W_S, de telle façon que les composés soient reliées aux foncteurs identiques par des flèches qui sont dans W_S, de sorte que par passage aux localisés ces foncteurs induisent des (équivalences) quasi-inverses des foncteurs déduits de ceux du diagramme. Tous ces foncteurs en sens opposé résultent essentiellement par composition, de trois foncteurs bien familiers. Deux de ceux-ci sont indiqués en pointillés sur le diagramme, comme Φ, Ψ.

Le troisième est un foncteur canonique [page 9]

$$C : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Parf}}\, S,$$

qu'on va expliciter également.

Commentary · Examples [ms. 8]

The walking arrow detects the failed equivalence

Grothendieck's first comparison theorem would identify all the categories in the large diagram after the specified localizations. The later marginal note withdraws it. The obstruction already occurs over the smallest base with a noninvertible arrow and explains why the distinction between fine and coarse equivalence occupies the rest of the chapter.

Let S = [1] = (0 →1) and take W = W∞. Consider the contravariant diagrams

F(1) = ∅,

F(0) = {∗}, G(0) = G(1) = {∗}. There is a unique natural transformation F →G. Its Grothendieck construction is the functor {0} ,→[1] over S. Both source and target are split fibrations, and both total categories have contractible nerve, so this map is a coarse weak equivalence. Its fibre at 1 is ∅→{∗}, which is not a weak equivalence.

This difference persists after localization; it is not merely a difference between two presenting classes of arrows. Evaluation at 1 descends from the category of strict diagrams localized at objectwise weak equivalences to Hot. The displayed map has image ∅→{∗} there and therefore cannot become an isomorphism. Its coarse image is invertible by definition. Thus the forgetful comparison from fibrewise localization to coarse localization is not an equivalence. The same argument applies whenever W ⊆W0, since then empty and nonempty categories cannot become isomorphic after applying $\pi 0$.

The locally constant subcategory is also genuinely smaller. If a diagram H(1) →H(0) has a weak equivalence as its transition and were isomorphic to F after objectwise localization, evaluation would make H(1) empty and H(0) contractible in Hot, contradicting the invertibility of its transition. Reversing all arrows gives the corresponding example for split opfibrations. This does not invalidate the formal localization lemma on the next pages: the missing hypothesis is that its comparison transformations lie in the particular weak-equivalence classes being used.

Le foncteur Φ (resp. Ψ) appliqué à $\underline{\mathrm{Fib}}_0 S$ (resp. $\underline{\mathrm{Cofib}}_0 S$), induit un foncteur p. 7

$$(*) \qquad \underline{\mathrm{Fib}}_0 S \longrightarrow \underline{\mathrm{Fibsc}}_0 S \qquad \text{resp.} \qquad \underline{\mathrm{Cofib}}_0 S \longrightarrow \underline{\mathrm{Cofibsc}}_0 S$$

(ce qu'il faudra vérifier). Cela fournit toutes les flèches 'inverses' dont on a besoin, à l'exception seulement de α, β, α', β'. Mais si on a prouvé, par la méthode indiquée, que toutes les flèches du diagramme induisent des équivalences sur les catégories localisées, pour prouver qu'il en est encore de même pour α, β, α', β', il suffit de le prouver pour les deux foncteurs

$$\underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fib}}\, S, \qquad \underline{\mathrm{Cofibsc}}_0 S \longrightarrow \underline{\mathrm{Cofib}}\, S,$$

6. C'est totalement canulé, cf. commentaires page 32 ff., solution des perplexités pages 41 ff. Voir surtout le Théorème-Scholie récapitulatif p. 70-81.

donc il reste à définir les foncteurs en sens inverse

$$\underline{\mathrm{Fib}}\, S \longrightarrow \underline{\mathrm{Fibsc}}_0 S, \qquad \underline{\mathrm{Cofib}}\, S \longrightarrow \underline{\mathrm{Cofibsc}}_0 S,$$

et comme les sources sont des sous-catégories pleines de Cat/S, il suffira de définir

$$\Phi_0 : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Fibsc}}_0 S, \qquad \Psi_0 : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Cofibsc}}_0 S.$$

Pour ceci, on posera

$$(**) \qquad \Phi_0 = \Phi r C, \qquad \Psi_0 = \Psi r C,$$

où $C : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Parf}}\, S$, Φ et Ψ sont les 3 foncteurs 'rétrogrades' inversés plus haut, et $r : \underline{\mathrm{Parf}}(S) \hookrightarrow \mathrm{Cat}/S$ est l'inclusion. Il faut donc vérifier que Φ_0, Ψ_0 définis par $(**)$, qui a priori ont comme catégories but $\underline{\mathrm{Fibsc}}\, S$ et $\underline{\mathrm{Cofibsc}}\, S$, prennent leur valeur dans les sous-catégories avec indice 0. [page 10]

Je vais donner un énoncé d'équivalence unique, qui couvrira (presque) tous les 16 cas à la fois :

Corollaire. *Considérons le diagramme*

$$\begin{array}{ccccc} & & \underline{\mathrm{Parf}}\, S & & \\ & & \downarrow{\scriptstyle r} & & \\ \underline{\mathrm{Fibsc}}_0 S & \overset{p}{\searrow} & & \overset{q}{\swarrow} & \underline{\mathrm{Cofibsc}}_0 S \\ & & \mathrm{Cat}/S & & \end{array}$$

et soit $\mathcal{F}$ une sous-catégorie pleine de Cat/S, telle que l'un des foncteurs p, q, r se factorise par $\mathcal{F}$. Soit $W_{\mathcal{F}}$ induit sur $\mathcal{F}$ par W_S dans Cat/S. Alors $\mathcal{F} \hookrightarrow \mathrm{Cat}/S$ induit une équivalence sur les catégories localisées.

DÉMONSTRATION. Je dis qu'il suffit de prouver, pour les trois foncteurs p, q, r, et pour les foncteurs en sens inverse [page 11] p. 8

$$\begin{array}{ccccc} & & \underline{\mathrm{Parf}}\, S & & \\ & & \uparrow{\scriptstyle C} & & \\ \underline{\mathrm{Fibsc}}_0 S & \overset{\Phi_0}{\nwarrow} & & \overset{\Psi_0}{\nearrow} & \underline{\mathrm{Cofibsc}}_0 S \\ & & \mathrm{Cat}/S & & \end{array}$$

que les six composés

$$p\Phi_0, \Phi_0 p, q\Psi_0, \Psi_0 q, rC, Cr$$

sont reliés aux foncteurs identiques (dans la catégorie pertinente) par une flèche qui est dans le localisateur correspondant. Pour chacun de ces trois couples de foncteurs (p, Φ_0), (q, Ψ_0), (r, C), cela prouvera déjà qu'en passant aux localisés, ils induisent des équivalences quasi-inverses l'une de l'autre. Mais on a mieux à l'aide du lemme formel suivant.

Lemme. *Soient (C, W), (C', W') deux catégories avec localisateurs $W \subseteq \mathrm{Fl}\, C$, $W' \subseteq \mathrm{Fl}\, C'$. Soit*

$$p : C \longrightarrow C'$$

un foncteur compatible avec les localisateurs, et supposons qu'il existe un foncteur $\varphi : C' \longrightarrow C$ également compatible, et tel que l'on ait des flèches (à direction non précisée)

$$\varphi p \xrightarrow{u} id_C, \qquad p\varphi \xrightarrow{v} id_{C'},$$

qui soient dans W resp. W' 'argument par argument'. [page 12]

Alors p et φ induisent des équivalences quasi-inverses l'une de l'autre en passant aux catégories localisées (elles n'ont pas de merite). De plus, pour toute sous-catégorie pleine C'_0 de C', telle que p se factorise (en $p_0 : C \longrightarrow C'_0$) par C'_0, si on désigne par W'_0 le localisateur induit dans C'_0 par C', alors $p_0 : C \longrightarrow C'_0$ et $\varphi_0 = \varphi|C'_0 : C' \longrightarrow C$ [plutôt $C'_0 \longrightarrow C$] induisent également des équivalences quasi-inverses l'une de l'autre sur les localisés.

En effet, $\varphi_0 p_0 = (\varphi i)p_0 = \varphi(ip_0) = \varphi p \xrightarrow{u} \mathrm{id}_C$ (ici $i : C'_0 \hookrightarrow C'$ désigne l'inclusion), et $F \overset{\text{déf}}{=} p_0\varphi_0 = p_0\varphi i$ satisfait à

$$iF = \underbrace{ip_0}_{p}\varphi i = (p\varphi)i.$$

Pour définir $F \xrightarrow{v_0} \mathrm{id}_{C'_0}$, qui soit dans W'_0 argument par argument, il suffit de définir [page 13]

$$\underbrace{iF}_{=(p\varphi)i} \xrightarrow{\bar{v}_0} i,$$

qui soit dans W' argument par argument, puisque W'_0 induit par W' et que $F \longmapsto iF$

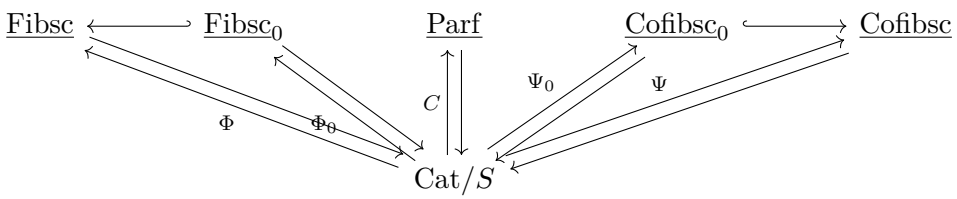
$$\underline{\mathrm{Hom}}(C'_0, C'_0) \longrightarrow \underline{\mathrm{Hom}}(C'_0, C')$$

Commentary · Exposition [ms. 12]

The localization lemma keeps its full force

Grothendieck separates a sound formal mechanism from the geometric assertions to which he hopes to apply it. The lemma is useful precisely because its hypotheses record both kinds of information: preservation of weak equivalences by the functors, and membership of the comparison maps in the specified weak-equivalence classes.

Let P : (C, W) →(D, V) and R : (D, V) →(C, W) be relative functors. Suppose natural transformations, in either direction, connect RP with idC and PR with idD, with all components respectively in W and V . Their images under localization are natural isomorphisms. The induced functors P^- and R^- are therefore quasi-inverse equivalences. One needs neither a calculus of fractions nor triangle identities for the original transformations. Quasi-inverse equivalences, unlike a prescribed adjunction, require only the two natural isomorphisms.



Now suppose P factors through a full subcategory i : D0 ,→D, written P = iP0, and put V0 = V ∩Mor(D0) and R0 = Ri. The first comparison restricts to R0P0 = RP. The second restricts to a transformation between iP0R0 and i. Because both of its endpoints lie in D0, fullness gives a unique transformation between P0R0 and idD0; faithfulness verifies its naturality. Every component belongs to V0. Consequently P0 and R0 also give inverse equivalences after localization. Applying the same argument to i shows that D0[V −1] →D[V −1] is an equivalence.

This explains the apparently strong corollary about an arbitrary full subcategory containing the image of a replacement functor. The weak-equivalence class on that full subcategory must be the induced one. For example, a full subcategory of Cat/S containing all perfect replacements may calculate the coarse localization. Nothing in the lemma permits changing its induced coarse class to the fibrewise class without proving their agreement. Nor does fullness apply to the passage from splitting-preserving maps to arbitrary maps over S: that functor is generally faithful but not full. These are the two points at which the first comparison diagram asks for additional mathematics.

est pleinement fidèle (i l'étant). Or il suffit de prendre p. 9

$$\bar{v}_0 = v * i : (p\varphi) \circ i \text{ —} \mathrm{id}_{C'} \circ i.$$

Pour résumer, il faut montrer que le composé des couples de foncteurs quasi-inverses marche dans les cinq cas suivants

D'ailleurs par dualité, on est ramené aux trois cas de $\underline{\text{Fibsc}}$, $\underline{\text{Fibsc}}_0$, $\underline{\text{Parf}}$. (Peut-être le cas $\underline{\text{Fibsc}}_0$, avec Φ_0 défini en termes de Φ et de C, se ramènera-t-il aux deux cas qui l'entourent, de $\underline{\text{Fibsc}}$ et $\underline{\text{Parf}}$.)

Je vois que je dois rectifier le tir, tout d'abord parce que j'ai oublié que les foncteurs Φ, Ψ [page 14] que j'avais en vue ne sont *pas* compatibles avec les localiseurs `[= localisateurs]` - une flèche $f : X \longrightarrow Y$ de Cat/S telle que la flèche correspondante dans Cat soit dans W, ne va pas induire une flèche dans $\underline{\text{Fibsc}}\, S$ ou $\underline{\text{Cofibsc}}\, S$ qui soit dans W sur chaque fibre. Ce n'est pas grave, car on peut remplacer les foncteurs par $\Phi' = \alpha'\Phi_0$, $\Psi' = \beta'\Psi_0$, qui sauf erreur doivent marcher. Mais en vue du Lemme précédent, il y a une perplexité, car j'ai l'air d'avoir prouvé que si $\mathcal{F}$ est une sous-catégorie pleine de Cat/S dont je suppose seulement qu'elle contient l'image essentielle d'une des trois catégories $\underline{\text{Fib}}_0 S$, $\underline{\text{Cofib}}_0 S$, ou $\underline{\text{Parf}}\, S$, alors l'inclusion dans Cat/S induit une équivalence des catégories localisées, en prenant dans $\mathcal{F}$ comme localisateur celui induit par Cat/S, i.e. $f : X \longrightarrow Y$ (triangle sur S) est dans $W_{\mathcal{F}}$ si et seulement si en tant que flèche de Cat, f est dans W. Or ceci coïncide bien (via un théorème non trivial sur lequel je devrai revenir dans le cadre d'un localisateur fondamental général W) avec l'ensemble de flèches de localisation 'fibre par fibre', dans le cas de $\mathcal{F} = \underline{\text{Parf}}\, S$, $\underline{\text{Fibhot}}\, S$, $\underline{\text{Fib}}_0 S$, $\underline{\text{Cofib}}_0 S$.

Par contre, ce n'est nullement le cas en prenant $\mathcal{F} = \underline{\text{Fib}}\, S, \underline{\text{Liss}}\, S$ ou $\underline{\text{Cofib}}\, S$. Ayant choisi [page 15] dans ces catégories comme localisateurs la notion de W-équivalences 'fibre par fibre', j'ai donc l'air de dire que je trouve pour ces quatre catégories les *mêmes* localisées (à équivalence près) que si je prenais le localisateur beaucoup plus grossier hérité par Cat/S. Cela semble difficile à croire, et il faudra que je fasse très attention en démontrant les énoncés-clef.

Pour voir que les flèches en traits pleins du grand diagramme p. 6 sont toutes compatibles avec les localis(at)eurs `[sic]`, donc aussi les flèches composées au moyen de celles-ci, j'ai à utiliser déjà ceci (pour le cas des flèches $\underline{\text{Liss}} \longrightarrow \text{Cat}/S$, $\underline{\text{Prop}} \longrightarrow \text{Cat}/S$):

① Si X, Y lisses ou propres sur S, et $f : X \longrightarrow Y$ un S-foncteur, si $f_s : X_s \longrightarrow Y_s$ est p. 10 dans W pour tout $s \in S$, alors $f \in W$. ([7]).

Cela renforce considérablement la condition L5 sur W, où on supposait que f est un foncteur *cartésien* entre catégories *fibrées* sur S. (À dégager, pour les différentes propriétés dont on a besoin pour W, à quelles propriétés standard on peut les ramener. Tout sera OK si $W = W_\infty$.)

I) **Définition de Φ, Ψ.** [page 16]

Commentary · Exposition [ms. 15]

The precise local-to-global argument

Grothendieck needs fibrewise equivalence to imply total equivalence without requiring a map of fibrations to preserve cartesian arrows. Smoothness or properness provides the comparison between strict fibres and comma categories that makes this possible. The treatment of these notions in the commentary on Chapter I explains the lifting categories behind those comparisons; here their role is descent for a map of total categories.

For a proper functor p : X →S, the canonical functor Xs →X/s is a W∞-equivalence; for a smooth functor, the corresponding functor is Xs →s\X. These assertions, in the appropriate aspherical form, are the criterion developed in Maltsiniotis (2005, Theorem 1.2 and its dual). Suppose X, Y are proper over S and f : X →Y is any functor over S. Naturality gives

Xs

Ys

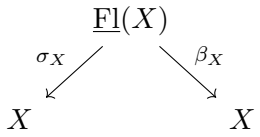
X/s

Y/s. Under W∞⊆W, the vertical maps belong to W. The two-out-of-three property implies that fs ∈W if and only if f/s ∈W. If this holds for every s, relative L4 bis gives f ∈W. For smooth functors the proof uses the undercategories and the dual relative axiom. No cartesian or cocartesian condition on f occurs.

7. OK si on suppose L3 quater et L4.

The argument also explains the eventual universal statement on pages 41–43. Proper and smooth functors are stable under change of base. For S′ →S, the strict fibre of the pulled-back map at s′ is fs′ = fp(s′). Applying the same proof over S′ shows that a fibrewise equivalence between two proper objects, or between two smooth objects, remains a total equivalence after every base change.

The parenthetical assertion here that L3 quater and L4 suffice suppresses one hypothesis: the version of Theorem A actually used is relative L4 bis. Absolute L4 directly covers the case Y = S, since S/s has a terminal object. For general Y it is the stronger formulation that is needed in the displayed proof. Grothendieck explicitly identifies this distinction on manuscript page 44. We follow that correction rather than assigning an unproved consequence to the initial axiom.



On va calquer la construction canonique de $\underline{\mathrm{Ch}}(X) \longrightarrow X \times X$ (ou $\underline{\mathrm{Ch}}_\infty(X) \longrightarrow X \times X$) factorisant $X \xrightarrow{\mathrm{diag}} X \times X$, et la factorisation canonique correspondante d'un $f : X' \longrightarrow X$ en $X' \xrightarrow{i} \bar{X}' \xrightarrow{\bar{f}} Y$ [plutôt $\bar{X}' \xrightarrow{\bar{f}} X$]. On remplacera simplement $\underline{\mathrm{Ch}}(X)$ par la sous-catégorie $\underline{\mathrm{Ch}}_+(X)$, laquelle n'est autre que la catégorie des flèches de X

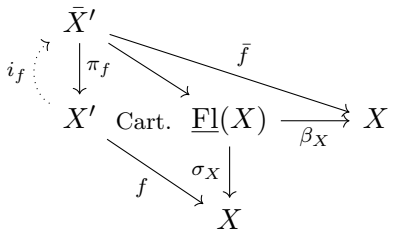
$$\underline{\mathrm{Fl}}(X) = \underline{\mathrm{Hom}}(\mathbf{\Delta}_1, X),$$

muni des foncteurs

$$X \xrightarrow{i_X} \underline{\mathrm{Fl}}(X) \xrightarrow{p_X=(\sigma_X,\beta_X)} X \times X,$$

où i_X est la flèche $x \longmapsto \mathrm{id}_x$, et σ_X, β_X sont les foncteurs source et but. La fibre de p_X en $(a, b) \in \mathrm{Ob}(X \times X)$ est la catégorie discrète définie par l'ensemble $\mathrm{Hom}(a, b)$, ça dépend grandement de (a, b) et pas seulement de sa composante connexe dans $X \times X$ - donc p_X n'a rien d'une Hot-fibration. Il n'est en géneral ni propre ni lisse ni rien, par contre les deux flèches composées avec pr_1 et pr_2

sont sympathiques, on a en effet



Lemme. *On a* [page 17]

$$\sigma_X^{-1}(\{x\}) \simeq x\backslash X, \qquad \beta_X^{-1}(\{x\}) \simeq X/x.$$

Le foncteur σ_X est Cat*-fibrant à fibres contractiles (donc asphériques, donc W-asphériques), le foncteur β_X cofibrant à fibres contractiles (donc asphériques, donc W-asphériques). Ce sont donc aussi des* Hot*-équivalences, a fortiori des W-équivalences* ([8]).

Corollaire 1. *Le foncteur $i_X : X \longrightarrow \underline{\mathrm{Fl}}(X)$ est une* Hot*-équivalence* (puisque son composé avec la Hot-équivalence σ_X est l'identité).

Voici la construction générale de la factorisation de $f : X' \longrightarrow X$, correspondant au choix précédent d'une 'catégorie de chemins' $\mathcal{C}(X) = \underline{\mathrm{Fl}}(X)$ p. 11

8. En fait, ce sont même des homotopismes, cf. remarque marginale plus bas (plus générale - on retrouve le cas de σ_X en faisant $X' = X$.)

où i_f est déduit de la section i [plutôt i_X] de $\underline{\mathrm{Fl}}(X)$ sur X ([9]). Ainsi, $\bar{X}'$ est la catégorie des couples

$$\{(x', u) \mid x' \in \mathrm{Ob}\, X', \quad \underbrace{u}_{\in \mathrm{Fl}\,(X)} : f(x') \longrightarrow y\},$$

le foncteur $\bar{f}$ est défini par

$$\bar{f}(x', u) = \mathrm{but}(u) = y$$

et i_f par

$$i_f(x') = (x', \mathrm{id}_{f(x')} : f(x') \xrightarrow{\mathrm{id}} f(x')),$$

donc on a bien

$$f(x') = \bar{f} i_f(x').$$

Corollaire 2. *Le foncteur* [page 18]

$$\bar{f} : \bar{X}' \longrightarrow X$$

a comme fibres les catégories X'/x, il est cofibrant, les foncteurs de changement de base sont les foncteurs $X'/x \longrightarrow X'/y$ associés aux flèches $x \longrightarrow y$ dans X.

Commentary · Exposition [ms. 17]

The arrow category has two different good endpoints

Grothendieck introduces a path construction which remembers the direction of an arrow. Its endpoint maps are excellent replacement tools separately, although the pair of endpoints is not a homotopy-fibration model of the diagonal. The elementary adjunctions make all of these assertions transparent. Write Ar(A) = Fun([1], A), and let i(a) = ida, σ(a →b) = a, β(a →b) = b. A commutative square from i(x) to a →b is determined by its arrow x →a. A square from a →b to i(y) is determined by b →y. Therefore

$\beta \dashv$i $\dashv\sigma$.

In particular σi = βi = id, and the squares associated with an arrow a →b give natural transformations iσ ⇒id and id ⇒iβ. Both endpoint projections and i are categorical homotopy equivalences, hence belong to every W satisfying L1 and L2.

The fibration properties can be checked without choosing anything. Pulling a →b back along a′ →a means precomposing to obtain a′ →b; the resulting square is cartesian for σ. Pushing it forward along b →b′ means postcomposing to obtain a →b′; that square is cocartesian for β. The fibres are a\A and A/b, with initial and terminal identities respectively. This example already belongs to the original descent formalism; see Grothendieck (1971, Exposé VI, §11(a)).

For the combined map (σ, β) : Ar(A) →A × A, however, the fibre at (a, b) is the discrete set HomA(a, b). Take A = [1]. Its fibre at (1, 0) is empty, while that at (0, 0) is a point, although the base is connected. Thus it is not a Hot-fibration. It is neither smooth nor proper: at (1, 0) its undercategory has the object arising from (1, 0) →(1, 1), and its overcategory has the object arising from (0, 0) →(1, 0), whereas its strict fibre is empty. In fact each of these comma categories is a point. The necessary fibre-to-comma weak-equivalence condition fails in both directions. This distinction is why the directed arrow construction gives Φ and Ψ, while the two-sided replacement C requires the longer path category Ch∞(S).

En fait, on voit que cette catégorie est non seulement cofibrée, mais canoniquement *scindée.* ([10]).

Appliquant ceci à des $f : X \longrightarrow S$, on trouve une construction

$$\mathrm{Cat}/S \xrightarrow{\Psi} \underline{\mathrm{Cofibsc}}\, S,$$

9. **NB** $\pi_f i_f = \mathrm{id}$, et $i_f \pi_f \longrightarrow \mathrm{id}$, donc i_f, π_f sont des homotopismes inverses l'un de l'autre dans Cat hot. Cela précise [le] cor. 3, page 18.

10. **Corollaire 3.** *La flèche $i_f : X' \longrightarrow \bar{X}'$ est un X-morphisme (si X' sur X par f, $\bar{X}'$ par $\bar{f}$), i.e. $f = \bar{f} \circ i_f$, et c'est une* Hot-*équivalence* (car $\pi_f : \bar{X}' \longrightarrow X'$ est Cat-fibrant, à fibres contractiles, donc une Hot-équivalence).

c'est bel et bien fonctoriel en X variant dans Cat/S. Si

$$\psi : X \longrightarrow Y$$

dans Cat/S, alors ψ induit des p. 12

$$\psi/s : X/s \longrightarrow Y/s \ ,$$

pour $s \in S$, et ceci de façon compatible avec les foncteurs 'cochangement de base' associés aux $u : s \longrightarrow t$ dans S [page 19]

$$\begin{array}{ccc} X/s & \xrightarrow{u_*^X} & X/t \\ {\scriptstyle \psi/s}\downarrow & & \downarrow{\scriptstyle \psi/t} \\ Y/s & \xrightarrow{u_*^Y} & Y/t \end{array} \quad .$$

Cela définit donc un morphisme de catégories scindées sur S

$$\Psi(X) \longrightarrow \Psi(Y),$$

c'est lui!

On a un morphisme fonctoriel en X

$$X \xrightarrow{i_X} \Psi(X)$$

dans Cat/X, et c'est une Hot-équivalence, donc $\in W$. Sur les fibres, le morphisme i_X induit

$$X_s \xrightarrow{i_{X,s}} X/s,$$

l'inclusion canonique.

Corollaire 1. *Si* $X \xrightarrow{f} Y$ *dans* Cat/S *est dans* W*, alors* $\Psi(X) \xrightarrow{\Psi(f)} \Psi(Y)$ *aussi.* Mais on se gardera de croire que c'est dans W_S au sens de Cofib S ou Cofibsc S. [page 20]

Commentary · Exposition [ms. 19]

A canonical opfibration and its two projections

Grothendieck's replacement Ψ packages all the overcategories X/s into one category. Writing down its arrows shows both why it is strictly functorial and why a projection used to prove homotopy invariance need not be a morphism over the original base.

For p : X →S, an object of Ψ(X) is (x, u : p(x) →s). A morphism to (y, u′ : p(y) →t) is a pair vu = u′p(a).

(a : x →y, v : s →t), The structural projection q sends this object to s and this morphism to v. For v : s →t, the morphism (idx, v) : (x, u) →(x, vu) is the specified cocartesian lift. Composition of these lifts is literal composition, so the opfibration is split and its fibre at s is X/s.

There is also the forgetful projection π : Ψ(X) →X, which sends (x, u) to x, and the functor i : X →Ψ(X) sending x to (x, idp(x)). A map from i(x) to (y, u′) is uniquely determined by a : x →y, because its base arrow must be u′p(a). Hence i ⊣π, with πi = idX and counit

−−−−→(x, u).

iπ(x, u) = (x, idp(x)) This proves that i and π are inverse up to categorical homotopy. The identity qi = p makes i a functor over S, but pπ(x, u) = p(x) generally differs from q(x, u) = s. Thus π generally is not a functor over S. The printed statement that i is a morphism in Cat/X is nonetheless true when Ψ(X) carries π: i is a section. Both descriptions of i are legitimate, and neither licenses using π as an inverse in Cat/S.

For a functor f : X →Y over S, define Ψ(f)(x, u) = (f(x), u) and Ψ(f)(a, v) = (f(a), v). This preserves the specified cocartesian lifts and is strictly functorial in f. The maps i form a natural transformation in Cat/S. Their being in W shows, by the resulting commutative square, that Ψ preserves and reflects coarse weak equivalences. On fibres, however, its effect is f/s. This last observation specifies the stronger class for which Ψ becomes a replacement preserving fibrewise weak equivalences.

Car sur les fibres de $\Psi(X)$, $\Psi(Y)$ on trouve les flèches

$$f/s : X/s \longrightarrow Y/s$$

induits par f, qui n'ont aucune raison d'être dans W. Qu'elles le soient signifie que $f : X \longrightarrow Y$ est dans W 'localement au dessus de S' ([11]), ce qui (pour les W qui nous intéressent) est beaucoup plus fort que d'être dans W. (Si $Y = S$, cela signifie en fait que $p : X \longrightarrow S$ est W-asphérique, beaucoup plus fort que $p \in W$.)

Donc pour prouver que

$$\underline{\mathrm{Cofib}}\, S \longrightarrow \mathrm{Cat}/S \qquad \text{ou} \qquad \underline{\mathrm{Cofibsc}}\, S \longrightarrow \mathrm{Cat}/S$$

induisent des équivalences pour les catégories localisées, le foncteur Ψ directement ne sera pas utilisable. Cependant : p. 13

Corollaire 2. *Supposons X, Y dans* $\underline{\mathrm{Prop}}\, S$ *ou dans* $\underline{\mathrm{Fibhot}}\, S$*, et considérons*

$$\Psi(f) : \Psi(X) \longrightarrow \Psi(Y),$$

pour que ce soit une W-équivalence dans $\underline{\mathrm{Cofibsc}}\, S$*, i.e. une W-équivalence fibre par fibre, il faut et il suffit que f soit une W-équivalence fibre par fibre* (et cela doit impliquer ([12]) que f est une W-équivalence). [page 21]

Commentary · Exposition [ms. 20]

Which comma construction repairs which variance

Grothendieck now isolates the extra condition that makes Ψ a relative replacement for fibrewise homotopy theory. Its fibre map is exactly f/s, so the condition is that every overcategory map lie in W. When the target is S itself this says that f is W-aspherical, since S/s has a terminal object. For a general target it is a relative condition, later called fine equivalence on the left.

The interval calculation after manuscript page 8 already shows why total equivalence cannot suffice. The complete comparison of both endpoint inclusions, given alongside manuscript page 32, also separates the two comma tests. On a smooth object, the strict fibre compares to the undercategory s\X; on a proper object, to the overcategory X/s. Consequently the relevant fibrewise replacement for a fibration is Φ, and for an opfibration it is Ψ. This is the geometric reason the later fine-right equivalence belongs on the fibration side of the large diagram, while fine-left equivalence belongs on the opfibration side. The direction names refer to the comma constructions, not to the position of the objects in that diagram.

En effet, dans le diagramme commutatif

$$\begin{array}{ccc} X_s & \xrightarrow{f_s} & Y_s \\ \downarrow & & \downarrow \\ X/s & \xrightarrow{f/s} & Y/s \end{array}$$

les flèches verticales sont dans W, car X, Y `[sont]` propres sur S (ou X, Y dans $\underline{\mathrm{Fibhot}}\, S$), donc f_s est dans W si et seulement si f/s l'est.

`[Le foncteur]` Φ se définit de façon duale à Ψ, ce qui revient à échanger les rôles de σ_X, β_X dans le diagramme page 17.

([13])

11. cf. (1) page 15.
12. cf. (1) page 15.
13. **Corollaire 3.** *Si $X \in Ob\, \underline{\mathrm{Fibhot}}\, S$, alors $\Psi(X)$ est dans* $\underline{\mathrm{Fibsc}}_0 S$.

Cela signifie en effet que les $X/s \longrightarrow X/t$ sont dans W, or l'hypothèse sur X implique que c'est dans W_∞. OK.

II) Définition de $C : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Parf}}\, S$

Cette fois, c'est la factorisation des flèches $p : X \longrightarrow S$ dans Cat, en

$$X \xrightarrow{j_{X/S}} \bar{X} \xrightarrow{\bar{p}} S,$$

où i_X `[plutôt` $j_{X/S}$`]` est une Hot-équivalence (donc dans W), et $\bar{p}$ parfait. Cela se construit formellement comme tantôt, en utilisant $\underline{\mathrm{Ch}}_\infty(S)$ au lieu de $\underline{\mathrm{Fl}}(S)$, et la factorisation

$$S \xrightarrow{j_S} \underline{\mathrm{Ch}}_\infty(S) \xrightarrow{p_S=(\sigma_S,\beta_S)} S \times S$$

de $\mathrm{diag}_S : S \longrightarrow S \times S$. La situation est plus jolie, car p_S est déjà 'parfait', ce qui implique formellement que le $\bar{p}$ qui s'en déduit, pour factoriser $p : X \longrightarrow S$, est lui-même parfait.

Ici encore, la construction est fonctorielle, on trouve le foncteur

p. 14

$$C : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Parf}}\, S$$ [page 22]

qu'il faut composer au foncteur en sens inverse

$$r : \mathrm{Cat}/S \longleftarrow \underline{\mathrm{Parf}}\, S.$$

Tout d'abord, vérifions que C, tout comme r, est compatible avec les localiseurs. Soit $f : X \longrightarrow Y$ dans Cat/S, supposons f est dans W, prouvons $C(f)$ est dans W_S. On a commutativité dans

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle j_X}\downarrow & & \downarrow{\scriptstyle j_Y} \\ CX & \xrightarrow{Cf} & CY \end{array}$$

et j_X, j_Y sont dans W, donc f est dans W si et seulement si Cf l'est. Mais dans le cas $W = W_\infty$ on sait que cela équivaut à ce que Cf soit dans W_∞ fibre par fibre. Admettant ① p. 15 pour W, il reste à s'assurer d'une réciproque dans $\underline{\mathrm{Parf}}$, i.e.

Commentary · Later developments [ms. 21]

From comma fibres to homotopy fibres

Grothendieck introduces the longer path category because he now wants a replacement whose transport is homotopically invertible in both directions. The guiding theorem is Quillen's Theorem B: if every transition X/s →X/t induced by an arrow s →t is a weak homotopy equivalence, then N(X/s) computes the homotopy fibre of NX →NS over s. A precise restatement appears in Cisinski (2004, Theorem 2.3.2). This is the point at which locally constant comma data become actual fibre data for the homotopy type of a map.

For an object already Hot-fibred over S, the comparison Xs →X/s is a weak equivalence, and the transitions between these comma categories are weak equivalences. Consequently Ψ(X) is a split opfibration with homotopically invertible transition functors. The footnote's printed target Fibsc0S is therefore a slip: the target is Cofibsc0S. Its dual statement concerns Φ and split fibrations. The slip does not affect the argument in the adjacent square.

The functor C uses results about Ch∞(S) established outside these pages. The input here is a natural factorization X −−→C(X) →S with jX ∈W∞and C(X) →S perfect. Given this input, all subsequent uses of its functoriality are formal. For instance, the naturality square of j implies that f ∈W if and only if C(f) ∈W, provided W∞⊆W. What is not formal is replacing the last total condition by a condition on fibres for an arbitrary larger W. That is the question on pages 22–24, and the stronger L5 introduced later addresses exactly it. The correct comparison therefore depends on which localizer is being studied, not only on the quality of the replacement object.

② Soit $\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$ dans $\underline{\mathrm{Parf}}\, S$ (ou seulement dans $\underline{\mathrm{Fibhot}}\, S$). Si f est dans W, alors les $f_s : X_s \longrightarrow Y_s$ aussi. [page 23]

Essayons de le prouver, en calquant la démonstration dans le cas $C = C_\infty$ (XI, th. 2). On peut supposer S connexe ([14]), en utilisant La (i.e. $W \subseteq W_0$) et en admettant le

Lemme. *Soit $f : X \longrightarrow Y$ dans* Cat. *Alors $f \in W$ si et seulement si $\pi_0(f)$ est bijectif, et pour toute composante connexe X_i de X, si Y_i est la composante connexe correspondante de Y, $f_i : X_i \longrightarrow Y_i$ induit par f est dans W.*

Utilisons alors l'existence de

$$S' \longrightarrow S$$

Hot-fibration avec S' Hot-asphérique ([15]). On peut supposer même que $S' \longrightarrow S$ est parfait. Supposons qu'on sache qu'un changement de base par de telles fibrations parfaites transforme W-équivalences en itou. (Ça doit être vrai pour les W_i, mais on a vu que c'était faux pour l'équivalence k-homologique, cf. I p. 87 ff.) Alors $X' \xrightarrow{f'} Y'$ sur S' est une W-équivalence. Or pour $s' \in S'$, comme $\{s'\} \longrightarrow S'$ est une Hot-équivalence (S' Hot-asphérique), et X', Y' étant Hot-fibrés sur S, il s'ensuit que $X'_{s'} \longrightarrow X'$, $Y'_{s'} \longrightarrow Y'$ sont des Hot-équivalences, donc aussi $X'_{s'} \xrightarrow{f'_{s'}} Y'_{s'}$, comme on voit sur le carré commutatif p. 15

$$\begin{array}{ccc} X'_{s'} & \xrightarrow{f'_{s'}} & Y'_{s'} \\ \wr\downarrow & & \wr\downarrow \\ X' & \xrightarrow{f'} & Y'. \end{array}$$

Comme $S' \longrightarrow S$ est surjectif, cela montre que les $f_s : X_s \longrightarrow Y_s$ sont dans W, qed. [page 24]

Commentary · Exposition [ms. 23]

The contractible-base argument without a component reduction

Grothendieck's strategy is to inspect a chosen fibre after making the base contractible. Its force is easiest to see when the required base-change assumption is stated before the reduction. It then becomes clear that the componentwise lemma is unnecessary for this particular argument, as his marginal annotation already observes.

Assume W∞⊆W, two-out-of-three, and the following additional property: pullback along a perfect functor preserves W-equivalences. Let f : X →Y be a functor over S, with X, Y Hot-fibred over S, and suppose its total functor lies in W. Fix s ∈S. Use the perfect replacement of the point {s} →S to obtain

−→jS′ −→rS, {s} j ∈W∞, where r is perfect and S′ is weakly contractible. The distinguished object s′ = j(s) lies over s. This construction is allowed even when S is disconnected; its image lies in the relevant component.

Put X′ = X ×S S′ and Y ′ = Y ×S S′. The extra pullback hypothesis gives f ′ : X′ →Y ′ in W. Base change preserves the Hot-fibration property. Since S′ is weakly contractible, the inclusions of the fibres at s′ into X′ and Y ′ are weak homotopy equivalences. Equivalently, their homotopy-fibre squares are pulled back along the weak equivalence {s′} →S′. In the commutative square

Xs

Ys

X′

Y ′, three sides lie in W, so fs ∈W. This proves the fibre-detection assertion under precisely the stated additional hypothesis. It does not prove fs ∈W∞from f ′ ∈W.

The proof uses neither La nor a decomposition of f into connected components. Its genuinely substantial input is stability of W under these perfect base changes, later called L6. The speculation here that truncated homotopy equivalences should satisfy that stability is withdrawn in the later annotations; the obstruction is discussed at manuscript pages 43–45. The proof itself is valid as a conditional argument, and its dependence on L6 is the mathematical information to retain.

14. ne sert à rien

15. **NB** Il suffit d'avoir une Hot-fibration $S' \longrightarrow S_0 \hookrightarrow S$, où S_0 est la composante connexe de S contenant l'élément $s \in \mathrm{Ob}\, S$ envisagé.

Ainsi, (2) sera conséquence de ②. Soit $p : Y' \longrightarrow Y$ une Hot-fibration (ou même un foncteur parfait, si ça peut aider …). Soit $f : X \longrightarrow Y$ une S-flèche (dans Cat/S), alors $f' : X' \longrightarrow Y'$ par changement de base. Si $f \in W$, $f' \in W'$

$$\begin{array}{ccc} X' & \xrightarrow{q} & X \\ {\scriptstyle f'}\downarrow & \text{cart.} & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{p} & Y \end{array} \qquad f \in W \text{ et } p \text{ parfait} \Longrightarrow f' \in W$$

En tous cas, il nous faut absolument ② pour pouvoir conclure que C est compatible avec les localiseurs.

Considérons $rC : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S$, on a une flèche

$$\begin{cases} \mathrm{id}_{\mathrm{Cat}/S} \xrightarrow{j} rC \\ j_X : X \longrightarrow CX \quad \text{la flèche canonique } i_{X/S} \texttt{ [plutôt } j_{X/S}\texttt{]} \text{ (p. 21),} \end{cases}$$

et j_X est toujours dans W.

Considérons $Cr : \underline{\mathrm{Parf}}\, S \longrightarrow \underline{\mathrm{Parf}}\, S$, i.e. appliquons la construction C à un X parfait sur S. Alors on a encore

$$\begin{cases} \mathrm{id}_{\underline{\mathrm{Parf}}\, S} \xrightarrow{j'} Cr \\ j'_X = j_{r(X)} : X = r(X) \xrightarrow{j_X} CX. \end{cases}$$

Ce morphisme est dans W, donc aussi une W-équivalence fibre par fibre, puisque source et but sont parfaits, donc des Hot-fibrés sur S.

Cela prouve déjà que les foncteurs r et C induisent des équivalences quasi-inverses l'une de l'autre sur les catégories localisées. Par le lemme p. 11, cela montre que pour toute sous-catégorie pleine $\mathcal{F}$ de Cat/S contenant $\underline{\mathrm{Parf}}\, S$, l'inclusion de $\mathcal{F}$ dans Cat/S induit une équivalence sur les localisés, en prenant comme localiseur dans $\mathcal{F}$ le localiseur 'grossier' induit par Cat/S. Cela s'applique notamment aux sous-catégories pleines [page 25] p. 16

$$\underline{\mathrm{Liss}}\, S, \quad \underline{\mathrm{Fibhot}}\, S, \quad \underline{\mathrm{Prop}}\, S,$$

mais en prenant dans $\underline{\mathrm{Liss}}\, S$ et $\underline{\mathrm{Prop}}\, S$ non pas le localiseur fin 'fibre par fibre', comme je l'avais annoncé à tort, mais le localiseur grossier induit par Cat/S. (Pour $\underline{\mathrm{Fibhot}}\, S$, il n'y a pas de risque d'ambiguïté). Il faudrait que je me convainque que si je prends la W-équivalence fine (dans le cas $W = W_\infty$, disons), je ne trouve *pas* les 'bons' localisés, i.e. le foncteur des localisés, vers le localisé de Cat/S, n'est pas une équivalence. Ceci en fait suppose que dans $\underline{\mathrm{Fib}}\, S$ et $\underline{\mathrm{Cofib}}\, S$ également, c'est l'équivalence *grossière* qu'il convient de prendre. (Dans $\underline{\mathrm{Fib}}_0 S$ et $\underline{\mathrm{Cofib}}_0 S$, ou $\underline{\mathrm{Fibsc}}_0 S$ et $\underline{\mathrm{Cofibsc}}_0 S$, les deux équivalences sont identiques, puisque ces quatre catégories sont contenues dans $\underline{\mathrm{Fibhot}}\, S$.) La suite nous montrera s'il en est bien ainsi. Par contre, dans $\underline{\mathrm{Fibsc}}\, S$ et $\underline{\mathrm{Cofibsc}}\, S$, il n'y a pas de doute, suivant les principes généraux de construction d'un dérivateur à partir d'un $(\mathcal{M}, W)$, qu'il faut prendre l'équivalence fine, fibre par fibre. À ce sujet, il faut faire attention que les foncteurs verticaux du diagramme p. 8 [page 26]

$$\underline{\mathrm{Fibsc}}\, S \longrightarrow \underline{\mathrm{Fib}}\, S, \quad \underline{\mathrm{Cofibsc}}\, S \longrightarrow \underline{\mathrm{Cofib}}\, S,$$

quoique essentiellement surjectifs et fidèles, ne sont pas pleinement fidèles. Ils le seraient, et mêmes des équivalences de catégories, si dans $\underline{\mathrm{Fib}}\, S$ resp. $\underline{\mathrm{Cofib}}\, S$ je me bornais aux S-foncteurs *cartésiens* resp. *cocartésiens*. Donc on peut interpréter, à équivalence près, $\underline{\mathrm{Fibsc}}\, S$ et $\underline{\mathrm{Cofibsc}}\, S$ comme $\underline{\mathrm{Fib}}\, S$ et $\underline{\mathrm{Cofib}}\, S$, où on aurait restreint les morphismes aux seuls S-foncteurs *cartésiens* resp. *cocartésiens*. Il semblerait donc qu'en restreignant ainsi les flèches, mais en restreignant de façon plus draconienne encore le localiseur, on trouve des catégories localisées équivalentes.

Commentary · Exposition [ms. 24]

What the path replacement actually proves

Grothendieck wants a category over S whose strict fibres already have the homotopy types of the homotopy fibres. The replacement jX : X −→C(X) achieves this geometrically: jX is a weak homotopy equivalence, is natural over S, and C(X) −→S is perfect. The difficulty is to decide which weak equivalences this replacement preserves. Two assertions must be separated, because one is formal and the other detects a substantive property of the coefficient theory.

Write W tot for maps over S whose underlying functor lies in W. Assuming W∞⊆W and two-outof-three, naturality gives

f ∈W tot

⇐⇒C(f) ∈W tot C(f)jX = jY f, S . Thus no base-change axiom is needed to make C a functor between the coarse relative categories. If F ⊆ Cat/S is full and contains every perfect object, C factors through F. The two natural transformations j on Cat/S and its restriction to F become invertible after coarse localization. Consequently the inclusion of F induces an equivalence. This proves the assertion of manuscript page 25 under the stated elementary hypotheses, independently of the conjectural pullback assertion on the present page.

The stronger assertion is that C(f) is a W-equivalence on every fibre whenever f ∈W tot S . This does require the implication later named L5 on manuscript page 43. The preceding argument with a contractible covering base explains a sufficient condition precisely. For a chosen s ∈S, take a perfect S′ −→S with contractible total category and an object over s; it suffices to cover the component containing s. If pullback along this map preserves W, the resulting total map X′ −→Y ′ belongs to W. For homotopy fibrations the inclusions of the chosen fibres into X′ and Y ′ are weak homotopy equivalences. Two-out-of-three then gives the desired fibre map in W. The final comparison gives a Wequivalence, not necessarily a weak homotopy equivalence: the sentence immediately before manuscript page 24 compresses these two conclusions.

For W = W∞this is the familiar invariance of a homotopy fibre under equivalence of total spaces over a fixed base. For a coarser W it is an additional demand. The covering calculation at manuscript page 43 below will show its failure even when both maps to the base are discrete fibrations and discrete opfibrations. In particular the phrase “il nous faut absolument” concerns compatibility with the fibrewise localizer, not the already established compatibility with the coarse one.

C’est assez étrange - on va voir si c’est bien vrai! [page 27]

Commentary · Context [ms. 26]

Strict splittings and Cartesian maps

The comparison with diagram categories depends on what the morphisms preserve. The definition on manuscript page 4 uses functors preserving the chosen Cartesian lifts strictly. A Cartesian functor between split fibrations need only carry a chosen lift to some Cartesian lift; the latter is isomorphic to the chosen lift at the image object. These conditions give strict and pseudonatural transformations, respectively. They are different conditions on actual functors, before localization.

Here is a concrete failure of fullness. Put S = [1] and let G = C2 = {1, c}. The projection S ×BG −→S has its constant splitting, with chosen lift (u, 1) of u : 0 −→1. Define an endofunctor over S which fixes the two fibre groupoids and sends a cross-fibre arrow (u, g) to (u, cg). This is a functor: composition with a vertical arrow is compatible with the formula because G is abelian. Every arrow over u is Cartesian, since its group component is invertible. Our endofunctor is therefore Cartesian, but it does not preserve the splitting, since (u, 1) is sent to (u, c). Restricting the target category to Cartesian functors does not make the forgetful functor from strictly split morphisms full.

There is a separate qualification concerning objects. The functor BC4 −→BC2 induced by reduction modulo 2 is a Grothendieck fibration: each base arrow has a lift and every arrow is Cartesian. A splitting would be a homomorphic section C2 −→C4. Such a section cannot exist, because each lift of the nonidentity element has order 4. Hence this fibration is not isomorphic over BC2 to an object with a splitting. This is the group-extension example already explained in Grothendieck (1971, Exposé VI, §9). An equivalence over the base to a split replacement is the appropriate statement; essential surjectivity in the ordinary category Cat/S would ask for an isomorphism of categories over the base.

These distinctions do not damage the intended homotopical comparison. Equivalences of fibre categories belong to W∞, and strict replacements can be connected by such equivalences. What

needs proof is precisely that replacing coherent choices by strict ones induces the correct localized comparison. Grothendieck encounters that issue directly in the failure of the proposed unit on manuscript page 30 and returns to it on pages 55–60. The underlying classical language comes from the descent formalism of SGA 1; the new task here is to control the weak equivalences during this passage. We retain the printed assertion and read it with this necessary qualification, rather than changing the category of morphisms silently.

III) Construction de Φ_0, Ψ_0 : $\mathrm{Cat}/S \to \underline{\mathrm{Fibsc}}_0 S$, $\mathrm{Cat}/S \to \underline{\mathrm{Cofibsc}}_0 S$.

On doit avoir

$$\Phi_0(X) = \Phi rC(X) \qquad\qquad \Psi_0(X) = \Psi rC(X),$$

où

$$r : \underline{\mathrm{Parf}}\, S \longrightarrow \mathrm{Cat}/S$$

est l'inclusion canonique. En tant que foncteurs à valeurs dans Fibsc resp. Cofibsc, cela définit déjà Φ_0, Ψ_0 par

$$\Phi_0 = \Phi rC \qquad\qquad \Psi_0 = \Psi rC,$$

mais il faut voir que Φ_0, Ψ_0 prennent leurs valeurs dans les sous-catégories pleines à indice 0. p. 17
Cela équivaut donc au Lemme suivant, appliqué à $Y = rC(X)$:

Lemme. *Soit Y parfait sur S (ou seulement un* Hot*-fibré sur S). Alors $\Phi(Y)$ est dans $\underline{\mathrm{Fibsc}}_0 S$, $\Psi(Y)$ dans $\underline{\mathrm{Cofibsc}}_0 S$.*

Il faut prouver (pour $\Psi(Y)$) que si $s \longrightarrow t$ est une flèche dans S, alors

$$\Psi(Y)_s \longrightarrow \Psi(Y)_t$$

est une W-équivalence. Or cette flèche s'identifie à

$$Y/s \longrightarrow Y/t$$

et on sait bien que c'est une Hot-équivalence, par définition des Hot-fibrés, donc c'est une [page 28]
W-équivalence.

On a donc les foncteurs

$$\underline{\mathrm{Fibsc}}_0 S \underset{\Phi_0}{\overset{p}{\rightleftarrows}} \mathrm{Cat}/S,$$

il faut voir qu'ils satisfont aux conditions générales du lemme p. 11 (et ce sera pareil pour q, Ψ_0). On sait déjà que p est compatible avec les localiseurs. Prouvons le pour Ψ_0. Soit

$$f : X \longrightarrow Y$$

dans Cat/S une W-équivalence, alors $rC(f)$ l'est aussi. Il suffit de prouver ceci :

Soit

$$q : X' \longrightarrow Y'$$

un morphisme dans $\underline{\mathrm{Fibhot}}\, S$ (par exemple un morphisme de $\underline{\mathrm{Parf}}\, S$), qui soit W-équivalence, donc `[qui induit]` des W-équivalences sur les fibres. Alors $\Psi(q) : \Psi(X') \longrightarrow \Psi(Y')$ est une W-équivalence fibre par fibre, i.e.

$$X'/s \longrightarrow Y'/s \qquad \text{[page 29]}$$

une W-équivalence pour tout $s \in S$ (a été vu dans le corollaire 2, page 20).

Considérons

$$p\Phi_0 : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S,$$

ça transforme donc X en $\Phi C(X)$, regardé comme objet de Cat/S sans plus. On a un morphisme fonctoriel

$$X \xrightarrow{j_X} C(X) \qquad\qquad j : \mathrm{id}_{\mathrm{Cat}/S} \longrightarrow C,$$

d'où un morphisme fonctoriel p. 18

$$\Phi(X) \xrightarrow{\Phi(j_X)} \Phi C(X) \qquad\qquad \Phi * j : \Phi \longrightarrow \Phi_0$$

et également un morphisme fonctoriel

$$X \xrightarrow{i_X} \Phi(X),$$

d'où en composant

$$X \xrightarrow{i_X} \Phi(X) \xrightarrow{\Phi(j_X)} \Phi C(X), \qquad X \xrightarrow{\alpha_X} \Phi C(X)$$

i.e.

$$\alpha : \mathrm{id}_{\mathrm{Cat}/S} \longrightarrow p\Phi_0.$$

Pour X fixé dans Cat/S, on sait que j_X est dans W, donc aussi $\Phi(j_X)$ (quoique non fibre par fibre), cf. cor. 1 page 20. On sait aussi que i_X est dans W, donc aussi le composé α_X.

Considérons

$$\Phi_0 p : \underline{\mathrm{Fibsc}}_0\, S \longrightarrow \underline{\mathrm{Fibsc}}_0\, S \quad .$$

On part de X dans $\underline{\mathrm{Fibsc}}_0\, S$, on oublie le scindage et le fait même qu'il soit Cat-fibrant (on a appliqué p), on lui applique Φ_0, i.e. on regarde ΦCX comme objet de $\underline{\mathrm{Fibsc}}\, S$ (et même de $\underline{\mathrm{Fibsc}}_0\, S$). On veut définir encore [page 30]

$$X \xrightarrow{\beta_X} \Phi_0 p(X) = \Phi C(X) \qquad \textbf{dans } \underline{\mathrm{Fibsc}}_0\textbf{,}$$

fonctoriel en X. Or on a comme tantôt

$$X \xrightarrow{j_X} C(X),$$

d'où en appliquant Φ

$$\Phi(X) \xrightarrow{\Phi(j_X)} \Phi C(X),$$

mais regardé cette fois comme flèche dans $\underline{\mathrm{Fibsc}}_0\, S$ (N.B. on a bien $\Phi(X)$ dans $\underline{\mathrm{Fibsc}}_0\, S$, car X, provenant de $\underline{\mathrm{Fibsc}}_0\, S$, est dans $\underline{\mathrm{Fibhot}}\, S$, et on applique la remarque 'Cor. 3' page 21.) D'autre part, on a une flèche dans Cat/S

$$X \xrightarrow{i_X} \Phi(X),$$

est-elle une flèche dans $\underline{\mathrm{Fibsc}}_0(S)$, i.e. est-elle cartésienne? On voit tout de suite que non, que l'on a seulement, pour une flèche $u : s \longrightarrow t$ dans S, un homomorphisme de commutation (pas un isomorphisme) dans

p. 19

$$\begin{array}{ccc} X_s & \xrightarrow{u_*^X} & X_t \\ \downarrow{\scriptstyle i_s} & \overset{\alpha}{\nearrow} & \downarrow{\scriptstyle i_t} \\ X/s & \xrightarrow[=u_*^{\Phi(X)}]{(\mathrm{id}_X)/u} & X/t \end{array}$$

[page 31]

Donc il me faut remballer! On peut considérer i_X au mieux comme une flèche de $\underline{\mathrm{Fib}}_0\, S$, et en prenant les composés on trouve une flèche dans $\underline{\mathrm{Fib}}_0\, S$:

$$X \xrightarrow{i_X} \Phi(X) \xrightarrow{\Phi(j_X)} \Phi C(X),$$
$$\beta_X (= \alpha_X)$$

i.e. (regardant maintenant Φ_0 comme foncteur à valeurs dans $\underline{\mathrm{Fib}}_0\, S$) un homomorphisme de foncteurs

$$\beta : \mathrm{id}_{\underline{\mathrm{Fib}}_0} S \longrightarrow \Phi_0 p_0,$$

où $p_0 : \underline{\mathrm{Fib}}_0 S \hookrightarrow \mathrm{Cat}/S$ est l'inclusion canonique. Ce β est dans W argument par argument, et de même pour α page 29, interprété cette fois comme

$$\mathrm{id}_{\mathrm{Cat}/S} \longrightarrow p_0 \Phi_0.$$

Ce qu'on a prouvé finalement est ceci:

Commentary · Exposition [ms. 30]

Why the obvious unit fails to be Cartesian

Grothendieck has found a natural weak equivalence of total categories and now asks it to be a morphism of coherent diagrams. The request is stronger. For the fibration construction Φ(X) the fibre at s is s\X, whereas the obvious map sends x ∈Xs to (x, 1s). A Cartesian lift u∗y −→y in X, lying over u : s −→t, is sent to an arrow whose source is (u∗y, 1s). The chosen Cartesian lift in Φ(X) ending at (y, 1t) instead starts at (y, u). These two objects are connected by the lift in X, but in general they are not isomorphic in s\X.

The smallest example is X = S = [1] with the identity projection. Every arrow of X is Cartesian over S. In 0\[1] the two objects 10 : 0 −→0 and u : 0 −→1 are joined by a noninvertible arrow. Thus the image of the Cartesian arrow u under iX is not Cartesian in Φ(X). Indeed, in the Grothendieck construction of a strict diagram, an arrow over u is Cartesian exactly when its vertical comparison component is invertible. Here that comparison component is the displayed noninvertible arrow. The obstruction remains even though both comma categories are contractible.

The square printed across manuscript pages 30–31 uses X/s, X/t and covariant symbols u∗. Those are the symbols of the dual construction Ψ, while the surrounding discussion concerns Φ. The intended argument is correct with s\X, t\X and contravariant transport, or after dualizing the entire discussion. This variance slip should not be turned into a purported failure of the comma construction itself.

Passing to the full category Fib0S permits the map iX, because its morphisms are arbitrary functors over S. The natural weak equivalence X −→ΦC(X) then proves the coarse comparison in the "théorème-remballage". The theorem does not yet compare strict coherent diagrams by fibrewise weak equivalences. This is the exact boundary between what the argument has proved and what the next attempt must establish. The later Cartesian comparison is directed towards X, rather than away from it; its construction supplies the missing information about coherence.

Théorème-remballage. *Soit $\mathcal{F}$ une sous-catégorie pleine de* Cat/S *qui contient une des trois sous-catégories pleines* $\underline{\mathrm{Fib}}_0 S$, $\underline{\mathrm{Parf}}\, S$, $\underline{\mathrm{Cofib}}_0 S$, *et munissant $\mathcal{F}$ du localiseur W 'grossier' (induit par celui de* Cat/S*). Alors l'inclusion*

$$\mathcal{F} \longrightarrow \mathrm{Cat}/S$$

induit une équivalence sur les localiseurs.

Par contre, les catégories localisées des quatre catégories de fibrés scindés [page 32]

$$\underline{\mathrm{Fibsc}}\, S, \quad \underline{\mathrm{Cofibsc}}\, S, \quad \underline{\mathrm{Fibsc}}_0 S, \quad \underline{\mathrm{Cofibsc}}_0 S$$

échappent à nos arguments. *Et pour cause!* Il est totalement ouvert, sur S connexe disons (p. ex. $S = \mathbf{\Delta}^1$), que pour un type d'homotopie relatif ξ sur S, les types induits ξ_s ($s \in S$)

forment un système local sur S, à valeurs dans Hot_W, comme ce serait le cas si le théorème annoncé au début était vrai. Au contraire, *toute* flèche de Hot_W doit provenir d'un objet de $\mathrm{Hot}_W(\mathbf{\Delta}^1)$. Les localisés des 9 autres catégories du diagramme p. 8, et de toutes celles dont il est question dans le théorème qu'on vient de prouver, doivent correspondre 'visiblement' aux sous-catégories pleines de $\mathrm{HOT}_W(S)$ formées des HOT-coefficients localement constants sur S.

Aussi, je me rends compte que c'était absurde de m'attendre à ce que $\underline{\mathrm{Fibsc}}\, S$ et $\underline{\mathrm{Cofibsc}}\, S$ donnent des catégories localisées canoniquement équivalentes. Car les éléments ξ de la première des deux catégories donnent naissance chacun à un foncteur contravariant sur S p. 20 [page 33]

$$\bar{\xi} : S^o \longrightarrow \mathrm{Hot}_W,$$

ceux η de la seconde (qui n'est autre que $(\underline{\mathrm{Fibsc}}(S^o))^o$) donnent naissance chacun à un foncteur *covariant*

$$\bar{\eta} : S \longrightarrow \mathrm{Hot}_W,$$

ce qui n'est pas pareil! Ce n'est 'pareil' que si ce sont des coefficients locaux, ce qui signifie exactement que ξ est dans $\underline{\mathrm{Fibsc}}_0 S$ resp. η dans $\underline{\mathrm{Cofibsc}}_0 S$. On s'attend donc bien $\textcircled{1^o}$ que les flèches

$$\underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fib}}_0 S, \quad \underline{\mathrm{Cofibsc}}_0 S \longrightarrow \underline{\mathrm{Cofib}}_0 S$$

induisent des équivalences sur les localisés (chose que j'ai été incapable de prouver tantôt) ([16]). Par contre, il est pire que déraisonnable de s'attendre à ce qu'il en soit de même pour les foncteurs

$$\underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fibsc}}\, S, \quad \underline{\mathrm{Cofibsc}}_0 S \longrightarrow \underline{\mathrm{Cofibsc}}\, S,$$

ça devrait donner par localisation les foncteurs pleinement fidèles d'inclusion, des catégories d'objets localement constants dans $\mathrm{HOT}_W(S)$ resp. dans $(\mathrm{HOT}_W(S^o))^o$. Et de même pour les foncteurs induits sur les localisés par [page 34]

$$(*) \qquad \underline{\mathrm{Fibsc}}\, S \longrightarrow \underline{\mathrm{Fib}}\, S, \quad \underline{\mathrm{Cofibsc}}\, S \longrightarrow \underline{\mathrm{Cofib}}\, S.$$

Comme les localisés des catégories but de ces deux foncteurs ont tout l'air de s'identifier aux sous-catégories précédentes d'objets localement constants, il semblerait donc que : $\textcircled{2^o}$ Les foncteurs précédents définissent des rétractions de la catégorie $\mathrm{HOT}_W(S)$ resp. $\mathrm{HOT}_W(S^o)^o$ sur la sous-catégorie des objets localement constants sur S, les foncteurs localisés des foncteurs d'inclusion

$$\underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fibsc}}\, S, \quad \underline{\mathrm{Cofibsc}}_0 S \longrightarrow \underline{\mathrm{Cofibsc}}\, S$$

étant pleinement fidèles et ayant comme images essentielles les sous-catégories en question.

Commentary · Examples [ms. 32]

A relative type which is not locally constant

Grothendieck's reversal becomes transparent on the walking arrow. Let S = [1] = {0 −→1}, let X be the one-object category over 0, and let Y = S with its identity projection. The inclusion

f : {0} −→[1]

is a map of split fibrations over S. The corresponding contravariant diagrams are

X1 = ∅−→X0 = ∗,

Y1 = ∗−→Y0 = ∗. Both total categories are contractible, so f ∈W∞. But the fibre at 1 is ∅−→∗, which is not a weak homotopy equivalence. Fibre evaluation is a functor on the localization by objectwise weak equivalences, and sends isomorphisms there to isomorphisms of homotopy types. Therefore the image of f in that localization is not invertible. Since its image in the coarse localization is invertible, the comparison between these two localizations is not an equivalence.

All four tests of manuscript page 41 can be computed here. For the overcategories,

16. Les quasi-inverses étant bel et bien donnés par Φ_0, Ψ_0 - car [?] par quoi d'autre donc ???

X/0 = ∗,
Y/0 = ∗, X/1 = ∗, Y/1 = [1], so f is a local, or left-fine, weak equivalence. For the undercategories,
1\X = ∅,
0\X = ∗, 0\Y = [1], 1\Y = ∗. Thus it fails the colocal, or right-fine, test. Pulling back along the point 1 −→S gives the same failure, so it is not a universal weak equivalence. The example lies inside the category of split fibrations, hence also inside the category of smooth functors. Its opposite supplies the corresponding example for opfibrations and proper functors. This will also resolve the contradictory sentence on manuscript page 47.

An object equivalent to a locally constant diagram must have isomorphic fibre homotopy types along every base arrow: invertibility is invariant under isomorphism in the homotopy category of diagrams. The first diagram above does not have this property. Accordingly, the full subcategory of locally constant objects is proper even when the classifying space of the indexing category is contractible. Contractibility of the base makes local systems constant up to equivalence; it does not force every coherent diagram to be locally constant.

This gives a definite negative answer to the question on manuscript page 25 for the fibrewise localization of smooth or fibred objects. It also explains why the initial thirteen-category comparison could not have been correct with a single choice of weak equivalences. A derived category of diagrams must retain the noninvertible transition ∅−→∗, whereas the total homotopy type in this example forgets it.

Cette rétraction m'apparait comme une chose tout à fait mystérieuse. C'est lié au fait que pour le dérivateur très spécial $\mathbf{D} = \mathrm{HOT}$, quand on a un $\xi \in \mathbf{D}(S)$, on en déduit (à HOT/S-équivalence près) un type de diagramme X au dessus de S, qu'on peut regarder alors [page 35]
(via la construction C) comme définissant un type d'homotopie relatif *localement constant* sur S.

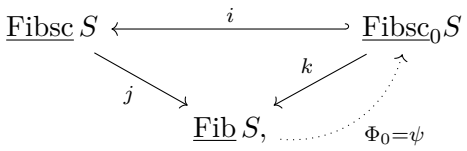
p. 21

Donc pour élucider la situation, i.e. les relations entre les 13 catégories localisées provenant du diagramme de la page 8, il reste à regarder si les assertions hypothétiques que je viens de faire sont bien valables, savoir

(1°) Le foncteur déduit de

$$\underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fib}}_0 S$$

par passage aux localisés est une équivalence de catégories (et on peut dans cette question remplacer $\underline{\mathrm{Fib}}_0 S$ par n'importe quelle autre sous-catégorie pleine de Cat/S la contenant - cela revient au même), et



(2°) Le foncteur déduit de

$$\underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fibsc}}\, S$$

par localisation est pleinement fidèle. (Que son image soit exactement formée des objets localement constants du premier localisé, interprété comme $\mathrm{HOT}_W(S)$, est tautologique.)

Il n'y a plus lieu de se soucier du côté cofibrés, puisque tout ce qu'on pourra en dire revient [page 36]
à ce que je viens d'expliciter, pour X^o au lieu de X.

Dans la direction de (1°), nos arguments précédents à coups de Φ_0, p nous donnent déjà un renseignement utile. Mais il sera plus commode à présent de laisser tomber $\underline{\mathrm{Fib}}_0 S$ ou plutôt, de le remplacer par $\underline{\mathrm{Fib}}\, S$ (ce qui est licite, on l'a dit dans (1°)), de sorte qu'on a maintenant un diagramme commutatif (traits pleins)

où i est une inclusion (strictement) pleinement fidèle, j (donc aussi k) fidèle. Enfin, on a un foncteur canonique ψ $(= \Phi_0)$ (en pointillés). Les localiseurs sur la ligne du haut sont les

localiseur fins (pour $\underline{\mathrm{Fibsc}}_0 S$ c'est pareil que la W-équivalence grossière), sur $\underline{\mathrm{Fib}}\, S$ par contre on prend la W-équivalence grossière. (On sait que le localisé est le même, à équivalence près, que si on se restreint à la sous-catégorie pleine $\underline{\mathrm{Fib}}_0 S$, ce qui est assez remarquable.

Tous les quatre foncteurs i, j, k, Φ_0 sont compatibles aux localiseurs, donc passent aux localisés [page 37] p. 22

$$\begin{array}{ccc} \mathrm{HOT}_W(S) & \xleftarrow{\quad\bar{\imath}\quad} & \mathrm{HOT}^?_W(S) \\ & {\scriptstyle\bar{j}}\searrow \quad \swarrow{\scriptstyle\bar{k}} \quad \uparrow{\scriptstyle\bar{\psi}} & \\ & \mathrm{HOT}^{\mathrm{lc}}_W(S), & \end{array}$$

où l'exposant ? dans la notation signifie que je ne sais interpréter cette catégorie, sauf si je prouve que $\bar{k}$ est une équivalence, et l'exposant lc dans la catégorie du bas dois suggerer l'intuition qu'il s'agit en tous cas d'une sorte de 'types d'homotopie relatifs' (dans un sens modifié) *localement constants* sur S. Le problème est de comprendre ce diagramme. La conjecture naturelle est

1°) $\bar{k}$ est une équivalence. (Ce qui implique que $\bar{\psi}$ est l'équivalence quasi-inverse, que $\bar{k}$, $\bar{\psi}$ permettent essentiellement d'identifier $\mathrm{HOT}^?_W$ et $\mathrm{HOT}^{\mathrm{lc}}_W$, de sorte que $\bar{\imath}$ et $\bar{\jmath}$ deviennent des foncteurs entre HOT_W et $\mathrm{HOT}^{\mathrm{lc}}_W$.)

2°) $\bar{\imath}$ est pleinement fidèle (NB l'image essentielle est bien comprise de toutes façons.)

En direction de 1°), je sais pour l'instant que l'on a [page 38]

$$\bar{k}\bar{\psi} \simeq \mathrm{id}_{\mathrm{HOT}^{\mathrm{lc}}_W(S)},$$

donc $\bar{k}$ est essentiellement surjectif (sur les objets), et induit des *surjections* sur les $\mathrm{Hom}(-,-)$, tandis que $\bar{\psi}$ est injectif sur les classes d'isomorphismes d'objets, et sur les $\mathrm{Hom}(-,-)$ (i.e. *fidèle*).

Si les relations entre $\mathrm{HOT}^?_W$ et $\mathrm{HOT}^{\mathrm{lc}}_W$ s'avèrent imbitables (p. ex. $\bar{\psi}$ pas même pleinement fidèle, i.e. $\bar{k}$ pas même fidèle), alors la catégorie $\mathrm{HOT}^?_W$ mérite d'être larguée dans la corbeille, et on ne gardera que

$$\begin{array}{c} \mathrm{HOT}_W(S) \\ {\scriptstyle\bar{\jmath}}\downarrow \quad \uparrow{\scriptstyle\bar{\psi}'} \\ \mathrm{HOT}^{\mathrm{lc}}_W(S), \end{array}$$

où on définit $\bar{\psi}'$ comme

$$\bar{\psi}' = \bar{\imath}\bar{\psi} = \overline{i\psi}.$$

Et la question (plus modeste) devient à présent :

3°) $\bar{\psi}'$ est-il pleinement fidèle? (L'image *essentielle* est la même que celle de $\underline{\mathrm{Fib}}_0$ ($\approx \underline{\mathrm{Fib}}$), elle est formée sauf erreur des objets localement constants - à vérifier au besoin …)

Il est difficile d'imaginer que $\bar{k}$, ou ce qui revient au même $\bar{\psi}$, puisse être une équivalence, sans qu'il existe au moins une 'W_S-homotopie' p. 23 [page 39]

$$\mathrm{id}_{\underline{\mathrm{Fibsc}}_0 S} \;\leftrightarrow\leftrightarrow^h\leftrightarrow\leftrightarrow\; \psi k$$

dans la catégorie des endofoncteurs de $\underline{\mathrm{Fibsc}}_0 S$. À vrai dire, je me rends compte maintenant que la description de $\bar{\psi}$ à partir de $\psi : X \longmapsto \Phi_0 X = \Phi C X$ est inutilement compliquée, car on avait fait le détour par $C(X)$ uniquement pour être sûr de tomber dans $\underline{\mathrm{Fibsc}}_0 S$, pas seulement dans $\underline{\mathrm{Fibsc}}\, S$. Mais si on laisse tomber $\underline{\mathrm{Fibsc}}_0 S$, on s'en fout, et le foncteur $\Phi : X \longmapsto \Phi(X)$ est beaucoup plus naturel. Et si on ne laisse pas tomber, il n'y a pas d'inconvénient de remplacer

la source $\underline{\mathrm{Fib}}\, S$ par $\underline{\mathrm{Fib}}_0 S$ (qui a même localisé, à équivalence près), et sur $\underline{\mathrm{Fib}}_0 S$ à nouveau il n'y a pas lieu de s'encombrer de CX, pour le plaisir de lui appliquer Φ, car $\Phi(X)$ lui-même est déjà dans $\underline{\mathrm{Fibsc}}_0 S$.

Commentary · Examples [ms. 38]

What a one-sided inverse does and does not give

Grothendieck has a useful piece of the comparison: a natural isomorphism $\mathrm{k}^- \psi^- \simeq 1$. It proves essential surjectivity of k^- and faithfulness of ψ^-, and it shows that ψ^- is injective on isomorphism classes of objects. The statement about surjectivity on all morphism sets requires an additional hypothesis.

To locate the issue, let A be the discrete category on two objects a0, a1, and let B = ∗be terminal. There is a unique functor k : A −→B; let ψ pick a0. Then kψ = 1B strictly. Yet

HomA(a0, a1) = ∅−→HomB(∗, ∗) = {1}

is not surjective. Thus a functor with a section need not be full. In this example ψ is even fully faithful, so the parenthetical suggestion that failure of faithfulness of k is equivalent to failure of full faithfulness of ψ cannot be justified solely from the retract relation. For that converse take instead A = B $\coprod$BM, with B = ∗and a nontrivial monoid M, let k be the unique functor to ∗and let ψ select the first summand. Then ψ is fully faithful while k is not faithful.

The precise positive statement is easy and sufficient for the progress claimed so far. Choose −→1. For b, b′ ∈B and h : b −→b′, the morphism ψ(h) maps under k, followed by conjugation ε : kψ with ε, to h. Hence the map

HomA(ψb, ψb′) −→HomB(b, b′)

is split surjective. If ψ(h) = ψ(h′), applying k and conjugating gives h = h′, proving faithfulness. If ψb ≃ψb′, the same argument gives b ≃b′. None of these statements identifies an arbitrary a ∈A with ψka.

A natural zigzag of weak equivalences between 1 and ψk, sought on the following pages, would supply exactly that missing identification after localization. The full comparison theorem can therefore remain correct although the present formal inference is too strong. We record an error in this intermediate inference, with its corrected scope, rather than a gap in the later comparison once that zigzag has been constructed.

Donc, la question est celle-ci : Si X varie [page 40]

dans $\underline{\mathrm{Fibsc}}_0 S$, y-a-t'il une homotopie dans $\underline{\mathrm{Fibsc}}_0 S$, 'naturelle', i.e. fonctorielle en X,

$$X \xrightarrow{\quad c \quad} \Phi(X) = \text{ Catégorie fibrée scindée de fibres les } s\backslash X$$

Mais un chemin qui soit formé de flèches

$$X = X_0 \longrightarrow X_1 \longrightarrow X_2 \cdots \longrightarrow X_n = \Phi(X)$$

qui soient toutes cartésiennes (et de plus, bien sûr, dans W!). Cela signifie donc qu'on aurait des catégories fibrées scindées sur S, X_1, …, X_{n-1}, dépendant *fonctoriellement* de X, qui relient

$$X = X_0 \qquad \text{à} \qquad \Phi(X) = X_n$$

i.e.

$$X_s \qquad \text{à} \qquad s\backslash X \qquad ???$$

Je ne vois rien à l'horizon.

p. 24
[page 41]

Commentary · Present state [ms. 40]

The locally constant comparison is now a theorem

Grothendieck is asking for morphisms that retain coherent transport while forgetting arbitrary choices of Cartesian lifts. His unsuccessful unit is not evidence that the locally constant subcategory fails to embed fully. It identifies a defect of that particular representative of the comparison. The

arguments on manuscript pages 55–60 repair the comparison, and pages 65–69 establish the relevant reflection.

The higher coherence retained by local constancy was illustrated at manuscript page 7. The later theory treats the local constancy question for a general derivator. Cisinski (2009, Proposition 3.10 and Theorem 3.13) proves that locally constant objects form a full subderivator and that its inclusion has both a left and a right adjoint. These are the published numbering; the earlier arXiv version numbers the corresponding statements 3.9 and 3.12. The theorem establishes the positive status of the full embedding and the existence of the two adjoints, without identifying all the coarse localizations of this chapter for an arbitrary W.

That last restriction matters. If W is homological or a finite homotopy truncation, a coarse Wequivalence of total spaces need not be a W-equivalence on homotopy fibres. The local constancy construction in a derivator still makes sense, but the additional identification with the coarse localization of Cat/S uses the stronger hypothesis isolated below. For W∞the categorical path model and the modern description by coherent space-valued diagrams fit together; the commentary on manuscript pages 65–69 gives the precise reflector. This question is therefore settled in its intended homotopy-theoretic setting, while its unqualified extension to every localizer is false.

15.11.90

Je crois qu j'ai enfin compris, cette nuit, la situation exacte. Il y a lieu, dans Cat/S et dans les autres catégories du diagramme p. 8 (s'envoyant toutes dans Cat/S) d'envisager quatre sortes de 'W-équivalences'.

$$\begin{array}{ccc} f : X & \longrightarrow & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

a) La *W-équivalence 'grossière'* : dans Cat/S est une W-équivalence grossière si en tant que flèche de Cat, c'est une W-équivalence. ([17]).

b) La *W-équivalence 'par fibres'* (sur S) : $\forall\ s \in S$, $f_s : X_s \longrightarrow Y_s$ est une W-équivalence. ([18]).

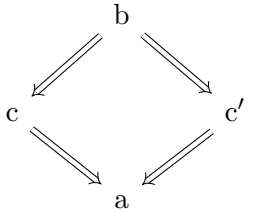
c) La *W-équivalence 'locale sur S'* : $\forall\ s \in S$, $f/s : X/s \longrightarrow Y/s$ est une W-équivalence. Signifie que c'est une W-équivalence, et le reste par tout changement de base $S' \longrightarrow S$ qui est un isomorphisme local. ([19]).

c′) La *W-équivalence 'colocale sur S'* : $\forall\ s \in S$, $s\backslash f : s\backslash X \longrightarrow s\backslash Y$ est une W-équivalence. Signifie que c'est une W-équivalence, et le reste par tout changement de base $S' \longrightarrow S$ qui est un co-isomorphisme local. ([20]).

Je vais résumer dans un énoncé récapitulatif les relations entre ces quatre notions de W-équivalence, en pensant au cas $W = W_\infty$. Une fois la chose faite, je me préoccuperai de dégager les conditions minimales sur un W général qui assurent que c'est vrai pour W.

$$\begin{array}{ccc} f : X & \longrightarrow & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

Proposition 1. *Soit* *dans* Cat/S.



1) *La W-équivalence locale sur S, et la W-équivalence colocale sur S, impliquent la W-équivalence grossière :*

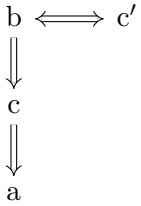
$$\begin{array}{ccc} \mathrm{c} & & \mathrm{c}' \\ & \searrow \quad \swarrow & \\ & \mathrm{a} & \end{array}$$

p. 25

17. stable par changement de base à la fois lisse et propre, plus généralement si $S' \longrightarrow S$ est une Hot-fibration.
18. stable par tout chagement de base $S' \longrightarrow S$
19. devrait être stable par changement de base *lisse* $S' \longrightarrow S$
20. devrait être stable par changement de base *propre* sur S

2) *Si X, Y sont propres sur S, ou X, Y lisses sur S, ou X, Y des* Hot-*fibrés sur S, alors la W-équivalence par fibres implique que c'est une W-équivalence* universelle *sur S (W-équivalence, et le reste par* tout *changement de base $S' \longrightarrow S$), donc dans ces trois cas, on a*

([21]).



Mais on peut préciser chacun de ces trois cas :

(2 fib) *Si X, Y sont* Hot-*fibrés sur S, alors la W-équivalence grossière de f implique que c'est une W-équivalence par fibres, donc les quatre notions de W-équivalence sont équivalentes pour f.*

$$a \Longleftrightarrow c \Longleftrightarrow c' \Longleftrightarrow b$$

([22])

(2 lisse) *Si X, Y sont lisse sur S, alors la W-équivalence par fibres sur S équivaut à la W-équivalence colocale sur S et implique la W-équivalence* universelle *sur S, donc dans ce cas* [page 42]

Commentary · Exposition [ms. 41]

Four tests on a map over the base

Grothendieck now separates the total homotopy type from the two possible diagram directions. For p : X −→S there are three kinds of fibre to consider. The strict fibre Xs remembers only objects and arrows mapping to s and 1s. The comma category X/s also allows arrows p(x) −→s in the base; it varies covariantly with s. The comma category s\X allows arrows s −→p(x) and varies contravariantly. Thus for f : X −→Y over S the tests are

total

f ∈W,

fibrewise fs ∈W (s ∈S),

local, or left-fine f/s ∈W (s ∈S),

colocal, or right-fine s\f ∈W (s ∈S). The word "local" here refers to these particular comma tests, not to a chosen Grothendieck topology. The names "left" and "right" are the manuscript's conventions. They must not be interchanged merely because the fibrations are drawn on the left side of the thirteen-category diagram.

For the ordinary weak homotopy equivalences, the role of the comma tests is to detect the maps of coherent diagrams produced by Ψ and Φ. A map can preserve the total homotopy type while changing one of those diagrams, as the walking-arrow example at manuscript page 32 proves. Conversely, strict fibres alone do not detect a total equivalence without some condition on the maps to S. For example, the functor from the discrete two-object category {0, 1} to [1], over [1], is an isomorphism on both strict fibres but changes the total space from

21. Il suffit X, Y W-propres sur S, ou W-lisses sur S, ou W-fibrés sur S.

22. a $\Longrightarrow$ b seulement moyennant L5, voir ci-dessous p. 43.

two components to a contractible space. It also fails both comma tests: over 1, and under 0, respectively, it compares a discrete two-point category to a contractible one.

The assertion concerning arbitrary base change of a fibrewise equivalence is formal: the fibre of a pullback over s′ ∈S′ is the original fibre over its image in S. The assertion concerning base change of a coarse equivalence along every homotopy fibration is not formal for a general W; it is exactly the additional stability later called L6 bis. Footnote 17 is valid for W∞, the setting explicitly adopted for the proposition, and must not be read as a theorem about every localizer.

The local-isomorphism formulation has an elementary explanation in the usual categorical convention of discrete fibrations. If T −→S is a discrete fibration, then

(X ×S T)/t ∼= X/p(t).

An object on the right determines the object of T above its source by the unique lifting property. Thus local equivalence is preserved by this pullback, and relative axiom L4 bis gives total equivalence afterward. Conversely the representable discrete fibrations S/s −→S recover the comma tests themselves. Dualizing gives the colocal statement. This explains both the strength and the orientation of the local tests without equating them to arbitrary base-change invariance.

p. 26

([23]).

(2 prop) *Si X, Y sont propres sur S, alors la W-équivalence par fibres sur S équivaut à la W-équivalence locale sur S :*

$$\begin{array}{ccc} \mathrm{b} & \Longleftrightarrow & \mathrm{c} \\ \Downarrow & & \\ \mathrm{c}' & & \\ \Downarrow & & \\ \mathrm{a} & & \end{array}$$

([24]).

Démonstration 1) n'est autre que L4 ([25]) et son dual L4′ pour un localiseur fondamental W, et on a vu que si on suppose L1, L3, alors L4 équivaut à L4′, et dans la notion de localiseur fondamental on supposera toujours que c'est vérifié. Également, nous supposons que L3 est vrai même sous la forme plus forte L3 quater (p. 1) : $W_\infty \subseteq W$, i.e. toute Hot-équivalence est une W-équivalence.

(2 lisse) Si X, Y `[sont]` lisses sur S, alors les $X_s \longrightarrow s\backslash X$, $Y_s \longrightarrow s\backslash Y$ sont des W_∞-équivalences, donc des W-équivalences (il suffirait même que X, Y soient W-lisses/S), donc le diagramme commutatif

$$\begin{array}{ccc} X_s & \xrightarrow{f_s} & Y_s \\ {\scriptstyle i_s^X}\downarrow & & \downarrow{\scriptstyle i_s^Y} \\ s\backslash X & \xrightarrow{s\backslash f} & s\backslash Y \end{array}$$

nous montre que f_s est une W-équivalence si et seulement si $s\backslash f$ l'est, d'où b $\Longleftrightarrow$ c′. Pour voir que la W-équivalence par fibres est même une W-équivalence *universelle* sur S, on est ramené à montrer que c'est une W-équivalence grossière (puisque la lissité `[est]` stable par changement de base sur S), et on gagne puisque c′ $\Longrightarrow$ a par 1).

Le cas (2 propre) est dual.

(2 fib) Si X, Y sont des Hot-fibrés sur S, alors les inclusions p. 27

[page 43]

$$X_s \longrightarrow s\backslash X, \qquad X_s \longrightarrow X/s,$$

23. il suffit même X, Y W-lisses sur S.
24. Il suffit même X, Y W-propres sur S.
25. Non, il y a confusion, L4 est plus faible, cf. p. 44 l'axiome L4 bis.

et de même pour Y, sont des W_∞-équivalences, donc des W-équivalences (il suffirait même que X, Y soient des W-fibrations sur S ([26]), i.e. par définition que les foncteurs précédents soient des W-équivalences, et que la même condition soit satisfaite après tout changement de base sur S), l'argument dans le cas lisse resp. propre montre déjà que

$$\begin{array}{ccccc} \mathrm{c} & \Longleftarrow & \mathrm{b} & \Longrightarrow & \mathrm{c}' \\ & & \Downarrow & & \\ & & \mathrm{a}, & & \end{array}$$

et que la W-équivalence par fibres (ou la W-équivalence locale sur S, resp. colocale sur S) implique déjà la W-équivalence *universelle* sur S. ([27])

Commentary · Exposition [ms. 42]

When strict fibres compute a comma fibre

Grothendieck's proposition is useful because it states exactly when a strict fibre is a valid homotopical substitute for one of the comma categories. The discussion of smoothness and properness in the commentary on Chapter I, manuscript pages 52–59, supplies the geometric input; here we use that input to compare weak equivalences of objects over the same base.

If X −→S is smooth, the canonical inclusion Xs −→s\X is a weak homotopy equivalence. When both X and Y are smooth, the commutative square

Xs

Ys

s\X

s\Y has vertical arrows in W if W∞⊆W. Two-out-of-three proves the equivalence of the fibrewise and right-fine tests. For proper objects the same argument uses Xs −→X/s and proves equivalence with the left-fine test. The proof requires no comparison of total spaces at this stage. The same argument works with W-smooth or W-proper objects when the vertical maps are directly known to be in W.

To obtain universality, make any change of base T −→S. Smoothness and properness are preserved, and the fibrewise maps remain in W. The preceding comparison gives a colocal or local W-equivalence over T, respectively. Relative axiom L4 bis, or its dual, now makes the total map over T a W-equivalence. The base change was arbitrary, so the map is universally a W-equivalence. This fills the quantifier in the proof; it is not a new appeal to L6. Here base change acts on a map already known to be a fibrewise equivalence between suitably regular objects.

For homotopy fibrations both comma comparisons are weak homotopy equivalences, universally on the base. Hence the fibrewise, local and colocal conditions coincide and imply universal total equivalence. The reverse implication from a total equivalence is the extra statement later named L5. It holds for W∞ by invariance of homotopy fibres, and the next examples show why it cannot be appended for every W.

The modern extension to asphericity structures is given by Maltsiniotis (2005, Corollary 4.16 and Theorem 5.4): Grothendieck fibrations are smooth, and smoothness is characterized by the appropriate base-change property. This is the direct continuation of the present comparison argument. In highercategorical straightening one likewise distinguishes equivalence in the diagram direction from equivalence of underlying total spaces; the latter agrees with the former for locally constant fibrations, not for every right or left fibration.

La question a $\Longrightarrow$ b est par contre nettement plus délicate, et on a vu que ce n'est nullement le cas pour tout localisateur fondamental - sans doute pas pour celui associé au dérivateur Der($\mathbf{Z}$-Mod), en tous cas pas à celui associé à Der(k-Mod), quand 2 est inversible dans k. (Il suffirait même que $\exists\, n \in \mathbf{N}$, $n \geq 2$, tel que n inversible dans k - le contrexemple typique est $X = S^1 \xrightarrow{n} S^1 = Y = S$, le revêtement étale d'ordre n du cercle.)

L'implication a $\Longrightarrow$ b est donc une condition très forte sur W, je vais la noter L5 (l'ancienne L5, cf. page 2, ne méritant pas de survivre, car c'est une côte mal taillée).

26. comparer déf. 3, p. 117, dans (I).

27. valable en supposant seulement X, Y des W-fibrés sur S.

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

L5 *Soit* *dans* Cat*, avec X, Y des* Hot-*fibrés sur S. Si f est une W-équivalence ('grossière' par rapport à S), alors c'est une W-équivalence par fibres* ([28]).

On a vu qu'à un ε près ('lemme' p. 23), L5 est une conséquence de

L6 *Soit $f : X \longrightarrow Y$ une W-équivalence, $Y' \longrightarrow Y$ un morphisme parfait (i.e. lisse et propre), alors $f' : X' = X \times_Y Y' \longrightarrow Y'$ est une W-équivalence.*

Notons la variante bien naturelle [page 44]

Commentary · Examples [ms. 43]

The circle covering as a categorical counterexample

Grothendieck's covering of the circle gives a complete obstruction to L5 for homology coefficients in which its degree is invertible. It is useful to realize it inside Cat, so that no passage from topological coverings to categorical fibres is left implicit.

Fix n ≥2. Let S = BZ, the one-object category with endomorphism group Z. Let X be the action groupoid for translation of Z on Z/n. Its objects are residues a, and a morphism a −→b is an integer m with b = a + m modulo n; composition is addition. The projection p : X −→S sends that morphism to m. Unique lifting of each integer with specified source or target makes p both a discrete fibration and a discrete opfibration. Its strict fibre is the discrete set Z/n.

The groupoid X is connected. The automorphism group of the object 0 is nZ, so the inclusion B(nZ) −→X is an equivalence. Under this identification, p is the homomorphism nZ ,→Z. Thus both classifying spaces are circles, and the induced map on H1(−; k) is multiplication by n after choosing the usual generators. It is the identity on H0 and both sides have zero homology in higher degrees. If k is a nonzero commutative ring in which n is invertible, p is a k-homology equivalence. Regard it now as the map from X −→S to S −→1S. On strict fibres it induces

H0(−; k) : kn −→k.

Z/n −→∗, The latter map adds coordinates and has nonzero kernel. Hence it is not a fibrewise homology equivalence, although both objects over S are perfect.

The same example disproves L6 itself, not only the fibre-detection formulation. Let E be the translation groupoid of Z acting on itself, and let E −→BZ be the evident discrete fibration and opfibration. There is exactly one arrow between each ordered pair of objects of E, so E is contractible. The objects of X ×S E are pairs (a, z); simultaneous translation preserves a −z modulo n. Each of the resulting n components has exactly one arrow between any two of its objects and is contractible. Therefore

X ×S E −→E

induces kn −→k on H0 and fails to be a homology equivalence. The base-change map is perfect, as required by L6. The argument explains why replacing "homotopy fibration" by "perfect" cannot repair the homological version.

Commentary · Development (commentators') [ms. 43]

An integral-coefficient version of the obstruction

Grothendieck also suspects failure for integral homology, where a nontrivial finite covering of the circle no longer gives a homology equivalence. The following explicit construction settles that case. Its ingredients are standard: a semidirect product and the mapping-torus homology sequence. We checked the discussion of homological local constancy in Cisinski (2009, Scholium 1.26) and the mapping-torus calculation in Hatcher (2002, Example 2.48); we did not find this particular categorical application to the sentence here in those sources. The marking records the application and proof supplied by us, not a priority claim for the group or its homology.

Proposition (integral homology does not detect the fibre). [ours]There is a perfect functor p : X −→S which induces an isomorphism on integral homology in every degree, while its strict fibre has nonzero first integral homology. Consequently the localizer of integral homology equivalences fails L5.

28. Dans XII (p. 12) on voit que si W satisfait à L1, L3 quater, L4 bis (cf. page suivante), L5, alors $\boxed{W = W_\infty}$. Donc c'est parfaitement illusoire, si on suppose L5 de continuer à traîner un W.

Proof. Put A = Z[1/2], let h : A −→A be multiplication by 2, and put G = A ⋊h Z. Take X = BG, S = BZ and let p be induced by the quotient G ↠Z. Since this homomorphism is surjective, every base arrow admits lifts with either prescribed source or prescribed target; all arrows in these groupoids are invertible and hence Cartesian and cocartesian. Thus p is both a Grothendieck fibration and an opfibration, and is perfect. Its strict fibre is BA.

We compute the fibre's homology first. The group A is the filtered union of the cyclic subgroups 2−rZ. The nerve, its free simplicial chain complex and homology all commute with this filtered union: each finite tuple of group elements occurs at a finite stage, and filtered colimits of abelian groups are exact. Since BZ has the homotopy type of a circle, this gives

(i ≥2).

H0(BA; Z) = Z, H1(BA; Z) = A, Hi(BA; Z) = 0 The map induced by h acts by 2 on H1 and by the identity on H0.

The group automorphism h induces a homeomorphism of the realization of the nerve of A. Its mapping torus Th is a bundle over the circle. Its fundamental group is A ⋊h Z after choosing the orientation of the circle, and its higher homotopy groups vanish by the homotopy sequence, since the fibre is K(A, 1). Hence Th is a classifying space for G, compatibly with the projection to BZ. The mapping-torus homology sequence has the terms

· · · −→Hi(BA)

−−−→Hi(BA) −→Hi(Th) −→Hi−1(BA) −→ · · · . In degree 1, 1 −h∗= −1 on A is invertible; in degree 0 it is zero on Z. Exactness therefore gives Hi(Th) = 0 for i ≥2 and an isomorphism H1(Th) −→Z. Naturality with respect to the map of fibres BA −→∗identifies this last isomorphism with the homology map induced by the projection to the circle. Both spaces are connected, so the projection is also an isomorphism on H0. This proves that p is an integral homology equivalence. Its map of fibres to the fibre of 1S is BA −→∗, which fails on H1 = A = 0. □

The example distinguishes absolute homology of the total category from homology after changing the base. The monodromy multiplies the fibre's homology by 2, and 1 −2 is invertible; its contribution disappears from the total homology without disappearing from the fibre. Thus the obstruction is present even with integral coefficients, independently of inverting the degree of a finite covering.

L6 bis *Comme L6, mais en supposant seulement $Y' \longrightarrow Y$ une* Hot-*fibration.*

Il y a des chances que pratiquement, quand L6 (ou seulement L5) est verifié, L6 bis l'est aussi. p. 28

On va introduire un axiome

L7 a) *Soit $(f_i : X_i \longrightarrow Y_i)_{i\in I}$ une famille de flèches dans* Cat*, soit $f : \coprod X_i \longrightarrow \coprod Y_i$ la flèche correspondante sur les catégories somme. Pour que $f \in W$, il faut et il suffit que $f_i \in W$ pour tout $i \in I$.*

b) *Soit $f : X \longrightarrow Y$ dans W. Si Y est* 0*-connexe, X aussi.*

Cet axiome équivaut à la conjonction de La ($f \in W \Longrightarrow \pi_0 f$ bijectif) et de la validité du 'Lemme' page 23, que je remets ici pour mémoire :

Lemme. *L'axiome L7 précédent sur le localiseur fondamental W équivaut à la condition suivante : $f : X \longrightarrow Y$ est dans W si et seulement si $\pi_0(f)$ est bijectif, et f induit des W-équivalences $f_i : X_i \longrightarrow Y_i$ sur les composantes connexes.*

Il me faut revenir encore sur le 1) de la proposition, il n'est pas vrai que 'c'est' la condition L4 sur W (que j'admets, ai-je dit), c'est L4 dans le cas particulier où $Y = S$. Réflexion faite, je le vois comme une variante renforcée de L4, qui ne semble pas devoir découler de L4 :

$$\begin{array}{ccc} X & \xrightarrow{\ f\ } & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$$

L4 bis *Soit* *dans* Cat*, supposons que f soit une W-équivalence locale sur S (i.e. $f/s : X/s \longrightarrow Y/s$ une W-équivalence $\forall\ s \in S$), alors f est une W-équivalence* ([29]).

Par la suite, par un 'localiseur fondamental', nous entendrons un ensemble [page 45]

$$W \subseteq \mathrm{Fl}\,\mathrm{Cat}$$

29. équivaut à l'axiome dual, en termes des $s\backslash f$

satisfaisant (tout au moins) les axioms

L1, L3 quater, L4 bis, L7,

i.e.

Commentary · Exposition [ms. 44]

Componentwise locality and relative Theorem A

Grothendieck separates two axiomatic matters here. The first concerns disjoint components; the second concerns descent over a base that need not be the target of the map being tested. Keeping them separate clarifies which part of the preceding argument each axiom repairs.

The component criterion is exactly equivalent to L7. To prove the nontrivial direction, let f : X −→Y belong to W and decompose Y = ‘ j Yj into its nonempty connected components. Put Xj = f −1(Yj), a union of components of X. Then f = ‘ j fj, so L7(a) implies fj ∈W for every j. L7(b) implies that every Xj is nonempty and connected. Hence $\pi 0$(f) is bijective, and the fj are precisely the component maps. Conversely, if $\pi 0$(f) is bijective and every component map belongs to W, L7(a) gives f ∈W. The empty target creates no exception: a functor into the empty category has empty source.

To recover L7 from the criterion, consider a family (fi). The component map of ‘ i fi is just a component map of one fi; moreover its map on components is bijective exactly when each $\pi 0$(fi) is bijective. The criterion therefore gives both directions of L7(a). If the target of a W-equivalence is connected, its component bijection makes the source connected, giving L7(b). This is a complete proof of the lemma, including the reflection direction in the coproduct assertion.

For the second matter, the original L4 applies to a map X −→Y when the overcategories of its fibres over objects of Y are aspherical. In Proposition 1, however, one compares X/s and Y/s for an independent base S. These overcategories need not be aspherical; only the map between them is assumed to be a W-equivalence. Thus the printed sentence identifying the proposition directly with the original L4 does not establish it. L4 bis is exactly the required relative formulation. The dual condition uses s\X −→s\Y .

The accepted modern definition of a fundamental localizer includes the relative formulation; see Cisinski (2004, §1.1). Its minimal member is W∞by that paper's Theorem 2.2.11. This gives a precise later framework for the corrected argument. We make no claim here that the absolute and relative formulations are logically independent under every possible package of the earlier axioms; what the text has exhibited is the need for the relative assertion in this proof. Opposite-category invariance then transfers the relative assertion to its dual, using the category-of-simplices comparison discussed earlier in the chapter.

a) *Saturation* de W (conditions a) b) c) p. 1)

b) $W_\infty \subseteq W$ [$\subseteq W_0$] ([30]) ([31]).

c) Si $f : X \longrightarrow Y$ sur S est localement sur S une W-équivalence, alors $f \in W$ (L4 bis)

d) Pour que $f : X \longrightarrow Y$ soit dans W, il faut et il suffit que $\pi_0(f)$ soit bijectif, et que les $f_i : X_i \longrightarrow Y_i$ induits sur les composantes connexes soient dans W. p. 29

Ces axiomes sont vérifiés par tous les W qui je connais, et qu' on aurait envie de regarder comme localiseurs. Par contre, L5, L6, L6 bis (p. 43, 44) sont des axiomes de nature beaucoup plus spéciale. J'ai envie de dire qu'ils distinguent les localiseurs de nature proprement *'homotopique'* de ceux qui sont de nature *'homologique'* (ou 'cohomologique'). Il faudrait que je m'assure qu'ils sont satisfaits pour les W_i (i-équivalence d'homotopie) ([32]).

Le fait que L4 bis, i.e. c) ci-dessus, implique l'axiome dual, résulte du fait que L4 bis implique ceci

30. Je ne suis plus sûr s'il est vraiment utile d'imposer $W_\infty \subseteq W$. Prendre au lieu de ça l'axiome de l'objet final, soit b′). Si on veut a) b′) c) + L5, alors on aura $W \subseteq W_\infty$. **NB** a) b) c) + L5 implique $W = W_\infty$, cf. annotation page 43.

31. cf. d)

32. C'est *faux*, cf. annotation ci-dessus.

Proposition 2. *Soit $f : X \longrightarrow Y$ dans* Cat*, alors $f \in W$ si et seulement si $f^o : X^o \longrightarrow Y^o$ est dans W.*

Se voit par l'argument de I, page 75 (cor. 2) - n'utilise que L4, pas même L1, L3.

[page 46]

Commentary · Present state [ms. 45]

Why the new fibration axiom selects full homotopy theory

Grothendieck's second L5 is much stronger than the first axiom with that label. The first passed from equivalences of fibres to an equivalence of totals. The new one attempts the reverse implication for homotopy fibrations. The annotations correctly recognize that this is incompatible with the proposed range of examples, but the displayed uniqueness claim needs the standing connectedness condition W ⊆W0. Without it the maximal class of all functors satisfies L1, L3 quater, L4 bis and L5, so those four conditions alone do not force W = W∞.

Here is the mechanism of the uniqueness assertion, retaining W∞⊆W ⊆W0, two-out-of-three, the new L5, and the path replacement already available in the chapter. Suppose first that T −→∗ belongs to W. Its classifying space is connected by W ⊆W0. For a chosen object t form the perfect replacement P = CT (∗) −→T of the inclusion of that object. Its total category is weakly contractible. Two-out-of-three implies P −→T ∈W. Applying L5 to this map between the homotopy fibrations P −→T and T −→1T shows that its fibre F −→∗belongs to W. The fibre models the based loop space of BT. Repeating the argument with F and successive fibres gives categorical models for all iterated loop spaces, each W-aspherical and hence connected. Therefore

πn(BT, t) = π0(ΩnBT) = 0

(n ≥1). Together with connectedness this says that T is weakly contractible.

Now let f : X −→Y belong to W. Replace it by the perfect map CY (X) −→Y . Its total map is still in W, and L5 makes every strict fibre W-aspherical. What we have just proved makes those fibres weakly contractible. Since this is a homotopy fibration, its homotopy fibres are weakly contractible, so its total map is a weak homotopy equivalence; the replacement X −→CY (X) is also one. Thus f ∈W∞. This proves W = W∞. The argument uses the previously established homotopy-fibre property of the path replacement, not a new assertion that arbitrary strict fibres compute homotopy fibres. The later abstract characterization in Cisinski (2004, Theorem 2.3.6) likewise includes preservation of connected components.

One can see the failure for every finite truncation directly. Let W≤n mean maps inducing isomorphisms on πi for 0 ≤i ≤n, with all basepoints understood. Choose a nonzero abelian group A and a categorical model S of K(A, n + 1). The perfect replacement P = CS(∗) −→S has contractible total space, so belongs to W≤n, while its fibre models K(A, n) and is not W≤n-aspherical. For n = 0 that fibre is the nontrivial discrete group A. This disproves L5. Pulling P −→S back along itself yields a total space weakly equivalent to ΩBS, because the base P is contractible and the map is a homotopy fibration. The projection P ×S P −→P therefore fails to belong to W≤n, disproving L6 even for this perfect base change. The finite truncations are homotopical theories, but they do not satisfy the unrestricted fibre-detection requirement of this L5.

Je vais essayer de résumer ce que je crois avoir compris :

1) La W-équivalence 'par fibres' n'a d'intérêt (pour construire des catégories localisées) que dans le cas où on sait qu'elle implique déjà, soit la W-équivalence locale, soit la W-équivalence colocale (soit même la W-équivalence universelle) sur S, donc quand on suppose X, Y pour le moins tous deux soit W-lisses, soit W-propres, soit W-fibrés sur S.
2) On pourrait appeler la W-équivalence locale sur S la *'W-équivalence fine à gauche'* sur S, et la W-équivalence colocale sur S la *'W-équivalence fine à droite'* sur S. Elles coïncident dans $\underline{\mathrm{Fibhot}}\, S$, a fortiori dans $\underline{\mathrm{Parf}}\, S$ et dans les quatre catégories (cf. diagramme p. 8) $\underline{\mathrm{Fib}}_0 S$, $\underline{\mathrm{Fibsc}}_0 S$, $\underline{\mathrm{Cofib}}_0 S$, $\underline{\mathrm{Cofibsc}}_0 S$ ([33]). Par contre, elles ne coïncident pas sur les catégories *bordantes* du diagramme, notamment sur $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Prop}}\, S$, $\underline{\mathrm{Fib}}\, S$, $\underline{\mathrm{Cofib}}\, S$, $\underline{\mathrm{Fibsc}}\, S$, $\underline{\mathrm{Cofibsc}}\, S$. À cet égard, c'est la *W-équivalence fine* **droite** (en termes des $s\backslash X$) qui est intéressante sur le côté (hélas) gauche du diagramme, i.e. pour $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Fib}}\, S$, $\underline{\mathrm{Fibsc}}\, S$, alors que c'est la *$W$-équivalence fine* **gauche** (en termes des X/s) qui est pertinente du côté droit, pour $\underline{\mathrm{Prop}}\, S$,

33. On pourrait les appeler les six catégories *internes* du diagramme.

Cofib S, Cofibsc S. On n'aura jamais à regarder simultanément les deux équivalences fines sur une même catégorie du diagramme, à la seule exception de Cat/S tout entier.

[page 47]

3) La W-équivalence grossière, elle, est 'bonne partout' - mais ça dépend pour qui. Pour les 6 catégories qui sont au dessus de Fibhot S, i.e.

$$\text{Fibhot}\, S, \quad \text{Parf}\, S, \quad \text{Fib}_0 S, \quad \text{Fibsc}_0 S, \quad \text{Cofib}_0 S, \quad \text{Cofibsc}_0 S,$$

elle coïncide avec toutes les autres équivalences (moyennnant l'axiome L5), pour les trois catégories bordantes supérieures gauches p. 30

$$\text{Liss}\, S, \quad \text{Fib}\, S, \quad \text{Fibsc}\, S$$

du diagramme, elle coïncide avec la W-équivalence fine droite, et dualement sur

$$\text{Prop}\, S, \quad \text{Cofib}\, S, \quad \text{Cofibsc}\, S$$

elle coïncide avec la W-équivalence fine gauche. Quant à Cat/S tout entier, c'est la seule des catégories du diagramme où il y ait *trois* notions intéressantes différentes de W-équivalence, à savoir : la grossière, et les deux fines (à gauche, à droite). Sur les autres six catégories bordantes du diagramme, il y en a en principe deux : la grossière, et une spécifiée des deux fines (défendu de regarder l'autre - à ses risques et périls …) : la droite du côté gauche, la gauche du côté droit. (NB Je devrais refaire le diagramme, décidément, en mettant les fibrations à droite, pas à gauche.) Quant aux six catégories internes au diagramme, dans elles il n'y a plus qu'une seule notion de W-équivalence (puisque sur elles les quatre notions coïncident).

(**NB** il n'y a pas de page 48)

[page 48 (vide)]

[page 49]

Commentary · Exposition [ms. 47]

Reading the corrected classification

Grothendieck is now trying to separate the homotopy theory of a diagram from the homotopy type of its total category. This separation is the reason for retaining three localizations. Write WS for equivalences of total categories, W d S for the condition that every s\X →s\Y belongs to W, and W g S for the analogous condition on X/s →Y/s. The superscripts record the two comma directions, not the placement of a category in the drawing. One sentence in the present paragraph must be corrected mathematically. The assertion that WS coincides with W d S on the smooth or fibred side, and dually with W g S on the proper or cofibred side, is false. The edition prints it without a negation. On the fibred side it is fibrewise equivalence that coincides with W d S; total-category equivalence remains a weaker condition. The walking-arrow example in the commentary at manuscript p. 32 proves the distinction: {0} ,→[1], viewed over [1], is an equivalence of total homotopy types, but its fibres over 1 are respectively empty and nonempty. The same paragraph subsequently says that there are two notions on each border, and p. 49 uses the correct distinction.

On the six internal categories the equality with WS uses the new L5 of p. 43. This is different from the earlier axiom carrying that name. Under L5, a map between homotopy fibrations which is an equivalence on total categories is an equivalence on fibres. The ordinary replacement arguments compare all the coarse localizations without this additional axiom, and comma resolutions independently compare the fine theories. L5 is needed when we identify the coarse class on internal objects with their fine class, and thereby realize the coarse theory as a fully faithful locally constant part of the fine theory. This distinction prevents the corrected theorem from inheriting the false equality in its provisional summary.

Je résume maintenant ce que je crois avoir compris sur les catégories localisées correspondantes. Il y en a, à équivalence près, *trois* différentes seulement en tout et pour tout, quand on prend les localiseurs 'admissibles' dans les catégories, comme je viens de le dire (c'étant ça en somme l'intérêt objectif des prescriptions!) De façon précise :

1°) La *W-équivalence grossière* donne 'la même' catégorie localisée pour les 13 catégories du diagramme, i.e. toutes les flèches de transition du diagramme induisent des équivalences pour cette W-équivalence grossière. Le localisé sera noté $\boxed{\mathrm{HOT}^{\mathrm{lc}}_W(S)}$, où l'exposant lc signifie: (W-types d'homotopie relatif sur S) *'localement constants.'* (Il ne me reste qu'un petit doute pour $\underline{\mathrm{Fibsc}}\, S$ et $\underline{\mathrm{Cofibsc(S)}}$ ([34]), si l'équivalence grossière y est bel et bien raisonnable. On verra en faisant la démonstration.)

2°) La *W-équivalence fine à droite* donne le même résultat pour toutes les catégories du diagramme où elle est considérée comme admise, *et où elle ne coïncide pas avec la W-équivalence grossière* déjà considérée, donc sur les quatre catégories bordantes gauches

$$\mathrm{Cat}/S, \quad \underline{\mathrm{Liss}}\, S, \quad \underline{\mathrm{Fib}}\, S, \quad \underline{\mathrm{Fibsc}}\, S$$

([35]). Le localisé est noté $\boxed{\mathrm{HOT}_W(S)}$.

[page 50]
p. 31

$2'^o$) Dualement, la *W-équivalence fine gauche* donne le même résultat sur toutes les catégories du diagramme où elle est admise, et où elle ne coïncide pas avec la grossière, i.e. sur les 4 catégories

$$\mathrm{Cat}/S, \quad \underline{\mathrm{Prop}}\, S, \quad \underline{\mathrm{Cofib}}\, S, \quad \underline{\mathrm{Cofibsc}}\, S.$$

Il y a lieu de noter la catégorie des fractions commune par le sigle

$$\mathrm{HOT}_W(S^o)^o \qquad (\text{ou aussi } \mathrm{HOT}^o_W(S)),$$

puisqu'elle est isomorphe à celle notée par ce sigle.

Si on veut des notations sans ambiguïté, désignant des catégories bien définies, et non pas seulement 'à équivalence près', je choisirai

$$\mathrm{HOT}_W(S) \overset{\text{déf}}{=} \underline{\mathrm{Fibsc}}(S)(W^{\mathrm{d}}_S)^{-1}$$

d'où

$$\mathrm{HOT}_W(S^o) \underbrace{\simeq}_{\text{isomorphisme de catégories}} \underline{\mathrm{Cofibsc}}(S)(W^{\mathrm{g}}_S)^{-1},$$

où W^{d}_S, W^{g}_S désignent les ensembles de flèches correspondants à la W-équivalence fine droite resp. gauche. Pour $\mathrm{HOT}^{\mathrm{lc}}_W(S)$, je préfère une définition aussi symétrique que possible en S, S^o, et de plus une catégorie aussi petite que possible, ce qui me conduit à choisir

$$\mathrm{HOT}^{\mathrm{lc}}_W(S) \overset{\text{déf}}{=} (\underline{\mathrm{Parf}}\, S)W_S^{-1},$$

où on a noté par W_S les W-équivalences dans $\underline{\mathrm{Parf}}\, S$. (Inutile cette fois de préciser lesquelles - toutes les quatre `[notions]` coïncident dans $\underline{\mathrm{Parf}}\, S$!)

[page 51]

Commentary · Exposition [ms. 50]

The covariant theory and the extra opposite

Grothendieck wants a notation which makes the symmetry between fibrations and opfibrations immediate. There is a genuine symmetry, but the edition alternates between two incompatible formulas. With the definition fixed on manuscript p. 3, the precise identities are

[Cofibsc(S)][(W g

HOTW (S) = [Sop, Cat][W −1 S)−1] ≃[S, Cat][W −1 obj] = HOTW (Sop). obj], Here Wobj means objectwise membership in W. There is no opposite on the value category in the last expression. The displayed isomorphism in the middle of p. 50 has this correct form; the preceding prose and the

34. Ce doute n'est pas fondé, tout marche parfaitement!

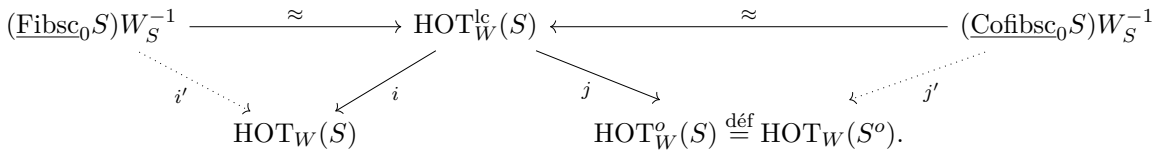
35. **NB** Sur les trois dernières cette équivalence est la W-équivalence par fibres.

editorial correction at p. 51 insert an additional opposite. We retain those readings as part of the source, while using the comma-category models to determine the variance of every assertion.

Indeed, taking opposite total categories sends a fibration over Sop to an opfibration over S. It sends a functor X →Y to a functor Xop →Y op in the same direction. Thus it defines a covariant isomorphism of the categories of structured objects; it does not reverse their morphisms. The same observation justifies the correctly stated symmetry of the perfect-fibration localization at p. 51.

The extra opposite cannot be repaired by an unspecified equivalence. Take S = e and W = W∞. The category of homotopy types is not equivalent to its opposite. Its initial object ∅is strict: a morphism T →∅exists only when T ≃∅. Such an equivalence would force the initial object of the opposite category, namely the one-point homotopy type, to be strict there. This would say that every map ∗→T is an isomorphism, contradicted by the inclusion of one point into a two-point set. The external opposite is therefore a substantive variance slip, even though both fine localizations themselves are correctly constructed.

The notation HOTo W (S) may still be used as a label for the covariant theory, provided it is defined by the left-fine localization. It should not be interpreted here as taking the opposite of HOTW (Sop). This convention also gives the stated direction to the functor j in the diagram which follows.



Notons l'isomorphisme

$$\underline{\mathrm{Parf}}(S^o) \simeq \underline{\mathrm{Parf}}\, S$$

(provenant du fait que $f : X \longrightarrow Y$ dans Cat est une fibration parfaite si et seulement si f^o l'est). Cet isomorphisme $X \longmapsto X^o$ est compatible avec les localiseurs (car $f \in W \iff f^o \in W$), d'où

$$\mathrm{HOT}^{\mathrm{lc}}_W(S^o) \simeq \mathrm{HOT}^{\mathrm{lc}}_W(S)$$

(isomorphisme de catégories). On aura deux foncteurs canoniques entre les trois catégories de W-types d'homotopie relatifs sur S

[plutôt $\overset{\text{déf}}{=} \mathrm{HOT}_W(S^o)^o$] Ces flèches i, j sont suggerées par les flèches en pointillés i', j', provenant des inclusions p. 32

$$\underline{\mathrm{Fibsc}}_0 S \hookrightarrow \underline{\mathrm{Fibsc}}\, S, \quad \underline{\mathrm{Cofibsc}}_0 S \hookrightarrow \underline{\mathrm{Cofibsc}}\, S,$$

qui définiraient i, j à l'aide du choix de foncteurs quasi-inverses pour les flèches horizontales. Mais i, j ne seraient définis qu'à isomorphisme (unique) près. Il sera plus joli de choisir les quasi-inverses de façon canonique, à l'aide des flèches

$$\underline{\mathrm{Fibsc}}_0 S \xleftarrow{\Phi_0} \underline{\mathrm{Parf}}\, S \xrightarrow{\Psi_0} \underline{\mathrm{Cofibsc}}_0 S$$

(où $\Phi_0 = \Phi|\underline{\mathrm{Parf}}\, S$, $\Psi_0 = \Psi|\underline{\mathrm{Parf}}\, S$) du diagramme p. 8. La question principale qui reste non élucidée, c'est si ces foncteurs i, j sont bien *pleinement fidèles,* comme je m'y attends certes. [page 52]

Je veux maintenant prouver les affirmations précédentes sur les localisés.

① Le localisé pour la W-équivalence grossière. Il suffira, à un ε près, d'établir les conditions du lemme p. 11, dans les trois cas suivants. $\underline{\mathrm{Parf}}\, S \xrightarrow{r} \mathrm{Cat}/S$ (ça donnera le cas de

$\underline{\mathrm{Fibhot}}\, S$, $\underline{\mathrm{Liss}}\, S$ et $\underline{\mathrm{Prop}}\, S$ sur Cat/S) et $\underline{\mathrm{Fibsc}}_0 S \xrightarrow{p} \mathrm{Cat}/S$, $\underline{\mathrm{Cofibsc}}_0 S \xrightarrow{q} \mathrm{Cat}/S$,

qui donneront respectivement les cas de

$$\underline{\mathrm{Fib}}_0 S,\ \underline{\mathrm{Fib}}\, S,\ \underline{\mathrm{Liss}}\, S \qquad \text{et} \qquad \underline{\mathrm{Cofib}}_0 S,\ \underline{\mathrm{Cofib}}\, S,\ \underline{\mathrm{Prop}}\, S \qquad \text{sur } S.$$

Mais l'ennui pour p et q, c'est que les foncteurs en sens inverse que j'avais construit (et noté encore Φ_0, Ψ_0 (mais c'étaient essentiellement $\Phi \circ r \circ C$ et $\Psi \circ r \circ c$, à ne pas confondre avec les foncteurs Φ_0, Ψ_0 en bas de la page précédente, et marqués aussi dans le diagramme p. 8), notons les plutôt Φ', Ψ', marchent bien du côté Cat/S, i.e. $p\Phi'$, $q\Psi'$ reçoivent le foncteur $\mathrm{id}_{\mathrm{Cat}/S}$ par une W-flèche, mais pas du côté des catégories but - on n'arrive pas à trouver une flèche naturelle entre $\Phi' p$ resp. $\Psi' q$, et les foncteurs identiques de $\underline{\mathrm{Fibsc}}_0 S$ resp. $\underline{\mathrm{Cofibsc}}_0 S$. Je ne vois pas, en effet, qu'il y en ait - la difficulté, par cette voie, parait irrémédiable. Par contre, [page 53]
si on regarde Φ', Ψ' comme foncteurs à valeurs dans $\underline{\mathrm{Fib}}_0 S$, $\underline{\mathrm{Cofib}}_0 S$ respectivement (donc dans les catégories où on n'exige pas que les flèches soient catésiennes resp. cocartésiennes), on trouve encore des W-morphismes

$$\mathrm{id} \longrightarrow \Phi' p, \qquad \mathrm{id} \longrightarrow \psi' q,$$

ce qui liquide au moins déjà le cas de toutes les catégories des diagrammes p. 8 qui sont des sous-catégories pleines de Cat/S ([36]). Il ne reste à traiter que le cas des quatre catégories de p. 33
structures 'scindées'

$$\underline{\mathrm{Fibsc}}\, S, \quad \underline{\mathrm{Fibsc}}_0 S \qquad \text{et} \qquad \underline{\mathrm{Cofibsc}}\, S, \quad \underline{\mathrm{Cofibsc}}_0 S.$$

Bien sûr il suffit de le faire d'un côté, disons du côté des fibrés, par dualité ($S \longmapsto S^o$) cela établira le résultat symétrique. On va donc regarder d'un peu plus près le carré de foncteurs

$$\begin{array}{ccc} \underline{\mathrm{Fibsc}}\, S & \xleftarrow{\alpha'} & \underline{\mathrm{Fibsc}}_0 S \\ {\scriptstyle\varphi}\big\downarrow{\scriptstyle p} & & {\scriptstyle p_0}\big\downarrow{\scriptstyle\varphi_0} \\ \underline{\mathrm{Fib}}\, S & \xleftarrow{\alpha} & \underline{\mathrm{Fib}}_0 S \end{array}$$

([37], [38]). Le foncteur

$$\Phi : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Fibsc}}\, S$$

induit des foncteurs en sens inverse de p, p_0 sur les sous-catégories pleines $\underline{\mathrm{Fib}}\, S$, $\underline{\mathrm{Fib}}_0 S$ de Cat/S, foncteurs marqués en pointillés comme φ, φ_0.

[page 54]

Commentary · Context [ms. 53]

Why the free split fibration is the right comparison

The difficulty with the first attempt is a difficulty about morphisms, not about the existence of enough good objects. A path completion puts every object into a particularly well-behaved class, but its unit need not preserve a chosen splitting. The comma construction Φ has a stronger universal property: it freely supplies the selected Cartesian lifts. That property gives the reverse comparison map with exactly the morphism convention required by Fibsc(S).

This construction was already part of the theory of fibred categories before the present manuscript. Gray's treatment constructs the free split fibration, and the modern formulation identifies split fibrations and splitting-preserving functors with strict algebras for the comma-category 2-monad on Cat/S (Gray, 1966; Emmenegger et al., 2024). In the latter reference, Theorem 2.6 separates strict algebras from pseudo-algebras; Theorem 5.4 treats the two adjoints used to split an already fibred category. These are distinct operations. The present Φ is the free construction on an arbitrary category over S.

36. Mais c'est idiot de prendre des foncteurs si compliqués, parce qu'on veut tout ramener à Cat/S. Il est de plus simple de comparer $\underline{\mathrm{Fibhot}}\, S$ directement à $\underline{\mathrm{Fibsc}}_0 S$ et à $\underline{\mathrm{Cofibsc}}_0 S$. Φ_0 et Ψ_0 (qui sont en fait définis sur $\underline{\mathrm{Fibhot}}$, pas seulement sur $\underline{\mathrm{Parf}}$), et on trouve comme ci-dessous $\mathrm{id} \xrightarrow{W} \pi_0\Phi_0$ et $\Phi_0\pi_0 \xrightarrow{W} \mathrm{id}$ (itou pour Ψ_0 et $\underline{\mathrm{Cofibsc}}_0 S$), où $\pi_0 : \underline{\mathrm{Fibsc}}_0 S \longrightarrow \underline{\mathrm{Fibhot}}\, S$.

37. NB Il s'agit de prouver seulement que p, p_0 induisent des équivalences pour les localisés (pour la W-équivalence grossière). On sait déjà qu'il en est ainsi pour α, et ça en résultera pour α'.

38. inutile de regarder ce carré, cf. annotations marginales ci-dessus (haut de la page)

Its importance for localization is elementary. Let U : Fibsc(S) →Cat/S forget the splitting. There are transformations

η : id −→UΦ,

γ : ΦU −→id. The first lives in Cat/S; the second lives in the category with splitting-preserving morphisms. Both become isomorphisms after the relevant localization. Consequently U and Φ induce inverse equivalences. One does not need a comparison transformation in a category with an incorrectly enlarged or restricted class of arrows.

For coarse equivalences, this conclusion requires only that W contain categorical homotopy equivalences and satisfy two-out-of-three. The ordinary functor forgetting the initial base object gives UΦ(X) →X, with a section ηX and a natural contraction. Although the forgetful map is usually not over S, the contraction proves that ηX is an equivalence of total homotopy types. The counit is then a coarse equivalence because its composite with the unit on UY is the identity. The more informative fibrewise verification comes on pp. 58–60.

Il faut seulement vérifier que si X/S est dans $\underline{\mathrm{Fib}}_0 S$, alors $\varphi(X) = \Phi(X)$ est dans la sous-catégorie pleine $\underline{\mathrm{Fibsc}}_0 S$ de $\underline{\mathrm{Fibsc}}\, S$. Mais on a vu que c'est le cas, pour peu seulement que X/S soit dans $\underline{\mathrm{Fibhot}}\, S$, car les morphismes de changement de base dans $\Phi(X)$, associés aux flèches $u : s \longrightarrow t$ dans S

$$u^*_{\Phi_X} : t\backslash X \longrightarrow s\backslash X$$

sont des W_∞-équivalences si X est Hot-fibré sur S. D'autre part, pour X quelconque dans Cat/S, on a une flèche, fonctorielle en X,

$$X \longrightarrow \Phi(X),$$

i.e. $\mathrm{id}_{\mathrm{Cat}/S} \longrightarrow \pi\Phi$ où $\pi : \underline{\mathrm{Fibsc}}\, S \longrightarrow \mathrm{Cat}/S$ est le foncteur canonique, qui est une W_∞-équivalence (même un homotopisme), donc une W-équivalence. A fortiori les foncteurs $p\varphi$, $p_0\varphi_0$ donnent lieu ($\underline{\mathrm{Fib}}\, S$ et $\underline{\mathrm{Fib}}_0 S$ étant des sous-catégories pleines de Cat/S) à des flèches

$$\mathrm{id} \longrightarrow p\varphi, \qquad \mathrm{id} \longrightarrow p_0\varphi_0.$$

Il reste à trouver une flèche (et W-équivalence grossière)

p. 34

$$\varphi p \longrightarrow \mathrm{id},$$

laquelle induira automatiquement

$$\varphi_0 p_0 \longrightarrow \mathrm{id}$$

[page 55]

puisque $\underline{\mathrm{Fibsc}}_0 S$ est [une] sous-catégorie pleine de $\underline{\mathrm{Fibsc}}\, S$. En fait, on va définir $\varphi p \longrightarrow \mathrm{id}$, donc

$$\boxed{\gamma_X : \Phi(X) \longrightarrow X}$$

quand X est fibrée scindée sur X - une flèche *cartésienne,* donc (si on veut) compatible avec les scindages de $\Phi(X)$, et de X. En fait, on aura une telle flèche, fonctorielle en X, pour X variable dans $\underline{\mathrm{Fib}}\, S$ (donc sans se borner à des S-morphismes cartésiens entre catégories fibrées sur S), mais la flèche $\longrightarrow$ étant bien sûr *cartésienne.* (Ça a un sens, sans choisir de scindage sur X, et sans qu'il en existe forcément.) La définition de cette flèche γ fait appel de façon essentielle à l'hypothèse que X soit Cat-fibrant sur S. Bien sûr, composé à la flèche d'inclusion évidente

$$X \xrightarrow{i_X} \Phi(X)$$

on va avoir

$$\gamma_X i_X = \mathrm{id}_X$$

([39]). On définit γ fibre par fibre,

$$\gamma_{X,s} : \Phi(X)_s \overset{\text{déf}}{=} s\backslash X \longrightarrow X_s,$$

39. NB Comme on sait que $i_X \in W$, il en résultera bien $\gamma_X \in W$ comme on le veut.

donc par une *rétraction* de $s\backslash X$ sur la sous-catégorie pleine X_s. Un objet de $s\backslash X$ est un couple (x, u), $x \in \mathrm{Ob}\, X$, $u : s \longrightarrow p_X(x)$ ($p_X : X \longrightarrow S$ le morphisme structural de X). On pose

$$\gamma(x, u) = u_X^*(x) \in \mathrm{Ob}\, X_s,$$

ce qui suppose donc qu'on a choisi des foncteurs image inverse $u_X^* : X_t \longrightarrow X_s$, pour la catégorie Cat-fibrée X/S. (Mais à isomorphisme unique près, γ ne dépend pas de ces choix.) Je me dispense de la vérification fastidieuse que cette loi est bien 'fonctorielle en s', i.e. définit bien une flèche cartésienne [page 56]

$$\gamma_X : \Phi(X) \longrightarrow X,$$

et de vérifier que celle-ci est fonctorielle en X.

Peut-être est-il plus élégant de montrer que $\pi : \underline{\mathrm{Fibsc}}\, S \longrightarrow \mathrm{Cat}/S$ et $\Phi : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Fibsc}}\, S$ sont adjoints l'un de l'autre : p. 35

$$\boxed{\mathrm{Homcart}_S(\Phi(\underbrace{X}_{\in \mathrm{Cat}/S}), \underbrace{Y}_{\in \underline{\mathrm{Fibsc}}}) \simeq \mathrm{Hom}_S(X, \pi Y),}$$

d'où résulteront des flèches d'adjonction

$$\Phi\pi \longrightarrow \mathrm{id}_{\underline{\mathrm{Fibsc}}}, \qquad \pi\Phi \longleftarrow \mathrm{id}_{\underline{\mathrm{Fib}}},$$

[plutôt $\pi\Phi \longleftarrow \mathrm{id}_{\mathrm{Cat}/S}$] et on aura gagné. Mais pour prouver cette formule d'adjonction, j'ai l'impression qu'il faut utiliser $\varphi p \longrightarrow \mathrm{id}$ … Il y a des vérifications fastidieuses …

Finalement, je vois maintenant qu'on a cinq cas à traiter, et trois si on joue sur les symétries : [page 57]

Commentary · Exposition [ms. 56]

The free split adjunction, with its arrows specified

Grothendieck's proposed adjunction is the efficient way to finish the comparison, once "Cartesian" in the Hom-set on the left is read as preserving the selected Cartesian lifts. We give its construction because the same calculation resolves the naturality issue in the preceding paragraph.

For p : X →S, an object of ΦX is (s, x, u) with u : s →p(x). A morphism

(s, x, u) −−→(t, y, v)

is a pair (a, f) with a : s →t, f : x →y, and p(f)u = va. The chosen lift along a with target (t, y, v) is

−−−−−→(t, y, v).

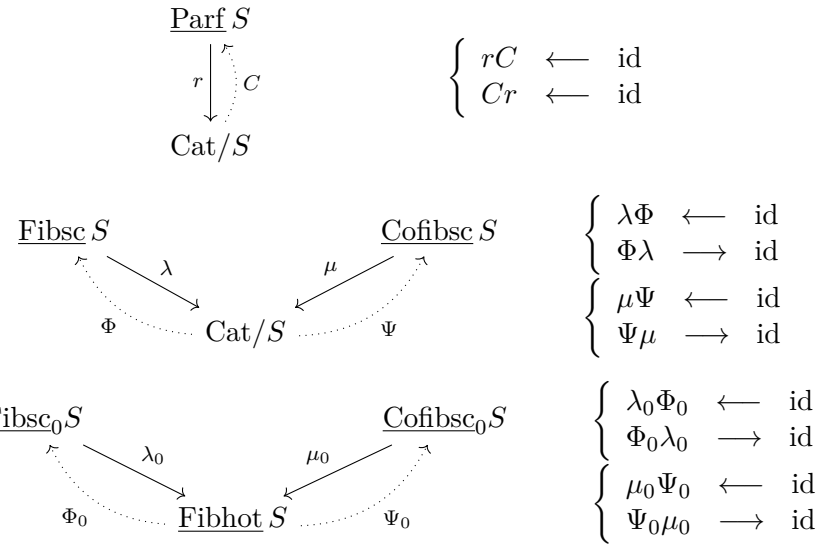
(s, y, va) Identity and composition laws for these chosen lifts hold strictly. The unit sends x to (p(x), x, id). Let q : Y →S be split, and let h : X →UY be any functor over S. Write cu,z : u∗z →z for the chosen lift. Define

bh(s, x, u) = u∗h(x).

For (a, f) as above, define bh(a, f) as the unique arrow over a such that

cv,h(y) bh(a, f) = h(f)cu,h(x).

The Cartesian property of cv,h(y) gives existence and uniqueness. These same uniqueness statements prove the identity and composition laws: both possible images of a composite have the required base arrow and the same composite with the terminal chosen lift. The strict splitting laws show that a selected lift (a, id) is taken to the selected lift in Y . Thus bh is splitting-preserving.



Conversely, every splitting-preserving H : ΦX →Y is forced by h = HηX. The chosen arrow (s, x, u) →(p(x), x, id) forces its object value to be u∗h(x), and Cartesian uniqueness forces its value on every morphism. The two constructions are inverse and natural, proving the actual adjunction

Homsplit/S(ΦX, Y) ∼= HomS(X, UY).

Its counit is γY (s, y, u) = u∗y, and γY ηUY = idUY . Its naturality is strict for splitting-preserving functors, which are precisely the morphisms needed on this side of the comparison. This is the free-algebra adjunction underlying the 2-monad description cited above.

For a merely cloven fibration the same formula still gives a Cartesian functor ΦX →X, using the coherence isomorphisms of the cleavage. Different choices yield canonically isomorphic functors

compatible with their Cartesian comparison arrows. But an arbitrary functor over S need not preserve Cartesian arrows, so the formula is not strictly natural on the full category Fib(S). Nor can "Cartesian" alone imply preservation of the selected splitting. Those stronger assertions in the source are unnecessary; the strict adjunction just proved gives the comparison in Fibsc(S), and the next block explains what survives after localization for all functors over S.

([40])

NB Les quatre derniers homomorphismes de foncteurs, relatifs au troisième diagramme (avec les indices 0) sont simplement induits par ceux relatifs au diagramme qui le précède. Donc les vérifications-clef sont relatives aux deux premiers diagrammes, et par symétrie, on n'a finalement qu'à regarder les *deux* couples de foncteurs (r, C), (λ, Φ), et pour chacun de ces couples, exhiber les deux homomorphismes fonctoriels, des deux composés avec les foncteurs identiques.

[page 58]

Commentary · Development (commentators') [ms. 57]

Naturality recovered after localization

Grothendieck wants the comparison to accommodate all functors over the base, since the categories Fib(S) and Liss(S) are full subcategories of Cat/S. The raw pullback construction does not have that naturality. The localization nevertheless supplies exactly the required repair. We spell out the following elementary elaboration of his argument; the "ours" label concerns this formulation and proof, not priority. We checked the free-fibration and strictification formulations in Emmenegger et al. (2024, Sections 2 and 5). They distinguish strict and pseudo preservation of cleavages but do not state the following repair for arbitrary functors over the base. We make no broader claim about its absence from the literature.

Localized naturality of pullback retractions. [ours]Suppose W∞⊆W. Choose normalized cleavages on fibrations X →S. Then the functors γX : ΦX →X determine a natural isomorphism between the functors induced by UΦ and the identity on the right-fine localization of the full category Fib(S). The same conclusion holds for coarse localization.

Proof. First, any natural transformation over S between functors F, G : A →B makes their images equal in (Cat/S)[(W d S)−1]. It is represented by a functor H : A × [1] →B over S. The projection r : A × [1] →A is right-fine: for every s its comma functor is the projection

(s\A) × [1] −→s\A,

a categorical homotopy equivalence. Its two sections become the same inverse of r, hence F = Hj0 and G = Hj1 become equal. The identical proof applies to coarse localization. If A is fibred, A × [1] is fibred, so this argument also takes place within the indicated full subcategory.

40. **NB** Tous les foncteurs marqués sont compatibles avec la W-équivalence grossière, et des dix homomorphismes fonctoriels sont des W-équivalences grossières.

Now let f : X →Y be any functor over S, without a Cartesian hypothesis. For (s, x, u) define a vertical arrow

θf,(s,x,u) : f(u∗

Xx) −→u∗ Y f(x) by the equation

cY

u,f(x)θf,(s,x,u) = f(cX u,x). Existence and uniqueness follow from the Cartesian property of the lift in Y . This defines a natural transformation fγX ⇒γY Φ(f) over S. To check naturality, compose the two candidate arrows with the chosen lift to the terminal object of a morphism (a, g) in ΦX. Both composites are f(g)f(cX u,x), u,x) = f(gcX and both have the same base arrow; Cartesian uniqueness identifies them. The first paragraph of the proof therefore gives naturality after localization.

The comparison maps are right-fine equivalences. On a fibre, γX,s is right adjoint to Xs ,→s\X: an arrow y →x over u : s →p(x) factors uniquely through u∗ Xx. Every adjunction gives a homotopy equivalence of nerves. Since source and target of γX are fibrations, right-fine equivalence is equivalent to fibrewise equivalence. Thus the localized natural transformation is an isomorphism. Its coarse version follows either from the same argument or from γXηX = id and coarse invertibility of ηX. □

The defect before localization is real. Take S = [1], X = S, Y = S × [1], and f(s) = (s, s). At the object (0, 1, 0 →1) of ΦX, the two functors in the comparison square have values (0, 0) and (0, 1). These objects are not isomorphic. The comparison θ is the noninvertible arrow between them. Thus the source's strict naturality assertion cannot simply be replaced by a claim of naturality up to isomorphism; the localization, or the restriction to splitting-preserving morphisms, performs an essential part of the repair.

② Les localisés pour la *W-équivalence fine droite.* Il n'y a plus lieu, on l'a dit, de regarder les catégories internes du diagramme p. 8, où ladite équivalence coïncide avec la W-équivalence grossière, pour laquelle on connait déjà les localisés. Il reste à regarder les catégories

$$\mathrm{Cat}/S, \quad \underline{\mathrm{Liss}}\, S, \quad \underline{\mathrm{Fib}}\, S, \quad \underline{\mathrm{Fibsc}}\, S.$$

Le lemme de la page 11 nous dit qu'il suffit de montrer que dans la situation

$$\underline{\mathrm{Fibsc}}\, S \xrightarrow{\lambda} \mathrm{Cat}/S,$$

il y a un foncteur en sens inverse, avec les propriétés specifiées. Il en résultera que toute sous-catégorie pleine $\mathcal{F}$ de Cat/S qui contient $\underline{\mathrm{Fib}}\, S$, quand on la munit du localiseur de la W-équivalence fine droite, donne un localisé équivalent, par le foncteur induit par l'inclusion, au localisé correspondant de Cat/S, i.e. essentiellement à $\mathrm{HOT}_W(S)$.

Comme foncteur en sens inverse, il s'impose de prendre encore Φ. Il y a à vérifier trois choses :

a) Φ [est] compatible avec les localiseurs, i.e. si $\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow \quad \swarrow & \\ & S & \end{array}$ sur S est une W-équivalence fine droite, i.e. les $s\backslash X \longrightarrow s\backslash Y$ sont des W-équivalences, alors $\Phi(f)$ aussi. Mais ladite équivalence coïncide dans $\underline{\mathrm{Fibsc}}\, S$ (comme aussi dans $\underline{\mathrm{Fib}}\, S$ et $\underline{\mathrm{Liss}}\, S$) avec la W-équivalence par fibres, et d'autre part $\Phi(f)_s$ n'est autre que la flèche précédente $s\backslash X \longrightarrow s\backslash Y$. [page 59] Donc il est évident que

$$f \in \underbrace{W_S^{\mathrm{d}}}_{W\text{-équivalence droite}} \iff \Phi(f) \in \underbrace{W_S^{\mathrm{f}}}_{W\text{-équivalence par fibres}}.$$

b) Que $X \xrightarrow{i_X} \lambda\Phi(X)$ est dans W_S^{d}, pour tout X dans Cat/S. Cela signifie donc que i_X induit

$$s\backslash X \longrightarrow s\backslash\Phi(X)$$

qui est une W-équivalence. Ce serait O.K. s'il était clair que $X \longmapsto \Phi(X)$ commute à tout changement de base propre sur S (donc en particulier à $s\backslash S \longrightarrow S$), puisqu'on sait que

$X \longrightarrow \Phi(X)$ est une W-équivalence. C'est sans doute trop demander, mais du moins que ça commute au changement de base qui est un co-isomorphisme local (telles les $s\backslash S \longrightarrow S$).

Pour un tel changement de base $S' \xrightarrow{p} S$, vérifier que la fibre de $\Phi(X')$ en s' est isomorphe à celle de $\Phi(X)$ en $s = p(s')$, je m'en contenterai. Or cette fibre est $s'\backslash X'$, déduit de X' sur S' par le changement de base $s'\backslash S' \longrightarrow S'$, donc déduit de X par $s'\backslash S' \longrightarrow S$. Or $s'\backslash S' \longrightarrow s\backslash S$ est un isomorphisme par hypothèse sur p (co-isomorphisme local), donc le changement de base $s'\backslash S' \longrightarrow S$ s'identifie à $s\backslash S \longrightarrow S$, et l'image inverse est bien isomorphe à $s\backslash X$, OK. p. 37 [page 60]

Commentary · Exposition [ms. 59]

The comma resolution is right-fine

Grothendieck has reduced the fine comparison to checking that the unit and counit are fine equivalences. This is the decisive point at which the comma categories preserve the relative diagram, rather than merely its total homotopy type. A direct contraction proves the assertion for every X →S and makes the proposed base-change verification unnecessary.

Fix s ∈S. An object of s\ΦX consists of

−→vt

−→up(x). s Define R : s\ΦX →s\X by composition, R(v, u, x) = (x, uv). A morphism represented by (a, f) satisfies av = v′ and p(f)u = u′a; it is sent to f, which satisfies p(f)uv = u′v′. Thus R is a functor. The functor J = s\ηX sends (x, w) to the factorization

−→p(x)

−→p(x). s We have RJ = id. The arrow (u, idx) gives a natural transformation

ids\ΦX −→JR.

It is over s, since uv is the composite arrow of the target factorization. These identities prove that J and R are inverse up to categorical homotopy. Hence ηX belongs to W d S whenever W contains W∞.

For a split fibration Y , the fibre of the counit is

(y, u) 7−→u∗y.

γY,s : s\Y −→Ys, If K : Ys ,→s\Y is the inclusion, Cartesian factorization gives

Homs\Y (Kz, (y, u)) ∼= HomYs(z, u∗y).

Thus K ⊣γY,s, with identity unit for a normalized splitting. In particular both functors are W∞equivalences. The counit is therefore fibrewise, and hence right-fine, an equivalence. Finally, Φ(f)s is literally s\f; this verifies compatibility of Φ with the two localizers without an additional argument. All parts of the comparison now fit together. The unit and counit induce inverse natural isomorphisms between the localized composites. We obtain

S)−1] ≃Fibsc(S)[W −1

(Cat/S)[(W d obj]. If F is any full subcategory of Cat/S containing the fibrations, the resolution UΦ lands in F and its unit is a morphism of F on restriction. The same argument proves the asserted equivalence with F[(W d S)−1]. Reversing the comma directions gives the corresponding statement for opfibrations and W g S.

c) Que de même

$$\Phi\lambda \longrightarrow \mathrm{id}$$

est non seulement dans W_S (grossier), mais que c'est une W-équivalence par fibres. Donc on part de X fibrée sur S. On regarde

$$\Phi(X) \longrightarrow X,$$

pour voir que c'est une W-équivalence par fibres, il suffit de voir qu'il en est ainsi de $X \longrightarrow \Phi(X)$,

$$X_s \longrightarrow s\backslash X$$

est une W-équivalence pour tout $s \in S$. Mais ceci est déjà vrai dès que X est lisse sur S.

Comme le cas de la W-équivalence fine gauche se ramène au cas actuel par $S \longmapsto S^o$, on a donc prouvé tout ce qu'était attendu, à la seule exception de la pleine fidèlité des foncteurs i, j de la page 51. [page 61]

Mais dans le résumé prospectif de la situation pour les localiseurs, p. 49-51, j'ai oublié d'autres foncteurs que i, j, de nature si possible encore plus triviale. Ce sont ceux qu' on peut décrire à partir du foncteur identique, sur une des catégories du diagramme où aient cours deux, voire trois, notions de W-équivalence différentes. Ce sont, je le rappelle

Commentary · Exposition [ms. 60]

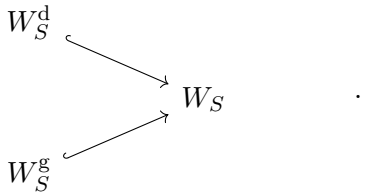
The hypotheses of the fine comparison

The comparison just established has survived the earlier changes of axioms. Its proof uses the inclusion W∞⊆W, the elementary saturation properties, and the smooth-fibre criterion already checked on p. 42. In particular it does not use the new L5. On split fibrations, right-fine equivalences are exactly objectwise W-equivalences of the associated strict diagrams; the analogous statement holds on split opfibrations. This is the part of the construction which remains useful for homological and truncated equivalences.

The pure coarse comparison with the internal categories also needs no new L5. The path replacement C produces homotopy fibrations, its unit X →C(X) is a total homotopy equivalence, and naturality together with two-out-of-three makes C preserve coarse equivalences. L5 enters in the additional identification of coarse equivalences between these replacements with fibrewise, hence fine, equivalences. This is what makes C induce the functor back into the fine category used for the reflection. The later annotation correctly says that this requirement is highly restrictive. The commentary on pp. 43–45 explains why it must not be silently transferred to arbitrary homological localizers.

For W = W∞, the modern literature gives a precise model for the coarse part: small categories, nerve weak equivalences, and smooth proper functors form a category of fibrant objects; perfect objects over a base suffice to compute the corresponding localization. See Cisinski (2009, Proposition 4.4 and Corollary 4.5). This places Grothendieck's path replacement inside a developed homotopical framework. The explicit comma proof above is still useful, since it shows exactly which comparison remains valid when the coefficient equivalences are enlarged.

1°) Les quatre catégories



$$(*) \qquad \underline{\mathrm{Fibsc}}\, S \longrightarrow \underline{\mathrm{Fib}}\, S \longrightarrow \underline{\mathrm{Liss}}\, S \longrightarrow \mathrm{Cat}/S, \qquad W_S^{\mathrm{d}} \subseteq W$$

avec la W-équivalence fine droite d'une part, grossière de l'autre, et dualement

$$(*') \qquad \underline{\mathrm{Cofibsc}}\, S \longrightarrow \underline{\mathrm{Cofib}}\, S \longrightarrow \underline{\mathrm{Prop}}\, S \longrightarrow \mathrm{Cat}/S, \qquad W_S^{\mathrm{g}} \subseteq W$$

pour la W-équivalence fine gauche d'une part, la grossière de l'autre, et de plus

2°) Cat/S, qui était inclue dans les deux suites précédentes, et qui est la seule catégorie du diagramme donnant lieu à trois notions de W-équivalence différentes

Dans chacun des quatre cas (C, munie de deux localiseurs $\Sigma \subseteq \Sigma'$) de la suite ($*$), le foncteur p. 38

$$C\Sigma^{-1} \longrightarrow C\Sigma'^{-1}$$

est essentiellement 'le même', à cause des théorèmes de comparaison. Il suffit de regarder ce foncteur dans un seul das, p. ex. un des deux extrêmes $\underline{\mathrm{Fibsc}}\, S$ ou Cat/S. Même remarque pour la suite ($*'$). Donc finalement il reste deux foncteurs remarquables à examiner, qui n'ont [page 62] pas l'air du tout de provenir des foncteurs du diagramme p. 8 ou de quelque composé (ça ne

donne que des équivalences canoniques ou bien les foncteurs i, j de page 51, quand on va des catégories internes au diagramme vers les catégories bordantes). Le plus joli est sans doute de les regarder à partir de Cat/S, puisque c'est là seulement qu'on les a tous les deux à la fois

$$\begin{array}{ccc} (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1} \approx \mathrm{HOT}_W(S) & & \\ & \overset{\rho}{\searrow} & \\ & & (\mathrm{Cat}/S)W_S^{-1} \approx \mathrm{HOT}^{\mathrm{lc}}_W(S). \\ & \underset{\sigma}{\nearrow} & \\ (\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1} \approx \mathrm{HOT}^{o}_W(S) & & \end{array}$$

Par contre, les foncteurs (qu'on a envie d'appeler 'foncteurs d'inclusion') i, j de la page 51, en sens inverse de ρ, σ, sont ceux qui proviennent, par localisation W_S^{d} ou W_S^{g} selon le cas, d'un des foncteurs du diagramme page 8 (ou d'un composé de tels foncteurs), allant d'une des six catégories internes (où toutes les W-équivalences envisagées coïncident) vers l'une des sept catégories bordantes, sauf quand cette dernière est Cat/S, est déterminé déjà avec quelle W-équivalence, W_S^{d} ou W_S^{g}, on va travailler `[structure de cette phrase?]`. La détermi-nation peut-être la plus jolie est par [page 63]

$$(*) \qquad \underline{\mathrm{Parf}}\, S \longrightarrow \mathrm{Cat}/S$$

qui donne le foncteur i quand on travaille avec W_S^{d}, le foncteur j quand on travaille avec W_S^{g}. On voit alors tout de suite que si on compose avec le foncteur pertinent, soit ρ soit σ, défini par l'inclusion $W_S^{\mathrm{d}} \subseteq W_S$ resp. $W_S^{\mathrm{g}} \subseteq W_S$ (comme parties de $\mathrm{Fl}(\mathrm{Cat}/S)$), on trouve le foncteur

$$(**) \qquad (\underline{\mathrm{Parf}}\, S)W_S^{-1} \xrightarrow{\approx} (\mathrm{Cat}/S)W_S^{-1}$$

qui est l'*équivalence canonique* entre ces deux catégories. Ainsi le foncteur correspondant à i, j page 51, exprimé en termes de Cat/S comme foncteur en sens inverse de ρ, σ (p. 62), est-il le composé de l'équivalence quasi-inverse de $(**)$, laquelle s'explicite par le foncteur C, et du foncteur sur le localisé W_S^{d} ou W_S^{g} déduit de $(*)$, i.e.

p. 39

$$\begin{array}{ccccc} & & & & \mathrm{HOT}_W(S) \approx (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1} \\ & & \overset{i}{\nearrow} & & \uparrow \text{car } W_S = W_S^{\mathrm{d}} \text{ sur } \underline{\mathrm{Parf}} \\ \mathrm{HOT}^{\mathrm{lc}}_W(S) \approx (\mathrm{Cat}/S)W_S^{-1} & & \xrightarrow{\quad C \quad} & & (\underline{\mathrm{Parf}}\, S)W_S^{-1} \\ & & \underset{j}{\searrow} & & \downarrow \text{car } W_S = W_S^{\mathrm{g}} \text{ sur } \underline{\mathrm{Parf}} \\ & & & & \mathrm{HOT}^{o}_W(S) \approx (\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1}. \end{array}$$

On voit par là qu'on a des isomorphismes canoniques [page 64]

$$\rho i \simeq \mathrm{id}, \qquad \sigma j \simeq \mathrm{id}$$

dans la catégorie des endofoncteurs de $(\mathrm{Cat}/S)W_S^{-1}$ ($\approx \mathrm{HOT}^{\mathrm{lc}}_W(S)$), isomorphisme qui s'explicite ici par le fait que ρi, σj sont déduits du même foncteur C par passage aux localisés W_S^{-1} (donc en fait $\rho i = \sigma j$!), et qu'on a une flèche fonctorielle en X

$$X \xrightarrow{i_X} C(X),$$

qui est dans W pour tout X. Ainsi, ρ et σ sont à isomorphisme près des *rétractions* des catégories $\mathrm{HOT}_W(S)$, $\mathrm{HOT}^{o}_W(S)$ sur la catégorie $\mathrm{HOT}^{\mathrm{lc}}_W(S)$. De plus, ces rétractions sont ce qu'on appelle des foncteurs de localisation (comme on voit sur le diagramme de la page 62).

(On dit que $C \xrightarrow{F} C'$ est un *foncteur de localisation* si, désignant par $\Sigma \subseteq \mathrm{Fl}\, C$ l'ensemble des flèches de C transformées en des isomorphismes par F, le foncteur

$$C\Sigma^{-1} \xrightarrow{\bar{F}} C'$$

qui factorise F est une équivalence de catégories.)

On sait d'ailleurs que si un foncteur f a un adjoint g (à gauche ou à droite), alors f est un foncteur [de] localisation si et seulement si l'adjoint g est pleinement fidèle. Pour prouver que i, j sont pleinement fidèles, il serait donc tentant de prouver qu'ils sont adjoints des foncteurs ρ, σ. [page 65]

Commentary · Exposition [ms. 64]

What the section of localization still has to prove

Grothendieck has now produced the same locally constant category from both comma directions. The identity of Cat/S induces

S)−1] −→(Cat/S)[W −1

ρ : (Cat/S)[(W d S], and path replacement induces a functor in the reverse direction. The equation ρi ≃id says that the coarse category is a retract. It does not yet say that i is fully faithful; this is the distinction already encountered at manuscript p. 38.

The required additional datum is now visible. There is a natural arrow X →C(X) in the fine category, and it becomes invertible in the coarse category. Its direction suggests a unit for ρ ⊣i, not for the opposite adjunction. The inverse coarse arrow C(X) →X then supplies a counit. Grothendieck's change of orientation on p. 67 is consequently forced by where the unit is invertible.

A localization with a fully faithful right adjoint is a reflection onto a full subcategory. In this case its image consists of the relative homotopy types whose transport along every base arrow is invertible. The adjective "locally constant" therefore describes an intrinsic condition on a diagram, not constancy of a chosen presentation of its total category. The path construction supplies a representative satisfying that condition and a universal map to it. The argument on the next pages establishes that universality through the two triangle identities, so that no fullness conclusion is extracted merely from a retraction.

Pour nous y reconnaître, je vais poser

$$\begin{cases} \mathcal{A} = \mathrm{Cat}/S, \quad \Sigma_0 = W_S^{\mathrm{d}}, \quad \Sigma = W_S & (\subseteq \mathrm{Fl}(\mathcal{A})) \\ C : \mathcal{A} \longrightarrow \mathcal{A} \quad \text{le foncteur familier, qui a la vertu} \\ \qquad\qquad C(\Sigma) \subseteq \Sigma_0 \quad . \end{cases}$$

On a donc la situation p. 40

$$(*) \qquad (\mathcal{A}, \Sigma_0) \underset{C}{\overset{\rho_0 = \mathrm{id}_{\mathcal{A}}}{\rightleftarrows}} (\mathcal{A}, \Sigma),$$

induisant par passage aux localisés

$$\mathcal{A}\Sigma_0^{-1} \underset{\bar{C}}{\overset{\rho = \bar{\rho}_0}{\rightleftarrows}} \mathcal{A}\Sigma^{-1},$$

on veut vérifier que ρ et C [plutôt $\bar{C}$] sont adjoints l'un de l'autre, C [plutôt $\bar{C}$] *sûrement à droite,* ce qui signifie que l'on doit avoir des homomorphismes fonctoriels

$$\begin{cases} \mathrm{id}_{\mathcal{A}\Sigma^{-1}} & \rightleftarrows & \rho\bar{C} & (= \overline{\rho_0 C}) \\ \mathrm{id}_{\mathcal{A}\Sigma_0^{-1}} & \rightleftarrows & \bar{C}\rho & (= \overline{C\rho_0}) \end{cases}$$

([41]) [les flèches en bas vont en direction corrigée, mais les flèches en haut ne sont pas effacées] satisfaisant deux relations de compatibilité sur lesquelles on reviendra. On peut espérer trouver ces homomorphismes fonctoriels à partir de

$$\begin{cases} \mathrm{id}_{\mathcal{A}} & \xrightarrow{i} & \rho_0 C & = & C \\ \mathrm{id}_{\mathcal{A}} & \xleftarrow{p} & C\rho_0 & = & C \end{cases}$$

et dans notre cas on dispose bel et bien de [page 66]

$$i : \mathrm{id}_{\mathcal{A}} \longrightarrow C \qquad \text{i.e. de } \; i_X : X \longrightarrow C(X)$$

fonctoriel en $X \in \mathrm{Ob}\,\mathcal{A}$ (et de plus i_X est dans Σ). Il n'y a pas cependant de flèche naturelle en sens inverse p_X

$$C(X) \xrightarrow{?} X.$$

J'avais songé à la projection $\pi_X : C(X) \longrightarrow X$, déduite de la construction $C(X) \simeq X \times_S (\underline{\mathrm{Ch}}_\infty(S), \sigma)$, mais ce n'est malheureusement pas un S-morphisme. Comme on cherche une flèche dans $\mathcal{A}\Sigma_0^{-1}$, on pourrait se contenter d'avoir une flèche fonctorielle en sens inverse, du moment qu'elle soit dans Σ_0, donc puisse s'inverser quand on travaille dans $\mathcal{A}\Sigma_0^{-1}$. Le candidat evident est $i_X : X \longrightarrow C(X)$ dont on vient de parler. L'ennui, c'est que i_X est seulement dans Σ, pas dans Σ_0 ([42]). Pourtant, quand X est lui-même de la forme $C(Y)$ (plus généralement, s'il est un Hot-fibré sur S), alors le fait que $X \longrightarrow C(X)$ soit dans Σ implique déjà qu'il soit dans Σ_0. Notons donc ceci

$$\begin{cases} i : \mathrm{id}_{\mathcal{A}} \longrightarrow C \text{ tel que} & 1^o) & i_X : X \longrightarrow C(X) \textit{ dans } \Sigma \\ & & \text{pour tout } X \in \mathrm{Ob}\,\mathcal{A} \\ & 2^o) & i_X \text{ dans } \Sigma_0 \text{ si } X \text{ de la} \\ & & \text{forme } C(Y) \end{cases}$$

L'idée me vient, après des essais merdouillants [sic], que $\bar{C}$ pourrait être l'adjoint à droite, et non à gauche [c'est la version corrigée (droite et gauche échangées) cf. p. 65], i.e. que les flèches cherchées pourraient aller en sens inverse p. 41 [page 67]

$$\begin{cases} \mathrm{id}_{\mathcal{A}\Sigma^{-1}} & \xleftarrow{p} & \rho\bar{C} & (= \overline{\rho_0 C}) \\ \mathrm{id}_{\mathcal{A}\Sigma_0^{-1}} & \xrightarrow{i} & \bar{C}\rho & (= \overline{C\rho_0}) \end{cases}$$

(j'inverse du coup les notations pour p et i), donc on est amené si possible à chercher des flèches

$$\begin{array}{lcll} \mathrm{id}_{\mathcal{A}} & \xleftarrow{p} & \rho_0 C & = C \\ \mathrm{id}_{\mathcal{A}} & \xrightarrow{i} & C\rho_0 & = C, \end{array}$$

donc des flèches fonctorielles en X

$$X \xrightarrow{i_X} C(X) \xrightarrow{p_X} X.$$

On tient bel et bien une i_X fonctorielle - toujours la même! Pour p_X, on n'en a pas plus qu'avant, mais se rappelant qu'il suffit de le trouver dans $\mathcal{A}\Sigma^{-1}$ (et non plus $\mathcal{A}\Sigma_0^{-1}$!), il suffit

41. mais si C est à *droite,* les flèches ici doivent aller en sens inverse et c'est bien à quoi je dois me résoudre p. 67.

42. S'il n'en était pas ainsi, le type d'homotopie relatif sur S défini par X/S serait localement constant (puisqu'il en est ainsi pour celui défini par $C(X)$), ce qui n'est pas toujours le cas.

d'inverser la flèche i_X, qui est en effet un *isomorphisme* dans $\mathcal{A}\Sigma^{-1}$ (mais non dans $\mathcal{A}\Sigma_0^{-1}$). On posera donc

$$p_X = i_X^{-1} : C(X) \longrightarrow X \qquad \text{dans } \mathcal{A}\Sigma^{-1}.$$

Il faut prouver deux compatibilités seulement, pour les foncteurs $\bar{C}$ et ρ entre $\mathcal{A}\Sigma_0^{-1}$ et $\mathcal{A}\Sigma^{-1}$ (et j'écrirai C au lieu de $\bar{C}$) : les deux composés

$$\begin{cases} \rho \xrightarrow{\rho * i} \rho C \rho \xrightarrow{p * \rho} \rho \overset{\text{id}}{\cdots\cdots} \rho & \text{(relation pour foncteurs à valeurs dans } \mathcal{A}\Sigma^{-1}) \\ C \xrightarrow{i * C} C\rho C \xrightarrow{C * p} C \overset{\text{id}}{\cdots\cdots} C & \text{(relation pour foncteurs à valeurs dans } \mathcal{A}\Sigma_0^{-1}) \end{cases}$$

doivent être l'identité id_ρ resp. id_C.

La première relation se vérifie tautologiquement, elle revient à dire que dans $\mathcal{A}\Sigma^{-1}$, on a [page 68] un composé identité des

$$X \xrightarrow{i_X} C(X) \xrightarrow{i_X^{-1}} X \qquad !$$

La seconde signifie que pour tout X, on a un composé identité dans $\mathcal{A}\Sigma_0^{-1}$

$$C(X) \xrightarrow{i_{C(X)}} C(C(X)) \xrightarrow{C(p_X)} C(X).$$

Or $p_X : C(X) \longrightarrow X$ avait été défini dans $A\Sigma^{-1}$ comme inverse i_X^{-1} de i_X, d'autre part le foncteur C sur $\mathcal{A}$ définit par hypothèse $\mathcal{A}\Sigma^{-1} \longrightarrow \mathcal{A}\Sigma_0^{-1}$, plus précisément $C(\Sigma) \subseteq \Sigma_0$ ainsi p. 42 $C(i_X)$ est inversible dans $\mathcal{A}\Sigma_0^{-1}$, et $C(p_X) = C(i_X)^{-1}$. Donc la compatibilité revient à la relation

$$C(i_X)^{-1} i_{C(X)} = \mathrm{id} \qquad \textit{dans } \mathcal{A}\Sigma_0^{-1},$$

i.e.

$$\boxed{i_{C(X)} = C(i_X)} : C(X) \longrightarrow C^2(X).$$

En d'autre termes, il faut prouver le :

Commentary · Exposition [ms. 67]

A precise reflection lemma

The remaining argument is formal once the two classes of arrows and the two uses of the unit are distinguished. We state the lemma in the form needed here; it also shows that the iterated-unit equality can be established without further geometry. This is the ordinary categorical form of the recognition principle for reflective localizations; compare Lurie (2009, Proposition 5.2.7.4) for its higher categorical formulation.

Lemma. Let Σ0 ⊆Σ be classes of arrows of a category A, and suppose the localizations below exist. Let C : A →A and η : id →C satisfy

C(Σ) ⊆Σ0,

ηX ∈Σ, ηCX ∈Σ0 (X ∈A). Then the identity and C induce functors

P : A0 = A[Σ−1

0] −→A1 = A[Σ−1], R : A1 −→A0, with P ⊣R and R fully faithful. The unit is induced by η, and the counit is the inverse of its image in A1.

Since C(Σ0) ⊆Σ0, the endofunctor C and its natural transformation descend to an Proof. endofunctor T = RP and a transformation e : idA0 →T. Naturality extends across the formal inverses because both functors invert the required arrows. At every object x, both

a = eT x : Tx →T 2x,

b = T(ex) : Tx →T 2x are isomorphisms: the first by the third hypothesis, the second by the first two. We claim that a = b.

Naturality at ex gives bex = aex. Apply T and cancel the isomorphism b on the right to obtain T(b) = T(a). Naturality at a gives

T(a)a = eT 2xa,

so T(a) = eT 2x. Naturality at b gives
T(b)a = eT 2xb.

Substitute the preceding equalities and cancel the isomorphism T(a). This proves a = b. Notice that we have never cancelled ex, which need not be invertible in A0.

Let ϵ : PR →idA1 be the inverse of the transformation induced by η in A1. Its first triangle identity is ϵP xP(ex) = idP x, true by construction. For the second, every object of A1 is represented by an object X of A. On its image under R, the composite R(ϵX)eRX is b−1a, which is the identity by the calculation above. Hence P ⊣R. The counit is an isomorphism, so R is fully faithful. □

The full image is exactly the class of x for which ex is invertible. Objects in the image satisfy this by the third hypothesis; conversely, invertibility identifies x with RPx. Applied to Σ0 = W d S and Σ = WS, this proves the desired full faithfulness of i. The left-comma version proves the corresponding assertion for j, with the covariant convention explained at p. 50. Grothendieck's concatenation argument is a particularly transparent geometric verification of the same identity, and remains useful for understanding the replacement itself.

Lemme. *Soit X dans* Cat/S*, considérons les deux flèches*

$$i_{C(X)},\ C(i_X) : C(X) \rightrightarrows C(C(X)).$$

Ces flèches sont égales, sinon au sens absolu, du moins dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$.

Ici $f_X : X \longrightarrow S$ est la projection standard et

$$C(X) \;=\; \{(x,c) \;\mid\; x \in \mathrm{Ob}\, X,\ c : f_X(x) \underbrace{\longrightarrow}_{\text{chemin dans } S} t\}$$

$$C^2(X) \;=\; \{(x,c,c') \;\mid\; x \in \mathrm{Ob}\, X,\ \underbrace{f_X(x) \xrightarrow{c} t \xrightarrow{c'} t'}_{c,\ c' \text{ chemins dans } S}\},$$

les projections dans S sont données par

$$\begin{aligned} (x,c) &\longmapsto t = \text{but } c \\ (x,c,c') &\longmapsto t' = \text{but } c' \end{aligned}$$

On trouve [page 69]

$$i_{C(X)}(x,c) = (x,c,1_t) : \quad \begin{array}{c} x \\ \downarrow \\ f_X(x) \xrightarrow{c} t \underset{\text{chemin vide}}{\xrightarrow{1_t}} t \end{array}$$

$$C(i_X)(x,c) = (x,1_{f_X(x)},c) : \quad \begin{array}{c} x \\ \downarrow \\ f_X(x) \underset{\text{chemin vide}}{\xrightarrow{1_{f_X(x)}}} f_X(x) \xrightarrow{c} t \end{array}$$

Mais on a le choix entre deux théories de chemins, pour construire $C(X)$: soit avec les $\underline{\mathrm{Ch}}_\infty(S)$, soit avec les $\underline{\mathrm{Ch}}(S)$. 'Ça donne les mêmes résultats', mais suivant les situations l'un est plus commode que l'autre. Je vais travailler avec les $\underline{\mathrm{Ch}}(S)$, auquel cas les 1_S sont des unités à gauche et à droite, et on a une loi de composition pour les chemins. Cette loi nous permet de définir

$$\begin{aligned} C^2(X) &\xrightarrow{\gamma} C(X) \\ (x,c,c') &\longmapsto (x, c' \circ c), \end{aligned}$$

et les composés de $i_{C(X)}$ et de $C_{i(X)}$ avec cette flèche sont $\mathrm{id}_{C(X)}$ dans les deux cas p. 43

$$C(X) \rightrightarrows C^2(X) \xrightarrow{\gamma} C(X). \qquad \text{(id)}$$

[page 70]

Donc pour montrer que $i_{C(X)} = C(i_X)$ dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$, il suffit de prouver que γ est dans W_S^{d}. Mais on sait que le foncteur C transforme W_S en W_S^{d}, donc $C(i_X)$ est dans W_S^{d}, et comme $\gamma \circ C(i_X) = \mathrm{id}$, γ est dans W_S^{d}, OK!

J'ai envie de grouper ce qui a été prouvé dans un énoncé récapitulatif.

Commentary · Exposition [ms. 69]

Concatenation and the two iterated units

Grothendieck's path model makes the reflection tangible. An object of C(X) is an object x together with a path from p(x) to its new base point. Iterating C adds a second path. The two units place the empty path in different positions, so there is no reason for the resulting functors to be literally equal before localization.

Using the finite-path version with strict empty-path units, concatenation gives a functor over S (x, c, c′) 7−→(x, c′c).

μX : C2(X) −→C(X), On morphisms it concatenates the two compatible path diagrams; compatibility of their endpoints makes this well-defined, and composition is respected because it is respected in each path segment. The two empty-path laws give the strict equations

μXηC(X) = idC(X),

μXC(ηX) = idC(X). The relevant homotopical input is C(WS) ⊆W d S. Since ηX ∈WS, we have C(ηX) ∈W d S. Two-out-ofthree applied to the second equation yields μX ∈W d S. After fine localization both ηC(X) and C(ηX) are therefore the inverse of the same arrow μX, which proves their equality.

This proof does not cancel the unit X →C(X) in the fine category. That would erase precisely the distinction the chapter has worked to establish. Instead it cancels a map between already completed objects. Nor does the argument require the associativity of concatenation: the two unit identities and two-out-of-three suffice for the triangle equation. Associativity equips C with the familiar monadic structure, but the adjunction needs only the part displayed here.

The formal lemma in the preceding block shows that the equality also follows from the stated hypotheses on pp. 65–66. Thus there is no outstanding coherence gap in this part of the proof. The choice of finite paths supplies an explicit common inverse and exhibits why adjoining paths becomes idempotent after the appropriate localization.

Commentary · Later developments [ms. 69]

Path completion and the modern category of local systems

The theorem reaches its most familiar modern form when W = W∞. Let S denote the infinitycategory of spaces, and let

ℓ: N(S)op −→Π∞N(S) be groupoid completion; we identify the completion of N(S)op with that of N(S) by reversing paths. Then the fine theory models homotopy coherent contravariant space-valued diagrams, and the locally constant theory models diagrams which carry every base arrow to an equivalence:

HOTW∞(S) ≃Ho Fun(N(S)op, S),

HOTlc

W∞(S) ≃Ho Fun(Π∞N(S), S). The first comparison can be justified through an actual model equivalence. Thomason's adjunction

c Sd2 : sSet ⇄Cat : Ex2 N

is a Quillen equivalence for nerve weak equivalences (Thomason, 1980, Theorem 4.9 and the introduction). Apply both functors objectwise to Sop-diagrams with their projective model structures. The right adjoint preserves fibrations and trivial fibrations objectwise. If F is projectively cofibrant and G projectively fibrant, the criterion for an adjoint pair of maps to be weak equivalences is checked at each object using the original Quillen equivalence; projective cofibrancy implies objectwise cofibrancy. Thus the diagram adjunction is again a Quillen equivalence. The simplicial-set diagram model then presents the coherent functor category by Lurie (2009, Proposition 4.2.4.4). This explains why strict category-valued diagrams, after objectwise localization, retain coherent space-valued diagrams.

Here Ho is taken after forming the category of coherent diagrams. It is not the category of ordinary functors into Ho(S). The higher transport information discussed earlier in the chapter is retained by this order of operations.

Restriction $\ell*$is fully faithful by the universal property of groupoid completion. Its left adjoint is left Kan extension $\ell!$, and the reflector on diagrams is $\ell*\ell!$. This identifies the universal property of Grothendieck's C, rather than asserting that the particular path-category construction is literally a chosen infinity-categorical Kan extension. The standard straightening comparison and the adjunction for Kan extension are given in Lurie (2009, Theorem 2.2.1.2 and Proposition 4.3.3.7); the reflection for a left proper combinatorial model category of coefficients is Cisinski (2009, Corollary 2.5).

A local system of spaces on the infinity-groupoid Π∞N(S) can equivalently be viewed as a space over |N(S)|, by taking its total space and homotopy fibres. Consequently the coarse theory has the interpretation

HOTlc

W∞(S) ≃Ho(S/|N(S)|). For a direct model-categorical comparison see Cisinski (2009, Example 1.7, equation (1.7.1)). This is a homotopy category of a slice, and not generally the ordinary slice of a homotopy category. The distinction already matters for a base with nontrivial fundamental group, as the following example shows.

These interpretations explain what became of the full-faithfulness question: for spaces it is settled by the reflector, and more general coefficient theories have their own locally constant subcategories and reflection results. They do not justify identifying an arbitrary W-coarse localization with that subcategory. Such an identification requires the additional exactness properties discussed on pp. 43–45. The existence of a locally constant reflection and the adequacy of a particular coarse test are separate assertions.

Commentary · Exposition [ms. 70]

Three theories within the comparison diagram

Grothendieck now wants the many presentations to express one intelligible distinction. The proof that supplies it has already been explained in the commentary at manuscript pp. 64, 67, and 69: the path replacement defines a section of the coarse localization, and the two iterated units agree after fine localization. Here the new work is to organize the consequences and identify the image of that section.

For a map $v : X \to Y$ over S, the three tests are

$$\begin{array}{l|l} W_S & v \in W \text{ on total categories,} \\ W_S^{\mathrm{d}} & s\backslash X \longrightarrow s\backslash Y \in W \text{ for every } s, \\ W_S^{\mathrm{g}} & X/s \longrightarrow Y/s \in W \text{ for every } s. \end{array}$$

The relative Theorem A supplies the inclusions of both fine classes in W_S. Thus the identity on Cat/S gives ρ and σ; these are quotient functors between homotopy categories, before any assertion about adjoints. In the other direction one must first replace X: the functor C sends a coarse equivalence to both kinds of fine equivalence. This is why the inclusion of locally constant objects is represented by a nontrivial construction on total categories.

The replacement by a split fibration does something different. Its fibre at s is $s\backslash X$, so it preserves the right-fine information already present in X. Dually, the split opfibration has fibre X/s. Neither construction forces its transition maps to become equivalences. The path replacement does force this, and consequently belongs to the upper part of the diagram. Confusing these two purposes would make the distinction between $\mathrm{HOT}_W(S)$ and $\mathrm{HOT}_W^{\mathrm{lc}}(S)$ disappear before it has been proved.

Part I is therefore a statement about coarse localization of all the presentations. Part II identifies the appropriate fine localization along each side. Part III says when a strict fibre is a valid test and when the two fine tests agree. The hypothesis L5 is used at precisely the passage from a coarse equivalence between homotopy fibrations to a fibrewise equivalence. It should not be silently dropped when the diagram is reused. The subsequent remarks at manuscript pp. 81–82 explicitly reopen this dependency.

Théorème-Scholie. On considère le diagramme de catégories de la page 8 ([43]).

Commentary · Examples [ms. 70]

Two computations of the reflection

The reflection records how the base arrows must become invertible. For the interval S = [1], a contravariant diagram is an arrow B −−→uA. Since |N[1]| is contractible, locally constant diagrams are equivalent to constant diagrams. The reflector is

−−→uA) 7−−→(A

−−→A), (B with unit given by u at 1 and the identity at 0. To verify its universal property at the coherent level, a map from B →A to the constant diagram on K consists of maps A →K, B →K, and a specified homotopy relating the second to the composite through A. The space of choices of the second map together with such a homotopy is contractible over the first. Thus the mapping space is naturally equivalent to Map(A, K), exactly as required. This argument also includes empty values.

For example, the diagram ∅→∗becomes the constant point diagram. Its total Grothendieck construction is the category supported at 0, while that of the reflected diagram is [1]. Their total nerves are equivalent, although the unit fails to be an objectwise equivalence at 1. This is the earlier counterexample viewed as the unit of an adjunction. The inclusion of constant diagrams also has a right adjoint, sending B →A to B: the dual mapping-space computation gives Map(K, B). The left and right adjoints are distinct constructions even for this smallest base.

For a second computation take the one-object groupoid S = BZ. Every arrow of the base is already invertible, so every coherent diagram on S is locally constant and the reflection is an equivalence. Nevertheless the coarse slice contains more morphisms than the ordinary slice of Ho(S). Consider the object z : ∗→BZ given by a base point. In the infinity-categorical slice,

EndHo(S/BZ)(z) ∼= Z.

Map/BZ(z, z) ≃ΩBZ, Indeed, the underlying map ∗→∗is unique, but being a map over BZ includes a path from the chosen base point to itself. Homotopy classes of such paths are the integers. In the ordinary category Ho(S)/BZ, the same object has only its identity endomorphism, because the over-condition is imposed merely as an equality of homotopy classes.

44. De plus, si $\mathcal{F}$ est une sous-catégorie pleine de Cat/S qui contient une des deux sous-catégories $\underline{\mathrm{Fib}}_0 S$, $\underline{\mathrm{Cofib}}_0 S$ (ce qui inclut le cas des 8 catégories des diagrammes, autres que Cat/S elle-même), l'inclusion $(\mathcal{F}, W_S|\mathcal{F})$ dans $(\mathrm{Cat}/S, W_S)$ induit une équivalence pour les localisés.

45. Plus généralement, ça marche pour toute sous-catégorie pleine de Cat/S qui contient $\underline{\mathrm{Fib}}\, S$ (et dualement, avec W^{g}_S au lieu de W^{d}_S, si $\mathcal{F}$ contient $\underline{\mathrm{Cofib}}\, S$).

The associated local system has fibre Z with its regular translation action. A translation-equivariant map Z →Z is determined by the image n of 0 and is k 7→k + n; composition adds the integers. This recovers the endomorphism calculation directly from local systems. Path completion of the point over BZ supplies the categorical analogue of its universal-cover replacement, recovering exactly the transport that the ordinary slice would forget.

Overview · VI-a

The problem of the chapter. Grothendieck starts from a category of coefficients, here the category of small categories itself, and asks how its homotopy theory should vary with a diagram shape. The value at a small category S is to be

HOTW (S) = Fun(Sop, Cat)[W −1

obj], where a natural transformation belongs to Wobj when all its components belong to W. The essential operation is to localize the category of diagrams before forgetting their coherence. A functor from Sop to the already localized category of coefficients generally retains less information. This is the same motivation that led to the diagram formulation in Grothendieck (1983, §69), and that the letter to Thomason subsequently places at the centre of the derivator programme (Grothendieck, 1991). The discussions of coherence and evaluation in the commentary on Chapter I, manuscript pages 7, 17–18 and 27, remain the background; the present chapter supplies categorical constructions rather than repeating those objections.

The first seventy manuscript pages, dated 14–15 November 1990, record the discovery of the correct comparison theorem. Thirteen categories of objects over S initially appear to offer interchangeable models. They include split fibrations, arbitrary fibrations, smooth and proper functors, homotopy fibrations, perfect functors, and all of Cat/S. The objects alone do not decide the homotopy theory. The permitted morphisms and the chosen weak equivalences matter just as much. The first theorem overlooks that distinction, is expressly withdrawn, and is replaced by a comparison between three theories. The manuscript's revisions are part of the proof's development, not noise to remove from it. The axioms and the four tests. The axiom list also changes. The original L4 is an absolute Theorem A: an aspherical functor is a weak equivalence. L4 bis, introduced on manuscript page 44, is the relative assertion about a map X →Y over a third category S, tested on every map X/s →Y/s. It is the latter formulation that supports the relative descent arguments. The initial L5 passes from fibrewise weak equivalences of Cartesian maps between fibrations to weak equivalences of total categories. The new L5 on page 43 goes in the opposite direction for maps between homotopy fibrations. Their common label must not obscure their different content. The commentary proves the initial claim that L1, L2 bis and the original L5 already imply the required elementary axioms, including relative descent, by a twisted-arrow argument for opposite invariance.

For a map f : X →Y over S, the decisive tests are

coarse

f ∈W,

fibrewise fs : Xs →Ys belongs to W for every s,

left-fine

f/s : X/s →Y/s belongs to W for every s,

right-fine

s\f : s\X →s\Y belongs to W for every s. Over a smooth object, the strict fibre compares to the undercategory; over a proper object, it compares to the overcategory. These comparisons and relative descent explain when fibrewise equivalence implies a universal equivalence of totals. The modern asphericity formulation retains precisely this mechanism (Maltsiniotis, 2005, Theorem 1.2, Corollary 4.16 and Theorem 5.4). Coarse equivalence alone does not give either fine condition on the external borders of the diagram. Over [1], the inclusion {0} →[1] is a coarse equivalence of split fibrations, but its fibre at 1 is the map from the empty category to a point. Evaluation at that fibre proves that the two localizations themselves differ. The two comma resolutions. The functor Φ replaces X →S by the split fibration whose fibre at s is s\X; Ψ gives the split opfibration with fibre X/s. Their units are categorical homotopy equivalences on total categories. More precisely, the unit of Φ is right-fine, and the unit of Ψ is left-fine. Composition of the two arrows in a comma object gives an explicit contraction proving this

stronger fact. Consequently the right-fine localization of Cat/S computes the contravariant diagram theory, while the left-fine localization computes its covariant counterpart.

The comparison with chosen splittings needs a genuine repair of the argument, but not a change in the desired theorem. A Cartesian functor need not preserve the selected Cartesian lifts strictly, and an arbitrary functor over the base need not preserve Cartesian arrows at all. The actual free split adjunction is

Homsplit/S(ΦX, Y) ∼= HomS(X, UY).

Its counit supplies the comparison in the strict category. For arbitrary functors between fibrations the pullback retraction has a canonical, possibly noninvertible natural comparison. Natural transformations over S induce equality after fine localization, since the cylinder projection A × [1] →A is fine. This yields the natural isomorphism needed after localization. The exposition constructs the adjunction and the localized comparison in full; the historical and modern strictification references are separated from this particular elaboration (Gray, 1966; Emmenegger et al., 2024).

The covariant theory is HOTW (Sop). The additional outer opposite that appears in several passages of the edition is incorrect with the initial definition above: taking opposite total categories preserves the direction of functors between them. The corrected variance is used throughout the commentary, while both the original statements and the editorial brackets are preserved in the source. The strength of path completion. The two-sided path replacement gives a natural map X →C(X) which is a weak homotopy equivalence, with C(X) →S perfect. This immediately proves comparisons for the coarse localizations, without the new L5. To identify coarse and fibrewise equivalences on the internal categories, and then identify their common theory with a full subcategory of the fine theory, is stronger. That step is what the new L5 supplies.

Its restriction on W is severe. A degree-n covering of the circle is an equivalence for homology with coefficients in a ring where n is invertible, but its fibre has n components. The commentary realizes the covering as an action groupoid, so that perfectness and the strict fibre can be checked

directly. For integral homology it gives a different explicit example:

Z[1/2] ⋊2 Z

−→BZ. B The fibre has first homology Z[1/2]. The mapping-torus sequence shows that the total projection is nevertheless an integral homology equivalence, because 1 −2 acts invertibly on that fibre homology. This calculation settles the tentative integral-coefficient assertion on manuscript page 43. The development label marks the supplied application and proof, with a bounded account of the literature checked; it claims no priority for the group or the homology calculation.

Finite homotopy truncations fail as well: a path fibration over K(A, n + 1) has contractible total space and fibre K(A, n). Retaining the standing condition W∞⊆W ⊆W0, the new L5 actually forces W = W∞. Iterating path fibres shows that every W-aspherical category has connected iterated loop spaces, hence is weakly contractible; applying this to the fibres of a replacement of an arbitrary W-map proves the conclusion. The shortened annotation omitting the component condition cannot stand literally, since the maximal class of all functors is a counterexample. Cisinski's later characterization explicitly includes the corresponding condition on components (Cisinski, 2004, Theorem 2.3.6). The reflection and its modern meaning. The final argument proves full faithfulness through an adjunction. Put

Σ0 = W d

A = Cat/S, S ⊆Σ = WS. Path completion carries Σ into Σ0, its unit ηX belongs to Σ, and ηCX belongs to Σ0. These conditions give

P : A[Σ−1

0] ⇄A[Σ−1] : R, P ⊣R, with R fully faithful. The unit is induced by η, and the counit is its inverse in the coarse category. The commentary verifies both triangle identities. In

particular, the equality C(ηX) = ηCX after fine localization follows formally from naturality and the stated invertibilities. Grothendieck's concatenation of paths gives an additional geometric proof by providing a common inverse. There is no need to cancel ηX in the fine category, where it need not be invertible.

For W = W∞, the resulting interpretation is

HOTW∞(S) $\simeq$Ho Fun(N(S)op, S),

HOTlc

W∞(S) $\simeq$Ho Fun($\Pi\infty$N(S), S) $\simeq$Ho(S/|N(S)|). Here S is the infinity-category of spaces, and the homotopy category is taken after forming coherent diagrams or the slice. The reflector is restriction after left Kan extension along groupoid completion. The commentary explains the comparison through Thomason's model and straightening (Thomason, 1980; Lurie, 2009). It also computes the interval reflector and the endomorphisms of the point over BZ, which distinguish the homotopy category of the slice from the ordinary slice of the homotopy category.

The locally constant embedding and its two adjoints are now theorems in the derivator setting (Cisinski, 2009, Proposition 3.10 and Theorem 3.13). Their existence does not identify an arbitrary coarse W-localization with that subcategory. The surviving qualification is about hypotheses, not an unresolved version of the full-faithfulness problem for spaces. We also do not label the

relationship between the weakest absolute and relative axiom packages as a current open problem: this audit establishes the implications used here and records where a weaker package is insufficient for the printed proof. The construction of the path categories themselves is an input from outside these pages. The first part of the chapter ends in the opening clauses of the theorem–scholium on manuscript page 70; the continuation on pages 71–81 is commented in the second part.

et les localiseurs W_S^{g} dans ces catégories ($f \in W_S^{\mathrm{g}}$ si et seulement si les $f/s : X/s \longrightarrow Y/s$ sont dans W). On trouve une 'même catégorie localisée', notée p. 44

$$\mathrm{HOT}_W^o(S),$$

et on a tautologiquement

$$\mathrm{HOT}_W^o(S) \approx \mathrm{HOT}_W(S^o). \qquad \text{[page 71]}$$

[plutôt $(\mathrm{HOT}_W(S^o))^o$ cf. p. 50]

(III) Sur les six catégories internes du diagramme, les trois notions de W-équivalence, en termes de W_S, W_S^{d}, W_S^{g} coïncident, et coïncident avec la W-équivalence par fibres W_S^{f}. Sur les trois catégories de $(*)$ autres que Cat/S, les localiseurs W_S^{f}, W_S^{d} coïncident; sur les trois catégories de $(*')$ autres que Cat/S, les localiseurs W_S^{f}, W_S^{g} coïncident. Mais en général ([46]), sur ces six catégories, ces localiseurs W_S^{f} ne sont pas égaux à W_S, plus précisément donnent des localisées non équivalentes, elles sont donc munies chacune de *deux* localiseurs essentiellement distincts, W_S^{f} et W_S. La catégorie Cat/S est la seule catégorie du diagramme sur laquelle les localiseurs W_S, W_S^{d} et W_S^{g} sont tous les trois essentiellment distincts. C'est la seule qui permette d'obtenir simultanément les trois catégories localisées, comme

$$\begin{array}{ccccc} & & \mathrm{HOT}_W^{\mathrm{lc}}(S) \simeq (\mathrm{Cat}/S)W_S^{-1} & & \\ & \overset{\rho}{\nearrow} & & \overset{\sigma}{\nwarrow} & \\ \mathrm{HOT}_W(S) \simeq (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1} & & & & \mathrm{HOT}_W^o(S) \simeq (\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1} \end{array}$$

Commentary · Exposition [ms. 71]

Opposite categories and opposite derivators

The dual statement is meant to recover the covariant theory from the contravariant one. At the level of the ordinary localized categories used here, its variance can be checked directly. Taking opposites gives a functor

$$O_S : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S^{\mathrm{op}}, \qquad (X \to S) \longmapsto (X^{\mathrm{op}} \to S^{\mathrm{op}}),$$

which sends $v : X \to Y$ to $v^{\mathrm{op}} : X^{\mathrm{op}} \to Y^{\mathrm{op}}$, with the same direction. Moreover

$$s\backslash(X^{\mathrm{op}}) \cong (X/s)^{\mathrm{op}}.$$

For the opposite-invariant localizer under consideration, O_S interchanges the left-fine and right-fine classes. Its square is the identity. Consequently the localization definitions of this Scholie give

$$(\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1} \simeq (\mathrm{Cat}/S^{\mathrm{op}})(W_{S^{\mathrm{op}}}^{\mathrm{d}})^{-1},$$

with no opposite on the resulting category.

The editorial insertion on this page asks for an additional outer opposite. That insertion belongs to the different convention of an *opposite derivator*, whose value is $\mathbb{D}(S^{\mathrm{op}})^{\mathrm{op}}$; it is not compatible with identifying both sides here with the displayed ordinary localizations. We preserve the edition's insertion, and distinguish the conventions rather than altering its words. See also manuscript p. 50, where the same issue first appears. The two diagram functors at manuscript p. 73 confirm the present interpretation: their values lie in Hot_W, with the index category reversed, rather than in $\mathrm{Hot}_W^{\mathrm{op}}$.

A small check prevents a significant error later. At $S = e$ and for ordinary weak homotopy equivalences, both fine localizations are Ho(Spaces). This category is not equivalent to its opposite: its initial object is strict, since a map to the empty space can only have empty source, whereas its terminal object is not costrict: a map $* \to S^0$ need not be invertible. These properties are preserved by equivalences and exchanged by passage to the opposite. In particular dualizing the present comparison does not reverse the order of the two adjoints: both $\rho \dashv i$ and $\sigma \dashv j$ have the order printed in Part IV. The later hesitation at manuscript p. 84 comes from precisely this variance distinction.

46. sans doute dans tous les cas où S n'est pas équivalente à une catégorie dicrète.

Commentary · Development (commentators') [ms. 71]

The groupoid test for collapse of the comparison

Grothendieck asks in footnote 46 whether the distinction between coarse and fine localization persists for every base not equivalent to a discrete category. A group with one object already shows that the proposed dividing line is too narrow. The relevant issue is the presence of noninvertible arrows, not the presence of nontrivial automorphisms.

Proposition (the canonical comparison). [ours] For $W = W_\infty$, the ordinary weak homotopy equivalences of categories, the canonical localization

$$\rho : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_W(S)$$

is an equivalence if and only if S is a groupoid. The same assertion holds for σ.

We use the established interpretation of the right-fine theory as coherent space-valued presheaves and its locally constant subcategory. Equivalently, one can use Part V and the split-fibration presentation; the proof below needs only discrete representables for the difficult implication. If S is a groupoid, every functor defined on S^{op} sends arrows to equivalences. Hence every object is locally constant, and the fully faithful right adjoint i is essentially surjective. Its left adjoint ρ is therefore an equivalence.

Conversely, suppose ρ is an equivalence. For each object z, consider the discrete presheaf $h_z(s) = \mathrm{Hom}_S(s, z)$ and its category of elements over S. It defines an object of $\mathrm{HOT}_W(S)$. Since this object must be locally constant, precomposition by every $u : a \to b$ induces a weak equivalence of discrete spaces

$$\mathrm{Hom}_S(b, z) \xrightarrow{-\circ u} \mathrm{Hom}_S(a, z).$$

A weak equivalence between discrete spaces is a bijection. With $z = a$, surjectivity gives $v : b \to a$ with $vu = 1_a$. With $z = b$, injectivity applied to uv and 1_b gives $uv = 1_b$, because both become u after precomposition by u. Thus every arrow is invertible. Reversing the argument proves the covariant assertion.

For example, take $S = BG$ with $G \neq 1$. Its unique object has automorphism group G, so BG is not equivalent to a discrete category; nevertheless both canonical comparisons are equivalences. This disproves the printed conjecture even for the ordinary localizer. The proposition concerns the specified comparison functor: detecting a nonconstant representable proves that this functor fails to be an equivalence, without asserting an unrelated classification of possible abstract equivalences between the two categories.

This is our explicit application of Yoneda to the question in the footnote, not a claim of priority. We checked the locally constant comparison in Cisinski (2009, §§1–2) and the presheaf interpretation in Lurie (2009, Theorem 2.2.1.2); neither is being claimed as a new result. We did not find the footnote's proposed criterion stated in the passages checked.

Ici, ρ et σ sont des foncteurs de localisation (comme il est évident sur la définition).

Tout foncteur ou foncteur composé du diagramme page 8, allant d'une catégorie interne au diagramme vers une catégorie bordante, induit un foncteur pour les localisées pour W_S^{d} (quand la catégorie but fait partie des quatre gauches, rappelées dans (∗), p. 70), soit pour W_S^{g} (quand [page 72] ces catégories font partie des quatre du côté droit, rappelées dans (∗′)), lesquels localiseurs coïncident aussi avec W_S^{f} sauf dans le seul cas de la catégorie Cat/S. Tous les foncteurs ainsi obtenus se réduisent, à équivalence près, à deux, suivant que la catégorie localisée but est $\mathrm{HOT}_W(S)$ (cas de la localisation W_S^{d}), ou qu'elle est $\mathrm{HOT}^o_W(S)$ (cas de la localisation W_S^{g}). On trouve ainsi des foncteurs (en sens inverse de ρ et de σ) p. 45

$$\begin{array}{ccc} & \mathrm{HOT}^{\mathrm{lc}}_W(S) & \\ {\scriptstyle i}\swarrow & & \searrow{\scriptstyle j} \\ \mathrm{HOT}_W(S) & & \mathrm{HOT}^o_W(S). \end{array}$$

Les foncteurs ρ, σ s'interchangent par dualité $S \longmapsto S^o$, et de même pour i, j.

(IV) Les foncteurs ρ, i sont adjoints l'un de l'autre dans cet ordre, i.e. on a pour deux

objets $\xi \in \mathrm{ObHOT}_W(S)$, $\eta \in \mathrm{ObHOT}^{\mathrm{lc}}_W(S)$

$$\mathrm{Hom}(\rho(\xi), \eta) \simeq \mathrm{Hom}(\xi, i(\eta))$$

(isomorphisme de bifoncteurs). Et dualement les foncteurs σ, j sont adjoint l'un de l'autre dans cet ordre : pour $\xi \in \mathrm{ObHOT}^{o}_W(S)$, $\eta \in \mathrm{ObHOT}^{\mathrm{lc}}_W(S)$

$$\mathrm{Hom}(\xi, j(\eta)) \simeq \mathrm{Hom}(\sigma(\xi), \eta).$$

Il s'ensuit notamment que *les foncteurs i, j sont pleinement fidèles.* [page 73]

Ⓥ On a des foncteurs évidents

$$\begin{array}{lccc} (*) & \mathrm{HOT}_W(S) & \longrightarrow & \underline{\mathrm{Hom}}(S^o, \mathrm{Hot}_W) \\ (*') & \mathrm{HOT}^{o}_W(S) & \longrightarrow & \underline{\mathrm{Hom}}(S, \mathrm{Hot}_W). \end{array}$$

Le premier s'interprète sur les quatre catégories $(*)$ (bordantes gauches) de page 70, qui servent indifférement à décrire $\mathrm{HOT}_W(S)$, par

$$s \longmapsto \mathrm{hot}_W(X_s)$$

dans le cas des trois catégories distinctes de Cat/S, et par

$$s \longmapsto \mathrm{hot}_W(s\backslash X)$$

dans le cas de Cat/S. La dépendence fonctorielle par rapport à s est évidente dans le cas de Cat/S (donnée par $s \longmapsto \mathrm{hot}_W(s\backslash X)$), et dans le cas de $\underline{\mathrm{Fibsc}}\, S$, $\underline{\mathrm{Fib}}\, S$, où on dispose, pour $u : s \longrightarrow t$ dans S, du changement de base

$$u^* : X_t \longrightarrow X_s.$$

Dans le cas de $\underline{\mathrm{Liss}}\, S$, la dépendence fonctorielle se déduit de celle de $\mathrm{hot}_W(s\backslash X)$, grâce au fait que l'inclusion

$$X_s \longrightarrow s\backslash X$$

est alors une W-équivalence.

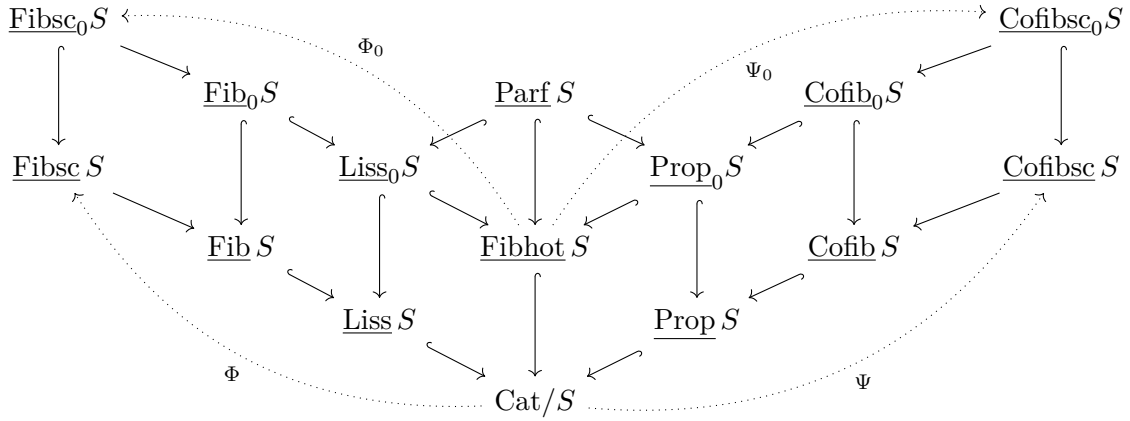
On a une interprétation duale de l'application $(*)'$, `[mot illisible]` p. 46

$$s \longmapsto \mathrm{hot}_W(X_s) \qquad \text{ou} \qquad s \longmapsto \mathrm{hot}_W(s\backslash X), \quad \text{[page 74]}$$

avec la loi fonctorielle en s déduite du foncteur $t\backslash X \longrightarrow s\backslash X$ `[plutôt` $X/s \longrightarrow X/t$`]` (pour $u : s \longrightarrow t$) dans le cas du Cat/S, du foncteur cochangement de base dans les cas de $\underline{\mathrm{Cofib}}\, S$ et $\underline{\mathrm{Cofibsc}}\, S$, et de la variante pour Cat/S et de la W-équivalence

$$X_s \longrightarrow X/s$$

dans le cas de $\underline{\mathrm{Prop}}\, S$.



On trouve alors ceci : pour qu'un objet ξ de $\mathrm{HOT}_W(S)$ (resp. $\mathrm{HOT}^{o}_W(S)$) soit dans l'image essentielle de $\mathrm{HOT}^{\mathrm{lc}}_W(S)$, il faut et il suffit que le foncteur associé $S^o \longrightarrow \mathrm{Hot}_W$ (resp. $S \longrightarrow \mathrm{Hot}_W$) soit un système local ([47]), i.e. transforme toute flèche de S en un isomorphisme, i.e. se factorise par $(\Pi S)^o \longrightarrow \mathrm{Hot}_W$ resp. $\Pi S \longrightarrow \mathrm{Hot}_W$ ([48]). Donc pour un X dans Cat/S, cela signifie soit que les foncteurs

$$t\backslash X \longrightarrow s\backslash X$$

associés à des $u : s \longrightarrow t$ dans S soient tous des W-équivalences (cas de $\mathrm{HOT}_W(S)$), soit que les foncteurs

$$X/s \longrightarrow X/t \qquad \text{[page 75]}$$

le soient (cas de $\mathrm{HOT}^o_W(S)$). (NB. ces conditions ne sont nullement équivalentes. Mais si X [est] lisse [sur] S, la première implique la seconde, et l'inverse est vrai si X est propre sur S, et dans ce cas, la condition équivaut à ce que X soit dans $\underline{\mathrm{Fibhot}}$. Enfin, si X est déjà dans $\underline{\mathrm{Fibhot}}\,S$, alors les deux conditions sont automatiquement satisfaites ([49]).

([50]). De plus, si deux éléments $\xi \in \mathrm{ObHOT}_W(S)$, $\xi' \in \mathrm{ObHOT}^o_W(S)$ proviennent d'un même p. 47
$\eta \in \mathrm{ObHOT}^{\mathrm{lc}}_W(S)$, alors les deux foncteurs correspondants

$$(\Pi S)^o \xrightarrow{\varphi} \mathrm{Hot}_W \xleftarrow{\varphi'} \Pi S$$

sont *associés,* i.e. chacun est isomorphe à 'l'inverse' de l'autre.

$$\begin{cases} \varphi^o(s) &= \varphi(s) \\ \varphi^o(u) &= \varphi(u)^{-1}. \end{cases}$$

Commentary · Exposition [ms. 74]

Completing the test for local constancy

The fibre diagram is being used here to recognize objects in an already constructed full subcategory. This is weaker than claiming that an arbitrary diagram in Hot_W reconstructs the coherent object, an issue treated in the commentary at manuscript p. 7. The recognition statement nevertheless needs the verification requested in footnote 47.

Represent ξ by $X \to S$, and replace it by the split fibration $\Phi X \to S$. Its strict fibre at s is $s\backslash X$, and the transition along $u : s \to t$ is precomposition

$$u^* : t\backslash X \longrightarrow s\backslash X.$$

The replacement map is right-fine, so X and ΦX represent the same object of $\mathrm{HOT}_W(S)$. If all the u^* belong to W, this split fibration belongs to $\underline{\mathrm{Fib}}_0 S$: it is a categorical fibration with weakly constant fibres. By the comparison already proved, it belongs to $\underline{\mathrm{Fibhot}}S$. Its class is therefore in the image of i. This proves sufficiency without selecting transport maps in an arbitrary nonsplit representative.

For necessity, choose a homotopy-fibration representative $Y \to S$ of an object in the image. Its comma-fibre transition maps are weak equivalences by the defining local-constancy property. The diagram functor sends an isomorphism in $\mathrm{HOT}_W(S)$ to an isomorphism of diagrams in Hot_W. Whether every structural arrow of such a diagram is invertible is invariant under an isomorphism of diagrams. Hence the property holds for every representative of the same class. The covariant argument uses ΨX and the transitions $X/s \to X/t$.

47. il faudra encore écrire la vérification
48. où ΠS est le groupoïde fondamental de S
49. On aurait dû dans le diagramme introduire aussi $\underline{\mathrm{Liss}}_0 S$, $\underline{\mathrm{Prop}}_0 S$!
50. Le diagramme de *quinze* catégories remarquables.

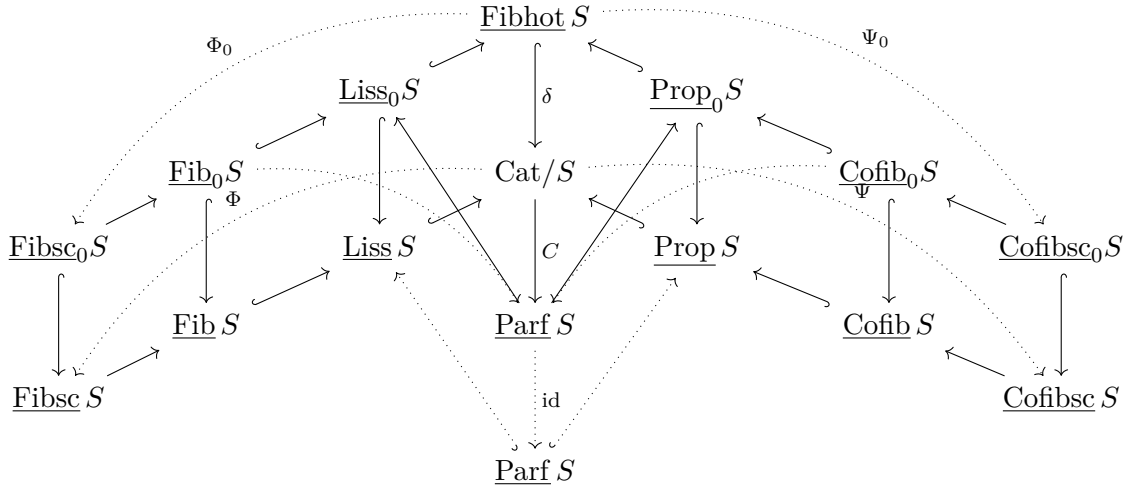
To pass from "invertible in Hot_W" to "belongs to W", one uses strong saturation. It holds for W_∞ and, in the standard theory, for every basic localizer; see Cisinski (2006c, Proposition 4.2.4). This makes explicit a logical input that the sentence "cela signifie" suppresses. Without saturation, the invariant statement uses the saturation of W, rather than arbitrary membership in the originally chosen class.

Finally, the factorization through ΠS in the text concerns only the underlying homotopy-category-valued diagram. Its existence follows from the ordinary universal property of groupoid completion. It does not replace the coherent local system by a representation of the fundamental groupoid. For space-valued coefficients, higher homotopies of the base can still act on the fibres. This leaves the argument above intact: invertibility of all arrows detects local constancy, while the object being detected still retains its coherence.

(VI) NB Dans la nouvelle version du diagramme, où j'ai rajouté des catégories $\underline{\mathrm{Liss}}_0 S$ et $\underline{\mathrm{Prop}}_0 S$ pour rendre le tracé plus transparent, les catégories appelés 'bordantes' deviennent le 'rez-de-chausseée', et les catégories 'internes', le 'premier étage' ou 'étage'. Tous les 7 carrés du diagramme sont catésiens. Toutes les flèches sont des inclusions pleinement fidèles, sauf les quatre flèches horizontales extérieures des catégories de Cat-fibrés ou de Cat-cofibrés *scindés*, avec morphismes exclusivement cartésiens ou cocartésiens et même compatibles avec les scindages, vers les catégories correspondantes de structures non scindées.

Commentary · Exposition [ms. 75]

What the fifteen categories remember



The expanded diagram separates two choices which are often bundled together in contemporary notation: a property of the projection $X \to S$, and a restriction on the morphisms allowed between such projections. This separation is responsible for both its size and its usefulness.

Except for the categories of split fibrations and split opfibrations, the displayed categories are full subcategories of Cat/S. A map between two fibred objects is therefore an arbitrary functor over S; it need not preserve Cartesian arrows. For the split categories, Grothendieck imposes preservation of the splitting, and hence preservation of the chosen Cartesian or cocartesian arrows. Their forgetful functors are not full. The commentary at manuscript p. 30 explains why the naive unit for a splitting construction need not lie in this narrower morphism category.

The seven Cartesian squares assert that the relevant conditions on objects and morphisms are simultaneous conditions. In particular, the square with $\underline{\mathrm{Parf}} S$ expresses the conjunction of the left and right properties, while the outer squares impose the locally constant condition on a split or nonsplit fibration. These assertions should be read in the ordinary category-of-categories sense in which the given subcategories and forgetful functors have been specified. They are not additional assertions that the corresponding nerves form homotopy pullback squares.

The explicit comma replacements remove the possible difficulty caused by the narrow morphism categories. Applied to a functor over S, the rule $s \mapsto s\backslash X$ gives a strictly natural transformation of strict Cat-valued diagrams, and therefore a splitting-preserving map of their categories of elements. This supplies a functor even when the original map did not preserve Cartesian arrows. The equivalence after localization follows from the natural comparison zigzags established earlier, not from pretending that all the forgetful functors were already fully faithful. A later systematic treatment of such comma and category-of-elements comparisons is Maltsiniotis (2005, Theorem 3.8).

[page 76]

Commentary · Examples [ms. 75]

Maps over a group retain the action

The common locally constant category still remembers the map to the base. A completely discrete example makes this visible without any higher coherence. Let $G = C_2 = \{1, \tau\}$, let $S = BG$, and let $E = G$ with its regular right action. Its category of elements has two objects, with one arrow between any ordered pair; the arrow from e to e' lies over the unique g with $e' = eg$. Its total category is equivalent to e, while its projection to BG records the free transitive action.

The associated fibre diagram has one value, the discrete two-point space E, with the nontrivial element of G acting by transposition. An endomorphism over the base is an equivariant map $E \to E$. Such a map is determined by the image of 1, and either choice gives a map: $e \mapsto ae$ for $a \in G$. Thus there are exactly two endomorphisms. Since these diagrams have discrete values, a coherent natural transformation has no nontrivial higher homotopies; their derived mapping space is the same discrete set of two equivariant maps. Consequently the endomorphism set is also two-element in each of the equivalent coarse and fine theories over BG.

Forgetting the base would instead replace the total category by a point, whose endomorphism set in Ho(Spaces) is a singleton. The coarse theory over BG therefore cannot be obtained by simply computing maps between the total homotopy types. It localizes maps *over* BG, and the permitted zigzags continue to remember that structure.

The same computation can be made with spaces. The object is the universal covering $EG \to BG$, with contractible total space and discrete fibre G. Its derived space of self-maps over BG is $\Omega BG \simeq G$. The ordinary space of self-maps of its contractible total space is contractible. This is the relative distinction behind the Hom formula at manuscript p. 81. It also explains why a groupoid base is not a degenerate case of the theory, even though the fine-to-coarse comparison is an equivalence for such a base.

J'ai tracé en pointillés verts `[couleur dans l'original seulement]` les cinq foncteurs Φ, Ψ, Φ_0, Ψ_0, C qui par passage aux localisés donnent des quasi-inverses pour toutes les équivalences de catégories énoncées dans Ⓘ Ⓘ du présent Scholie. De façon précise, le foncteur

$$\Phi : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Fibsc}}\, S$$

associe à toute X dans Cat/S la catégorie scindée sur S

$$s \longmapsto s\backslash X$$

sur S. Ce foncteur, et ses restrictions à $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Fib}}\, S$ et, plus généralement, à toute sous- p. 48
catégorie pleine $\mathcal{F}$ de Cat/S contenant $\underline{\mathrm{Fib}}\, S$, est compatible avec les localiseurs W_S d'une

part (sur $\mathcal{F}$ et $\underline{\mathrm{Fibsc}}\, S$), W_S^{d} d'autre part, et passe donc aux localisés correspondants, pour fournir le quasi-inverse cherché de

$$(\underline{\mathrm{Fibsc}}\, S)\Sigma^{-1} \longrightarrow \mathcal{F}\Sigma^{-1} \qquad (\Sigma = W_S \text{ ou } W_S^{\mathrm{d}})$$

On peut aussi, pour toute sous-catégorie pleine $\mathcal{F}'$ intermédiaire

$$\underline{\mathrm{Fib}}\, S \subseteq \mathcal{F}' \subseteq \mathcal{F} \subseteq \mathrm{Cat}/S,$$

regarder Φ comme un foncteur $\mathcal{F} \longrightarrow \mathcal{F}'$ (plus précisément, prendre le composé

$$\mathcal{F} \xrightarrow{\Phi|\mathcal{F}} \underline{\mathrm{Fibsc}}\, S \longrightarrow \underline{\mathrm{Fib}}\, S \hookrightarrow \mathcal{F}'\ ),$$

soit $\Phi_{\mathcal{F}',\mathcal{F}}$, et de ce qui vient d'être dit résulte que les deux foncteurs

$$\mathcal{F}' \underset{\Phi_{\mathcal{F}',\mathcal{F}}}{\overset{}{\hookrightarrow}} \mathcal{F}$$

établissent des équivalences quasi-inverses l'une de l'autre [page 77]

$$\mathcal{F}'\Sigma^{-1} \underset{\Phi_{\mathcal{F}',\mathcal{F}}}{\overset{\approx}{\longrightarrow}} \mathcal{F}\Sigma^{-1} \qquad (\Sigma = W_S \text{ ou } W_S^{\mathrm{d}})$$

Énoncé dual pour le foncteur

$$\Psi : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Cofibsc}}\, S,$$

associant à X dans Cat/S la catégorie cofibrée scindée sur S

$$s \longmapsto X/s.$$

Il donne des couples de foncteurs quasi-inverses

$$(\underline{\mathrm{Cofibsc}}\, S)\Sigma^{-1} \underset{\Psi_{\mathcal{F}}}{\overset{}{\longrightarrow}} \mathcal{F}\Sigma^{-1} \qquad (\Sigma = W_S \text{ ou } W_S^{\mathrm{g}})$$

pour tout sous-catégorie pleine $\mathcal{F}$ de Cat/S telle que

$$\underline{\mathrm{Cofib}}\, S \subseteq \mathcal{F} \subseteq \mathrm{Cat}/S,$$

et des couples de foncteurs quasi-inverses p. 49

$$\mathcal{F}'\Sigma^{-1} \underset{\Psi_{\mathcal{F}',\mathcal{F}}}{\overset{\approx}{\longrightarrow}} \mathcal{F}\Sigma^{-1} \qquad (\Sigma = W_S \text{ ou } W_S^{\mathrm{g}})$$

pour deux sous-catégories pleines $\mathcal{F}'$, $\mathcal{F}$

$$\underline{\mathrm{Cofib}}\, S \subseteq \mathcal{F}' \subseteq \mathcal{F} \subseteq \mathrm{Cat}/S.$$

Les foncteurs Φ, Ψ envoient la sous-catégorie pleine $\underline{\mathrm{Fibhot}}\, S$ de 'l'étage', dans les sous-catégories $\underline{\mathrm{Fibsc}}_0 S$, $\underline{\mathrm{Cofibsc}}_0 S$, respectivement, donc induisent à l'étage des foncteurs Φ_0, Ψ_0

$$\underline{\mathrm{Fibsc}}_0 S \xleftarrow{\Phi_0} \underline{\mathrm{Fibhot}}\, S \xrightarrow{\Psi_0} \underline{\mathrm{Cofibsc}}_0 S, \qquad \text{[page 78]}$$

jouant à l'étage exactement le même rôle que Φ, Ψ au rez-de-chaussée. La seule différence, c'est que à l'étage on a $W_S = W_S^{\mathrm{d}} = W_S^{\mathrm{g}}$ $(= W_S^{\mathrm{f}})$, donc il n'y a qu'une suite de catégories localisées à examiner. On trouve ainsi

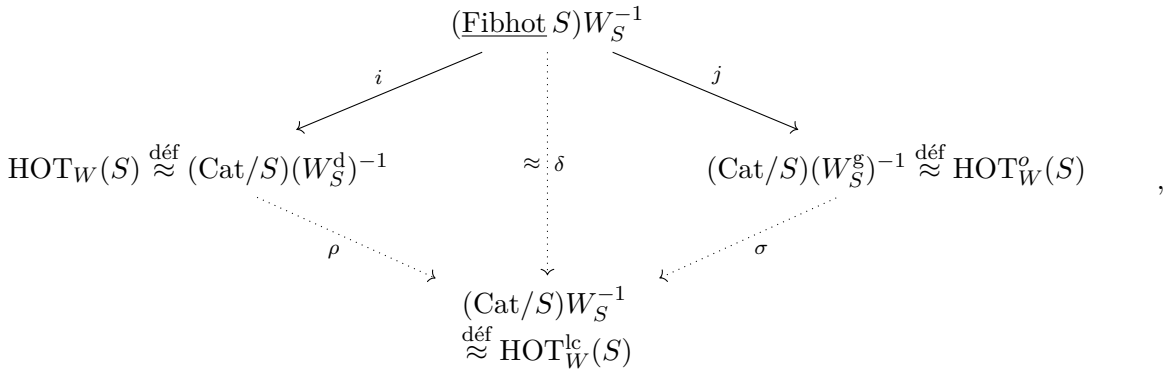
$$(\underline{\mathrm{Fibsc}}_0 S)W_S^{-1} \xrightarrow{\approx} \mathcal{F}W_S^{-1} \quad \text{(} \approx \text{ via } \Phi_{0,\mathcal{F}}\text{)}$$

$$\mathcal{F}'W_S^{-1} \xrightarrow{\approx} \mathcal{F}W_S^{-1} \quad \text{(} \approx \text{ via } \Phi_{0,\mathcal{F}',\mathcal{F}}\text{)}$$

pour $\mathcal{F}$ (ou $\mathcal{F}$, $\mathcal{F}'$) sous-catégorie(s) pleine(s) de $\underline{\mathrm{Fibhot}}\, S$ telle(s) que

$$\underline{\mathrm{Fib}}_0 S \subseteq \mathcal{F} \subseteq \underline{\mathrm{Fibhot}}\, S \qquad \text{resp.} \qquad \underline{\mathrm{Fib}}_0 S \subseteq \mathcal{F}' \subseteq \mathcal{F} \subseteq \underline{\mathrm{Fibhot}}\, S,$$

et de même du côté droit pour les sous-catégories pleines $\mathcal{F}$ ou $\mathcal{F}$, $\mathcal{F}'$ de $\underline{\mathrm{Fibhot}}\, S$ satisfaisant



$$\underline{\mathrm{Cofib}}_0 S \subseteq \mathcal{F} \subseteq \underline{\mathrm{Fibhot}}\, S \qquad \text{resp.} \qquad \underline{\mathrm{Cofib}}_0 S \subseteq \mathcal{F}' \subseteq \mathcal{F} \subseteq \underline{\mathrm{Fibhot}}\, S,$$

NB. La catégorie $\underline{\mathrm{Parf}}\, S$ contient à la fois $\underline{\mathrm{Fib}}_0 S$ et $\underline{\mathrm{Cofib}}_0 S$, et fait donc partie des catégories admissibles tout comme $\mathcal{F}$, ou [?] $\mathcal{F}'$.

Ainsi, les quatre foncteurs Φ, Ψ, Φ_0, Ψ_0 donnent tous les quasi-inverses qu'on peut souhaiter au rez-de-chaussée d'une part (Φ et Ψ), à l'étage de l'autre (Φ_0, Ψ_0). Ils ramènent donc toutes les localisées pertinentes aux quatre suivantes

$$(\mathrm{Cat}/S)W_S^{-1}, \quad (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}, \quad (\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1} \qquad \text{(au rez-de-chaussée)}$$
$$(\underline{\mathrm{Fibhot}}\, S)W_S^{-1} \qquad \text{(à l'étage)}.$$

(VII) Il reste à comparer la localisée à l'étage avec les localisées au rez-de-chaussée. Les flèches verticales descendantes de l'étage au rez-de-chaussée, sont compatibles avec W_S^{d} du côté gauche du diagramme, avec W_S^{g} du côté droit, donc elles induisent essentiellement *deux* foncteurs différents i, j sur $(\underline{\mathrm{Fibhot}}\, S)W_S^{-1}$, dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$ et $(\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1}$: p. 50 [page 79]

,

de façon à faire commuter le carré complété par les pointillés, représentant les foncteurs de localisation ρ, σ. On a bien sûr

$$(*) \qquad \rho i = \sigma j : (\underline{\mathrm{Fibhot}}\, S)W_S^{-1} \longrightarrow (\mathrm{Cat}/S)W_S^{-1}$$
induit par l'inclusion
$\delta : \underline{\mathrm{Fibhot}}\, S \hookrightarrow \mathrm{Cat}/S$

Nous avons énoncé dans (I) que cette flèche est une équivalence, de sorte que ρ et σ peuvent être interprétées, à isomorphisme de foncteurs près, comme des rétractions de $\mathrm{HOT}_W(S)$ et de

$\mathrm{HOT}^o_W(S)$ sur une sous-catégorie commune, s'interprétant soit comme $(\underline{\mathrm{Fibhot}}\, S)W_S^{-1}$, soit comme $(\mathrm{Cat}/S)W_S^{-1}$. Il reste à décrire le foncteur quasi-inverse de $(*)$, ce qui donnera en même temps les quasi-inverses de tous les foncteurs verticaux (de l'étage vers le rez-de-chaussée) dans le diagramme p. 76, plus exactement pour leurs localisés, pour W_S.

Commentary · Examples [ms. 78]

A finite comma diagram with an infinite reflection

The comma replacement and the path replacement can have very different fibres. To see the distinction explicitly, let S have two objects a, b and exactly two nonidentity arrows $u, v : a \rightrightarrows b$. Its nerve realizes to a circle. Take $X = e$ over b.

The right comma diagram $F(s) = s\backslash X$ is discrete, with

$$F(b) = \{*\}, \qquad F(a) = \{u, v\}, \qquad F(u)(*) = u, \quad F(v)(*) = v.$$

Its category of elements has three objects, two over a and one over b, with one arrow from each object over a to the object over b. The latter is terminal, so the total category is contractible. This split fibration is right-fine equivalent to X, but it is not locally constant: neither map from a singleton to the two-point set is an equivalence. Dually, X/s is empty at a and a singleton at b, since there is no arrow $b \to a$.

We can exhibit a locally constant replacement of F without writing the entire category of paths. Put

$$L(a) = L(b) = \mathbb{Z}, \qquad L(u)(n) = n, \qquad L(v)(n) = n + 1,$$

viewing L as a presheaf of discrete spaces. Define $F \to L$ by sending $*$ to 0, u to 0, and v to 1. The two naturality squares commute. All transition maps of L are bijections. Its category of elements has objects a_n, b_n and arrows

$$a_n \longrightarrow b_n, \qquad a_{n+1} \longrightarrow b_n \qquad (n \in \mathbb{Z}).$$

There are no nonidentity composable pairs. Its nerve is the infinite line subdivided into edges, hence is contractible. The functor from the three-object category of elements of F to this infinite category is therefore a coarse weak equivalence. Both its source and target are nonempty and contractible, which verifies the assertion directly rather than by a fibrewise test.

Since L is locally constant, the established reflection identifies its class with $i\rho(F)$. The fibre of this reflection is $\mathbb{Z}$, whereas the original comma fibres had at most two points. Transport around the generating loop of the circle is translation by one, up to the choice of orientation. Geometrically, the total locally constant object is the universal cover of the circle. The reflection must add all iterates of transport; it cannot be computed by merely declaring the two original transition maps invertible within their finite sets. This example gives a concrete role to the path construction in a place where the comparison diagram alone can conceal it.

[page 80]

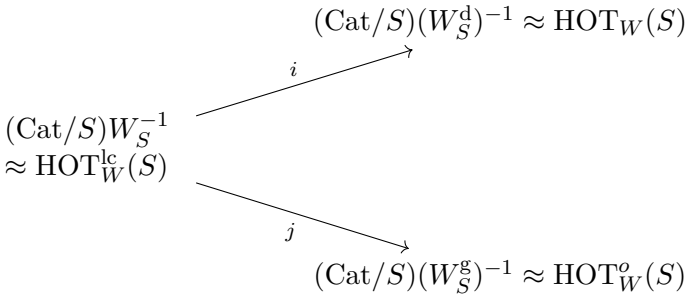
C'est ce qui est obtenu à l'aide du foncteur 'montant' (du rez-de-chaussée vers l'étage) C, qu'on peut regarder comme un foncteur $\mathrm{Cat}/S \longrightarrow \underline{\mathrm{Fibhot}}\, S$, mais qui en fait prend ses valeurs dans $\underline{\mathrm{Parf}}\, S$. (C'est là un détail sans grande importance, me semble-t-il.)

$$\mathrm{Cat}/S \xrightarrow{C} \underline{\mathrm{Parf}}\, S \hookrightarrow \underline{\mathrm{Fibhot}}\, S.$$

Ce foncteur est compatible avec les localiseurs W_S des deux côtés, et établit des équivalences (quasi-inverses des équivalences

$$(\underline{\mathrm{Parf}}\, S)W_S^{-1} \xrightarrow{\sim} (\mathrm{Cat}/S)W_S^{-1} \qquad \text{et} \qquad (\underline{\mathrm{Fibhot}}\, S)W_S^{-1} \xrightarrow{\sim} (\mathrm{Cat}/S)W_S^{-1}),$$
$$(\mathrm{Cat}/S)W_S^{-1} \xrightarrow{\sim} (\underline{\mathrm{Parf}}\, S)W_S^{-1} \left(\xrightarrow{\sim} (\underline{\mathrm{Fibhot}}\, S)W_S^{-1}\right).$$

Donc, quand les trois catégories HOT pour S sont interprétées en termes de localisées de Cat/S, c'est le foncteur C (plus exactement le composé $\mathrm{Cat}/S \xrightarrow{C} \underline{\mathrm{Parf}}\, S \hookrightarrow \mathrm{Cat}/S$) qui p. 51



fournit à la fois le foncteur d'inclusion (!) i, et le foncteur d'inclusion j dans $\mathrm{HOT}_W(S)$ et $\mathrm{HOT}^o_W(S)$ respectivement. Le foncteur en question

$$C' : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S$$

satisfait bien

$$C'(W_S) \subseteq W_S^{\mathrm{d}} \cap W_S^{\mathrm{g}}$$

et définit les deux foncteurs

Cela nous permet d'expliciter les formules d'adjonction de (IV), quand on y interprète ξ, η comme provenant de X, Y dans Cat/S : [page 81]

$$\boxed{\mathrm{Hom}_{W_S^{\mathrm{d}}}(X, CY) \simeq \mathrm{Hom}_{W_S^{\mathrm{g}}}(X, CY) \simeq \mathrm{Hom}_{W_S}(X, Y),}$$

où $\mathrm{Hom}_{W_S^{\mathrm{d}}}$, $\mathrm{Hom}_{W_S^{\mathrm{g}}}$ et Hom_{W_S} désignent respectivement les Hom dans les catégories localisées pour W_S^{d}, W_S^{g} et W_S, i.e. dans $\mathrm{HOT}_W(S)$, $\mathrm{HOT}^o_W(S)$ et $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ respectivement ([51]).

Commentaire. Toutes les constructions et les énoncés de (I) à (VI), à l'exception du fait que les foncteurs descendants induisent des équivalences pour les localisés *grossiers*, et des formules d'adjonction de (IV), sont de nature quasiment soritale, et n'exigent d'autres conditions sur le localiseur fondamental $W \subseteq \mathrm{Fl}\,\mathrm{Cat}$ que L1, L3 quater, L4 bis, récapitulées comme a) b) c) de la page 45. (On n'a même pas à utiliser d).) Il est vrai qu'en l'absence de la condition L5 (page 43), on ignore si à l'étage les deux localiseurs pertinents, W_S et W_S^{f} (égal à W_S^{d} du côté gauche, à W_S^{g} du côté droit) sont égaux. Donc à priori on trouve à l'étage *deux* catégories localisées essentiellement distinctes, et non pas une seule, savoir $(\underline{\mathrm{Fibhot}}\,S)\Sigma^{-1}$ avec $\Sigma = W_S$ ou $\Sigma = W_S^{\mathrm{f}}$ $(= W_S^{\mathrm{d}} = W_S^{\mathrm{g}})$.

Par contre, le fait que les foncteurs de descente induisent des équivalences entre les localisés grossiers est plus profond, il exige (me semble-t-il) qu'on connaisse un foncteur 'montant' C, disons de Cat/S vers $\underline{\mathrm{Fibhot}}\,S$, compatible avec W_S, et muni de p. 52

$$X \xrightarrow{i_X} C(X),$$

qui soit dans W_S pour X quelconque. Quand on sait que Cat est une catégorie de Quillen, même sans avoir les propriétés des foncteurs $\underline{\mathrm{Ch}}_\infty$ ou $\underline{\mathrm{Ch}}$ ([52]), on doit sans doute pouvoir se débrouiller. Mais la formule d'adjonction me semble rester inattendue et profonde, même en [page 82]

51. Cette formule suggère que si $X \in \mathrm{Ob}\,\mathrm{Cat}/S$, $Y \in \mathrm{Ob}\,\underline{\mathrm{Fibhot}}\,S$, alors

$$\mathrm{Hom}_{W_S^{\mathrm{d}}}(X, Y) \simeq \mathrm{Hom}_{W_S^{\mathrm{g}}}(X, Y) \simeq \mathrm{Hom}_{W_S}(X, Y),$$

mais ça résulte de la formule d'adjoinction et de $Y \longrightarrow C(Y)$ dans $W_S^{\mathrm{d}} \cap W_S^{\mathrm{g}}$ pour Y dans $\underline{\mathrm{Fibhot}}\,S$.

52. ni même être sûr de l'existence d'une factorisation *fonctorielle* de $X \xrightarrow{f} S$ en $X \xrightarrow{i_X} C(X) \xrightarrow{\bar{f}} S$ avec $i_X \in W$ et $\bar{f}$ parfait.

admettant les résultats de Quillen et Thomason ([53]). Elle parait liée ici à une propriété assez particulière du foncteur C, savoir le lemme p. 68

$$i_{C(X)} \underset{\uparrow}{=} C(i_X) : C(X) \longrightarrow C(C(X)),$$

$$\text{dans } \underbrace{(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}}_{\mathrm{HOT}_W(S)} \text{ et dans } \underbrace{(\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1}}_{\mathrm{HOT}^o_W(S)}$$

ce qui n'a pas l'air purement formel. Il serait intéressant d'examiner dans quelle mesure cette formule garde un sens dans une 'catégorie de modèles' $(\mathcal{M}, W)$ plus ou moins quelconque, ou provenant d'un triple de Quillen $(W, \mathrm{Cof}, \mathrm{Fib})$ dans $\mathcal{M}$. Il est clair que la factorisation $X \xrightarrow{f} S$ en $X \xrightarrow{i_X} C(X) \xrightarrow{\bar{f}} S$ ($i_X \in W$, $\bar{f} \in \mathrm{Parf}$), jouant le rôle des 'fibrations' dans le contexte Quillen, a un sens intrinsèque indépendant du choix d'une construction particulière, chose qu'on peut préciser de façon parfaite. C'est la description des localiseurs W_S^{d}, W_S^{g} dans $\mathcal{M}/S$ (pour $S \in \mathrm{Ob}\,\mathcal{M}$) qui n'est pas comprise de façon générale, en dehors du cas $\mathcal{M} = \mathrm{Cat}$. En d'autre termes, je ne comprends pas comment construire des catégories $\mathrm{HOT}_{\mathcal{M},W}(S)$, $\mathrm{HOT}^o_{\mathcal{M},W}(S)$, même si $(\mathcal{M}, W)$ provient d'un triple de Quillen, je vois seulement la description d'une catégorie $\mathrm{HOT}^{\mathrm{lc}}_{\mathcal{M},W}(S) = (\mathcal{M}/S)(W_S^{\text{grossière}})^{-1}$, et un foncteur de localisation $\mathcal{M}/S \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_{\mathcal{M},W}(S)$. Il faut arriver à décrire dans $\mathcal{M}/S$ des W-équivalences (*'relatives à S'*) plus fines que la grossière donnée par W sur la source X sans plus. Dans Cat j'y arrive en utilisant soit la famille des isomorphismes locaux (pour décrire W_S^{d}), soit celle des isomorphismes colocaux (pour décrire W_S^{g}) - en tous les cas, il y a une notion de 'localisation' (soit sur S, soit sur S^o …), avec toute la richesse des intuitions liées à une telle notion. Peut-être, sans le savoir ai-je [page 83]
toujours traité Cat non comme une catégorie 'nue', mais comme un site, ou plutôt (puisqu'il y p. 53
a l'involution $X \longmapsto X^o$ qui ne peut être éludée), comme un 'bi-site' - on y a *deux* manières de localiser, soit par les X/x (topologie de Zariski!) soit par les $x\backslash X$ (topologie co-Zariskienne). Il y a aussi la topologie lisse (toute proche sans doute de l'intuition de la cohomologie étale), et la topologie propre - et on s'attend que la lisse donne essentiellement les mêmes résultats que la Zariskienne (vue que la topologie étale lui est égale - il n'y a pas lieu d'en faire un plat …); et la topologie propre les mêmes résultats (p. ex. la même cohomologie?) que la topologie co-Zariskienne.

Commentary · Exposition [ms. 81]

The target controls the comparison of morphisms

The formula on this page is a universal property of the replacement of the *target*. It is stronger than saying that X and $C(X)$ have the same total homotopy type, and it explains why homotopy fibrations are the right objects in which to receive maps.

Write $Q_{\mathrm{d}}, Q_{\mathrm{g}}, Q$ for the three localization functors out of Cat/S. The adjunction $\rho \dashv i$ identifies

$$\mathrm{Hom}_{\mathrm{HOT}_W(S)}(Q_{\mathrm{d}}X, iQY) \cong \mathrm{Hom}_{\mathrm{HOT}^{\mathrm{lc}}_W(S)}(QX, QY).$$

The chosen model for iQY is $Q_{\mathrm{d}}CY$, and the analogous model for jQY is $Q_{\mathrm{g}}CY$. This gives both isomorphisms printed in the box, with their naturality in X and Y. One must retain CY on the fine sides unless Y is already local.

For $Y \in \underline{\mathrm{Fibhot}}S$, the map $i_Y : Y \to CY$ is both right-fine and left-fine. Postcomposition by this map identifies the corresponding Hom sets with targets Y and CY. Combining these identifications with the box proves footnote 51. In particular, the fine and coarse localizations have the same maps *into a local object*, although they can have different maps between arbitrary objects. This is the familiar defining property of a reflective full subcategory, here recovered from explicit relative-category models.

53. Voir cependant le théorème scholie 2, p. 108-113. Ce n'est finalement pas si profond qu'il me semblait, mais quasiment sorital!

There is also a useful way to recognize the arrows inverted by ρ. A map $f : A \to B$ in $\mathrm{HOT}_W(S)$ is inverted if and only if, for every local object L, precomposition induces a bijection

$$\mathrm{Hom}(B, L) \longrightarrow \mathrm{Hom}(A, L).$$

One implication follows from the adjunction. Conversely these bijections say that precomposition by ρf is a bijection against every object of the coarse category; Yoneda implies that ρf is invertible. The fibre diagram alone does not supply these Hom sets. The regular-action example above shows why even objects with contractible total spaces can have nontrivial relative endomorphisms.

Commentary · Exposition [ms. 82]

Coherence already follows from the two invertibilities

Grothendieck is trying to decide which part of the reflection depends on the special geometry of paths. Concatenation gives an attractive proof of the equality of the two iterated units, but under the hypotheses already written at manuscript p. 66 that equality is also formal. The distinction matters for the abstraction that follows.

Let T be an endofunctor of an ordinary category and $\eta : 1 \to T$ a natural transformation. Assume that both $T\eta_X$ and η_{TX} are invertible for every X. Put $a = T\eta_X$ and $b = \eta_{TX}$. Naturality at η_X gives $a\eta_X = b\eta_X$. Applying T and cancelling the invertible map a gives $Ta = Tb$. Next apply naturality to the two maps $a, b : TX \to T^2X$:

$$\eta_{T^2X} a = (Ta)b, \qquad \eta_{T^2X} b = (Tb)b.$$

The right sides agree, and η_{T^2X} is invertible. Hence $a = b$. Notice that the proof never cancels η_X, which need not be invertible.

Now work in $\mathcal{A}\Sigma_0^{-1}$. The functor C induces an endofunctor T because $\Sigma_0 \subseteq \Sigma$ and $C(\Sigma) \subseteq \Sigma_0$. Its coaugmentation is the image of i. The map Ti_X is invertible because $i_X \in \Sigma$, and i_{TX} is invertible by the second condition at manuscript p. 66. The lemma therefore gives $i_{C(X)} = C(i_X)$ in the fine localization. The first triangle identity is already tautological, and this proves the second. The same argument applies to the left-fine localization.

This is the ordinary-category case of the standard characterization of a localization by an idempotent coaugmented endofunctor; compare Lurie (2009, Proposition 5.2.7.4). The displayed proof is included to make the precise cancellation visible. No new geometric property of C is required at this step once both invertibilities are known. Establishing those invertibilities, and identifying the essential image of C, remain mathematical work. The source's later Theorem-Scholie 2, at manuscript pp. 108–113, puts exactly these inputs into a general replacement theorem.

Il semble bien que dans toutes les catégories de modèles utilisées jusqu'à présent pour décrire Hot comme une localisée, on dispose de notions de localisation : (Top), $\mathbf{\Delta}^\wedge$ (ou $A^\wedge$, avec A catégorie-test quelconque), (Cat); et dans Cat on dispose même de *deux* telles notions. Je pense par contre aux ∞-groupoïdes, c'est peut-être la seule catégorie de modèles à tel point proche déjà de Hot elle-même, qu'on n'y discerne pas de notion de localisation, et que l'idée même de vouloir s'y localiser (si ce n'est en 'localisant' Hot lui-même) paraît quasiment saugrenue. [page 84]

Commentary · Context [ms. 83]

The extra structure hidden in a categorical base

The word "bi-site" is Grothendieck's way of isolating information that a bare presentation of a homotopy theory does not remember. The categories S/s and $s\backslash S$ retain the orientation of arrows in S. Localizing the total category alone can destroy that orientation. Consequently a construction which is invariant under weak homotopy equivalence of the base cannot, without additional input, recover both of the directed diagram theories.

The labels also need a small correction in the surrounding prose. A local isomorphism is a discrete fibration, modelled by a slice projection $S/s \to S$; these test W_S^{g}. A co-local isomorphism is a discrete opfibration, modelled by $s\backslash S \to S$; these test W_S^{d}. The sentence at manuscript p. 82

interchanges the two superscripts. The conventions at pp. 83, 94, and 135 agree with the comma definitions above. The edition's wording is retained, and the correction register records the swap. This is a notational slip, not a change in the comparison theorem.

There is a useful historical continuity here. In Grothendieck (1983, §69, pp. 1–3 of the edited extract), Grothendieck describes the passage from one derived category to the family of derived categories of diagrams, relates the motivation to the SGA 5 trace formalism, and then formulates the two Kan-extension adjoints. The present passage asks for a converse kind of explanation: which geometric structure on a category of models permits its objects themselves to serve as indexing bases? For Cat, the answer uses comma categories and the two orientations. It is not supplied merely by knowing that its localization presents spaces.

This also explains the distinction from a slice of a model category. For $S \in \mathcal{M}$, the ordinary slice model structure, when available, localizes maps by their total weak equivalences. That is the coarse theory in these notes. A category of diagrams indexed by an ordinary category S, with objectwise weak equivalences, has a different role: it retains the directed indexing shape. In Cat the same symbol S can play both roles, which is precisely what makes their comparison possible and initially deceptive.

No Grothendieck topologies or covering axioms for the four adjectives are defined in this paragraph. The expectations about equal cohomology should therefore be recorded as a programme, rather than as a theorem about a specified pair of sites. In particular, the remark identifying "étale" and "Zariski" belongs to these categorical local-isomorphism intuitions; it is not an assertion that the Čech or sheaf theories of the *scheme-theoretic* ètale and Zariski topologies coincide. The precise comparison statements available in these pages are the comma and fine-localization equivalences already established.

Cette rapide digression ne convainc à présent que la compatibilité dite pour la construction de $C(X)$ et $i_X : X \longrightarrow C(X)$, ne peut en aucun cas être purement formelle, une pure histoire de catégories de Quillen disons. Ça donnera au mieux la compatibilité dans $(\mathcal{M}/S)W_S^{-1}$, ce qui est ridicule! Mais si on prend comme localiseur Σ dans $\mathcal{M}/S$ les isomorphismes sans plus, la relation de compatibilité va devenir fausse à tous les coups! Comme ensemble de flèches Σ un peu plus raisonnable, qui soit encore très petit, on peut songer p. ex. à la W-équivalence *universelle* sur S (nettement plus fine encore que W_S^{d}, W_S^{g} dans le cas particulier de Cat). Aurait-on encore compatibilité pour cet ensemble de flèches? Je suis aussi un peu perplexe par le fait (pas bien compris) que les formules d'adjonction pour les topologies Zariskienne et co-Zariskienne soient en sens opposé. (Ou me serai-je trompé en dualisant à la va-vite?) Mais à vrai dire, cette compatibilité à elle seule, même quand on utilise une structure de site sur $\mathcal{M}$, ne suffit pas à écrire une formule d'adjonction. On a deux catégories localisées,

$$\mathrm{HOT}^{\mathrm{lc}}_{\mathcal{M}} = (\mathcal{M}/S)W_S^{-1}, \qquad \mathrm{HOT}_W(S) = (\mathcal{M}/S)(W_S^{\mathrm{f}})^{-1},$$

où W_S^{f} désigne une W-équivalence 'fine', correspondant à la notion de localisation, plus exactement aux changements de base 'admissibles' qu'on a choisis, et on a un foncteur de localisation [page 85]

$$\mathrm{Hot}_W(S) \longrightarrow \mathrm{Hot}^{\mathrm{lc}}_W(S),$$

mais pas de foncteur en sens inverse. Mais si, mais si, en travaillant avec la catégorie similaire Fibhot S, ça doit garder un sens tout au moins quand on a une bonne notion de 'fibration'. Je vois un petit travail de dégrossissage conceptuel à faire, avec peut-être une formule d'adjonction à la clef, mais je ne vais pas m'y lancer à présent.

Commentary · Development (commentators') [ms. 84]

A universal version of the coherence calculation

For the categorical replacement used here, the question has an affirmative answer under the standing hypotheses of the Theorem-Scholie. Put $U_S = \{u \mid u \times_S T \in W_T \text{ for every } T \to S\}$. Part III of the Scholie identifies W_S with the fibrewise class W_S^{f} on the full subcategory of Hot-fibrant objects. These objects are stable under arbitrary strict base change, as the source states

explicitly at manuscript p. 119. If $u : P \to Q$ is a coarse weak equivalence between such objects and $f : T \to S$ is arbitrary, the fibre of its pullback at $t \in T$ is precisely

$$(u \times_S T)_t = u_{f(t)}.$$

It therefore belongs to W. The pulled-back source and target remain Hot-fibrant, so Part III over T gives $u \times_S T \in W_T^{\mathrm{f}} = W_T$. This proves that U_S and W_S agree between Hot-fibrant objects; the converse uses the identity base change.

The values of C are perfect, hence Hot-fibrant. Naturality of $\eta : 1 \to C$ and two-out-of-three imply $C(W_S) \subseteq W_S$, and the preceding comparison strengthens this to $C(W_S) \subseteq U_S$. Likewise η_{CX} is a coarse weak equivalence between Hot-fibrant objects and therefore lies in U_S. Both iterated units are now invertible in $(\mathrm{Cat}/S)U_S^{-1}$, so the cancellation lemma at manuscript p. 82 proves

$$C\eta_X = \eta_{CX} \quad \text{in } (\mathrm{Cat}/S)U_S^{-1}.$$

The unit and counit construction below then gives the corresponding reflection. Thus the source's particular question is answered using its fibrewise comparison and base-change stability; no additional identification of strict pullbacks with homotopy pullbacks is needed for that application.

There is also a useful sufficient criterion for other replacements, formulated directly in homotopy-theoretic terms. Here its additional hypothesis is explicit.

Proposition (universal comparison for good replacements). [ours] Fix S and $W = W_\infty$. Let $\mathcal{H} \subseteq \mathrm{Cat}/S$ be a full subcategory such that, for every $P \to S$ in $\mathcal{H}$ and every $T \to S$, the canonical square obtained by applying nerves to $P \times_S T$ is a homotopy pullback square. Suppose $C : \mathrm{Cat}/S \to \mathcal{H}$ has a natural map $\eta : 1 \to C$ whose components belong to W_S. Let U_S consist of those maps f over S for which $f \times_S T$ is a weak equivalence for every $T \to S$. Then

$$C(W_S) \subseteq U_S, \qquad C\eta_X = \eta_{CX} \quad \text{in } (\mathrm{Cat}/S)U_S^{-1}.$$

Moreover the canonical functor

$$(\mathrm{Cat}/S)U_S^{-1} \longrightarrow (\mathrm{Cat}/S)W_S^{-1}$$

has a fully faithful right adjoint induced by C.

To prove the assertion, first consider a coarse weak equivalence $f : P \to Q$ between objects of $\mathcal{H}$. For any $T \to S$, its base change is represented, up to weak equivalence, by the map between homotopy pullbacks

$$NP \times^h_{NS} NT \longrightarrow NQ \times^h_{NS} NT.$$

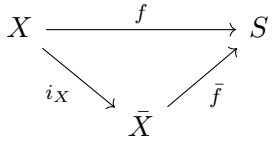
This is an equivalence because homotopy pullback preserves equivalences of diagrams. Thus $f \in U_S$. The converse holds by taking $T = S$. Consequently U_S and W_S agree on maps between objects of $\mathcal{H}$.

Naturality and two-out-of-three imply that C preserves W_S. Its values lie in $\mathcal{H}$, so the preceding paragraph gives $C(W_S) \subseteq U_S$. Also η_{CX} is a coarse equivalence between two objects of $\mathcal{H}$, hence belongs to U_S. In $(\mathrm{Cat}/S)U_S^{-1}$ the two iterated units are therefore invertible. The cancellation lemma at manuscript p. 82 proves their equality. The unit of the proposed adjunction is the image of η, and its counit in the coarse localization is the inverse of that image. The two triangle identities follow from this equality and from $\eta^{-1}\eta = 1$. Since the counit is invertible, the right adjoint is fully faithful. This proves all assertions.

This second criterion applies only after its homotopy-pullback hypothesis has been established, for example by a relative Theorem B argument after each base change. It does not infer that hypothesis solely from the word "fibration", and it does not assert that every category equipped only with weak equivalences has such a replacement. The later Theorem-Scholie 2, especially manuscript pp. 111–112, supplies the abstract comparison for any finer class agreeing on fibrant objects; the opening argument verifies that agreement for the source's universal class. Our contribution here is the explicit verification for universal equivalences by the two stated methods. We checked the localization criterion in Lurie (2009, Proposition 5.2.7.4) and the source's later abstract theorem; no priority is claimed for either ingredient.

p. 54

16.11.90



Je vais quand même essayer de faire un travail 'de dégrossissage', car le diagramme des 15 catégories a l'air un peut touffu, finalement! Je me donne

$$(\mathcal{M}, W) \qquad W \subseteq \mathrm{Fl}\,\mathcal{M},$$

un $S \in \mathrm{Ob}\,\mathcal{M}$, d'où $\mathcal{M}/S$, avec $W_S \subseteq \mathrm{Fl}(\mathcal{M}/S)$ induit par W. On va poser

$$\mathrm{Ho}^{\mathrm{lc}}(S) = (\mathcal{M}/S)W_S^{-1},$$

ça jouera le rôle des types d'homotopie relativement constants. Je suppose d'autre part que l'on a distingué une classe $F \subseteq \mathrm{Fl}(\mathcal{M})$ de flèches, jouant le rôle de 'fibrations' (ce seront les morphismes Hot-fibrants dans Cat, donnant lieu à la sous-catégorie $\underline{\mathrm{Fib}}\,\mathrm{hot}\,S$ de Cat/S). Je prévois qu'il faudra supposer, outre que $\mathcal{M}$ est stable par $\varprojlim$ finie, que F est stable par changement de base quelconque, et stable par composition, qu'il contient les isomorphismes. Et surtout qu'on a un théorème de factorisation [page 86]

$$i_X \in W,\ \bar{f} \in F$$

pout toute flèche f dans $\mathcal{M}$. Chez Quillen on exige même que i_X ait la propriété de relèvement à droite relativement à F, mais ça ne devrait pas être essentiel, puisque je n'ai pas eu à utiliser ce fait dans Cat. Quand je travaille dans la catégorie $\mathcal{M}/S$, où f est sous-entendu pour un objet X de ladite, je noterai (par abus de langage) $C(X)$ pour $\bar{X}$, bien qu'il n'est pas dit qu'on ait un choix canonique de $C(X)$, encore moins que $C(X)$ dépende fonctoriellement de X.

Commentary · Present state [ms. 85]

The locally constant inclusion has two adjoints

The programme has a sharper established form than the reflection proved here. For a derivator $\mathbb{D}$ and a small category A, Cisinski (2009, Proposition 3.10 and Theorem 3.13) proves that the full inclusion of locally constant coherent diagrams has both a left and a right adjoint, and that, for fixed A, these subcategories form a derivator in an additional diagram variable. This is not the assertion that the varying-base assignment $S \mapsto \mathrm{HOT}^{\mathrm{lc}}_W(S)$ is a derivator. These are the theorem numbers in the published 2009 article; its earlier preprint uses different numbering. The model-category construction is given there by the local structures of §2, with the fibrant objects characterized in Proposition 2.3.

For spaces, the reason is transparent in the language of homotopy-coherent functors. Let $q : NS \to \Pi_\infty S$ be groupoid completion. Restriction

$$q^* : \mathrm{Fun}((\Pi_\infty S)^{\mathrm{op}}, \mathrm{Spaces}) \longrightarrow \mathrm{Fun}((NS)^{\mathrm{op}}, \mathrm{Spaces})$$

is fully faithful and identifies its image with the functors carrying all arrows to equivalences. Its left and right Kan extensions give the two adjoints, since spaces admit small homotopy colimits and limits. Passing to homotopy categories gives the corresponding statement here.

The second adjoint of this one inclusion should not be identified with the functor j in the Scholie. The latter embeds the coarse category into a *different*, covariant fine theory. This keeps the later general theorem distinct from Grothendieck's two parallel reflections. The vague site comparison of the preceding paragraph requires a precise choice of sites before it acquires a similarly definite present status.

Désignons par

$$(*) \qquad \underline{\mathrm{Fib}}\,S \subseteq \mathcal{M}/S$$

la sous-catégorie de $\mathcal{M}/S$ formée des X dont le morphisme structural $f_X : X \longrightarrow S$ est dans F. Désignons (par abus de notation) par W_S le localiseur induit sur $\underline{\mathrm{Fib}}\, S$ par W_S, alors l'inclusion $(*)$ définit

$$(\underline{\mathrm{Fib}}\, S)W_S^{-1} \xrightarrow{\delta} (\mathcal{M}/S)W_S^{-1} \overset{\text{déf}}{=} \mathrm{Ho}_W^{\mathrm{lc}}(S).$$

Une première question, c'est de voir que c'est une équivalence. On voit que c'est essentiellement surjectif grâce à l'existence des $C(X)$, i_X. C'est peu! On va essayer de définir une flèche en sens inverse [page 87]

$$\bar{C} : (\mathcal{M}/S)W_S^{-1} \longrightarrow (\underline{\mathrm{Fib}}\, S)W_S^{-1},$$

i.e. un *foncteur* p. 55

$$\gamma : \mathcal{M}/S \longrightarrow (\underline{\mathrm{Fib}}\, S)W_S^{-1}$$

qui transforme $W_S \subseteq \mathrm{Fl}(\mathcal{M}/S)$ en isomorphismes. On choisira, pour X dans $\mathcal{M}/S$, un $C(X)$ dans $\underline{\mathrm{Fib}}\, S$ et une

$$i_X : X \longrightarrow C(X)\ , \qquad i_X \in W_S,$$

et on posera

$$\gamma(X) = C(X).$$

La difficulté, c'est de montrer que ça ne dépend pas des choix faits, à isomorphisme canonique près, et que c'est fonctoriel en X - et le deuxième implique le premier.

Pour voir que ça marche, visiblement il faut supposer quelque chose de plus. Je vois deux hypothèses qui, l'une et l'autre, pourraient faire marcher : l'une, c'est qu'on se donne déjà C comme foncteur et i_X fonctoriel en X (c'est ce qui était le cas dans Cat tantôt). L'autre, c'est que les i_X ont, par rapport à F, la propriété de relèvement à là Quillen. [page 88]

Commentary · Exposition [ms. 87]

Objectwise replacement and functorial replacement

The restart of 16 November isolates a familiar but consequential distinction. A weak equivalence $X \to C(X)$ with fibrant target gives a representative of each localized object; it does not by itself define a functor on localized morphisms. Grothendieck correctly stops at essential surjectivity before adding a hypothesis that controls maps.

In the functorial case the proof uses much less than a full model structure. Put $\mathcal{A} = \mathcal{M}/S$, let $\mathcal{H} = \underline{\mathrm{Fib}}S$ be full, and let $D : \mathcal{H} \hookrightarrow \mathcal{A}$ be its inclusion. Suppose $C : \mathcal{A} \to \mathcal{H}$ is a functor and $\eta : 1_{\mathcal{A}} \to DC$ has components in W_S. For $u : X \to Y$, naturality gives

$$DC(u)\eta_X = \eta_Y u.$$

If $u \in W_S$, two-out-of-three implies $C(u) \in W_S$. Hence both functors descend to the localizations. The transformation η becomes an isomorphism $1 \cong \overline{D}\,\overline{C}$. Restricting it to $\mathcal{H}$ gives $1 \cong \overline{C}\,\overline{D}$, since fullness ensures that the same components are maps in $\mathcal{H}$. Thus $\overline{C}$ and $\overline{D}$ are quasi-inverse equivalences.

For any full $\mathcal{F}$ with $\mathcal{H} \subseteq \mathcal{F} \subseteq \mathcal{A}$, the same proof applies to $C|_{\mathcal{F}}$ and the two inclusions. This proves the intermediate-category assertion at manuscript p. 89. No lifting axiom, finite-limit hypothesis, or base-change stability is used in this functorial branch. Those properties become relevant in the other branch, where lifts have to replace a functorial choice.

The word "fibrant" is relative to the chosen base: the objects of $\mathcal{H}$ are maps $X \to S$ in the distinguished class F. It does not assert that X is fibrant as an object of $\mathcal{M}$, unless S is terminal or an additional argument relates the two conditions. This distinction will also matter when path objects are formed inside the slice in the following pages.

Je commence par l'hypothèse que C est déjà un foncteur. Le diagramme

$$\begin{array}{ccc} X & \xrightarrow{i_X} & CX \\ {\scriptstyle u}\downarrow & & \downarrow{\scriptstyle C(u)} \\ X' & \xrightarrow{i_{X'}} & CX', \end{array}$$

où $i_X,\ i_{X'} \in W$, montre que C transforme W_S en W_S, donc en des isomorphismes de $\mathrm{Ho}^{\mathrm{lc}}_W(S)$. Donc on tient le foncteur cherché γ. On a en fait des foncteurs

$$\underline{\mathrm{Fib}}\, S \underset{C}{\overset{\overset{\text{incl.}}{D}}{\hookleftarrow}} \mathcal{M}/S$$

compatibles avec les localiseurs W_S, induisant δ et γ, et on a

$$\mathrm{id}_{\mathcal{M}/S} \longrightarrow DC, \qquad \text{dans } W_S \text{ argument par argument,}$$

car on a

$$X \xrightarrow{i_X} DC(X) = C(X)$$

avec $i_X \in W_S$. De même, on a

$$\mathrm{id}_{\underline{\mathrm{Fib}}\, S} \longrightarrow CD \qquad \text{dans } W_S \text{ argument par argument,}$$

avec le même p. 56

$$X \xrightarrow{i_X} CX \qquad (\text{cette fois } X \text{ dans } \underline{\mathrm{Fib}}\, S).$$

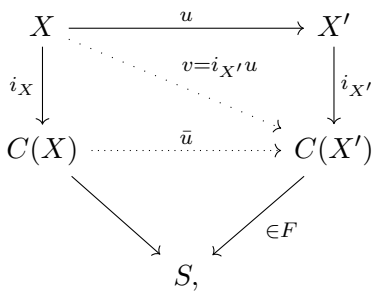
Donc on a sans larmes les deux foncteurs δ, γ comme quasi-inverses l'un de l'autre. Et le [page 89] lemme page 11 montre même que pour *toute* sous-catégorie pleine $\mathcal{F}$ de $\mathcal{M}/S$, telle que

$$\underline{\mathrm{Fib}}\, S \subseteq \mathcal{F} \subseteq \mathcal{M}/S,$$

les inclusions induisent des équivalences sur les localisés W_S

$$(\underline{\mathrm{Fib}}\, S)W_S^{-1} \xrightarrow{\sim} \mathcal{F}W_S^{-1} \xrightarrow{\sim} \underbrace{(\mathcal{M}/S)W_S^{-1}}_{\overset{\text{déf}}{=}\mathrm{Ho}^{\mathrm{lc}}_W(S)}.$$

Je vais traiter maintenant le cas de type Quillen, pour me convaincre que l'existence du foncteur C, et le choix particulier qu'on peut en faire, est irrelevant. (Ce dernier point est d'ailleurs évident a posteriori, quand on sait que δ est une équivalence, car le quasi-inverse γ sera alors unique à isomorphisme unique près, et le choix d'un foncteur C, et d'un homomorphisme fonctoriel $i : \mathrm{id} \longrightarrow C$, n'est qu'une façon parmi d'autres d'expliciter le quasi-inverse.)



On se place donc dans l'hypothèse quillénienne sur les i_X. On choisit $C(X)$, i_X pour [page 90] chaque X dans $\mathcal{M}/S$, et on pose comme tantôt

$$\gamma(X) = C(X) \qquad \text{comme objet de } (\mathcal{M}/S)W_S^{-1}.$$

Montrons que c'est fonctoriel en X. Soit

$$u : X \longrightarrow X'$$

dans $\mathcal{M}/S$, considérons le diagramme anodin (commutatif)

complétons le par la flèche en gros pointillés, $v = i_{X'}u$ (rendant le triangle supérieur commutatif). ([54]). L'hypothèse sur i_X implique que la flèche $\bar{u}$ en pointillés fins existe, de façon à avoir encore deux triangles commutatifs. Mais ça signifie exactement qu'il y a un *S-morphisme* $\bar{u}$, i.e. une flèche dans $\mathcal{M}/S$, rendant commutatif le carré p. 57

$$\begin{array}{ccc} X & \xrightarrow{u} & X' \\ {\scriptstyle i_X}\downarrow & & \downarrow{\scriptstyle i_{X'}} \\ C(X) & \xrightarrow{\bar{u}} & C(X'), \end{array}$$

et il s'impose de prendre [page 91]

$$\gamma(u) = \text{ image de } \bar{u} \text{ dans } \mathrm{Fl}((\underline{\mathrm{Fib}}\, S)W_S^{-1}).$$

Il faut prouver que cette flèche ne dépend pas du choix de $\bar{u}$. On doit dégager un Lemme, où on désigne par Cof_0 l'ensemble des flèches de $\mathcal{M}$ qu'ont la propriété de relèvement par rapport aux éléments de $\mathrm{Fib} = F$. (Cof_0 joue le rôle des cofibrations triviales.)

Commentary · Exposition [ms. 89]

What makes a comparison canonical

The desired independence of replacement is an independence with specified comparison maps. This qualification explains the otherwise too compressed phrase "unique à isomorphisme unique près" without introducing a new gap in the argument.

Suppose $\delta : \mathcal{H} \to \mathcal{A}$ is an equivalence, and γ, γ' are quasi-inverses equipped with isomorphisms $\epsilon : \delta\gamma \to 1$ and $\epsilon' : \delta\gamma' \to 1$. Full faithfulness of δ gives a unique natural transformation $\theta : \gamma \to \gamma'$ satisfying

$$\delta\theta = (\epsilon')^{-1}\epsilon.$$

Its components are invertible because their images are, so this is the unique comparison compatible with the specified identifications. This is the precise meaning needed for replacement functors. If the identifications are forgotten, a quasi-inverse can have nontrivial natural automorphisms; for the identity equivalence of the one-object category BC_2, its natural automorphisms are the two central elements of C_2.

At manuscript p. 90 the chosen map i_X has the *left* lifting property with respect to fibrations in current terminology: it is the left vertical side of the square, while $C(X') \to S$ is the right vertical side. The printed phrase "relèvement à droite" on p. 86 is resolved by this diagram. The lift supplies a possible $\bar{u} : C(X) \to C(X')$. Its uniqueness has not been asserted. What the next lemma proves is that different lifts give the same localized arrow. Once that is proved, identity and composition follow by choosing the identity lift and the composite lift. This is how a nonfunctorial choice of fibrant objects becomes a genuinely functorial construction after localization.

Lemme. *Soit un diagramme en traits pleins dans* $\mathcal{M}/S$

$$\begin{array}{ccc} X & \xrightarrow{u} & X' \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle i'} \\ C & \overset{v}{\cdots\!\rightarrow} & C' \end{array}$$

54. Lemme : soit

$$\begin{array}{ccc} X & \xrightarrow{u} & X' \\ {\scriptstyle i}\downarrow & & \downarrow \\ C & \cdots\!\rightarrow & C' \end{array}$$

dans $\mathcal{M}/S$ avec $i \in \mathrm{Cof}_0$, $(C' \longrightarrow S) \in F = \mathrm{Fib}$, alors la flèche en pointillés existe dans $\mathcal{M}/S$, de façon à rendre le carré commutatif. `[cf. Lemme p. 91]`

avec $i \in Cof_0$, et $C' \in Ob\,\underline{\mathrm{Fib}}\,S$ i.e. $(C' \longrightarrow S) \in Fib$. Alors v existe, de façon à rendre le carré commutatif. De plus, si $i \in W$ et $C \in \mathrm{Ob}\,\underline{\mathrm{Fib}}\,S$, la classe de v comme flèche de $(\underline{\mathrm{Fib}}\,S)W_S^{-1}$ en est indépendante du choix fait.

Il reste à prouver cette indépendance, ce qui résultera aussitôt du corollaire : [page 92]

Commentary · Context [ms. 91]

Choosing replacements without choosing a functor

Grothendieck is separating the existence of good representatives from the possibility of doing mathematics with them. A factorization of every object over S gives a representative in $\underline{\mathrm{Fib}}\,S$, but it does not yet identify the morphisms of the two localizations. That is the work of the next lemma. The question is narrower than the construction of a model category: we require enough lifting to extend a map into a fibrant object, and enough paths to make two extensions agree after localization.

The lifting class is

$$\mathrm{Cof}_0 = {}^{\perp}\mathrm{Fib}.$$

Thus its maps have the *left* lifting property against fibrations. Neither the notation nor the definition says that every member of this class lies in W; this is why the factorization hypothesis subsequently asks for $i_X \in \mathrm{Cof}_0 \cap W$. The manuscript's occasional phrase "relèvement à droite" describes the wrong side of the lifting square, as the editors explicitly correct on p. 108. For the extension problem here, the right vertical arrow is the structural map $C' \to S$. The square with top arrow $X \to C'$ and bottom arrow $C \to S$ has a lift because $i : X \to C$ belongs to ${}^{\perp}\mathrm{Fib}$. No choice of a cleavage or of a functorial factorization is involved.

What must become canonical is the *class* of the extension, not an actual extension. Once its class is independent of the lift, a composite of two chosen lifts is itself an allowable lift of the composite. Independence therefore supplies compatibility with composition. This is an instructive instance of a construction becoming functorial only after passing to a homotopy category.

In modern language the other route, hypothesis A, is a right deformation: an endofunctor C with a natural weak equivalence $\mathrm{id} \to C$ and values in a full subcategory of good objects. The equivalence of localizations follows from this data, without a model structure; compare the dual of Riehl (2014, Definition 2.2.1 and Remark 2.2.2). Hypothesis B replaces this strictly natural data by lifting and a proof of independence. Its advantage is that a model category supplies it even when we do not wish to choose a functorial factorization. Its cost is the relative path-object argument that Grothendieck now gives.

Corollaire. *Soit un diagramme dans $\mathcal{M}/S$*

$$X \xrightarrow{\ i\ } C \underset{v_2}{\overset{v_1}{\rightrightarrows}} C',$$

avec C et C' dans $\underline{\mathrm{Fib}}\,S$ (i.e. $C \longrightarrow S$ et $C' \longrightarrow S$ dans Fib), et $i \in Cof_0$ et $i \in W$. Si $v_1 i = v_2 i$, alors v_1 et v_2 définissent la même flèche de $(\underline{\mathrm{Fib}}\,S)W_S^{-1}$.

Démonstration. Soit [p. 58]

$$v = (v_1, v_2) : C \longrightarrow C' \times C',$$

[plutôt $C' \times_S C'$] qui rend commutatif par hypothèse le diagramme

$$\begin{array}{ccc} X & \xrightarrow{\ w\ } & C' \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle \mathrm{diag}_{C'}} \\ C & \xrightarrow{\ v\ } & C' \times_S C', \end{array}$$

où $w = v_1 i = v_2 i$. Factorisons $\mathrm{diag}_{C'}$ en

$$C' \xrightarrow{\ i'\ } \bar{C}' \xrightarrow{\ \delta'\ } C' \times_S C', \qquad \text{avec } \delta' \in \mathrm{Fib},$$

et $i' \in W$. On trouve un carré commutatif

$$\begin{array}{ccccc} X & \xrightarrow{w'=i'w} & \bar{C}' & & \\ {\scriptstyle i}\downarrow & \overset{\bar{v}}{\nearrow} & \downarrow{\scriptstyle \delta'} & & \\ C & \xrightarrow{v} & C' \times_S C' & \underset{\mathrm{pr}_2}{\overset{\mathrm{pr}_1}{\rightrightarrows}} & C' \end{array}$$

avec $i \in \mathrm{Cof}_0$, $\delta' \in \mathrm{Fib}$, d'où l'existence de la flèche en pointillés, rendant les deux triangles commutatifs. On veut prouver $\mathrm{pr}_1 \circ v = \mathrm{pr}_2 \circ v$ dans $(\underline{\mathrm{Fib}}\, S)W_S^{-1}$, comme $v = \delta'\bar{v}$ il suffit de prouver que l'on a $\mathrm{pr}_1\delta' = \mathrm{pr}_2\delta'$ dans $(\underline{\mathrm{Fib}}\, S)W_S^{-1}$.

Il faut seulement vérifier d'abord (pour justifier l'argument) que cette assertion a un [page 93] sens, i.e. que $\bar{C}'$ est lui aussi dans $\underline{\mathrm{Fib}}\, S$. Mais les hypothèses de stabilité de $F = \mathrm{Fib}$ par changement de base et composition assurent que 1°) $C' \times_S C'$ est dans $\underline{\mathrm{Fib}}\, S$ (qui est stable par produit), et par suite, 2°) que $\bar{C}'$ l'est aussi, puisque $\delta' \in \mathrm{Fib}$. Comme C' est aussi dans $\underline{\mathrm{Fib}}\, S$ et $C' \xrightarrow{i'} \bar{C}'$ est dans W_S, pour vérifier $\mathrm{pr}_1\delta' = \mathrm{pr}_2\delta'$ dans le localisé de $\underline{\mathrm{Fib}}\, S$, il suffit de voir que $(\mathrm{pr}_1\delta')i' = (\mathrm{pr}_2\delta')i'$, or comme $\delta'i' = \mathrm{diag}_{C'}$, on a l'égalité même dans $\underline{\mathrm{Fib}}\, S$ (sans localiser).

On a donc défini $\gamma(X)$, $\gamma(u)$ pour objets et flèches de $\mathcal{M}/S$. La transitivité pour $\gamma(u)$ est claire, et aussi $\gamma(\mathrm{id}) = \mathrm{id}$. Donc on tient le foncteur

$$\gamma : \mathcal{M}/S \longrightarrow (\underline{\mathrm{Fib}}\, S)W_S^{-1}.$$

Soit maintenant $\mathcal{F}$ une sous-catégorie pleine de $\mathcal{M}/S$, avec

$$\underline{\mathrm{Fib}}\, S \subseteq \mathcal{F} \subseteq \mathcal{M}/S,$$

considérons γ comme foncteur à valeurs dans $\mathcal{F}W_S^{-1}$. (J'ai oublié de vérifier que γ transforme W_S dans W_S, mais c'est tautologique.) Ainsi on a des foncteurs

p. 59

$$\mathcal{F}W_S^{-1} \underset{\gamma}{\overset{\delta}{\rightleftarrows}} (\mathcal{M}/S)W_S^{-1},$$

il faut voir qu'ils sont quasi-inverse l'une de l'autre. [page 94]

Commentary · Exposition [ms. 93]

The path object makes the choices agree

Grothendieck's proof works inside the subcategory whose localization we want to understand. This point prevents a circular argument: knowing that two lifts become equal in $(\mathcal{M}/S)[W_S^{-1}]$ would not yet show that they become equal in $(\underline{\mathrm{Fib}}\, S)[W_S^{-1}]$, since full faithfulness of the inclusion is precisely what remains to be proved.

Write $\mathcal{A} = \mathcal{M}/S$ and $\mathcal{F} = \underline{\mathrm{Fib}}\, S$. Suppose that $v_1, v_2 : C \to C'$ agree after precomposition with $i : X \to C$, where i has the left lifting property against fibrations and C, C' lie in $\mathcal{F}$. Factor the relative diagonal as

$$C' \xrightarrow{j} P \xrightarrow{(d_0,d_1)} C' \times_S C', \qquad j \in W, \quad (d_0, d_1) \in \mathrm{Fib}.$$

The object $C' \times_S C'$ is fibrant over S: either projection is a pullback of $C' \to S$, and its composite with the other structural map is a fibration. The same is true of P. The equalities $d_0 j = d_1 j = \mathrm{id}_{C'}$ therefore take place in $\mathcal{F}$. Since j is inverted in $\mathcal{F}[W^{-1}]$, we obtain $d_0 = d_1 = j^{-1}$ there.

The square with left side i, right side (d_0, d_1), bottom side (v_1, v_2), and top side $jv_1i = jv_2i$ has a lift $h : C \to P$. Consequently $v_1 = d_0h = d_1h = v_2$ in $\mathcal{F}[W^{-1}]$. This is the whole independence argument. In fact, the additional condition $i \in W$ is not needed for this particular conclusion. It is needed when the chosen i_X are used to compare an arbitrary object with its replacement.

For completeness, let $u : X \to Y$ and choose a lift $\bar{u} : CX \to CY$ satisfying $\bar{u}i_X = i_Y u$. Define $\gamma(u) = [\bar{u}]$. The identity of CX is a permissible lift for id_X, and $\bar{v}\bar{u}$ is a permissible lift for vu.

Independence proves the functor laws. If $u \in W$, the equation $\bar{u} i_X = i_Y u$ and two-out-of-three imply $\bar{u} \in W$. Thus γ descends through the localization at W_S.

The same squares finish the naturality checks left on p. 94. In the coarse localization they give a natural isomorphism $\mathrm{id} \xrightarrow{\sim} D\gamma$, where D denotes inclusion. On any full intermediate subcategory $\mathcal{F} \subseteq \mathcal{G} \subseteq \mathcal{A}$, both X and CX belong to $\mathcal{G}$, so the same maps give the second natural isomorphism $\mathrm{id} \xrightarrow{\sim} \gamma D$. These two isomorphisms establish the comparison theorem without identifying arbitrary fractions by hand. The proof also records exactly where closure of Fib under pullback and composition is used: in constructing the path object *inside* $\mathcal{F}$.

Du côté de $\mathcal{M}/S$: on doit comparer X et $\delta\gamma(X) = C(X)$, c'est fait par

$$i_X : X \longrightarrow C(X)$$

qui est dans W_S, d'où l'isomorphisme dans le localisé

$$X \simeq \delta\gamma(X) \qquad \text{dans } (\mathcal{M}/S)W_S^{-1}.$$

Il faut vérifier que c'est fonctoriel en X.

Du côté de $\mathcal{F}$, comparer X et $\gamma\delta(X)$, i.e. X et $C(X)$. Même tabac, on choisit $i_X : X \simeq C(X) = \gamma\delta(X)$. À vérifier la fonctorialité.

Il s'agit maintenant d'introduire un localisé plus fin de $\mathcal{M}/S$. Pour ceci, on suppose donné une autre classe de morphismes, je l'appelle $\mathcal{L}$ (comme 'localisation')

$$\mathcal{L} \subseteq \mathrm{Fl}(\mathcal{M}),$$

p. ex. dans le cas de $\mathcal{M} = \mathrm{Cat}$, $\mathcal{L}$ sera formée des isomorphismes locaux ([55]) (s'il s'agit de définir W_S^{g}), ou des isomorphismes colocaux ([56]) (s'il s'agit de définir W_S^{d}). On supposera que $\mathcal{L}$ contient les isomorphismes, et $\mathcal{L}$ stable par composition ([57]), mais non par changement de base. On définit alors

$$W_S^{\mathcal{L}} \subseteq \mathrm{Fl}(\mathcal{M}/S)$$

par

$$f \in W_S^{\mathcal{L}} \overset{\text{déf}}{\Longleftrightarrow} (f \times_S S') \in W, \quad \forall (S' \longrightarrow S) \in \mathcal{L}.$$

[page 95]

Comme $\mathcal{L}$ contient id_S, on aura

$$W_S^{\mathcal{L}} \subseteq W_S,$$

d'où un foncteur canonique

$$\underbrace{(\mathcal{M}/S)(W_S^{\mathcal{L}})^{-1}}_{\overset{\text{déf}}{=}\mathrm{Ho}_W^{\mathcal{L}}(S)} \xrightarrow{\rho} \underbrace{(\mathcal{M}/S)(W_S)^{-1}}_{\overset{\text{déf}}{=}\mathrm{Ho}_W^{\mathrm{lc}}\mathcal{L}(S)}$$

qui est un foncteur de localisation. Je voudrais définir un foncteur en sens inverse. Pour ceci, p. 60
il est naturel de supposer (en analogie avec la situation de Cat)

Hypothèse 1. *Sur* $\underline{\mathrm{Fib}}\, S$, $W_S = W_S^{\mathcal{L}}$, *i.e. si* $f : X \longrightarrow Y$ *est dans* W *et* X, Y *dans* $\underline{\mathrm{Fib}}\, S$, *alors pour tout changement de base* $S' \longrightarrow S$ *qui est dans* $\mathcal{L}$, $f' : X_{S'} \longrightarrow Y_{S'}$ *est encore dans* W.

Dans le contexte de Quillen, cette hypothèse a une nette tendance à être vérifiée quelque soit $\mathcal{L}$, i.e. pout *tout* changement de base $S' \longrightarrow S$ sans restriction. Il suffit en fait que la structure de Quillen soit 'propre', plus précisément (et moins restrictivement), qu'un `[morphisme]` $\in W$ reste tel après changement de base par un morphisme $\in$ Fib. Dégageons ceci comme un Lemme.

[page 96]

Lemme. *L'hypothèse est vérifiée si on suppose que $F = Fib$ et W sont reliés par la condition supplémentaire (en plus de la factorisation i_X) : pour tout carré cartésien*

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow{p} & S', \end{array}$$

si f est dans Fib et p dans W, alors $q \in W$.

Commentary · Exposition [ms. 95]

Testing equivalences after change of base

The class $W_S^{\mathcal{L}}$ is designed to remember information that a total-space equivalence can lose. It asks that an equivalence survive every observation of the base allowed by $\mathcal{L}$. At this stage $\mathcal{L}$ is a collection of tests, not a topology and not a system of weak equivalences. Its role is entirely expressed by pullback.

For a fixed base S, the definition can be written

$$W_S^{\mathcal{L}} = \bigcap_{(g:T\to S)\in\mathcal{L}} (g^*)^{-1}(W_T).$$

Each inverse image contains the isomorphisms and satisfies two-out-of-three; so does their intersection. The identity test gives $W_S^{\mathcal{L}} \subseteq W_S$. These statements use neither closure of $\mathcal{L}$ under composition nor closure under base change. The doubt in footnote 57 therefore has a positive answer for this part of the construction.

Composition becomes useful when we move the base. If $g : T \to S$ lies in $\mathcal{L}$ and $\mathcal{L}$ is composition-closed, then

$$g^*(W_S^{\mathcal{L}}) \subseteq W_T^{\mathcal{L}}.$$

Indeed, for a further test $h : U \to T$ in $\mathcal{L}$, the pullback h^*g^*u is canonically isomorphic to $(gh)^*u$, and gh is an allowed test over S. This proves contravariance along the chosen class. Contravariance along an arbitrary g would need the stronger condition that gh be allowed whenever h is allowed; it does not follow from the definition alone.

The localization functor ρ forgets the extra tests. The question about a right adjoint concerns a special class of objects on which those tests no longer distinguish additional weak equivalences. Hypothesis 1 says exactly that: two fibrations over S which are equivalent on total spaces remain equivalent after every allowed base change. It permits the inclusion of fibrant objects to descend to the finer localization. It does *not* say that every map $X \to CX$ is a fine equivalence; that would make the reflection an equivalence and erase the very distinction being introduced.

For the categorical localizers earlier in the chapter, local and colocal tests retain opposite directions of a diagram. Under the standing fundamental-localizer hypotheses, the two suggestions in footnotes 55–56 follow from the base-change theorem discussed at p. 122 below. Every proper base change preserves W_S^{d}, and hence preserves the total weak equivalence of such a map. Conversely, the coslice projections $s\backslash S \to S$ are proper: they are discrete opfibrations. Testing against all proper maps therefore includes the defining coslice tests and gives exactly W_S^{d}. The dual argument identifies testing against smooth maps with W_S^{g}. When properness or smoothness is taken relative to a specified W, the corresponding relative base-change criterion is the needed hypothesis. These conclusions do not extend to an arbitrary test class in an arbitrary relative category. The commentary on Chapter I, manuscript pp. 52–58, and on this chapter, pp. 41–44, explains the geometric criteria; the abstract argument here needs only equality of the two localizers on $\underline{\mathrm{Fib}}\, S$.

Démonstration. Soit

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & S & \end{array}$$

55. Ou aussi, des morphismes *lisses*. Ça doit donner le même résultat.
56. Ou aussi des morphismes propres.
57. Il n'en est peut-être pas besoin.

avec p, $q \in \mathrm{Fib}$, $f \in W$, montrons que pour *tout* changement de base $g : S' \longrightarrow S$, $f_{S'} : X_{S'} \longrightarrow Y_{S'}$ est encore dans W. On factorise g en

$$S' \xrightarrow{i} \bar{S}' \xrightarrow{\bar{g}} S, \qquad\qquad i \in W,\ g \in \mathrm{Fib},$$

[plutôt $\bar{g} \in$ Fib] et on est ramené à prouver que l'assertion est vraie dans les deux cas particuliers où $g \in \mathrm{Fib}$, ou $g \in W$. Le cas $g \in \mathrm{Fib}$ résulte aussitôt de l'hypothèse du Lemme (appliquée au carré cartésien

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{f} & Y, \end{array}$$

où $p \in \mathrm{Fib}$.) p. 61

Dans le cas où $S' \longrightarrow S$ est dans W, il s'ensuit par l'hypothèse du Lemme appliquée à

$$\begin{array}{ccc} Y & \xleftarrow{p} & Y' \\ \downarrow{\scriptstyle \in \mathrm{Fib}} & & \downarrow \\ S & \longleftarrow & S' \end{array}$$

que $p : Y' \longrightarrow Y$ est $\in W$, et de même pour $q : X' \longrightarrow X$, et $f \in W$ implique encore $f' \in W$. [page 97]

Revenons à l'hypothèse p. 95. On aura donc un foncteur

$$(\underline{\mathrm{Fib}}\, S, W_S = W_S^{\mathcal{L}}) \longrightarrow (\mathcal{M}/S, W_S^{\mathcal{L}}),$$

d'où pour les localisés un foncteur horizontal

$$\begin{array}{ccc} (\underline{\mathrm{Fib}}\, S)W_S^{-1} & \xrightarrow{\quad i_0 \quad} & (\mathcal{M}/S)(W_S^{\mathcal{L}})^{-1} \overset{\text{déf}}{=} \mathrm{Ho}_W^{\mathcal{L}}(S) \\ \downarrow{\scriptstyle \approx} & \nearrow & \\ \mathrm{Ho}_W^{\mathrm{lc}}(S) \overset{\text{déf}}{=} (\mathcal{M}/S)W_S^{-1} & & \end{array}$$

qui factorise le foncteur vertical induit par l'inclusion $(\underline{\mathrm{Fib}}\, S, W_S) \longrightarrow (\mathcal{M}/S, W_S)$ - foncteur dont on a vu (dans les deux cas envisagés) que c'est une équivalence. En inversant ce dernier et le composant avec i_0, on trouve donc un foncteur

$$\underbrace{\mathrm{Ho}_W^{\mathrm{lc}}(S)}_{\overset{\text{déf}}{=}(\mathcal{M}/S)W_S^{-1}} \xrightarrow{\ i\ } \underbrace{\mathrm{Ho}_W^{\mathcal{L}}(S)}_{\overset{\text{déf}}{=}(\mathcal{M}/S)(W_S^{\mathcal{L}})^{-1}} ,$$

tel que

$$\rho i \simeq \mathrm{id},$$

donc une *rétraction* de $\mathrm{Ho}_W^{\mathcal{L}}(S)$ sur $\mathrm{Ho}_W^{\mathrm{lc}}(S)$. On s'attend que i soit pleinement fidèle, et plus précisément encore, que ρ et i soient adjoints, i étant l'adjoint à droite de ρ : [page 98]

$$\mathrm{Ho}_W^{\mathrm{lc}}(S) \underset{i}{\overset{\rho}{\leftrightarrows}} \mathrm{Ho}_W^{\mathcal{L}}(S),$$

i.e. on cherche p. 62

$$i\rho \quad \underbrace{\xleftarrow{\ i\ }}_{\textit{pas}\ \text{iso}} \quad \text{id} \quad \text{dans } \mathrm{Ho}_W^{\mathcal{L}} \quad (\text{localisation par } W_S^{\mathcal{L}})$$

$$\rho i \quad \underbrace{\xrightarrow{\ p\ }}_{\text{iso}} \quad \text{id} \quad \text{dans } \mathrm{Ho}_W^{\mathrm{lc}} \quad (\text{localisation par } W_S),$$

`[trop de i's]` donc pour X dans $\mathcal{M}/S$, on cherche

$$\begin{aligned} i_X : \quad X \quad &\longrightarrow \quad C(X) \quad \text{tout au moins dans } (\mathcal{M}/S)(W_S^{\mathcal{L}})^{-1} \\ p_X : \quad X \quad &\longleftarrow \quad C(X) \quad \text{tout au moins dans } (\mathcal{M}/S)(W_S)^{-1}. \end{aligned}$$

On choisira pour i_X la flèche 'canonique' de X dans $C(X)$, définie dans $\mathcal{M}/S$ lui-même, sans avoir à localiser. Mais dans le 'cas Quillen' (quand C n'est pas donné comme foncteur $\mathcal{M}/S \longrightarrow \underline{\mathrm{Fib}}\, S$), il faut voir que cet i_X est fonctoriel en X, quand on le regarde dans le localisé $(\mathcal{M}/S)W_S^{-1}$. Mais c'est contenu dans la construction de C comme *foncteur*

$$\mathcal{M}/S \longrightarrow (\underline{\mathrm{Fib}}\, S)W_S^{-1}.$$

On notera que i_X est dans W_S sans plus, pas dans $W_S^{\mathcal{L}}$, donc ne définit pas en général un isomorphisme de $\mathrm{Ho}_W^{\mathcal{L}}$.

Commentary · Exposition [ms. 97]

Why the properness argument works

Grothendieck wants an easily checked condition which guarantees that a weak equivalence between fibrations remains an equivalence after a change of base. The lemma gives a sufficient condition in his sparse axiomatic setting. Its two cases are worth keeping distinct, because they apply the same properness axiom to different squares.

Let $u : X \to Y$ be a weak equivalence over S, with $X \to S$ and $Y \to S$ fibrations, and let $g : T \to S$. Factor g as

$$T \xrightarrow{a} \bar{T} \xrightarrow{b} S, \qquad a \in W, \quad b \in \mathrm{Fib}.$$

First pull back along b. The map $Y \times_S \bar{T} \to Y$ is a fibration, being a pullback of b. Right properness, applied to u along this fibration, says that $u_{\bar{T}}$ lies in W. The structural maps of its source and target over $\bar{T}$ are still fibrations.

Now pull back along a. Right properness applied to those two structural fibrations says that both projections

$$X \times_S T \longrightarrow X \times_S \bar{T}, \qquad Y \times_S T \longrightarrow Y \times_S \bar{T}$$

lie in W. In their commutative square the lower horizontal arrow is $u_{\bar{T}} \in W$. Two-out-of-three proves $u_T \in W$. This completes the argument, with no assumption that g itself be a fibration or a weak equivalence.

The sufficient condition is stronger than necessary in a full Quillen model category. For every map $g : T \to S$, the pullback functor between the slice model categories preserves fibrations and trivial fibrations. It is right adjoint to postcomposition with g, and is therefore a right Quillen functor. The dual of Ken Brown's lemma shows that it preserves weak equivalences between objects fibrant in the slice. Thus Hypothesis 1 holds for all base changes in any model category, without global right properness. The base S need not itself be fibrant: fibrancy of $X \to S$ is fibrancy as an object of the slice model category. The corresponding statement for a category of fibrant objects is proved as Lemma C.1.11 of Riehl and Verity (2022), using Lemma C.1.10. This does not invalidate Grothendieck's proof: his preceding axioms are weaker than the full model-category axioms, so a separate sufficient condition is useful.

Right properness concerns pulling back an arbitrary weak equivalence *along a fibration*. The conclusion here concerns pulling back a weak equivalence *between two fibrations over the same base* along an arbitrary map. The factorization argument explains the passage from one arrangement to the other.

On définit p_X à l'aide de i_X, comme l'inverse de i_X *dans* $(\mathcal{M}/S)W_S^{-1}$, qui existe car i_X est dans W_S, donc `[est un]` isomorphisme dans $(\mathcal{M}/S)W_S^{-1} = \mathrm{Ho}_W^{\mathrm{lc}}$, et p est donc `[un]` [page 99] isomorphisme. On retrouve donc $\rho i \simeq \mathrm{id}$, donc que ρ est une *rétraction* de $\mathrm{Ho}_W^{\mathcal{L}}$ sur $\mathrm{Ho}_W^{\mathrm{lc}}$.

Pour prouver l'adjonction, en procédant comme dans le cas de Cat, on est ramené à prouver que pour tout X,

$$\begin{cases} C(i_X) = i_{C(X)} : C(X) \rightrightarrows C(C(X)) \\ \textit{dans } \mathrm{Ho}_W^{\mathcal{L}} \text{ (localisation par } W_S^{\mathcal{L}}). \end{cases}$$

J'y étais arrivé dans Cat, en utilisant un morphisme

$$C(C(X)) \xrightarrow{c} C(X)$$

(essentiellement, un morphisme de composition des chemins) tel que $c \in W_S^{\mathcal{L}}$, et que $c \circ C(i_X) = c \circ i_{C(X)}$. Ça avait l'air très délicat, car c'était à grand peine que j'étais arrivé à construire un foncteur $\underline{\mathrm{Ch}}$ ('chemins') raisonnable, où on puisse bel et bien composer les chemins! Je renonce pour le moment à axiomatiser les propriétés du foncteur $\underline{\mathrm{Ch}}$ dont j'ai besoin pour faire marcher la machine (je devrais y revenir tantôt). Je vais commencer plutôt par le 'cas Quillen', avec des $i_X \in \mathrm{Cof}_0$.

On reprend la description du 'foncteur' C (à valeurs dans $(\underline{\mathrm{Fib}}\, S)W_S^{-1}$, et alors sans guillemets), on trouve que $C(i_X)$, où p. 63 [page 100]

$$X \xrightarrow{u=i_X} X' = C(X)$$

est défini simplement (dans $(\underline{\mathrm{Fib}}\, S)W_S^{-1}$) par 'la' flèche $C(u)$ rendant commutatif le diagramme (dans $\underline{\mathrm{Fib}}\, S$)

$$\begin{array}{ccc} X & \xrightarrow{u\ (=i_X)} & X'\ (=C(X)) \\ {\scriptstyle i_X}\downarrow & & \downarrow{\scriptstyle i_{X'}\ (=i_{C(X)})} \\ C(X) & \xrightarrow[C(u)\ (=C(i_X))]{} & C(X')\ (=C(C(X))), \end{array}$$

de sorte qu'on a dans $\mathcal{M}/S$ le diagramme

$$X \xrightarrow{\overbrace{i_X}^{\in \mathrm{Cof}_0 \cap W}} \overbrace{C(X)}^{\in \mathrm{Ob}\,\underline{\mathrm{Fib}}\, S} \underset{C(i_X)}{\overset{i_{C(X)}}{\rightrightarrows}} \overbrace{C(C(X))}^{\in \mathrm{Ob}\,\underline{\mathrm{Fib}}\, S},$$

commutatif, i.e. $i_{C(X)} i_X = C(i_X) i_X$. Le corollaire page 92 nous dit que les flèches $i_{C(X)}$ et $C(i_X)$ sont égales dans $(\underline{\mathrm{Fib}}\, S)W_S^{-1}$. Mais par hypothèse (p. 95), dans $\underline{\mathrm{Fib}}\, S$ on a $W_S = W_S^{\mathcal{L}}$, donc les flèches sont égales dans $(\underline{\mathrm{Fib}}\, S)(W_S^{\mathcal{L}})^{-1}$, et a fortiori dans $(\mathcal{M}/S)(W_S^{\mathcal{L}})^{-1}$, et on gagne.

Voyons ce qu'on peut faire dans le cas où on dispose d'un *foncteur* C. On suppose bien sûr que ce foncteur dans $\mathcal{M}/S$ n'est pas lié au S particulier dans $\mathcal{M}$ qu'on a choisi comme base, que sa construction provient à la Cartan-Serre d'un foncteur [page 101]

$$X \longmapsto \mathrm{Ch}(X) : \mathcal{M} \longrightarrow \mathcal{M},$$

('objet des chemins') et de morphismes fonctoriels

$$X \xrightarrow{\alpha_X} \mathrm{Ch}(X) \xrightarrow{p_X} X \times X, \qquad \boxed{p_X \alpha_X = \mathrm{diag}_X}$$

([58]). Je présume qu'il faudra supposer surtout ceci

Commentary · Exposition [ms. 100]

Naturality in the finer localization

The proposed unit of the reflection has to exist where fewer arrows have been inverted. This is the issue hidden by the notation i_X: in the coarse localization i_X is invertible, whereas in the finer localization it usually is not. The construction by lifts supplies the required stronger naturality, although the sentence on p. 98 mentions only the coarse category.

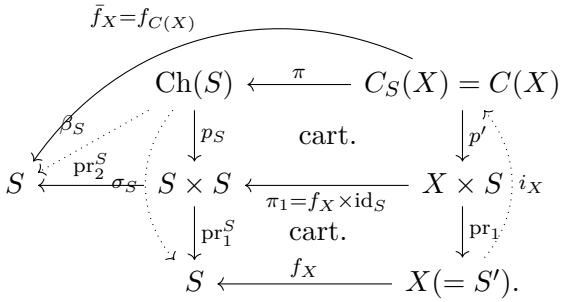
Put $\mathcal{A} = \mathcal{M}/S$, $\mathcal{F} = \underline{\mathrm{Fib}}\, S$, and write W_0 for either $W_S^{\mathcal{L}}$ or the more general fine localizer of Theorem-Scholie 2. We assume $W_0 \subseteq W_S$ and equality on arrows of $\mathcal{F}$. For a map $u : X \to Y$, a chosen lift satisfies the strict identity

$$\bar{u} i_X = i_Y u$$

58. **NB** On pose $\mathrm{pr}_1 \circ p_X = \sigma_X$, $\mathrm{pr}_2 \circ p_X = \beta_X$ (flèches 'source' et 'but' pour l'objet X).

in $\mathcal{A}$. Two choices of $\bar{u}$ agree in $\mathcal{F}[W_S^{-1}]$, hence also after mapping into $\mathcal{A}[W_0^{-1}]$, because W_S and W_0 coincide on $\mathcal{F}$. The displayed identity therefore defines a natural transformation in the finer localization. Naturality for formal inverses of W_0-arrows follows by multiplying a naturality square by those inverses; this is precisely the universal property of localization for natural transformations.

For $u = i_X$, both $\overline{i_X}$ and i_{CX} extend the map $i_{CX}i_X$. The path-object lemma identifies them in $\mathcal{F}[W_S^{-1}]$. This is stronger than the equality needed in $\mathcal{A}[W_0^{-1}]$. Let $\eta_X = [i_X]$ be the fine unit, and let the coarse counit be $[i_X]^{-1}$. One triangle identity is cancellation of $[i_X]$ with its inverse. The other is cancellation after the equality



$$[C(i_X)] = [i_{CX}]$$

just proved. Consequently $\rho \dashv i$, and the counit is invertible, so i is fully faithful.

No strict functor $C : \mathcal{A} \to \mathcal{F}$ has been manufactured in this argument. The expression $C(i_X)$ means a class represented by an allowable lift. The remark on p. 100 that the entire displayed square lies in $\underline{\mathrm{Fib}}\, S$ is a small source slip: its upper-left object X need not be fibrant. The square lies in $\mathcal{M}/S$; the two arrows whose classes are compared have fibrant sources and targets, which is all the proof uses.

Hypothèse 2. $\alpha_X \in W$, $p_X \in \mathrm{Fib}$.
Pour un X sur S, on construira $C_S(X)$ ou $C(X)$ ainsi

p. 64

Il est l'image inverse de $(\mathrm{Ch}(S), \mathrm{pr}_1^S p_S = \sigma_S)$ par $X \xrightarrow{f_X} S$, mais on a explicité la factorisation de σ_S sur le diagramme pour réinterpréter la flèche structurale $\bar{f}_X = f_{C(X)}$, définie comme

$$f_{C(X)} = \beta_S \pi (= \mathrm{pr}_2^S \underbrace{p_S \pi}_{= \pi_1 p'})$$

par la formule

$$f_{C(X)} = \underbrace{(\mathrm{pr}_2^S \pi_1)}_{\text{projection } \mathrm{pr}_2 \text{ de } X \times S \text{ dans } S} p'.$$

Or [page 102]

$p' \in \mathrm{Fib}$, car déduit de $p_S \in \mathrm{Fib}$ par changement de base π_1,

$(\mathrm{pr}_2 : X \times S \longrightarrow S) \in \mathrm{Fib}$ pourvu que $X \longrightarrow \underbrace{e}_{\text{objet final de } \mathcal{M}}$ soit dans Fib (même raison),

donc si $X \in \underline{\mathrm{Fib}}\, e$, on a $f_{C(X)} \in \mathrm{Fib}$. Comme c'est une propriété essentielle qu'on veut avoir pour *tout* X dans $\mathcal{M}/S$, on va faire l'hypothèse supplémentaire

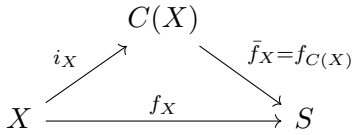
Hypothèse 3. $\forall\, X \in Ob\, \mathcal{M}$, $X \longrightarrow e$ *est dans Fib.*

Quant à

$$i_X : X \longrightarrow C(X),$$

il est déduit de la section α_S de $(\mathrm{Ch}(S), \sigma_S)$ sur S par changement de base $X \longrightarrow S$. Notons maintenant que

$$\mathrm{Ch}(S) \underset{\beta_S}{\overset{\sigma_S}{\rightrightarrows}} S \qquad \text{sont dans } W,$$



car leurs composés avec $S \xrightarrow{\alpha_S} \mathrm{Ch}(S)$ sont l'identité, et $\alpha_S \in W$. D'autre part, $\sigma_S = \mathrm{pr}_1^S \circ p$ est dans Fib, comme composé de deux éléments dans Fib (NB $S \longrightarrow e$ dans Fib par Hypothèse 3). Ainsi σ_S, β_S sont dans $\mathrm{Fib} \cap W$. On aura besoin de

Hypothèse 4. *L'ensemble de flèches Fib $\cap$ W est stable par tout changement de base.*

Cela implique donc que p. 65 [page 103]

$$C(X) \xrightarrow{\mathrm{pr}_1 \pi'} X$$

`[plutôt` $\mathrm{pr}_1 p'$`]` est $\in W$ (étant déduit de $\sigma_S : \mathrm{Ch}(S) \longrightarrow S$ par changement de base), donc toute section $i_X : X \longrightarrow C(X)$ de $C(X)$ sur X est dans i_X `[plutôt dans` W`]`. On a donc bien une factorisation, fonctorielle en X

avec

$$i_X \in W, \qquad f_{C(X)} \in \mathrm{Fib}.$$

C'est tout ce qu'on avait utilisé pour établir

$$(\underline{\mathrm{Fib}}\ S)W_S^{-1} \xrightarrow{\sim} (\mathcal{M}/S)W_S^{-1}.$$

Mais il s'agit maintenant, sous l'hypothèse où on introduit un $\mathcal{L}$, de prouver que pour tout X dans $\mathcal{M}/S$, les deux flèches

$$C(X) \underset{i_{C(X)}}{\overset{C(i_X)}{\rightrightarrows}} C(C(X))$$

sont égales dans $(\mathcal{M}/S)(W_S^{\mathcal{L}})^{-1}$. Comme par hypothèse on a $W_S^{\mathcal{L}} = W_S$ dans $\underline{\mathrm{Fib}}\ S$ (Hypothèse 1), et que $C(X),\ C(C(X)) \in \mathrm{Ob}\,\underline{\mathrm{Fib}}\ S$, il suffit de prouver que les deux flèches sont égales *dans* $(\underline{\mathrm{Fib}}\ S)W_S^{-1}$. Cet énoncé est indépendant de la donnée de $\mathcal{L}$, et on a envie de le prouver. [page 104]

Commentary · Exposition [ms. 103]

The mapping-path factorization and its hypotheses

Grothendieck now wants a replacement with visible geometry. A point of $C_S(X)$ consists of a point of X together with a path from its image to a new point of S. The new structural map remembers the endpoint. This changes the map to S while preserving the total homotopy type, and explains why the two projections of the path object play different roles.

Assume finite limits, pullback and composition stability of Fib, and natural maps

$$S \xrightarrow{\alpha_S} P(S) \xrightarrow{(\sigma_S, \beta_S)} S \times S$$

with composite the diagonal, $\alpha_S \in W$, and $(\sigma_S, \beta_S) \in \mathrm{Fib}$. Define

$$C_S(X) = X \times_{S,\sigma_S} P(S), \qquad q : C_S(X) \to X, \qquad \bar{f} = \beta_S \,\mathrm{pr}_{P(S)}\,.$$

The unit sends x to $(x, \alpha_S f(x))$, so $qi_X = \mathrm{id}_X$ and $\bar{f} i_X = f$. These formulas describe genuine morphisms: the generalized-element description is justified by the universal property of the pullback and the Yoneda embedding, not by an assumption that the category consists of sets.

To see that $\bar{f}$ is a fibration, rewrite the pullback as

$$C_S(X) = (X \times S) \times_{S \times S} P(S),$$

where $X \times S \to S \times S$ is $f \times \mathrm{id}$. Its projection $p' : C_S(X) \to X \times S$ is a fibration. The second projection $X \times S \to S$ is a pullback of $X \to e$, so it is a fibration if X is fibrant. Hypothesis 3 makes this true for every X. Thus $\bar{f} = \mathrm{pr}_2\, p'$ is a fibration.

To see that i_X is a weak equivalence, first note that $\sigma_S\alpha_S = \mathrm{id}$ makes σ_S a weak equivalence. It is a fibration since S is fibrant and (σ_S, β_S) is a fibration. Hypothesis 4 then makes its pullback q a trivial fibration. Since $qi_X = \mathrm{id}$, two-out-of-three gives $i_X \in W$. The proof uses pullback stability of *trivial fibrations*; it does not require arbitrary weak equivalences to survive arbitrary pullbacks.

This is the mapping-path mechanism behind Brown's factorization lemma. Its persistence in higher category theory is especially explicit in Riehl and Verity (2022, Lemma 1.2.19), where a map in an ∞-cosmos factors as a section of a trivial fibration followed by an isofibration. The categorical hypotheses and the meaning of equivalence differ, but the pullback calculation is the same.

The concise condition A′ on p. 112 must be read as the advertised *strengthening of A*. In particular, it retains the conclusion $i_X \in W$ already required in A. If its path data are instead used as an independent recipe for proving A, the pullback-stability step just exhibited must be supplied, for example by Hypothesis 4. This distinguishes an abbreviated restatement from a missing hypothesis in the theorem as actually formulated.

Peut-être y a-t-il moyen d'expliciter un langage géométrique, pour s'y reconnaître. Identifions les objets X de $\mathcal{M}$ aux foncteurs $\mathcal{M}^o \longrightarrow$ (Ens) qu'ils définissent,

$$X \longmapsto (T \longmapsto X(T) = \mathrm{Hom}_{\mathcal{M}}(T, X))\,.$$

Ainsi, pout tout T

$$\mathrm{Ch}(X)(T)$$

est un ensemble, appelé *l'ensemble des chemins dans* $X(T)$. Il s'envoie (par p_X) fonctoriellement (en T) dans $(X \times X)(T) = X(T) \times X(T)$, i.e. chaque chemin c dans $X(T)$ a une origine $\sigma(c)$, et un but $\beta(c)$. De plus, par α_X, $X(T)$ s'envoie (fonctoriellement en T) dans l'ensemble des chemins de $X(T)$: pour chaque élément x dans $X(T)$, il y a donc un chemin (noté 1_x ou α_x) bien défini de source et but x, qu'on appelle le chemin trivial, ou vide. Ceci dit,

pour X dans $\mathcal{M}/S$, $C(X)$ représente le contra-foncteur suivant dans $\mathcal{M}$: pour tout T dans $\mathcal{M}$, p. 66 [page 105]

$$C(X)(T) = \left\{(x, c) \;\middle|\; x \in X(T),\ c : f_X(x) \xrightarrow{c} s \ \text{ un chemin dans } S(T),\ \text{de source } f_X(x)\right\},$$

où $f_X : X \longrightarrow S$ est le morphisme structural.

Les 'calculs' faits, il y a deux (?) jours montrent qu'on a de même une interprétation

$$C(C(X))(T) = \left\{(x, c, c') \;\middle|\; x \in X(T),\ f_X(x) \xrightarrow{c} s \xrightarrow{c'} t,\ c \text{ un chemin de source } f_X(x),\ c' \text{ un chemin de source égale à } \beta(c)\right\}$$

et les applications $i_{C(X)}$ et $C(i_X)$ s'identifient respectivement à

$$\begin{array}{lcll} (x, c) & \longmapsto & (x, 1_{f(x)}, c) & f(x) \xrightarrow{1_x} f(x) \xrightarrow{c} s \\ (x, c) & \longmapsto & (x, c, 1_{\beta(c)}) & f(x) \longrightarrow s \xrightarrow{1_s} s \end{array}$$

[plutôt $f(x) \xrightarrow{1_{f(x)}} f(x) \xrightarrow{c} s$]. Pour les comparer, on a une envie irrésistible d'écrire

$$c \circ 1_x = 1_s \circ c = c,$$

mais a-t-on le droit? Il faudrait pouvoir composer les chemins, et c'est très, très difficile!

Mais on peut toujours axiomatiser. On suppose donc que pour X dans $\mathcal{M}$, $\mathrm{Ch}(X)$ n'est pas seulement une structure de (soi-disants) 'chemins' dans X amorphe, seulement la donnée de la source et du but des chemins et des chemins triviaux (ces structures sur $\mathrm{Ch}(X)$ [page 106]

dépendant fonctoriellement de X), mais qu'on a une composition des chemins quand ceux-ci sont 'composables', i.e. une flèche d'un produit fibré

$$(c, c') \longmapsto c' \circ c : (\mathrm{Ch}(X), \beta_X) \times_X (\mathrm{Ch}(X), \sigma_X) \xrightarrow{\pi_X} \mathrm{Ch}(X),$$

i.e. on peut composer des chemins dans $X(T)$

$$x \xrightarrow{c} y \xrightarrow{c'} z$$

si et seulement si $\mathrm{but}\, c = \mathrm{source}\, c'$, et de plus on exige bien sûr que $\mathrm{source}(c' \circ c) = \mathrm{source}\, c$, $\mathrm{but}(c' \circ c) = \mathrm{but}\, c'$, ce qui s'exprime par un diagramme commutatif

$$\begin{array}{ccc} (\mathrm{Ch}(X), \beta_X) \times_X (\mathrm{Ch}(X), \sigma_X) & \longrightarrow & \mathrm{Ch}(X) \\ & \searrow \quad \swarrow_{p_X} & \\ & X \times X. & \end{array}$$

Commentary · Examples [ms. 105]

A groupoid in which both inserted paths are visible

Grothendieck's element notation is most useful when it allows us to see the two maps $CX \rightrightarrows C^2X$ before localizing. A groupoid gives a completely algebraic example, including a small correction to the order of the formulas on p. 105.

Let G be a group, let $S = BG$ be its one-object groupoid, and let $X = e \to BG$ select the object. Work in groupoids with equivalences as weak equivalences and isofibrations as fibrations. Take $P(S)$ to be the arrow groupoid: its objects are $g \in G$, and a morphism $g \to g'$ is a pair (a, b) with

$$bg = g'a.$$

Source and target send this pair to a and b. The constant-path functor sends the unique object of BG to $1 \in G$ and an arrow a to (a, a). It is fully faithful, and every g is isomorphic to 1, so it is an equivalence. The endpoint functor $P(S) \to S \times S$ is an isofibration: prescribed endpoint isomorphisms (a, b) lift by choosing $g' = bga^{-1}$.

The pullback defining $C_S(e)$ fixes the source component of a morphism to be the identity. Its objects are still $g \in G$, but between g and g' there is exactly one morphism, whose image in BG is

$$b = g'g^{-1}.$$

Thus $C_S(e)$ is a contractible groupoid. Its projection to BG is an isofibration: an arrow h with source the image of g lifts to the unique arrow $g \to hg$. The inclusion $e \to C_S(e)$ chooses 1 and is an equivalence. The strict fibre over the object of BG, on the other hand, is the discrete set G, since $g'g^{-1} = 1$ precisely when $g' = g$. The replacement has preserved the total type while encoding the nontrivial fibre needed over BG.

Objects of $C_S^2(e)$ are pairs (g, h), representing successive paths. The two maps are

$$i_{C_S(e)}(g) = (g, 1), \qquad C_S(i_e)(g) = (1, g).$$

The first inserts a constant path at the *endpoint*; the second first replaces the original object e and therefore inserts a constant path at the *source*. These are the reverse of the labels assigned by "respectivement" in the edition. The formulas themselves are present there; their attribution is interchanged. We retain that source slip and use the correctly labelled formulas in the commentary.

Composition gives $\gamma(g, h) = hg$. It is also a functor on morphisms. The unique morphism $(g, h) \to (g', h')$ has image

$$d = h'g'g^{-1}h^{-1}$$

in BG, which is exactly the image of the unique morphism $hg \to h'g'$ in $C_S(e)$. Therefore $\gamma i_C = \gamma C(i) = \mathrm{id}$ already before localization. Since the two insertion maps are weak equivalences between fibrant objects, they become the same inverse of γ after localization. This example exhibits

the geometric comparison which the abstract argument needs; it does not identify categorical fibrations with model-category fibrations in general.

The same example makes a noninvertible fine unit concrete. Let W_0 on groupoids over BG consist of equivalences on each strict fibre. It is a two-out-of-three class, obtained by applying the fibre functors. It is contained in the total equivalences for maps between isofibrations, and there it agrees with the total equivalences. To obtain a class contained in the total equivalences on all objects, take its intersection with W; the agreement on isofibrations remains true. If G is nontrivial, the unit $e \to C_S(e)$ is a total equivalence but is not an equivalence on the strict fibre: there it is the inclusion of the singleton $\{1\}$ into the discrete groupoid G. The fibre functor, followed by localization at equivalences of groupoids, detects that this unit cannot become invertible in the fine localization. Thus the fine and coarse localizations differ even though their equivalences between fibrant objects coincide. This is precisely the situation of the reflection theorem.

p. 67

La pensée naturelle, c'est qu'avec cette composition et ces identités, les $X(T)$, $\mathrm{Ch}(T)$ deviennent les objets et les flèches d'une *catégorie* - i.e. que $(X, \mathrm{Ch}(X), \alpha_X, p_X, \pi_X)$ définissent une structure de 'catégorie dans $\mathcal{M}$'. Mais pour ce qu'on veut faire maintenant, on n'a sans doute pas besoin de tout, i.e. de l'axiome pertinent d'associativité de la composition et celui [page 107] sur les unités, mais seulement que les 1_x soient des unités bilatères pour la composition.

En supossant donné ce supplément de structure sur le foncteur Ch, et revenant à la considération du foncteurs associé

$$C : \mathcal{M}/S \longrightarrow \underline{\mathrm{Fib}}\ S,$$

on trouve un morphisme canonique

$$C(C(X)) \xrightarrow{\gamma_X} C(X)$$

par

$$(x, c, c') \longmapsto (x, c' \circ c),$$

et l'axiome des unités bilatères nous assure aussitôt que

$$(*) \qquad \gamma_X \circ i_{C(X)} = \gamma_X \circ C(i_X) = \mathrm{id}_{C(X)}.$$

Comme $i_{C(X)} \in W$, cela prouve déjà que $\gamma_X \in W$, donc $\gamma_X \in W_S$. Donc γ_X devient un isomorphisme dans $(\underline{\mathrm{Fib}}\ S)W_S^{-1}$, et la relation $(*)$ implique bien $i_{C(X)} = C(i_X)$ dans le localisé, q.e.d.

Je vais à nouveau résumer ce que j'ai dégagé.

Théorème-Scholie 2. Soit $\mathcal{M}$ une catégorie, munie de deux ensembles de flèches [page 108]

$$W,\ \mathrm{Fib} \subseteq \mathrm{Fl}(\mathcal{M}).$$

On fait les hypothèses suivantes.

Commentary · Exposition [ms. 107]

What composition contributes to the reflection

Grothendieck asks for a composition of paths because it contracts the two-step replacement back to a one-step replacement. For this purpose there is no triple of paths to compare. Associativity therefore has no role in the proof: the only identities used are $c \circ 1 = c$ and $1 \circ c = c$. This explains the deliberately weaker formulation on pp. 106–107.

With the corrected order of the two unit insertions, the formula

$$\gamma_X(x, c, c') = (x, c' \circ c)$$

gives a common left inverse of i_{CX} and $C(i_X)$. Two-out-of-three makes γ_X a weak equivalence, because $\gamma_X i_{CX} = \mathrm{id}$ and $i_{CX} \in W$. Both its source and target are fibrant over S, so Hypothesis 1

also makes it a fine weak equivalence. Its inverse in the fine localization is therefore both i_{CX} and $C(i_X)$. The path calculation of manuscript p. 69 has now been isolated from its construction in Cat.

An internal category would require associative composition in addition to the endpoint and unit identities, and its set of arrows on a test object T would be $P(X)(T)$. The edition's $\mathrm{Ch}(T)$ in the paragraph spanning pp. 106–107 is a type error: $\mathrm{Ch}(T)$ is an object of $\mathcal{M}$, whereas the discussion concerns a set of arrows between elements of $X(T)$. The intended expression is $\mathrm{Ch}(X)(T)$.

There is also a shorter route once the comparison of localizations has been proved. That comparison can transfer the required equality from the coarse localization back to the localized fibrant subcategory. We give the argument at p. 111. It shows that the path composition is a useful geometric witness, while the formal reflection theorem itself needs only the functorial replacement of A. This strengthens the stated theorem without changing the validity of the path proof.

1° W contient les isomorphismes, si f, g sont composables, si deux parmi f, g, gf sont dans W, le troisième aussi.

2° $\mathcal{M}$ est stable par $\varprojlim$ finies, Fib contient les isomorphismes, est stable par composition et par changement de base ([59]).

Pour S dans $\mathcal{M}$, $\boxed{\underline{\mathrm{Fib}}\ S}$ désigne la sous-catégorie pleine de $\mathcal{M}/S$ formée des $X \longrightarrow S$ qui sont dans Fib. On distingue deux versions différentes d'un axiome de factorisation d'une $f : X \longrightarrow S$ quelconque dans $\mathcal{M}$ en $X \xrightarrow{i} \bar{X} \xrightarrow{\bar{f}} S$, avec $i \in W$, $\bar{f} \in \mathrm{Fib}$.

A) On se donne, pour tout S dans $\mathcal{M}$, un foncteur p. 68

$$\mathcal{M}/S \longrightarrow \mathcal{M}/S \qquad\qquad X \longmapsto C(X) \ \ (= \bar{X})$$

et un morphisme de foncteurs en X

$$X \xrightarrow{i_X} C(X)$$

avec

$$i_X \in W, \qquad\qquad C(X) \in \mathrm{Ob}\,\underline{\mathrm{Fib}}\ S.$$

B) Désignant par

$$\mathrm{Cof}_0 \subseteq \mathrm{Fl}\,\mathcal{M}$$

l'ensemble des flèches de $\mathcal{M}$ qui possèdent la propriété de relèvement à droite `[plutôt à gauche]` par rapport à Fib, on suppose 'à la Quillen', que toute flèche $f : X \longrightarrow S$ se factorise en

$$X \xrightarrow{i_X} C(X) \xrightarrow{\bar{f}} S,$$

avec

$$i \in \mathrm{Cofib}_0 \cap W, \qquad\qquad \bar{f} \in \mathrm{Fib}.$$

`[où` $\mathrm{Cof}_0 = \mathrm{Cofib}_0$`]`.

Donnons nous S dans $\mathcal{M}$, considérons

$$W_S \subseteq \mathrm{Fl}(\mathcal{M}/S)$$

[page 109]

$$f : X \longrightarrow Y \qquad \searrow \quad \swarrow \qquad S$$

l'ensemble de flèches induit par W (est dans W_S si et seulement si il l'est en oubliant S), et désignons par W_S (par abus de notation) l'ensemble de flèches induit par W_S sur $\underline{\mathrm{Fib}}\ S$, ou plus généralement sur toute sous-catégorie pleine $\mathcal{F}$ de $\mathcal{M}/S$, avec

$$\underline{\mathrm{Fib}}\ S \subseteq \mathcal{F} \subseteq \mathcal{M}/S.$$

59. Ces hypothèses de stabilité sur Fib ne serviront que dans II, et encore seulement dans le cas A), repris in toto sous la forme A′ plus bas (p. 112).

Commentary · Exposition [ms. 108]

Reading the two versions of the abstract theorem

Theorem-Scholie 2 organizes the preceding work around two independent questions. The first is whether fibrant representatives compute the coarse localization. The second is whether those representatives form a reflective subcategory of a finer localization. Keeping the two questions separate makes the scope of each hypothesis transparent.

For I under A, we need a full subcategory $\mathcal{F} \subseteq \mathcal{A}$, a functor $C : \mathcal{A} \to \mathcal{F}$, and a natural transformation $\mathrm{id}_{\mathcal{A}} \to C$ whose components are in W. Two-out-of-three shows that C preserves W. Restricting the transformation to $\mathcal{F}$ gives the second comparison with the identity, and hence an equivalence of localizations. Finite limits, fibrations, and lifting properties are irrelevant to this formal argument. Their role is to provide the replacement in particular examples.

Under B, the functor only appears after localization. The left lifting property supplies its arrows, and the path-object lemma supplies independence. In the proof as written, finite limits and stability of Fib under pullback and composition are used at pp. 92–93 to keep the relative path object fibrant over S. Footnote 59 says that these stability hypotheses occur only in II, and only in A′. That description of the proof is incorrect. It does not affect the theorem, because the hypotheses are included in its statement.

The condition in II is equally precise:

$$W_0 \subseteq W, \qquad W_0 \cap \mathrm{Fl}(\mathcal{F}) = W \cap \mathrm{Fl}(\mathcal{F}).$$

It is an equality on arrows between good objects, not on all arrows with one good endpoint. In particular, the replacement map $X \to CX$ need not belong to W_0. The resulting unit in the fine localization is generally noninvertible, while its image in the coarse localization is invertible. That asymmetry is exactly what permits a nontrivial reflection.

The term “localement constant” in the abstract theorem is motivated by the application to Cat/S. For an arbitrary relative category $\mathcal{M}$, the localization $(\mathcal{M}/S)[W_S^{-1}]$ has been defined without a notion of transport along arrows of S. Its identification with local systems is an additional interpretation supplied by a model of homotopy types. The formal theorem establishes the reflection; it does not by itself define monodromy or a theory of locally constant diagrams.

Ⓘ Le foncteur

$$(*) \qquad (\underline{\mathrm{Fib}}\ S)W_S^{-1} \xrightarrow{\sim} (\mathcal{M}/S)W_S^{-1}$$

induit par l’inclusion est une équivalence de catégories, plus généralement pour toute $\mathcal{F}$ comme dessus

$$(\underline{\mathrm{Fib}}\ S)W_S^{-1} \longrightarrow \mathcal{F}W_S^{-1} \longrightarrow (\mathcal{M}/S)W_S^{-1}$$

sont des équivalences de catégories. Un foncteur quasi-inverse est obtenu (dans les deux cas A) et B)) à l’aide du foncteur

$$\gamma : \mathcal{M}/S \longrightarrow (\underline{\mathrm{Fib}}\ S)W_S^{-1}$$

qui est donné sur les objets par p. 69

$$\gamma(X) = C(X),$$

et qui sur les flèches se définit de façon évidente dans le cas A) (fonctorialité de $C(X)$ en X), et dans le cas de B) se construit ad hoc, comme la seule loi fonctorielle pour laquelle les homomorphismes

$$i_X : X \longrightarrow C(X)$$

(interprétés comme flèches dans $(\mathcal{M}/S)W_S^{-1}$) soient eux-mêmes fonctoriels en X. [page 110]

On désigne par

$$\mathrm{Ho}_W^{\mathrm{lc}}(S) \qquad \text{(lc comme ‘localement constant’)}$$

la catégorie des fractions $(\mathcal{M}/S)W_S^{-1}$, équivalente à $(\underline{\mathrm{Fib}}\, S)W_S^{-1}$.

(II) Donnons nous un localiseur W_S^0 dans $\mathcal{M}/S$

$$W_S^0 \subseteq W_S \subseteq \mathrm{Fl}(\mathcal{M}/S),$$

avec l'hypothèse formelle similaire à celle de W (cf. 1°). On suppose que

$3^o)$ $W_S^0 \cap \mathrm{Fl}(\underline{\mathrm{Fib}}\, S) = W_S|\underline{\mathrm{Fib}}\, S$.

(Cf. pages 94-96 pour une façon générale d'obtenir des tels localiseurs. Il faut bien voir que pour définir des 'types d'homotopie' relatifs sur S le localiseur W_S est beaucoup trop grossier, moralement il ne donne qu'une catégorie des types d'homotopie relatifs localement constants, et c'est justement ça qui est montré par l'equivalence de (I), où $\underline{\mathrm{Fib}}\, S$ est visualisé comme formé des 'fibrations localement triviales' sur S.) On a alors un deuxième localisé

$$\mathrm{Ho}_{W_S^0}(S) \overset{\text{déf}}{=} (\mathcal{M}/S)(W_S^0)^{-1},$$

et deux foncteurs

$$(*) \qquad \mathrm{Ho}_{W_S^0}(S) \underset{i}{\overset{\rho}{\rightleftarrows}} \mathrm{Ho}_W^{\mathrm{lc}}(S),$$

où ρ est le foncteur de localisation (strict) évident, dû à l'inclusion $W_S^0 \subseteq W_S$, et où i est essentiellement le foncteur déduit de l'inclusion [page 111]

$$(\underline{\mathrm{Fib}}\, S, \underbrace{W_S|\underline{\mathrm{Fib}}\, S}_{=W_S^0|\underline{\mathrm{Fib}}\, S}) \longrightarrow (\mathcal{M}/S, W_S^0)$$

par localisation *au moyen de* W_S^0, donc le foncteur

$$(**) \qquad (\underline{\mathrm{Fib}}\, S)(W_S^0)^{-1} \longrightarrow (\mathcal{M}/S)(W_S^0)^{-1},$$

compte tenu de l'équivalence $(*)$ de (I), i.e. i est le composé du quasi-inverse de $(*)$, avec le p. 70
foncteur $(**)$ précédent. Explicitement, il est défini par

$$i(X) = \text{classe de C(X) dans } (\mathcal{M}/S)(W_S^0)^{-1},$$

en tenant compte du fait que $X \longmapsto C(X)$ transforme W_S en W_S^o, grâce à la condition $3^o)$ sur W_S^0.

Ceci posé, *sous l'hypothèse* B ('Quillen'), on a : dans le couple de foncteurs (ρ, i) de $(*)$, page 110, *i est adjoint à droite de ρ,* i.e. on a pour $\xi \in \mathrm{Ob}\,\mathrm{Ho}_{W_S^0}(S)$, $\eta \in \mathrm{Ob}\,\mathrm{Ho}_W^{\mathrm{lc}}(S)$

$$\mathrm{Hom}_{W_S^0}(\xi, i(\eta)) \simeq \mathrm{Hom}_{W_S}(\rho(\xi), \eta),$$

ce qui s'explicite, pour X, Y dans $\mathcal{M}/S$, par

$$\boxed{\mathrm{Hom}_{W_S^0}(X, C(Y)) \simeq \mathrm{Hom}_{W_S}(X, Y)}$$

([60]). Il s'ensuit que *le foncteur i est pleinement fidèle.*

La même formule d'adjonction, et la pleine fidélité de i, sont valables dans le cas A, quand [page 112]
on renforce l'hypothèse A (relative à un S particulier) en une hypothèse plus restrictive et plus compréhensive, que voici.

60. **NB** Le premier membre est indépendant du choix de W_S^0! (Pourvu seulement que l'hypothèse $W_S^0 \cap \mathrm{Fl}\,\underline{\mathrm{Fib}}\, S = W_S \cap \mathrm{Fl}\,\underline{\mathrm{Fib}}\, S$, en plus de $W_S^0 \subseteq W_S$, soit satisfaite.)

Commentary · Later developments [ms. 111]

Functorial replacement already gives the reflection

Grothendieck's construction has supplied more than the final formulation uses. Hypothesis A alone suffices for II; the additional path composition in A′ is unnecessary for the adjunction. The missing observation is that I has already proved full faithfulness in the coarse localization. We can use that result to establish coherence without cancelling a noninvertible unit in the fine localization.

Here is the precise argument. Let $\mathcal{F} \subseteq \mathcal{A}$ be full, let $W_0 \subseteq W$ contain the isomorphisms and satisfy two-out-of-three, and assume that they agree on $\mathcal{F}$. Suppose given a functor $C : \mathcal{A} \to \mathcal{F}$ and a natural transformation $\eta : \mathrm{id}_{\mathcal{A}} \to C$ with $\eta_X \in W$. Put

$$\mathcal{D} = \mathcal{A}[W_0^{-1}], \qquad \mathcal{B} = \mathcal{A}[W^{-1}], \qquad \mathcal{K} = \mathcal{F}[W^{-1}].$$

By I, the inclusion $J : \mathcal{K} \to \mathcal{B}$ is an equivalence. The inclusion into the fine localization gives $k : \mathcal{K} \to \mathcal{D}$. The functor C induces $q : \mathcal{D} \to \mathcal{K}$, since it carries $W_0 \subseteq W$ into W between objects of $\mathcal{F}$. The transformation η descends to $\mathrm{id}_{\mathcal{D}} \to kq$.

We first compare the iterated units in $\mathcal{K}$. Naturality in $\mathcal{A}$ gives

$$C(\eta_X)\eta_X = \eta_{CX}\eta_X.$$

In $\mathcal{B}$, η_X is invertible, so $C(\eta_X) = \eta_{CX}$. Both arrows are arrows of $\mathcal{F}$. Since J is faithful, their classes are equal in $\mathcal{K}$ itself. There is no appeal here to the desired full faithfulness of k; the faithful functor is the coarse comparison J, whose equivalence was established before W_0 entered the argument.

For $Y \in \mathcal{F}$, the arrow $\eta_Y : Y \to CY$ is a weak equivalence in $\mathcal{F}$. Define a natural counit $\varepsilon : qk \to \mathrm{id}_{\mathcal{K}}$ by $\varepsilon_Y = [\eta_Y]^{-1}$. Naturality follows by inverting the natural isomorphism induced by $\eta|_{\mathcal{F}}$. The triangle identities are now explicit:

$$k(\varepsilon_Y)\eta_{kY} = \mathrm{id}_{kY}, \qquad \varepsilon_{qX}\, q(\eta_X) = [\eta_{CX}]^{-1}[C(\eta_X)] = \mathrm{id}_{qX}.$$

Thus $q \dashv k$. Its counit is an isomorphism, so k is fully faithful. Composing on the left with the equivalence J identifies q with the canonical localization $\rho : \mathcal{D} \to \mathcal{B}$ and gives

$$\rho \dashv kJ^{-1}.$$

The functor kJ^{-1} is Grothendieck's i. In particular,

$$\mathrm{Hom}_{\mathcal{D}}(X, CY) \simeq \mathrm{Hom}_{\mathcal{B}}(X, Y)$$

under A without A′, and for every choice of W_0 with the stated agreement property.

The bijection can also be written without invoking the adjunction as a black box. For $Y \in \mathcal{K}$, it sends $f : X \to kY$ to $\varepsilon_Y q(f) : qX \to Y$. Its inverse sends $h : qX \to Y$ to $k(h)\eta_X$. Substituting one formula into the other, naturality of η or ε moves the comparison map past f or h, and the corresponding triangle identity cancels the remaining pair. These formulas establish both naturality variables and show that the comparison with the coarse localization is the canonical one. In particular, no new choice of a map from X into a fibrant target has been made.

This strengthening belongs to the general theory of derived adjunctions, rather than being a new phenomenon. Apply the deformable-adjunction theorem, Riehl (2014, Theorem 2.2.11), to the identity adjunction between $(\mathcal{A}, W_0)$ and $(\mathcal{A}, W)$: its left functor is already homotopical, and its right functor admits the right deformation C, on whose image the two classes agree. The proof above is included to make the application independent of a stronger axiomatization of homotopical categories, and to show precisely how the reflection lemma of manuscript p. 67 receives its coherence condition here.

A′) Le foncteur $C : \mathcal{M}/S \longrightarrow \mathcal{M}/S$ et le morphisme fonctoriel $i_X : X \longrightarrow C(X)$ sont construits 'à la Cartan-Serre' à partir d'un foncteur défini sur $\mathcal{M}$ entier

$$\mathcal{M} \xrightarrow{\mathrm{Ch}} \mathcal{M},$$

du type 'chemins', i.e. muni en plus des données suivantes

a)
$$X \xrightarrow{\alpha_X} \mathrm{Ch}(X) \xrightarrow{p_X=(\sigma_X,\beta_X)} X \times X$$
(structure de source et but des chemins, et de chemins triviaux), et

b) Une composition des chemins, sans exiger ici l'associativité de la composition mais seulement que les chemins triviaux soient unités bilatères pour la composition. De plus, on suppose que pout tout X
$$\begin{cases} \alpha_X \in W,\ p_X \in \mathrm{Fib} \\ (X \longrightarrow e) \in \mathrm{Fib}. \end{cases}$$

Corollaire. Soient X dans $\mathcal{M}/S$, Y dans $\underline{\mathrm{Fib}}\, S$, alors p. 71 [page 113]
$$\mathrm{Hom}_{W_S^0}(X,Y) \xrightarrow{\sim} \mathrm{Hom}_{W_S}(X,Y).$$

Démonstration. Par la formule d'adjonction (p. 111), le deuxième membre est $\mathrm{Hom}_{W_S^0}(X, CY)$. Mais comme Y et $C(Y)$ sont dans $\underline{\mathrm{Fib}}\, S$, où W_S et W_S^0 coïncident, $Y \xrightarrow{i_Y} C(Y)$ est non seulement dans W_S, mais dans W_S^0, donc $\mathrm{Hom}_{W_S^0}(X,Y) \xrightarrow{\sim} \mathrm{Hom}_{W_S^0}(X, CY)$, d'où le résultat.

Revenons à Cat, Cat$/S$. La digression précédente sur $(\mathcal{M}, W, \mathrm{Fib})$ a permis de mieux situer ce qui concerne le foncteur C, et les relations entre les catégories localisées de
$$\mathrm{Cat}/S \ \ (\text{pour } W_S,\ W_S^{\mathrm{d}},\ W_S^{\mathrm{g}}) \qquad \text{et} \qquad \underline{\mathrm{Parf}}\, S \ \ (\text{pour } W_S^{\mathrm{f}} = W_S = W_S^{\mathrm{d}} = W_S^{\mathrm{g}})$$
ainsi que pour les catégories intermédiaires
$$\underline{\mathrm{Parf}}\, S \subseteq \mathcal{F} \subseteq \mathrm{Cat}/S$$
pleines de Cat$/S$ (sur le diagramme p. 76, il y en a cinq autres, savoir $\underline{\mathrm{Fibhot}}\, S$, $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Liss}}_0 S$, $\underline{\mathrm{Prop}}\, S$, $\underline{\mathrm{Prop}}_0\, S$). Pour ce qui concerne les relations entre les localisés de ces sept catégories, qui se trouvent au centre du diagramme, les énoncés du théorème-scholie 1 (p. 70-81) ne donnent rien de plus que le contenu du théorème-scholie 2 (p. 108-113). Pour les établir, on a donc le choix entre les deux hypothèses A) ou B) dudit théorème. Soit utiliser un foncteur C_S explicite, à l'aide d'un foncteur $X \longmapsto \underline{\mathrm{Ch}}(X)$ ('chemins dans X') sur Cat, donc les structures [page 114] de source, but et composition pour les chemins, et les chemins triviaux (agissant comme unités bilatères pour la composition). La construction d'un tel foncteur C n'a par l'air trivial et semble ne pas être connue - j'ai peiné pour y arriver! (Avec, en plus, l'associativité de la composition …). Ou bien utiliser, à la Quillen, l'existence d'une classe de morphismes dits Q-fibrants, avec des bonnes propriétés de factorisation. Ce n'est pas non plus évident dans Cat, et c'est établi par Thomason, par une voie un peu compliquée. Peut-être serai-je amené à revenir dessus - mais seulement en cas de besoin!

Commentary · Examples [ms. 113]

Different fine localizers can have the same fibrant targets

Grothendieck's corollary says more than full faithfulness on pairs of fibrant objects. The source X is arbitrary: it is only the *target* Y that must be fibrant. The canonical map of Hom sets is bijective because $Y \to CY$ is already inverted in the finer localization, and the reflection computes maps into CY. This is why the Hom set in footnote 60 is independent of the chosen fine localizer.

A finite-set example isolates the statement from homotopical geometry. Let $\mathcal{A}$ be a skeleton of finite sets, let W consist of all maps, let $\mathcal{F}$ consist only of a singleton 1, and put $C(X) = 1$. The unique maps $X \to 1$ form a natural transformation in W. The coarse localization is equivalent to the terminal category: after all arrows are inverted, $X \to 1$ is a natural isomorphism to the constant functor. The full subcategory $\mathcal{F}$ also localizes to the terminal category.

First take W_0 to be the bijections. Its localization is just the category of finite sets. The reflection to the terminal category has right adjoint selecting 1, since

$$\mathrm{Hom}_{\mathcal{A}}(X, 1) = \{*\}$$

for every finite X, including the empty set. It plainly does not follow that the fine localization is terminal: for example $\mathrm{Hom}(1, \{0, 1\})$ has two elements.

For a second fine class, let W_1 consist of the maps which preserve whether a finite set is empty. Equivalently, W_1 contains the identity of the empty set and every map between nonempty finite sets. It is the inverse image of the isomorphisms under the functor

$$E : \mathcal{A} \to [1], \qquad E(\varnothing) = 0, \quad E(X) = 1 \quad (X \neq \varnothing),$$

so it satisfies two-out-of-three. The localization at W_1 is equivalent to [1]. Indeed, the functor $j : [1] \to \mathcal{A}$ selecting $\varnothing$ and 1 satisfies $Ej = \mathrm{id}$, and the natural maps $X \to jE(X)$, identity on the empty set and the unique map to 1 otherwise, all lie in W_1. These exhibit quasi-inverse functors after localization.

Thus the two fine categories are FinSet and [1], which are very different. Nevertheless, both give a singleton set of maps from any object into the distinguished fibrant target. Both W_0 and W_1 agree with W on $\mathcal{F}$, so the corollary predicts exactly this agreement. The example also makes the direction of the result unmistakable: maps *out of* the distinguished object are not fixed. In FinSet there are two maps $1 \to \{0, 1\}$; in [1] their images coincide.

Par contre, les assertions concernant les catégories $\underline{\mathrm{Fib}}\, S$, $\underline{\mathrm{Fibsc}}\, S$, ou $\underline{\mathrm{Cofib}}\, S$, $\underline{\mathrm{Cofibsc}}\, S$, et leurs variantes à indices 0 (donc les huit catégories-ailes du diagramme), et leurs relations à Cat/S d'une part, à $\underline{\mathrm{Fibhot}}\, S$ de l'autre (pour les catégories à indice 0), ne peuvent être contenues dans un tapis général sur des catégories de modèles $(\mathcal{M}, W)$, me semble-t-il, vu la nature très spéciale des quatre catégories désignées ci-dessus, de leur rôle très particulier dans le formalisme catégorique. Or tout au moins les catégories 'scindées' $\underline{\mathrm{Fibsc}}\, S$, $\underline{\mathrm{Cofibsc}}\, S$, et par suite aussi leurs variantes à indice 0, jouent un rôle essentiel pour la théorie des $\mathrm{HOT}(S)$, vu que c'est elles qui interviennent dualement quand on applique la recette générale [page 115] de construction d'un dérivateur à partir d'une catégorie de modèles $(\mathcal{M}, W)$. Donc je ne vois pas de simplification substantielle à apporter au théorème-scholie 1. Tout au plus pourrait-on p. 72 élaguer le diagramme de catégories envisagées, en laissant tomber $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Liss}}_0 S$, $\underline{\mathrm{Prop}}\, S$, $\underline{\mathrm{Prop}}_0 S$, qui n'y jouent pas un rôle vraiment utile. Pour ce qui concerne les résultats énoncés, ce qui les concerne est couvert par ce qui est dit pour les sous-catégories pleines $\mathcal{F}$ de Cat/S qui contiennent (disons) $\underline{\mathrm{Parf}}\, S$ (ou au choix celles qui contiennent $\underline{\mathrm{Fib}}\, S$ ou $\underline{\mathrm{Cofib}}\, S$).

Commentary · Later developments [ms. 114]

The model-category route in Cat

Grothendieck invokes Thomason to explain that the abstract replacement argument is not restricted to topological or simplicial objects. Thomason's model structure has as weak equivalences the functors whose nerves are weak homotopy equivalences, and as fibrations the functors detected as Kan fibrations by $\mathrm{Ex}^2 N$; its existence is Theorem 4.9 of Thomason (1980). Factorization into a trivial cofibration followed by a fibration supplies hypothesis B. The theorem concerns the ordinary homotopy theory of nerves; it should not be cited as constructing a model structure for an unspecified class W.

There is a historical correction relevant to the preceding properness discussion. Thomason's original proof asserted that Dwyer maps are closed under retracts and hence that every cofibration is a Dwyer map. Cisinski (1999, pp. 228–229) gives a counterexample. His Lemma 4 and Proposition 2 on p. 231 replace Dwyer maps by pseudo-Dwyer maps and recover properness. The model-category existence theorem is unaffected. Thus the later correction repairs an auxiliary assertion in the cited literature, not the validity of Grothendieck's abstract comparison theorem.

The two uses of "fibration" in this chapter must remain distinct. A Grothendieck fibration over S carries cartesian lifts of arrows and presents a contravariant diagram of categories. A Thomason fibration is defined by a lifting condition after applying $\mathrm{Ex}^2 N$. A categorical comparison between

> their localized presentations is a theorem, not a consequence of the shared terminology. This is the reason the eight outer categories in the large comparison diagram do not disappear merely because one has a model structure on Cat: they encode strict or split diagrammatic data which the abstract factorization axioms have not named.
>
> The return to those categories is therefore mathematically necessary. The abstract detour has made the localizations and reflection intelligible; the split-fibration presentation will now make variation in S intelligible. These are complementary uses of the same models, and neither replaces the other.

La description des catégories du type $\mathrm{HOT}(S)$, pour S fixé, me paraît à présent parfaitement bien comprise. Il est temps de faire varier S, et de comprendre le caractère contravariant en S. On se donne donc

$$S' \xrightarrow{f} S,$$

et on se propose de décrire les foncteurs image inverse pour les trois types de catégories $\mathrm{HOT}(S)$. Mais nous allons nous borner à présent aux $\mathrm{HOT}_W(S)$ et $\mathrm{HOT}^{\mathrm{lc}}_W(S)$, puisque tout ce qui concerne $\mathrm{HOT}^o_W(S) = \mathrm{HOT}_W(S^o)$ `[plutôt` $\mathrm{HOT}_W(S^o)^o$`, cf. p. 50]` s'en déduira par dualité $S \longmapsto S^o$. Donc il s'agit de décrire [page 116]

$$(*) \qquad f^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S')$$

et le foncteur induit

$$f^* : \mathrm{HOT}^{\mathrm{lc}}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_W(S').$$

Quand on décrit les catégories $\mathrm{HOT}(S)$, conformément à la recette générale, à l'aide de foncteurs

$$F : S^o \longrightarrow \mathrm{Cat}$$

(préfaisceaux en catégories sur S), ou, ce qui revient au même, de catégories scindées, la description de la flèche $(*)$ est évidente : elle revient à la loi

$$\left|\begin{array}{ccc} F & \longmapsto & F \circ f^o \\ \underline{\mathrm{Hom}}(S^o, \mathrm{Cat}) & \longrightarrow & \underline{\mathrm{Hom}}(S'^o, \mathrm{Cat}), \end{array}\right.$$

en passant aux localisés pour la W-équivalence argument par argument. Dans le langage des catégories fibrées, il est bien connu que cette opération triviale sur les préfaisceaux en catégories correspond à l'opération *image inverse* de catégories sur S - laquelle opération passe aux scindages. Cela nous donne donc

$$f^*(\mathrm{hot}_{W,S}(X)) = \mathrm{hot}_{W,S'}(\underbrace{X \times_S S'}_{X'}),$$

pour toute X fibrée scindée sur S. Or on sait que le scindage de X ne joue aucun rôle, finalement, dans la description de la classe

$$\mathrm{hot}_{W,S}(X) \in \mathrm{HOT}_W(S)$$

associée à X. On peut oublier le scindage, et même (pour étudier les $\mathrm{Hom}_{\mathrm{Hot}_W(S)}(X,Y)$) travailler avec des S-foncteurs *quelconque* entre catégories fibrées sur S - pas la peine même de les supposer cartésiens, voir même compatibles avec des scindages. Cela me paraît une chose très importante pour le formalisme des $\mathrm{HOT}_W(S)$, et très spéciale au cas de la catégorie de modèles Cat. C'est un peu tacite dans le théorème-scholie - mais mes doutes initiaux concernant la catégorie Fibsc elle-même montrent bien que je sentais qu'il y avait là quelque chose de pas évident, ni même (presque) `[?]` de vraisemblable. Et pourtant l'existence du foncteur Φ montre qu'il en est bien ainsi. p. 73 [page 117]

Commentary · Exposition [ms. 116]

Pullback is precomposition in the split presentation

Grothendieck returns to split fibrations because a change of base is completely visible in that presentation. For a strict functor $F : S^{\mathrm{op}} \to \mathrm{Cat}$, write $\int_S F$ for its Grothendieck construction. An object is a pair (s, x) with $x \in F(s)$; an arrow $(s, x) \to (t, y)$ consists of $a : s \to t$ and a map $x \to F(a)y$ in $F(s)$. The projection to S is the associated split fibration.

If $f : S' \to S$, there is a canonical isomorphism over S'

$$S' \times_S \int_S F \;\cong\; \int_{S'} (F f^{\mathrm{op}}).$$

On objects it sends (s', x) with $x \in F(f(s'))$ to the same pair. On an arrow $a : s' \to t'$ it uses the same map $x \to F(f(a))y$. Identities and composition agree because F and f are functors. The chosen cartesian lifts are carried to the chosen cartesian lifts, so the isomorphism also respects the splittings.

An objectwise weak equivalence of functors remains objectwise a weak equivalence after precomposition: its component at s' is the original component at $f(s')$. This proves that the operation descends to the relevant localization and gives the formula for f^* on split representatives. If $g : S'' \to S'$ is another functor, precomposition satisfies

$$(F f^{\mathrm{op}}) g^{\mathrm{op}} = F(fg)^{\mathrm{op}}$$

strictly. After changing to equivalent presentations by arbitrary fibrations or by categories over S, these equalities are expressed by the canonical comparison isomorphisms for iterated pullbacks. The coherence comes from the same strict composition law, rather than from a new choice of replacement for each composite.

This paragraph only establishes the formula on the specified good representatives. Extending it to other objects or deciding when an arbitrary pullback computes the derived inverse image requires the base-change results on the following pages. The categorical calculation here explains why Grothendieck keeps the split models in the theory even after showing that their localized category is independent of the splitting.

On peut donc interpréter f^* en termes de $\underline{\mathrm{Fib}}\, S$, $\underline{\mathrm{Fib}}\, S'$, par le foncteur changement de base

$$f^* : \underline{\mathrm{Fib}}\, S \longrightarrow \underline{\mathrm{Fib}}\, S', \qquad X \longmapsto X \times_S S'/S',$$

lequel foncteur préserve évidemment la W-équivalence par fibres W_S^{f}, $W_{S'}^{\mathrm{f}}$, qu'est celle pertinente ici

$$f^*(W_S^{\mathrm{f}}) \subseteq W_{S'}^{\mathrm{f}},$$

de sorte que f^* induit bien

$$(\underline{\mathrm{Fib}}\, S)(W_S^{\mathrm{f}})^{-1} \longrightarrow (\underline{\mathrm{Fib}}\, S')(W_S^{\mathrm{f}})^{-1}$$

[plutôt $(\underline{\mathrm{Fib}}\, S')(W_{S'}^{\mathrm{f}})^{-1}$], i.e. le foncteur $(*)$ [page 118]

$$f^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S').$$

D'autre part, $\mathrm{HOT}_W(S)$ peut être décrit aussi comme localisé de Cat/S tout entier, par rapport au localiseur W_S^{d}, lequel sur $\underline{\mathrm{Fib}}\, S$, et même sur $\underline{\mathrm{Liss}}\, S$, coïncide avec W_S^{f}. Mais on se bute ici à la difficulté que le foncteur image inverse

$$f^* : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S', \qquad X \longmapsto X \times_S S'/S',$$

n'est *pas* compatible en général (si S n'est isomorphe à la catégorie ponctuelle, pour S' quelconque) avec les localiseurs W_S^{d}, $W_{S'}^{\mathrm{d}}$. On le voit p.ex. en prenant $S' = \{s\}$, et en se rappelant que W_S^{d} n'implique *pas*, sur Cat/S tout entier, la W-équivalence par fibres.

Commentary · Exposition [ms. 117]

Restriction must be calculated on a suitable model

Grothendieck now makes the base category vary. The comparison theorem has done more than identify several presentations of one category: it provides presentations on which an operation can be performed before localization. For inverse image the useful presentation consists of fibrations, or more generally smooth categories over the base. The calculation then reduces to the familiar operation on fibres.

Write $q_S : \mathrm{Cat}/S \to \mathrm{HOT}_W(S)$ for localization at W_S^{d}. If $X \to S$ is smooth, the strict fibre X_s computes the same homotopy type as the comma category $s\backslash X$. For $f : S' \to S$ and $s' \in S'$, the strict fibre of $X \times_S S'$ at s' is exactly $X_{f(s')}$. Consequently a map between smooth objects which is a W-equivalence on comma categories remains so after this pullback. The comparison with split fibrations identifies the resulting localized operation with restriction of category-valued presheaves. This proves Proposition 1, including its naturality in maps between smooth objects.

The qualification on the objects matters even when the morphism being pulled back already belongs to W_S^{d}. Its membership says something about all comma fibres; it says nothing by itself about its strict fibres. Pullback along the inclusion of an object extracts a strict fibre. Thus arbitrary pullback cannot act directly on the entire relative category $(\mathrm{Cat}/S, W_S^{\mathrm{d}})$. The commentary at manuscript p. 42 ("When strict fibres compute a comma fibre") isolates precisely the comparison required here.

There is also a useful distinction between the arrows allowed in this presentation and the arrows needed to describe transport. For calculating the category $\mathrm{HOT}_W(S)$, all functors over S between fibrations are allowed; Cartesian functors form a smaller presentation which gives the same localization. A chosen cleavage is therefore not part of a relative homotopy type. When a natural transformation between changes of base is considered on ms. 128–130, a cleavage will nevertheless provide a convenient formula for the induced map. Independence of that auxiliary choice is a separate assertion, not an additional restriction on the morphisms of $\mathrm{HOT}_W(S)$.

Ces ennuis n'ont pas lieu sûr $\underline{\mathrm{Liss}}\, S$, où W_S^{d} et W_S^{f} coïncident. On peut donc décrire f^* sur les HOT aussi à l'aide de

$$f^* : \underline{\mathrm{Liss}}\, S \longrightarrow \underline{\mathrm{Liss}}\, S', \qquad X \longmapsto X \times_S S'/S',$$

en passant aux localisés

$$f^* : (\underline{\mathrm{Liss}}\, S)(W_S^{\mathrm{f}})^{-1} \longrightarrow (\underline{\mathrm{Liss}}\, S')(W_{S'}^{\mathrm{f}})^{-1}.$$

En d'autres termes :

Proposition 1. *Si X dans Cat/S est lisse sur S, alors on a un isomorphisme canonique*

$$f^*(\mathrm{hot}_{W,S}(X)) \simeq \mathrm{hot}_{W,S'}(X'), \qquad \text{où } X' = X \times_S S'/S'.$$

Une remarque similaire s'applique à $\underline{\mathrm{Fibhot}}\, S$, où $W_S^{\mathrm{d}} = W_S^{\mathrm{f}}$ également. Le foncteur changement de base induit p. 74 [page 119]

$$\underline{\mathrm{Fibhot}}\, S \longrightarrow \underline{\mathrm{Fibhot}}\, S', \qquad X \longmapsto X \times_S S'/S',$$

compatible avec les localiseurs relatifs pertinents (tous ceux envisagés jusqu'à présent coïncident sur ces catégories, avec les hypothèses faites sur W), d'où

$$f^* : (\underline{\mathrm{Fibhot}}\, S)W_S^{-1} \longrightarrow (\underline{\mathrm{Fibhot}}\, S')W_{S'}^{-1}.$$

Les localisés cette fois ne sont pas les HOT_W, mais les $\mathrm{HOT}_W^{\mathrm{lc}}$, donc on trouve une description sympathique de

$$f^* : \mathrm{HOT}_W^{\mathrm{lc}}(S) \longrightarrow \mathrm{HOT}_W^{\mathrm{lc}}(S'),$$

plus avantageuse encore qu'en termes de $\underline{\mathrm{Liss}}_0 S$, $\underline{\mathrm{Liss}}_0 S'$, car s'appliquant à des catégories un peu plus vastes (NB $\underline{\mathrm{Liss}}_0 \subseteq \underline{\mathrm{Fibhot}}$). Notons donc le [page 120]

Corollaire 1. *La formule de la proposition 1 (p. 118) reste valable si X est supposé* Hot-*fibrant sur S (au lieu de lisse sur S).* (On trouve alors des types d'homotopie relatifs *localement constants* sur S, S'.)

On a donc une description de f^* qui s'applique à toutes les catégories du côté gauche du diagramme [page] 76, à la seule exception de Cat/S elle-même. Si X est dans Cat/S, sans être ni lisse ni Hot-fibrée sur S, comment trouver l'image inverse dans $\mathrm{HOT}_W(S')$? On a le choix entre Φ et C pour améliorer la situation! On sait que X définit la même classe dans $\mathrm{HOT}_W(S)$ que $\Phi(X)$, $C(X)$, qui sont l'une lisse (et même fibrée scindée), l'autre Hot-fibrée (et même parfaite) sur S. Donc

Commentary · Present state [ms. 120]

The two replacements do different work

Grothendieck wants one formula for the inverse image of an arbitrary category over S. The comma replacement Φ_S supplies it. The path replacement C_S supplies a formula for a different object, namely the reflection into locally constant relative types. At this point the text briefly identifies those two tasks. Both the sentence preceding Corollary 2 and its second displayed isomorphism are present in the edition; the discrepancy is not introduced by the transcription.

The distinction is already established in the source. The natural map

$$X \longrightarrow \Phi_S(X)$$

belongs to W_S^{d}, whereas $X \longrightarrow C_S(X)$ is generally only in W_S. Accordingly the valid general formula is

$$f^* q_S(X) \simeq q_{S'}\big(\Phi_S(X) \times_S S'\big).$$

If $i_S : \mathrm{HOT}_W^{\mathrm{lc}}(S) \to \mathrm{HOT}_W(S)$ denotes the inclusion, the formula involving C_S is

$$f^* i_S \rho_S q_S(X) \simeq q_{S'}\big(C_S(X) \times_S S'\big).$$

Here restriction preserves locally constant objects, so that $f^* i_S$ identifies with $i_{S'} f_{\mathrm{lc}}^*$. These equations become the same only when $q_S(X)$ is already locally constant.

A small calculation makes the error decisive without repeating the examples given in the commentary at manuscript pp. 8 and 32. Take $W = W_\infty$, $S = (0 \to 1)$ and $X = \{0\} \to S$. The comma fibres of X are a point at 0 and the empty category at 1. Its relative type is therefore the presheaf of spaces $(\varnothing \to *)$. The local-constant reflection is the constant point: maps from this presheaf to a locally constant arrow are determined by the value at 0, and evaluation at 0 identifies locally constant arrows with spaces. Pullback to 1 consequently gives $\varnothing$ from X and $*$ from $C_S(X)$. Corollary 2 cannot identify them.

This is a localized mistake in the calculation, not a defect in the comparison theorem. The later discussion on ms. 123–127 correctly distinguishes $\rho_S q_S(X)$ from $q_S(X)$, and the construction of the adjunction on ms. 139–145 consistently uses Φ_S. Keeping the printed error visible is useful: it shows exactly why the two replacement functors were needed.

Corollaire 2. *Si X dans* Cat/S *est quelconque, alors*

$$f^*(\mathrm{hot}_{W,S}(X)) \simeq \mathrm{hot}_{W,S'}(\Phi(X) \times_S S') \simeq \mathrm{hot}_{W,S'}(C(X) \times_S S').$$

On peut s'attendre, d'autre part, que pour certains changements de base particuliers, la formule de la proposition 1 soit valable sans restriction sur X dans Cat/S. Il doit revenir ± au même que le foncteur image inverse

$$X \longmapsto X \times_S S'$$

soit compatible avec les localiseurs W_S^{d}, $W_{S'}^{\mathrm{d}}$. La condition de W-équivalence 'colocale sur S' doit être vue comme une condition de nature 'homologique', pour le dérivateur HOT. p. 75
Elle s'associe, pour un dérivateur quelconque $\mathbf{D}$, à la condition (pour $f : X \longrightarrow Y$ dans [page 121]

Cat/S) que les $s\backslash X \longrightarrow s\backslash Y$ sont des **D**-équivalences, ce qui s'écrit ici élégamment en termes d'homologie relative, par la condition que $\forall\ a \in \mathcal{A} = \mathbf{D}(e)$, la flèche induit par f

$$\underbrace{H_\bullet^{\mathbf{D}}(X/S, a_X)}_{\overset{\text{déf}}{=}(p_X)_!(a_X)} \longrightarrow \underbrace{H_\bullet^{\mathbf{D}}(Y/S, a_Y)}_{\overset{\text{déf}}{=}(p_Y)_!(a_Y)}$$

soit [un] isomorphisme. (Utiliser le 'calcul' des faisceaux d'homologie relative $(p_X)_!(a_X)$, $(p_Y)_!(a_Y)$, par la caractérisation des fibres dans Der 4 bis). Or, les changements de base **D**-*propres* $S' \longrightarrow S$ commutent aux $p_!$, de sorte qu'on trouve le

Lemme. *La notion d'équivalence* **D**-*colocale sur* S *dans* Cat/S *est stable par tout changement de base* $S' \longrightarrow S$ **D**-*propre. (Quel que soit le dérivateur* **D**.*)*

On se rappelera que les $s\backslash S \longrightarrow S$ sont justement des changements des base propres! On peut dire que l'équivalence **D**-colocale peut se décrire en exigeant que $f : X \longrightarrow Y$ soit transformé en W-équivalences par certains types de changement de base $S' \longrightarrow S$, en prenant au choix l'un des trois types

a) Les changements de base $s\backslash S \longrightarrow S$ (ce qui redonne la définition que nous avions prise).

b) Les changements de base qui sont des co-isomorphismes locaux.

c) Les changements de base propres.

d) Les changements de base **D**-propres.

On ne peut appliquer ces résultats qu'au dérivateur HOT, faute de l'avoir encore construit, et verifié, les axiomes pertinents. On peut poser simplement la [page 122]

Commentary · Exposition [ms. 121]

A homological test for colocal equivalence

Grothendieck introduces relative homology here because it packages all the comma-category tests into a single morphism of coherent diagrams. Let $p_X : X \to S$, $p_Y : Y \to S$, and let $u : X \to Y$ be a functor over S. For $a \in \mathbf{D}(e)$, write a_X for the constant coefficient. The map of interest is

$$(p_X)_! a_X \longrightarrow (p_Y)_! a_Y.$$

Its component at s is the map on homotopy colimits of the constant coefficient over $s\backslash X$ and $s\backslash Y$. This is the pointwise Kan-extension formula in the contravariant convention used throughout these pages. If isomorphisms are detected by evaluation, requiring the displayed map to be invertible for every a is exactly the condition that all these comma-category maps be **D**-equivalences.

Now suppose $g : T \to S$ is **D**-proper in the sense that the relevant base-change comparisons for homological direct image are invertible. Pulling back the displayed map gives

$$(p_{X_T})_! a_{X_T} \longrightarrow (p_{Y_T})_! a_{Y_T}, \qquad X_T = X \times_S T, \quad Y_T = Y \times_S T.$$

The first map was invertible, and restriction preserves isomorphisms; hence the new map is invertible. Evaluating at every object of T gives the claimed stability of colocal equivalence. This proves the lemma without assuming that strict fibres compute comma fibres: the base-change theorem supplies that comparison at the level of relative homology.

The four classes of test maps listed in the text are genuinely nested. A representable coslice projection is a discrete opfibration, hence a co-local isomorphism; those maps are proper, and absolute properness implies **D**-properness. Testing against the largest class therefore implies testing against the first. Conversely the lemma shows that the first condition survives the largest class, and a colocal equivalence is in particular a global **D**-equivalence. The source's phrase "three types" precedes four entries and has no mathematical consequence.

The historical terminology keeps the geometrical motivation visible. Properness and smoothness were designed to distinguish the two positions in a base-change square, following the analogous cohomological theorems in algebraic geometry. For the categorical definitions, including their dual formulations by taking mates, see Maltsiniotis (2005, Definition 1.1). Here the lesson is particularly concrete: the general derivator theorem predicts the correct class of changes of base, but cannot yet be used to establish the axioms of the very derivator under construction.

Conjecture (sûre!) : *Soit $p : S' \longrightarrow S$ une flèche propre (sous-entendu :* HOT*-propre) dans* Cat*. Alors le foncteur changement de base*

$$\mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S', \qquad X \longmapsto X \times_S S'/S'$$

est compatible avec les localiseurs W_S^{d}, $W_{S'}^{\mathrm{d}}$. (Pour un foncteur $S' \longrightarrow S$ lisse, le changement de base serait compatible avec W_S^{g}, $W_{S'}^{\mathrm{g}}$.) ([61]).

Mais pout tout changement de base $S' \longrightarrow S$ (propre ou non) qui a la propriété précédente, donc qui induit un foncteur

$$\underbrace{(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}}_{\approx \mathrm{HOT}_W(S)} \longrightarrow \underbrace{(\mathrm{Cat}/S')(W_{S'}^{\mathrm{d}})^{-1}}_{\approx \mathrm{HOT}_W(S')} ,$$

il est immédiat, à l'aide du théorème de comparaison (p.ex. avec $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Liss}}\, S'$) sur S et sur S', que ce foncteur n'est autre (à isomorphisme canonique près) que le foncteur f^* image inverse des types d'homotopie relatifs. Donc énoncons le p. 76

Corollaire 3. *La formule de la proposition 1 reste valable sans hypothèse aucune sur X dans* Cat$/S$*, pourvu que la flèche de changement de base $f : S' \longrightarrow S$ soit telle que le foncteur $X \longmapsto X \times_S S'$ de* Cat$/S$ *dans* Cat$/S'$ *transforme W-équivalences colocales sur S en W-équivalences colocales sur S'.* (Ce qui devrait être le cas si (et seulement si?) f est W-propre, donc aussi si f est ('absolument') propre ([62]).) [page 123]

Commentary · Later developments [ms. 122]

The proper base-change conjecture has an elementary proof

The conjecture on ms. 122 is not an open question. Grothendieck himself proves it later in Chapter VI, ms. 168–169, printed p. 103 of the complete edition; the footnote points to that proof. The argument avoids the circular appeal to a derivator whose axioms are still being established (Grothendieck, 1990b, ms. 168–169).

For clarity, isolate its mechanism. If $v : T \to U$ is a universal W-equivalence and $a : A \to B$ is a map over U, there is a pullback square

$$\begin{array}{ccc} A \times_U T & \xrightarrow{a_T} & B \times_U T \\ \downarrow & & \downarrow \\ A & \xrightarrow{a} & B. \end{array}$$

Both vertical maps belong to W. The two-out-of-three property consequently gives $a_T \in W$ if and only if $a \in W$.

Apply this with $g : S' \to S$ proper and an object $s' \in S'$, putting $s = g(s')$. The properness criterion says that

$$s'\backslash S' \longrightarrow s\backslash S$$

is a universal homotopy equivalence; in the relative variant it is a universal W-equivalence. A map in W_S^{d} is a W-equivalence after pullback to $s\backslash S$. The preceding square shows that it remains so after further pullback to $s'\backslash S'$. This is exactly the definition of its pullback belonging to $W_{S'}^{\mathrm{d}}$. Passing to opposite categories gives the smooth, left-fine version.

Corollary 3 therefore gives the expected strict formula for proper changes of base. Its proof does not depend on choosing a preferred representative: the functor defined on all of Cat$/S$ agrees, on the smooth presentation, with the previously constructed restriction functor. The equivalence of the two presentations then identifies their descents. The later proof establishes the sufficient condition. The converse requires the additional test calculation given below, and its formulation depends on the chosen localizer.

61. NB Cette 'conjecture' est prouvé sans lemme à la page 168-169, sans avoir besoin de rien qui ne soit déjà connu ici. Cf. théorème 4, cas b) p. 162.

62. cf. I, pages 55-59.

On n'a travaillé jusqu'ici qu'avec les localiseurs W_S^{d}, $W_{S'}^{\mathrm{d}}$, à l'exclusion de W_S, $W_{S'}$. (Sauf sur les catégories contenues dans $\underline{\mathrm{Fibhot}}\, S$, où les deux coïncident.) Quand on ne fait pas d'hypothèse draconienne sur $p : S' \longrightarrow S$, du type Hot-fibration, on n'a aucune chance pour que $X \longmapsto X \times_S S'$ transforme W-équivalences grossières dans itou, donc aucune chance d'attraper l'image inverse du type d'homotopie relatif 'grossier' de X, en prenant celui de $X' = X \times_S S'$. Cela est lié au fait que pour un $S' \longrightarrow S$ général, les foncteurs de localisation

$$\mathrm{HOT}_W(S) \xrightarrow{\rho_S} \mathrm{HOT}_W^{\mathrm{lc}}(S), \qquad \mathrm{HOT}_W(S') \xrightarrow{\rho_{S'}} \mathrm{HOT}_W^{\mathrm{lc}}(S')$$

n'ont aucune envie de commuter au foncteur image inverse f^* sur les HOT_W. On peut hasarder la

Proposition 2. *Conditions équivalentes sur le foncteur $S' \longrightarrow S$:*

a) Le diagramme de foncteurs

$$\begin{array}{ccc} \mathrm{HOT}_W(S) & \xrightarrow{\rho_S} & \mathrm{HOT}_W^{\mathrm{lc}}(S) \\ \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*_{\mathrm{lc}}} \\ \mathrm{HOT}_W(S') & \xrightarrow{\rho_{S'}} & \mathrm{HOT}_W^{\mathrm{lc}}(S') \end{array}$$

commute (à isomorphisme de foncteurs composés près).

b) Le foncteur changment de base [page 124]

$$\underline{\mathrm{Liss}}\, S \longrightarrow \underline{\mathrm{Liss}}\, S', \qquad X \longmapsto X \times_S S'/S'$$

transforme W_S en $W_{S'}$. p. 77

b′) Énoncé analogue pour $\underline{\mathrm{Fib}}\, S \longrightarrow \underline{\mathrm{Fib}}\, S'$.

b″) Énoncé analogue pour $\underline{\mathrm{Fibsc}}\, S \longrightarrow \underline{\mathrm{Fibsc}}\, S'$.

([63], [64]).

Démonstration. Si $\mathcal{F}$ est une des trois catégories $\underline{\mathrm{Liss}}\, S$, $\underline{\mathrm{Fib}}\, S$ ou $\underline{\mathrm{Fibsc}}\, S$, le foncteur ρ_S peut se décrire comme le foncteur de localisation canonique

$$\mathcal{F}(W_S^{\mathrm{d}})^{-1} \longrightarrow \mathcal{F}W_S^{-1}$$

(ça marcherait pour n'importe quelle sous-catégorie pleine $\mathcal{F}$ de Cat/S qui contient $\underline{\mathrm{Fib}}\, S$). Or si b), b′) ou b″) est satisfait, on trouve un diagramme commutatif de foncteurs induits par le changement de base

$$\begin{array}{ccc} \mathcal{F}(W_S^{\mathrm{d}})^{-1} & \xrightarrow{\rho_S} & \mathcal{F}(W_S)^{-1} \\ {\scriptstyle f^*_{W_S^{\mathrm{d}}}}\downarrow & & \downarrow{\scriptstyle f^*_{W_S}} \\ \mathcal{F}'(W_{S'}^{\mathrm{d}})^{-1} & \xrightarrow{\rho_{S'}} & \mathcal{F}'(W_{S'})^{-1}, \end{array}$$

sous réserve, il est vrai, dans le cas $\mathcal{F} = \mathrm{Cat}/S$, que le foncteur image inverse soit aussi compatible avec W_S^{d}, $W_{S'}^{\mathrm{d}}$ (ce qui est automatique si $\mathcal{F} = \underline{\mathrm{Fib}}\, S$ ou $\underline{\mathrm{Fibsc}}\, S$). On sait que $f^*_{W_S^{\mathrm{d}}}$ décrit le foncteur f^* sur les types d'homotopie relatifs, et pour prouver a) comme conséquence de b) (renforcé), b′ ou b″, il reste à s'assurer que le foncteur $f^*_{W_S}$ décrit de même le foncteur induit par le précédent sur les types d'homotopie relatifs localement constants. Or on a les inclusions canoniques $\mathcal{F}_0 \subseteq \mathcal{F}$, $\mathcal{F}'_0 \subseteq \mathcal{F}'$, et sur $\mathcal{F}_0$, $\mathcal{F}'_0$ `[on a]` $W_S = W_S^{\mathrm{d}} = W_S^{\mathrm{f}}$, et les [page 125]

63. Pas prouvée, seulement que b, b′, b″ impliquent a). Pour l'implication inverse, il faudrait savoir que toute flèche de $\mathcal{F}'$ qui devient `[un]` isomorphisme dans $\mathcal{F}'W_{S'}^{-1}$, est dans $W_{S'}$ (saturation forte de $W_{S'}$ dans $\mathcal{F}'$), chose que je ne sais pas. Mais je crois que ce doit être vrai.

64. **NB** Si on suppose p propre, on doit pouvoir prendre aussi $\mathcal{F} = \mathrm{Cat}/S$.

catégories sont OK pour décrire $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ et $\mathrm{HOT}^{\mathrm{lc}}_W(S')$, et le foncteur f^* induit entre eux par images inverses ([65]) (**NB** Le foncteur changement de base $X \longmapsto X \times_S S'$ est compatible avec les localiseurs sur ces catégories, car c'est trivial sous la forme W^{f}_S.) On a alors, par images inverses $X \longmapsto X \times_S S'$, un diagramme commutatif

$$\begin{array}{ccc} \mathcal{F}_0(W_S)^{-1} & \xrightarrow{\approx} & \mathcal{F}(W_S)^{-1} \\ {\scriptstyle (f^*_{W_S})_0}\downarrow & & \downarrow{\scriptstyle f^*_{W_S}} \\ \mathcal{F}'_0(W_{S'})^{-1} & \xrightarrow{\approx} & \mathcal{F}'(W_{S'})^{-1}, \end{array}$$

où les flèches horizontales sont des *équivalences* de catégories, par le théorème-scholie 1 Ⓘ . p. 78
Cela prouve que $f^*_{W_S}$ lui aussi est bon pour calculer les images inverses de types d'homotopie relatifs.

On a prouvé que b, b′, b″ impliquent chacun a), prouvons que a) les implique. Or a) dit exactement que les images inverses f^* des éléments de $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ sont, à isomorphisme près, [page 126]
obtenus par le foncteur image inverse sur $\mathcal{F}$ tout entier, en interprétant $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ comme $\mathcal{F}W_S^{-1}$. Mais cela implique bien que $\mathcal{F} \longrightarrow \mathcal{F}'$ doit être compatible avec les localiseurs. Mais je charrie - on trouve seulement que si $u : X \longrightarrow Y$ dans $\mathcal{F}$ est dans W_S, alors la flèche $u' : X' \longrightarrow Y'$ donne un isomorphisme dans $\mathcal{F}'(W_{S'})^{-1}$. Je ne sais pas, d'autre part, si cela implique que u' est dans $W_{S'}$.

Corollaire 1. *Supposons que $p : S' \longrightarrow S$ soit une* Hot*-fibration. Alors le foncteur image inverse $X \longmapsto X \times_S S'$ de* Cat$/S$ *dans Cat$/S'$ applique W_S dans $W_{S'}$, donc le foncteur $p^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S')$ commute aux foncteurs de localisation ρ_S, $\rho_{S'}$ dans ces catégories.* (**NB** Il faut faire l'hypothèse adéquate sur W, savoir L6 bis page 44. C'est OK pour W_∞.)

Le fait que $X \longmapsto X \times_S S'$ soit compatible avec W_S, $W_{S'}$ est une tautologie, compte tenu de l'hypothèse L6 bis. Il ne semble pas qu'il soit aussi compatible à W^{d}_S, $W^{\mathrm{d}}_{S'}$ (je devrais faire un contrexemple, avec bien sûr S' non propre sur S). Donc on est sous les conditions de b), qui implique a).

[page 127]

Commentary · Exposition [ms. 126]

Saturation supplies the missing converse

Grothendieck wants to recognize when restriction commutes with the reflection into locally constant objects. His forward implication is sound: preservation of coarse weak equivalences on any of the indicated smooth or fibred presentations lets the square of localizations descend. For the converse he notices precisely what has not yet been justified. An arrow becoming invertible after localization need not, for an arbitrary chosen class of arrows, have belonged to that class.

There is a short repair once W is strongly saturated in Cat. Let $\mathcal{F}$ be any category of categories over a fixed base, with any chosen class of allowed morphisms, and let $W_{\mathcal{F}}$ consist of those allowed morphisms whose underlying functors belong to W. The forgetful functor descends to

$$\mathcal{F}[W_{\mathcal{F}}^{-1}] \longrightarrow \mathrm{Cat}[W^{-1}].$$

If an actual arrow u of $\mathcal{F}$ becomes invertible on the left, its underlying functor becomes invertible on the right. Strong saturation gives $u \in W$. The converse is part of localization. Thus the restriction of a strongly saturated coarse class remains strongly saturated, even when $\mathcal{F}$ is not full.

Assume now that the square in condition a) commutes. For $u \in W_S$ in a smooth or fibred presentation, its image under ρ_S is an isomorphism. Commutativity says that f^*u becomes an isomorphism in the coarse localization over S'. The preceding argument then gives $f^*u \in W_{S'}$. This proves each of b), b′), and b″). For W_∞, the needed saturation follows immediately by applying the nerve and the homotopy category of simplicial sets. In the later theory it holds for every fundamental localizer; see Cisinski (2006c, Proposition 4.2.4 in the author PDF). The gap belongs to the proof available at this point, not to the resulting equivalence.

65. NB $(\mathrm{Cat}/S)_0 = \underline{\mathrm{Fibhot}}\, S$, pour les autres cas, c'est clair.

Commutation itself is a real restriction. In the interval calculation above, let $f : \{1\} \to (0 \to 1)$ and let $F = (\varnothing \to *)$. Then

$$\rho_{\{1\}} f^* F = \varnothing, \qquad f^*_{\mathrm{lc}} \rho_S F = *.$$

This supplies a concrete obstruction without confusing it with the separate failure of arbitrary strict pullback to preserve W_S^{d}. Grothendieck's Hot-fibration hypothesis is sufficient because it ensures preservation of the coarse class by pullback. Strong saturation closes his converse in Proposition 2; it does not assert that every functor satisfies its equivalent conditions.

Commentary · Development (commentators') [ms. 126]

Properness and a three-object counterexample

The question on ms. 123 and the proposed counterexample on ms. 126 can both be settled concretely. The useful characterization of W-properness is the dual of Maltsiniotis (2005, Theorem 1.2(b)). For $f : A \to S$, $a \in A$, and $h : f(a) \to b$ in S, let $L_f(a, h)$ have objects arrows $k : a \to a'$ with $f(a') = b$ and $f(k) = h$. A morphism is an arrow $\ell : a' \to a''$ with $f(\ell) = \mathrm{id}_b$ and $\ell k = k'$. Then f is W-proper exactly when every $L_f(a, h)$ is W-aspherical. These are the outgoing comma categories for the inclusion $A_b \to A/b$.

Proposition (detecting properness by inverse image). [ours] For $W = W_\infty$, strict pullback along a fixed $f : A \to S$ preserves right-fine weak equivalences on all categories over S if and only if f is proper. For an arbitrary fundamental localizer W, W-properness is equivalent to this preservation property holding after every change of base of f.

Proof. Properness implies preservation by the preceding block, and properness is stable under base change. To prove the first converse, test the assumed preservation on the unit

$$\{b\} \longrightarrow \Phi_S(\{b\}) = S/b.$$

This is right-fine: its comma category at s maps the discrete set $\mathrm{Hom}_S(s, b)$ into the category of factorizations of those arrows, and each factorization category has an initial and a terminal object.

After pullback along f, take the comma category at a. In the target, objects are triples

$$(a', k : a \to a', r : f(a') \to b).$$

The composite $rf(k)$ defines a decomposition indexed by $h \in \mathrm{Hom}_S(f(a), b)$. The component indexed by h has initial object (a, id_a, h). The corresponding source component is exactly $L_f(a, h)$. A weak equivalence of these disjoint unions to the contractible target components forces every $L_f(a, h)$ to be weakly contractible. The cited criterion gives properness.

For the general converse, suppose preservation holds after every base change. Given $h : f(a) \to b$, pull back f along the functor $[1] \to S$ representing h. Apply the preservation hypothesis to $\{1\} \to [1]$ over $[1]$, which is the same unit test. At the object $(a, 0)$ of $A \times_S [1]$, its source comma category is $L_f(a, h)$ and its target comma category has an initial object. Since the map belongs to W, two-out-of-three implies $L_f(a, h) \to e \in W$. The criterion again gives W-properness. □

Example (why arbitrary localizers require base change). [ours] The distinction between the two formulations cannot be omitted for arbitrary fundamental localizers. Let W_{ne} consist of functors whose source and target are either both empty or both nonempty. This is a fundamental localizer: weak saturation and the terminal-object axiom are immediate, and the relative theorem-A axiom follows because an object of a nonempty target gives a nonempty target comma category, hence a nonempty source comma category. Take a nontrivial group G and $f : e \to BG$. Over the one-object category BG, every comma category of $X \to BG$ is nonempty exactly when X is nonempty. Right-fine W_{ne}-equivalence therefore detects only nonemptiness. Strict pullback along f does not change the object set of X, so it preserves that class. Yet $L_f(*, g)$ is empty for every nonidentity $g \in G$, and f is not W_{ne}-proper. This example concerns the broader localizer question, not a weakening of the stronger hypotheses used elsewhere in this chapter.

Example (a Hot-fibration which is not proper). [ours] Let E be the three-object poset with nonidentity arrows $u \to v$ and $u \to w$, and put

$$p : E \longrightarrow (0 \to 1), \qquad p(u) = p(v) = 0, \quad p(w) = 1.$$

This is a Grothendieck fibration. The lift $u \to w$ of $0 \to 1$ is Cartesian: for an object over 0, its arrows to u and its arrows to w are both singletons when the object is u, and both empty when it is

v. The two fibres are $(u \to v)$ and $\{w\}$; their transition functor chooses u and is a weak equivalence. Thus p lies in $\underline{\mathrm{Fib}}_0$, hence in $\underline{\mathrm{Fibhot}}$ under the standing comparison hypotheses.

There is also a direct verification of its particularly strong homotopical behaviour. The section choosing u over 0 and w over 1 has a natural transformation $sp \Rightarrow \mathrm{id}_E$ over the base, whose only nonidentity component is $u \to v$. This deformation retraction survives every strict base change. Every projection $E \times_S T \to T$ is therefore a nerve weak equivalence. Two-out-of-three in a square over S shows that pullback along p preserves all coarse weak equivalences.

Nevertheless p is not proper, since $L_p(v, 0 \to 1)$ is empty. More explicitly, the right-fine weak equivalence $\{1\} \to [1]$ pulls back to $\{w\} \to E$. Its comma functor at v is $\varnothing \to e$, so it is not right-fine. This is precisely the counterexample requested on ms. 126. We checked the properness criterion just cited; the elementary tests and examples here are explicit completions of the manuscript's questions, without a priority claim.

Je ne me sens pas capable d'exhiber un foncteur autre qu'une Hot-fibration (ou tout au moins une W-fibration), pour lequel le foncteur image inverse sur HOT_W soit compatible aux foncteurs de localisation ρ_S, $\rho_{S'}$. Bien sûr, si X est quelconque dans Cat/S, rien n'empêche de regarder son localisé pour W_S, i.e. $\rho_S(\mathrm{hot}_{W,S}(X))$, et de demander comment trouver son image inverse. Si $p : S' \longrightarrow S$ est une Hot-fibration, alors il suffit de prendre $\mathrm{hot}_{W,S'}(X')$, $X' = S \times_S S'$. Dans tout autre cas (j'entends, sans hypothèse sur X/S, plus précisément sans supposer que X est lui-même Hot-fibré sur S), cette formule est canulée sans espoir. On doit, pour calculer $f^*\rho_S(\mathrm{hot}_{W,S}(X))$, 'calculer' $\rho_S(\mathrm{hot}_{W,S}(X))$ en 'montant à l'étage', comme $\mathrm{hot}_{W,S}(C(X))$. On trouve alors l'image inverse $\mathrm{hot}_{W,S'}(C(X) \times_S S')$ (par `[le]` corollaire 1, p. 119).

Maintenant que la loi contravariante de $\mathrm{HOT}_W(S)$ en $S \in \mathrm{Ob}\,\mathrm{Cat}$ semble bien comprise, il s'agit de voir qu'on a bien un dérivateur HOT. Je ne m'attends pas à ce que les $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ définissent eux aussi un dérivateur, mais il faudrait m'en assurer expressément. (C'est pour l'existence de $f_!$, f_* que je doit chercher.) [page 128]

À dire vrai, il faudrait, pour bien faire, regarder aussi la structure de 2-*foncteur* de

$$S \longmapsto \mathrm{HOT}_W(S) \qquad \mathrm{Cat}^o \longrightarrow \mathrm{Cat},$$

donc pour S, S' données dans Cat, définir p. 79

$$\underline{\mathrm{Hom}}(S', S)^o \longrightarrow \underline{\mathrm{Hom}}(\mathrm{HOT}_W(S), \mathrm{HOT}_W(S')).$$

Cela revient surtout, pour

$$f, g : S' \rightrightarrows S$$

deux flèches de S' dans S, et un homomorphisme de foncteurs

$$u : f \longrightarrow g,$$

à décrire un homomorphisme de foncteurs

$$u^* : g^* \longrightarrow f^*$$

entre $\mathrm{HOT}_W(S)$ et $\mathrm{HOT}_W(S')$. C'est d'ailleurs chose faite, dans le cadre général des $(\mathcal{M}, W)$, quand on décrit $\mathrm{HOT}_W(S)$ et $\mathrm{HOT}_W(S')$ par localisation de $\mathrm{Hom}(S^o, \mathrm{Cat})$ et $\mathrm{Hom}(S'^o, \mathrm{Cat})$. Ces catégories s'interprètent respectivement comme $\underline{\mathrm{Fibsc}}\, S$ et $\underline{\mathrm{Fibsc}}\, S'$, donc comme des catégories de catégories sur S resp. S', on voudrait donc interpréter u^* en termes de telles catégories, et tant qu'à faire, pour des catégories X sur S aussi générales que possible. Nous nous attendrons alors à devoir faire des hypothèses, soit sur X, soit sur f et sur g, qui assurent que les images de $\mathrm{hot}_{W,S}(X)$ par f^* et g^* ne sont autres que $\mathrm{hot}_{W,S}(f^*X)$, $\mathrm{hot}_{W,S}(g^*X)$ respectivement, où on pose [page 129]

$$f^*(X) = X \times_S (S', f), \qquad g^*(X) = X \times_S (S', g).$$

Donc on devra sans doute se placer dans l'une des hypothèses suivantes:

a) X est lisse sur S.

b) X est Hot-fibrée sur S.

c) f et g sont propres (et sous réserve de la validité de la conjecture page 122).

On s'attend alors à ce que u^* soit associé à un homomorphisme

$$u^* : g^*(X) \longrightarrow f^*(X) \qquad \textit{dans } \mathrm{Cat}/S'$$

défini en termes de u. Y a-t-il moyen de le définir bel et bien, sans supposer X au moins fibrée sur S? Prenons $S' = e$, donc f, g correspondant à des objets $s, t \in \mathrm{Ob}\, S$, et u à une fléche

$$u : s \longrightarrow t,$$

les images inverses de X/S par f, g sont les fibres X_s, X_t, et on cherche

$$u^* : X_t \longrightarrow X_s.$$

On n'a aucune chance d'en trouver canoniquement, si on ne suppose X fibrée sur S! Donc ce ne sont pas a), b) ni c) qui peuvent nous servir, mais uniquement l'hypothèse $X \in \mathrm{Ob}\, \underline{\mathrm{Fib}}\, S$. Donc on ne peut espérer trouver une description de u^* entre $\mathrm{HOT}_W(S)$ et $\mathrm{HOT}_W(S')$ en termes d'opérations sur les catégories sur S, S', comme suggéré à l'instant, qu'en se bornant à des 'modèles' X qui sont dans $\underline{\mathrm{Fib}}\, S$, tout au moins. Et je ne doute pas en effet que ça marche sur $\underline{\mathrm{Fib}}\, S$ pas moins bien que directement sur $\underline{\mathrm{Fibsc}}\, S$, en termes de $\underline{\mathrm{Hom}}(S^o, \mathrm{Cat})$.

p. 80 [page 130]

Commentary · Development (commentators') [ms. 128]

Local constancy and the missing comma formula

Grothendieck asks whether the locally constant part, as the base varies, is itself a derivator. His expectation that it is not is correct for ordinary homotopy types, but the suggested obstruction to the existence of adjoints is not the obstruction. It is the pointwise formula for those adjoints that fails. We give the small calculation because it separates this question from the comparison theorem.

Proposition (the interval obstruction). [ours] Let $\mathcal{L}(S)$ be the full subcategory of the space derivator on S consisting of locally constant objects, with the induced restriction functors. Then $S \mapsto \mathcal{L}(S)$ does not satisfy the pointwise left Kan-extension axiom.

Proof. We use the source's presheaf convention. Let $S = (0 \to 1)$, let $a : \{0\} \to S$, and let $b : \{1\} \to S$. An object of $\mathcal{L}(S)$ is a coherent arrow $F_1 \to F_0$ which is an equivalence. Evaluation at 0 is an equivalence

$$a^* : \mathcal{L}(S) \longrightarrow \mathcal{L}(e) = \mathrm{Hot}.$$

Indeed the constant-arrow functor is a quasi-inverse: the diagram map from $F_1 \to F_0$ to $F_0 \xrightarrow{\mathrm{id}} F_0$ has components $F_1 \to F_0$ and id_{F_0}, both weak equivalences. This construction is natural in F, before taking the homotopy category. Thus a left adjoint $a_!^{\mathcal{L}}$ exists and is the constant-arrow functor, up to the unique isomorphism between adjoints.

Take the one-point space $*$. We obtain

$$b^* a_!^{\mathcal{L}}(*) \simeq *.$$

On the other hand, the comma category $1\backslash\{0\}$ of arrows $1 \to a(0)$ is empty. The pointwise formula for a left Kan extension in the presheaf convention would therefore identify this value with the homotopy colimit of the empty diagram, namely $\varnothing$. The categories $\mathcal{L}(e) = \mathrm{Hot}$ and $\mathcal{L}(\varnothing) = e$ have the usual initial-object adjunction, so that this last value is forced. Since $\varnothing$ is not isomorphic to $*$, the required base-change map cannot be invertible. □

This proof also identifies what the unrestricted direct image does: in the full space derivator $a_!(*)$ is the representable presheaf $S(-, 0)$, with values $*$ at 0 and $\varnothing$ at 1. It is not locally constant. The locally constant left adjoint first takes this extension and then reflects it. The reflection changes the value at 1, and the comma formula is lost.

Corollary (commutation beyond Hot-fibrations). [ours] The inclusion $a : \{0\} \to (0 \to 1)$ commutes with local-constant reflection for spaces, but is not a Hot-fibration.

Proof. The reflection of any arrow $F_1 \to F_0$ is the constant arrow on F_0. To see its universal property, map to a constant arrow on K; the space of maps is $\mathrm{Map}(\mathrm{hocolim}_{S^{\mathrm{op}}} F, K)$, and 0 is terminal in S^{op}, so this homotopy colimit is F_0. Evaluation a^* at 0 therefore commutes with reflection. Nevertheless the weak equivalence $\{1\} \to S$ pulls back along a to $\varnothing \to \{0\}$, which is not a weak equivalence. Hence a is not a Hot-fibration. This answers the question on ms. 127. □

The later general result is stronger than is needed for the example. Cisinski (2009, Corollary 3.11) proves that restriction on locally constant coefficients has both adjoints for every derivator. His Theorem 3.13 concerns a different construction: one fixes a category A and varies an additional diagram category I, retaining arbitrary coherent I-diagrams of locally constant A-coefficients. That construction is a derivator. It does not say that the varying-base assignment $S \mapsto \mathcal{L}(S)$ is one.

We checked those statements, the pointwise formula in Groth (2013, Proposition 1.26), and the localization description in Cisinski's paper. We did not find this exact interval calculation stated there. The marked result records our explicit completion of the question in these pages; it makes no claim of priority for the obstruction.

Pour les axiomes essentiels sur les dérivateurs, je renvoie à I p. 67-68 et p. 111-112. On a vu que Der 1, (Der 2) ([66]) sont satisfaits pour tout prédérivateur défini par un couple $(\mathcal{M}, W \subseteq \mathrm{Fl}\,\mathcal{M})$, donc c'est OK ici pour HOT_W. Il s'ensuit que c'est OK aussi pour $\mathrm{HOT}^{\mathrm{lc}}_W$, vu la caractérisation des $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ en tant que sous-catégories de $\mathrm{HOT}_W(S)$. Pour Der 1, ça marche-t-il même pour des sommes quelconque de catégories, i.e. a-t-on

$$\mathrm{HOT}_W(\coprod_i S_i) \xrightarrow{\sim} \prod_i \mathrm{HOT}_W(S_i)\,?$$

On a en tous cas

$$\underline{\mathrm{Fib}}(\overbrace{\coprod_i S_i}^{S}) \xrightarrow{\sim} \prod_i \underline{\mathrm{Fib}}(S_i),$$

et le localiseur W^{f}_S dans $\underline{\mathrm{Fib}}(S)$ s'identifie bel et bien au produit des localiseurs $W^{\mathrm{f}}_{S_i}$ dans les $\underline{\mathrm{Fib}}\,S_i$. Mais dans le cas d'une famille peut-être infinie de catégories $\mathcal{F}_i$, munies de localiseurs W_i, si on pose [page 131]

$$\mathcal{F} = \prod \mathcal{F}_i, \qquad W = \prod W_i \subseteq \mathrm{Fl}(\mathcal{F}),$$

le foncteur canonique

$$\mathcal{F}W^{-1} \longrightarrow \prod_i (\mathcal{F}_i W_i^{-1})$$

est-il toujours une équivalence? Même dans `[`Même dans' barré]` le cas I fini il faut (il me semble) un argument assez soigneux, soit par la propriété universelle par récurrence sur $\mathrm{card}\, I$ (on est ramené au cas de deux foncteurs), soit à coups de catégories de chemins, en notant que

$$(*) \qquad \underline{\mathrm{Ch}}^W_\infty(\mathcal{F}; (s_i), (t_i)) \xrightarrow{\sim} \prod_i \underline{\mathrm{Ch}}^{W_i}_\infty(\mathcal{F}_i; s_i, t_i),$$

et en passant aux π_0, qui donne

$$\mathrm{Hom}_W((s_i), (t_i)) \xrightarrow{\sim} \prod_i \mathrm{Hom}_{W_i}(s_i, t_i).$$

Mais la formule $(*)$, visiblement, ne marche que pour I fini. Dans le cas général, on trouve la sous-catégorie $\prod^!_i$ de $\prod_i$ formée des systèmes $(c_i)_{i\in I}$ de chemins qui sont de longueur bornée.

66. Canulé pour Der 2, je ne sais si c'est vrai même en supposant W *fortement* saturé, i.e. tel que $\mathrm{hot}_W(f)$ isomorphisme $\Longrightarrow f \in W$.

Commentary · Exposition [ms. 130]

A natural transformation is realized by transport

Grothendieck has explained restriction on objects; a prederivator also remembers how restriction varies with a natural transformation of indexing functors. For $u : f \Rightarrow g : S' \to S$, the presheaf convention requires a transformation $u^* : g^* \Rightarrow f^*$. A pullback square alone supplies no arrow in this direction. A fibration supplies it through Cartesian lifting.

Let $p : X \to S$ be a Grothendieck fibration. For every $a \in S'$ and $x \in X_{g(a)}$, choose a Cartesian arrow

$$\lambda_{a,x} : u_a^* x \longrightarrow x$$

over $u_a : f(a) \to g(a)$. Send (a, x) in g^*X to $(a, u_a^* x)$ in f^*X. For an arrow $(h, v) : (a, x) \to (b, y)$ in g^*X, the equality

$$g(h)u_a = u_b f(h)$$

and the Cartesian property of $\lambda_{b,y}$ give a unique arrow $w : u_a^* x \to u_b^* y$ over $f(h)$ satisfying

$$\lambda_{b,y} w = v \lambda_{a,x}.$$

Uniqueness proves preservation of identities and composition. This constructs the requested functor over S'.

Different choices of Cartesian lifts are related by unique vertical isomorphisms. The resulting transport functors are therefore naturally isomorphic. The same uniqueness gives the comparison between transport along a composite transformation and successive transport, together with its coherence. A splitting can make selected comparison maps identities, but the localized operation is independent of the splitting.

For an arbitrary functor $H : X \to Y$ over S, transport need not commute strictly with H: H need not preserve Cartesian arrows. Factoring $H(\lambda_{a,x})$ through a chosen Cartesian lift in Y gives a vertical natural transformation between the two resulting functors. A vertical natural transformation is a homotopy over S': it is represented by a functor from the cylinder $X \times [1]$, whose projection to X is a weak equivalence on fibres. Thus the two maps agree after localization. This supplies the naturality needed when all functors over the base, rather than just Cartesian functors, are used in the fibred presentation.

The source's negative observation is accordingly about finding a direct functor on insufficiently structured representatives. It does not obstruct the existence of the 2-functor. That 2-functor is already defined by precomposition on coherent presheaves; the lifting calculation explains how to recognize its 2-cells geometrically.

Commentary · Development (commentators') [ms. 130]

Strong saturation does not imply pointwise detection

Footnote 66 withdraws the assertion that every relative category defines a prederivator satisfying Der 2, even when its weak equivalences are strongly saturated. There is a distinction between two statements. If an actual natural transformation has invertible evaluations after localization, strong saturation makes each component a weak equivalence; that transformation is therefore inverted in the diagram category. An arbitrary morphism of the localized diagram category, however, need not have an actual natural transformation as representative. The following construction shows that this distinction can defeat pointwise detection. It also connects this footnote to the unbounded-length obstruction discussed on ms. 131.

Proposition (a strongly saturated counterexample to Der 2). [ours] There exist a small category M, a strongly saturated class W, and a countable discrete category I such that

$$M^I[(W^I)^{-1}] \longrightarrow \prod_{i \in I} M[W^{-1}]$$

is not conservative. In fact, the source has a morphism whose evaluations are all isomorphisms but has no morphism in the reverse direction. The category M can be chosen to be a disjoint union of finite categories.

Proof: the finite categories. Let R be the walking retraction, with objects $0, 1$ and arrows

$$i : 0 \longrightarrow 1, \qquad r : 1 \longrightarrow 0, \qquad ri = \mathrm{id}_0, \qquad e = ir \neq \mathrm{id}_1.$$

Its five arrows are $\mathrm{id}_0, \mathrm{id}_1, i, r, e$; in particular, its only isomorphisms are its identities. For example, this is the subcategory of sets generated by the inclusion of a singleton into a two-element set and its retraction.

Fix a positive odd integer n. Define a finite poset Q_n with elements

$$x_0, \dots, x_{n-1}, \quad y_0, \dots, y_{n-1}, \quad z.$$

For writing its order relations only, put $x_n = y_n = z$. Generate the order by the two fences

$$x_0 \longleftarrow x_1 \longrightarrow x_2 \longleftarrow \cdots \longleftarrow x_n, \qquad y_0 \longleftarrow y_1 \longrightarrow y_2 \longleftarrow \cdots \longleftarrow y_n,$$

together with $x_j \le y_j$ and $z \le y_j$ for $0 \le j < n$. An arrow in these displays means an order relation from its source to its target. The generated relation is antisymmetric: no y_j with $j < n$ reaches an x_k or z, and the nonidentity arrows among the x's have odd source and even target. Among the x's the only nonidentity comparisons are the fence edges. In particular, $z = x_n$ reaches just x_{n-1} among the other x's. The full subposet on the y's has initial object $y_n = z$.

Let C_n be the full subcategory of the finite product category $R \times Q_n$ on the objects

$$X_j = (0, x_j), \quad Y_j = (1, y_j) \quad (0 \le j < n), \qquad X_n = (0, z), \quad Y_n = (1, z).$$

Thus X_n and Y_n are distinct objects, despite having the same second coordinate. Write $F_n : C_n \to R$ for projection and set

$$W_n = F_n^{-1}(\mathrm{Iso}\, R).$$

This class is strongly saturated. Indeed, F_n inverts W_n and hence factors through $C_n[W_n^{-1}]$. If an original arrow becomes invertible in that localization, its image under F_n is an isomorphism, which is exactly the condition defining W_n. This argument also confirms that the section, the retraction and the idempotent e do not inadvertently become weak equivalences.

A short morphism with a long inverse. There are weak arrows $c_j : Y_n \to Y_j$ given by $(\mathrm{id}_1, z \le y_j)$, with $c_n = \mathrm{id}$, and arrows $i_j : X_j \to Y_j$ given by $(i, x_j \le y_j)$. The product category also supplies $r_n : Y_n \to X_n$, with

$$r_n i_n = \mathrm{id}_{X_n}.$$

For every fence edge $a : X_s \to X_t$, let $b : Y_s \to Y_t$ be the corresponding weak arrow. The following equations hold strictly:

$$i_t a = b i_s, \qquad b c_s = c_t.$$

In the localization put $t_j = c_j^{-1} i_j : X_j \to Y_n$. These equations give $t_t a = t_s$. Let $p_n : X_0 \to X_n$ be the morphism represented by the entire weak fence, traversed from index 0 to index n. Since every fence edge is weak, p_n is invertible. Transporting the preceding equation along its edges gives

$$i_n p_n = t_0 = c_0^{-1} i_0.$$

Consequently the three-arrow word

$$f_n = r_n c_0^{-1} i_0 : X_0 \longrightarrow X_n$$

equals p_n and is an isomorphism.

Nevertheless every zigzag representing a morphism $X_n \to X_0$ has at least n arrows. To prove this, assign the heights

$$h(X_j) = j, \qquad h(Y_j) = n \qquad (0 \le j \le n).$$

Every original forward arrow lowers height by at most one. For arrows between X objects this follows from the fence description. Arrows from an X to a Y cannot lower it. Arrows between Y objects preserve it. Finally, a Y object can map to an X object only from Y_n, and then the target is X_n or X_{n-1}; these are exactly the comparisons in Q_n with a y source and an x target. Such an arrow also lowers height by at most one.

A weak arrow has the same R coordinate at its two ends. Between Y objects it preserves height, and between X objects its two indices differ by at most one. Its formal inverse therefore lowers height by at most one as well. Every letter in a localization zigzag, whether a forward arrow or an inverted weak arrow, lowers height by at most one. A word from height n to height 0 consequently has length at least n. This argument concerns every possible representative and allows all the extra endomorphisms supplied by fullness in $R \times Q_n$.

The countable diagram. Take

$$M = \coprod_{n \text{ positive odd}} C_n, \qquad W = \coprod_{n \text{ positive odd}} W_n,$$

and let I be the discrete category of positive odd integers. The projections F_n together give $F : M \to R$, and $W = F^{-1}(\operatorname{Iso} R)$ is strongly saturated by the same argument. Define four I-diagrams by choosing, in the nth component, X_0, Y_0, Y_n, X_n, respectively. The families i_0, c_0, r_n give a single diagram-category zigzag

$$\mathcal{X} \longrightarrow \mathcal{U} \xleftarrow{W^I} \mathcal{V} \longrightarrow \mathcal{Z}.$$

Its localized morphism $f : \mathcal{X} \to \mathcal{Z}$ evaluates to f_n and is therefore pointwise invertible.

Suppose that any morphism $\mathcal{Z} \to \mathcal{X}$ existed in $M^I[(W^I)^{-1}]$. Choose a finite zigzag representing it, of length L. At the coordinate indexed by any odd $n > L$, evaluation gives a zigzag $X_n \to X_0$ with at most L letters. All its objects remain in C_n, since the disjoint union has no arrows between its components. The height bound gives $n \leq L$, a contradiction. There is thus no reverse morphism at all, and f is not invertible. □

The use of infinitely many coordinates is essential to this proof; it makes no assertion about the same question restricted to finite nondiscrete shapes. It refutes the unrestricted statement in footnote 66, including its strongly saturated version. It also strengthens the failure of the infinite-product comparison: that comparison can fail to reflect isomorphisms, not merely fail to be full.

For comparison, a precise sufficient hypothesis is available without a model structure. Suppose W is strongly saturated and every morphism in $M^I[(W^I)^{-1}]$ has a representative

$$X \xleftarrow{w} X' \xrightarrow{a} Y' \xleftarrow{v} Y, \qquad w, v \in W^I.$$

If its evaluations are isomorphisms, then every a_i becomes invertible in $M[W^{-1}]$. Saturation gives $a_i \in W$, so the displayed word is invertible. A left or right calculus of fractions is a special case, allowing one of the outside arrows to be an identity. The same argument proves the Der 2 part of Lagkas Nikolos (2018, Proposition 4.2.8, pp. 85–86); Remark 4.2.19, p. 95, explicitly discusses the role of two- and three-arrow descriptions in localization of prederivators.

The counterexample above was constructed for this commentary. The literature checks located the stated fraction criterion and the usual model-category results, but did not locate this particular finite-category construction. Its proof is included in full; the marking records our contribution to the present audit and does not assert historical priority for the general failure of localization to commute with infinite products.

Donc la question de la validité de Der 1 sans hypothèse de finitude sur l'ensemble d'indices I reste en suspens pour l'instant. (Je soupçonne que c'est vrai, mais il faudrait, pour le prouver, tenir une description des flèches dans $\mathrm{HOT}_W(S)$ par des chemins de longueur bornée, disons de longueur deux ou trois. C'est une question intéressante, mais que je réserve pour plus tard, si le besoin m'y contraint . . .) p. 81 [page 132]

Commentary · Development (commentators') [ms. 131]

Unbounded zigzags obstruct infinite products

Grothendieck identifies the right difficulty in commuting localization with an infinite product: a morphism in a localization is represented by a finite word, and the lengths needed in different coordinates may be unbounded. The following construction turns that observation into a counterexample, even when the localizing classes are strongly saturated.

Proposition (a product of finite fences). [ours] For $n \geq 1$, let P_n be the finite poset with objects $0, 1, \ldots, 2n$ and nonidentity relations

$$0 < 1 > 2 < 3 > \cdots < 2n-1 > 2n.$$

Let W_n consist of every arrow. Then each $P_n[W_n^{-1}]$ is equivalent to the terminal category, but

$$\left(\prod_{n\geq 1} P_n\right)\left[\left(\prod_{n\geq 1} W_n\right)^{-1}\right] \longrightarrow \prod_{n\geq 1} P_n[W_n^{-1}]$$

is not full. More precisely, two objects $x = (x_n)$ and $y = (y_n)$ in the category on the left can be connected by a morphism if and only if $\sup_n |x_n - y_n| < \infty$.

Proof. The only nonidentity arrows in P_n join adjacent integers; there are no composable pairs of nonidentity arrows. Inverting these arrows gives the free groupoid on the undirected path with vertices $0, \dots, 2n$. Between any two vertices there is exactly one reduced path. Hence this groupoid is equivalent to the terminal groupoid.

Put $P = \prod_n P_n$. Since every arrow of P is inverted, an arrow in its localization is represented by a finite zigzag in P. One step in such a zigzag changes the nth coordinate by at most one, for every n. A zigzag with k steps therefore implies $|x_n - y_n| \leq k$ for all n. This proves necessity of the bound.

Conversely, suppose $|x_n - y_n| \leq K$ for all n. In each fence take the unique shortest undirected path from x_n to y_n. Its arrow directions alternate. If its first arrow has the wrong orientation for a common alternating pattern beginning with a forward arrow, prepend an identity. After the path finishes, append identities. Every coordinate now has a zigzag of the same length $K + 1$ and the same pattern of directions. Taking coordinatewise products gives a zigzag in P. This proves sufficiency.

Take $x_n = 0$ and $y_n = 2n$. There is no arrow between them in $P[W^{-1}]$, while their images have exactly one arrow between them in the product of the localized categories. Thus the comparison is not full. The localizing classes are all-arrow classes, so they are strongly saturated. □

The original question for HOT_{W_∞} nevertheless has a positive answer. Diagram categories of simplicial sets carry model structures with pointwise weak equivalences. For a disjoint union of shapes, the diagram model category is the product of the diagram model categories of the components. Its cofibrant-fibrant replacements are chosen coordinatewise. Between cofibrant-fibrant objects, every homotopy-category morphism has an actual representative, and homotopy can be tested coordinatewise using coordinatewise cylinder objects. Therefore the homotopy category of this product is the product of the homotopy categories, with no bound on the number of factors. The common model-category description provides the uniform presentations absent from the fence example; compare Groth (2013, Proposition 1.30).

We checked the finite-word construction of localization in Gabriel and Zisman (1967, Chapter I, §1) and the model-category derivator result just cited. We did not find this exact fence formulation in those sources. It is an elementary elaboration of the obstruction explicitly singled out in the manuscript, not a claim that the general phenomenon is new. In particular, it does not support replacing Grothendieck's tentative general argument with an assertion that all relative categories satisfy the coproduct axiom.

Plus importante est la question de la validité de Der 3 et de ses variantes (I, p. 111-112). Le minimum qu'on demande d'un dérivateur $\mathbf{D}$, c'est que si $S' \longrightarrow S$ dans Diag est une Hot-équivalence, ce soit une $\mathbf{D}$-équivalence, i.e. (dans le cas actuel) que le foncteur

$$f^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S')$$

soit pleinement fidèle sur la sous-catégorie des objets *constants* dans $\mathrm{HOT}_W(S)$. Cette condition devient plus tangible quand on dispose déjà soit des foncteurs cohomologie $H^\bullet_{\mathbf{D}}(S, -)$, $H^\bullet_{\mathbf{D}}(S', -)$, soit de l'homologie $H^{\mathbf{D}}_\bullet(S, -)$, $H^{\mathbf{D}}_\bullet(S', -)$. En termes de cette dernière, elle signifie que

$$p_! p^*(a) \xrightarrow{\sim} p'_! p'^*(a) \qquad \texttt{[est un]}\ \text{isomorphisme},$$

pour tout a dans $\mathcal{A} = \mathbf{D}(e)$. (Où $p : S \longrightarrow e$, $p' : S' \longrightarrow e$ sont les morphismes structuraux sur la catégorie ponctuelle.) On a vu la formule heuristique générale [page 133]

$$p_! \underbrace{p^*(a)}_{a_S} = \mathrm{hot}(S) \times a,$$

où $\operatorname{hot} S$ est la classe de $S \in \operatorname{Ob}\operatorname{Cat}$ dans $\mathrm{Hot} = (\mathrm{Cat})W_\infty^{-1}$, et où le produit $\times$ est une opération externe de Hot sur $\mathcal{A} = \mathbf{D}(e)$

$$\mathrm{Hot} \times \mathcal{A} \longrightarrow \mathcal{A} \ .$$

Dans le cas actuel, $\mathcal{A} = \mathrm{Hot}$, et l'opération

$$\mathrm{Hot} \times \mathrm{Hot} \longrightarrow \mathrm{Hot}$$

ne doit être autre que le foncteur produit cartésien, lequel est déduit du foncteur similaire dans Cat. Quand on dispose de ce formalisme, le résultat cherché pour un $f : S' \longrightarrow S$ se réduit simplement à dire que si f est dans W, alors il en est de même de $f \times \mathrm{id}_X$ pour tout X dans Cat (en prenant X tel que $\mathrm{hot}(X) \simeq a$). Or là c'est un fait bien connu, résultant des axiomes mis sur W.

J'ai donc l'impression que je n'ai aucune chance de prouver Der 3a′ (p. 111), ni même Der 3a) (cas où S = e), sans avoir une maîtrise du formalisme des $p_!$. Et j'ai bon espoir que cetter maîtrise va s'obtenir à bon compte, alors que la question des p_* semble beaucoup plus délicate. p. 82 [page 134]

Commentary · Exposition [ms. 133]

Constant coefficients explain the turn to homology

Grothendieck turns from inverse image to homological direct image because the latter makes homotopy invariance of constant coefficients visible. For the space derivator, the homotopy colimit of a constant space K over S^{op} is

$$\mathrm{hocolim}_{S^{\mathrm{op}}} K \simeq |N(S^{\mathrm{op}})| \times K \simeq |NS| \times K.$$

One way to calculate it is the simplicial replacement: in degree n it is a coproduct of copies of K, one for every string of n composable arrows of S^{op}. Realization therefore gives the displayed product. The reversal of a string identifies the realizations of the nerves of a category and its opposite.

For $f : S' \to S$, the canonical homological comparison runs from the expression for S' to the expression for S and is represented by

$$|Nf| \times \mathrm{id}_K : |NS'| \times K \longrightarrow |NS| \times K.$$

When $f \in W_\infty$, this is a weak equivalence. The isomorphism written in the source may consequently be read in either direction after localization; before inversion the functorial map has the direction just displayed. For a general coefficient derivator the corresponding operation is tensoring with a homotopy type, rather than an internal Cartesian product of coefficients.

Adjunction now relates the calculation to the desired fully faithful restriction on constant objects. For constant coefficients a, b,

$$\mathrm{Hom}_{\mathbf{D}(S)}(p^*a, p^*b) \simeq \mathrm{Hom}_{\mathbf{D}(e)}(p_!p^*a, b).$$

If the homological comparison is an isomorphism for every a, it induces a bijection on these Hom sets for every b. Conversely, bijectivity for every b identifies the comparison by Yoneda. This is why the direct-image formalism gives exactly the statement Grothendieck wants, rather than merely an invariant of isomorphism classes.

The axiom numbers in these pages belong to the evolving manuscript. The condition called Der 3 here should not be confused with the usual modern axiom bearing that number, which asks for both Kan adjoints. Likewise the footnote retracting the unrestricted claim about Der 2 records a genuine limitation of the argument for arbitrary relative categories. The development at manuscript p. 130 gives a counterexample even when W is strongly saturated, using a countably discrete diagram shape. It does not address the restriction of that question to finite shapes. The model-category theorem establishes the pointwise detection axiom for the space derivator; it does not vindicate the cancelled general assertion.

Je vais donc me tourner d'abord vers l'axiome Der 4′ d'existence de

$$f_! : \mathrm{HOT}_W(S') \longrightarrow \mathrm{HOT}_W(S),$$

comme adjoint à gauche de f^*. Je vais essayer de construire ad-hoc un foncteur $f_!$, puis les deux flèches d'adjonction

$$\begin{array}{ccc} \mathrm{id} & \longrightarrow & f^* f_! \\ \mathrm{id} & \longleftarrow & f_! f^*, \end{array}$$

et enfin, de vérifier les deux compatibilités pertinentes.

L'idée géométrique 'évidente', c'est pour $X' \in \mathrm{Cat}/S'$, représentant $\xi' \in \mathrm{Ob}\,\mathrm{HOT}_W(S')$, de définir $f_!(\xi')$ par

$$f_!(\mathrm{hot}_{S',W}(X')) = \mathrm{hot}_{S,W}(X'),$$

où dans le second membre, X' est regardé comme objet de Cat/S, grâce à $f : S' \longrightarrow S$ et au foncteur

$$f_! : \mathrm{Cat}/S' \longrightarrow \mathrm{Cat}/S$$

qu'il induit. Le seul problème, c'est de voir si ce foncteur est compatible avec les localiseurs [page 135]
$W^{\mathrm{d}}_{S'}$, W^{d}_S, et sinon, s'il l'est tout au moins sur la sous-catégorie $\underline{\mathrm{Fib}}\,S'$ ou $\underline{\mathrm{Fibsc}}\,S'$, qui suffit pour calculer $\mathrm{HOT}_W(S')$ par localisation. Il faut donc voir si un $X'_1 \longrightarrow X'_2$ dans Cat/S', qui est dans $W^{\mathrm{d}}_{S'}$, i.e. qui est dans W et le reste par tout changement de base de la forme $s'\backslash S' \longrightarrow S'$, plus généralement pour tout co-isomorphisme local, est aussi dans W^{d}_S, i.e. si les changements de base de la forme $s\backslash S \longrightarrow S$ le transforment en W-équivalences (grossières). Or les co-isomorphismes locaux sont stables par *tout changement de base* (cf. I, p. 55 dans le cas dual des isomorphismes locaux), donc on gagne!

$$\begin{array}{ccc} \overline{S'} = s\backslash S' & \longrightarrow & S' \\ \downarrow & & \downarrow \\ \overline{S} = s\backslash S & \longrightarrow & S \end{array} \quad .$$

Je vais quand même le vérifier encore. Si

$$\begin{array}{ccc} \overline{S'} & \longrightarrow & S' \\ \downarrow & & \downarrow \\ \overline{S} & \longrightarrow & S \end{array}$$

est un carré cartésien dans Cat, on a dit dans loc. cit., essentiellement, que pour $\overline{s'}$ dans $\overline{S'}$, p. 83
ayant des images s', $\overline{s}$, s dans S', $\overline{S}$, S respectivement, le carré des colocalisés

$$\begin{array}{ccc} \overline{s'}\backslash\overline{S'} & \longrightarrow & s'\backslash S' \\ \downarrow & & \downarrow \\ \overline{s}\backslash\overline{S} & \longrightarrow & s\backslash S \end{array}$$

est encore cartésien. Je viens encore le de revérifier à l'instant, pour les objets tout au [page 136]
moins. Dire que $\overline{S} \longrightarrow S$ est un isomorphisme local, signifie que les $\overline{s}\backslash\overline{S} \longrightarrow s\backslash S$ sont `[des]` isomorphismes. Mais le carré cartésien précédent montre qu'alors les $\overline{s'}\backslash\overline{S'} \longrightarrow s'\backslash S'$ sont aussi `[des]` isomorphismes, on gagne!

Théorème 1. *Pour toute flèche $f : S' \longrightarrow S$ dans* Cat*, le foncteur induit*

$$f_! : \mathrm{Cat}/S' \longrightarrow \mathrm{Cat}/S$$

est compatible avec les localiseurs $(W^{\mathrm{d}}_{S'}, W^{\mathrm{d}}_{S})$*, donc dualement avec les localiseurs* $(W^{\mathrm{g}}_{S'}, W^{\mathrm{g}}_{S})$*, et trivialement avec les localiseurs* $(W_{S'}, W_S)$*. Il induit donc un diagramme commutatif de foncteurs sur les localisés*

$$\begin{array}{ccccc} \mathrm{HOT}_W(S') & \xrightarrow{\rho_{S'}} & \mathrm{HOT}^{\mathrm{lc}}_W(S') & \xleftarrow{\sigma_{S'}} & \mathrm{HOT}^{o}_W(S') \\ \downarrow{\scriptstyle f_!} & & \downarrow{\scriptstyle f^{\mathrm{lc}}_!} & & {\scriptstyle f^o_!}\downarrow \\ \mathrm{HOT}_W(S) & \xrightarrow{\rho_S} & \mathrm{HOT}^{\mathrm{lc}}_W(S) & \xleftarrow{\sigma_S} & \mathrm{HOT}^{o}_W(S). \end{array}$$

Définition 1. *On a défini ainsi les foncteurs verticaux* $f_!$*,* $f^{\mathrm{lc}}_!$*,* $f^o_! = (f^o)_!$*, appelés foncteurs image directe homologique, ou foncteurs d'intégration pour* f *(et les types d'homotopie relatifs).*

On a obtenu en même temps, gratuitement, la compatibilité de ces foncteurs aux foncteurs [page 137]
[de] localisation $\rho_{S'}$, $\sigma_{S'}$ pour $\mathrm{HOT}(S')$, et ρ_S, σ_S pour $\mathrm{HOT}(S)$. Par contre, on ne s'attendra pas qu'ils commutent avec les foncteurs pleinement fidèles d'inclusion des $\mathrm{HOT}^{\mathrm{lc}}_W$ dans HOT_W. En effet, si on ne suppose pas f dans Fibhot ([67]), il est tout à fait immoral de s'attendre à ce que $f_!$ dans $\mathrm{HOT}_W(S')$ transforme types localement constants en itou. La situation est donc exactement inverse de celle pour le foncteur f^*, qui était compatible avec les foncteurs d'inclusion i_S, $i_{S'}$ et j_S, $j_{S'}$ - c'était à tel point trivial qu'il n'a pas été question même de le dire, voire en faire une proposition! La situation est

Commentary · Exposition [ms. 136]

Changing the structure map gives direct image

Grothendieck's proposed direct image has a particularly economical description: keep the total category and compose its map to the base. The substantial point is that this operation respects right-fine equivalence even though inverse image did not respect it on arbitrary representatives. The proof uses a class of test changes of base which is itself stable under pullback.

Let $u : X \to Y$ be in $W^{\mathrm{d}}_{S'}$ and let $f : S' \to S$. For an object $s \in S$, form

$$E = (s\backslash S) \times_S S' \longrightarrow S'.$$

This projection is a discrete opfibration: an object is an arrow $s \to f(s')$, and an arrow out of s' has a unique lift obtained by composing that arrow in S. Right-fine equivalences remain global W-equivalences after pullback along such maps. Applying this characterization to u shows that

$$s\backslash(X/S) \longrightarrow s\backslash(Y/S)$$

is in W. Since this holds for every s, the same underlying functor, regarded over S, belongs to W^{d}_S.

The characterization can also be checked directly from the comma resolution. For a discrete opfibration $q : E \to S'$ and $e \in E$, unique lifting gives

$$e\backslash(X \times_{S'} E) \cong q(e)\backslash X.$$

Thus the map between the comma resolutions over E is a weak equivalence on fibres. The localizer's fibrewise-to-total property makes it a global weak equivalence, and the comparison from each comma resolution to its total category is a weak equivalence. Two-out-of-three gives the desired global conclusion. This uses only the comparison machinery already available.

The square of coslices considered in the source is Cartesian on morphisms as well as objects: an arrow is a pair of commuting triangles whose images in the bottom-right coslice agree. The universal property of the original pullback gives exactly one arrow in the top-left coslice with those data. Therefore the author's object check extends immediately to a proof of the asserted categorical pullback. The term "isomorphisme local" on ms. 136 must be read in its co-local sense, since it is outgoing coslices that occur throughout this argument.

We obtain

$$f_! q_{S'}(X) = q_S(X \to S' \xrightarrow{f} S).$$

Composition of structure maps gives the composition law for these functors. Their compatibility with ρ and σ is equally formal: the routes around the displayed square apply the same total-category functor and then invert a larger class. Neither observation says that direct image preserves locally constant objects. The interval example above shows that it need not.

67. Ce cas doit être regardé avec soin ultérieurement.

même encore meilleure pour le foncteur $f_!$ entre les HOT, puisque la description de ce foncteur peut se faire directement sur Cat/S' tout entier, sans avoir à se borner à des sous-catégories plus ou moins astucieuses, où le foncteur induit serait compatible avec les localiseurs ($\underline{\mathrm{Liss}}\, S$ et $\underline{\mathrm{Fibhot}}\, S$ dans le cas de f^*). p. 84 [page 138]

Commentary · Examples [ms. 137]

Integration and the local-constant reflection

Grothendieck distinguishes two compatibility statements here because integration changes the support of a relative type. The inclusion $a : \{0\} \to S = (0 \to 1)$ already exhibits the phenomenon. The one-point object over $\{0\}$ is locally constant. Its direct image in the full relative category has comma fibres

$$(0\backslash\{0\}) \simeq e, \qquad (1\backslash\{0\}) = \varnothing.$$

It is therefore not locally constant on S. Its reflection is the constant point, as calculated in the earlier block on ms. 128. Thus $a_! i_{\{0\}}$ and $i_S a_!^{\mathrm{lc}}$ cannot be identified in general.

The commutation with reflection goes in the direction stated in the theorem:

$$\rho_S f_! \simeq f_!^{\mathrm{lc}} \rho_{S'}.$$

There is a second explanation once the adjunctions have been established. The inclusions i_S commute with restriction, and ρ_S is left adjoint to i_S. Both functors in this display are consequently left adjoint to the same composite restriction followed by inclusion. The uniqueness of adjoints identifies them. In contrast, preserving the essential image of $i_{S'}$ under $f_!$ is a further property of f.

For ordinary weak equivalences, the Hot-fibration hypothesis in footnote 67 supplies precisely that property. If $s \to t$ is an arrow of S, the induced functor $t\backslash S' \to s\backslash S'$ is a weak equivalence. For a locally constant coefficient F, the pointwise value $(f_! F)(s)$ is the homotopy colimit of the pulled-back coefficient over $(s\backslash S')^{\mathrm{op}}$. A weak equivalence of indexing categories preserves this homotopy colimit with locally constant coefficients. Thus every transition of $f_! F$ is an equivalence: $f_!$ carries locally constant objects to locally constant objects, and $f_! i_{S'} \simeq i_S f_!^{\mathrm{lc}}$. This is the space-valued case of Cisinski (2009, Proposition 1.24, applied to the opposite indexing convention); the proof there makes the same pointwise homotopy-colimit comparison. It gives the affirmative answer sought in the footnote, while retaining the hypothesis that the preceding interval example shows to be substantive.

For the terminal map $p : S \to e$, composition of structure maps simply forgets the base. If a category $X \to S$ represents a coherent family of homotopy types, then $p_! q_S(X)$ is the homotopy type of the total category X. For a category of elements this is the homotopy-colimit formula expressed geometrically. It explains the word "integration": the coherent fibres, with their transport, are assembled into their total homotopy type. One should retain the word "coherent" here, since an ordinary diagram in the homotopy category alone does not determine that total type.

On a de façon immédiate la transitivité de $f_!$, $f_!^{\mathrm{lc}}$, $f_!^o$, i.e.

$$(gf)_! = g_! f_!, \qquad (gf)_!^{\mathrm{lc}} = g_!^{\mathrm{lc}} f_!^{\mathrm{lc}}, \qquad (gf)_!^o = g_!^o f_!^o.$$

Mais on ne va pas faire bouger S, S', f pour le moment, car il faut maintenant, avant toute autre chose, essayer d'établir l'adjonction de $f_!$ et de f^* (dans cet ordre).

Pour le moment, occupons-nous de HOT_W seulement - le cas de HOT_W^o s'en déduira en appliquant ce qu'on saura à f^o. Et on s'occupera de $\mathrm{HOT}_W^{\mathrm{lc}}$ plus tard.

1) *L'homomorphisme*

$$\alpha : \mathrm{id}_{\mathrm{HOT}_W(S')} \longrightarrow f^* f_!.$$

Si X' est dans Cat/S', $f_!(\mathrm{hot}_{S',W}(X'))$ est $\mathrm{hot}_{S,W}(X')$, mais on ne peut trouver son image inverse f^* sur S' en prenant l'image inverse catégorique. Car même si on fait des hypothèses draconiennes sur X' en tant qu'objet de Cat/S' (p.ex. X' fibrée sur S'), celles-ci seront réduites à néant quand on aura composé avec f, sur lequel nous ne voulons ici faire aucune hypothèse. Il faut donc d'abord appliquer le foncteur Φ_S à X' sur S, puis prendre son image inverse sur S' : [page 139]

$$f^* f_!(\mathrm{hot}_{S',W}(X')) = \mathrm{hot}_{S',W}(\Phi_S(X'/S) \times_S S').$$

Il faut donc trouver une flèche

$$\alpha_{X'} : X' \longrightarrow \Phi_S(X'/S) \times_S S'$$

dans le localisé $(\mathrm{Cat}/S')(W^{\mathrm{d}}_{S'})^{-1}$, voire même une flèche dans Cat/S' lui-même. Mais par les propriétés d'adjonction des foncteurs $f_!$ et f^* au *niveau catégorique,* une telle flèche revient à une flèche

$$f_!(X') \longrightarrow \Phi_S(X'/S)$$

dans Cat/S, i.e. à une flèche qui rend commutatif le carré

$$\begin{array}{ccc} X' & \longrightarrow & \Phi_S(X'/S') \\ \downarrow & & \downarrow \\ S' & \longrightarrow & S. \end{array}$$

Or on a une telle flèche canonique, savoir $i_{X'/S}$. Elle est fonctorielle en X' sur S (sans avoir même à se soucier si X' sur S provient d'un X' sur S', i.e. si la flèche structurale $X' \longrightarrow S$ se factorise par $S' \longrightarrow S$). p. 85

2) *L'homomorphisme* [page 140]

$$\beta : \mathrm{id}_{\mathrm{HOT}_W(S)} \longleftarrow f_! f^*.$$

Commentary · Exposition [ms. 139]

The unit comes from the comma replacement

The unit must compare an object over S' with the result of forgetting down to S and then deriving inverse image. Forgetting the intermediate base can destroy the useful smoothness or fibration hypothesis. This is why Φ_S appears between those two operations, even if the original category was already fibred over S'.

It is helpful to describe the construction on objects. For $p : X \to S$, the category $\Phi_S(X)$ has objects $(s, x, v : s \to p(x))$ and is projected to s. A morphism from (s, x, v) to (t, y, w) is a pair $(h : s \to t, k : x \to y)$ satisfying $p(k)v = wh$. The unit i_X sends x to $(p(x), x, \mathrm{id}_{p(x)})$. Thus for $p' : X' \to S'$ the unit of the desired adjunction is represented by

$$\alpha_{X'} : X' \longrightarrow \Phi_S(X'/S) \times_S S', \qquad x \longmapsto \big((fp'(x), x, \mathrm{id}_{fp'(x)}), p'(x)\big).$$

The same formula on arrows uses $fp'(k)$ in the first coordinate and $p'(k)$ in the second. It is a functor over S' and is natural in every functor $X' \to Y'$ over S'.

Equivalently, it is uniquely characterized by its two projections:

$$\mathrm{pr}_1 \alpha_{X'} = i_{X'/S}, \qquad \mathrm{pr}_2 \alpha_{X'} = p'.$$

This characterization is the ordinary slice adjunction between composition with f and pullback along f, applied before localization. The target of $\alpha_{X'}$ represents $f^* f_! q_{S'}(X')$ because $\Phi_S(X'/S)$ is a split fibration over S. Hence the natural map descends to $\mathrm{id} \to f^* f_!$.

Naturality before localization is enough here, but it is important to use the correct base in the replacement. The top-right object in the source's square on ms. 139 is printed as $\Phi_S(X'/S')$. Its structure map and the preceding formula show that $\Phi_S(X'/S)$ is intended. This is a source slip, retained in the transcription and registered separately. No replacement over S' can repair the loss of smoothness caused by composing its structure map with an arbitrary f.

Commentary · Exposition [ms. 139]

The replacement must be taken over the new base

Grothendieck now has a particularly economical candidate for direct image: a category over S' is regarded as a category over S. The difficulty is to show that this operation has the expected universal property after localization. Its prospective right adjoint is not arbitrary strict pullback. It

is pullback after a replacement which remembers arrows in the base. The next seven manuscript pages make that distinction precise enough to construct an adjunction, including its two triangle identities.

Write $Q_S = \Phi_S$ and $i_X : X \longrightarrow Q_S X$. For a category $p : X \longrightarrow S$, an object of $Q_S X$ is a triple $(s, x, a : s \longrightarrow p(x))$. A morphism from (s, x, a) to (t, y, b) consists of $v : s \longrightarrow t$ and $u : x \longrightarrow y$ satisfying $p(u)a = bv$. The projection to s is the split fibration associated with the contravariant functor $s \longmapsto s\backslash X$. The map i_X sends x to $(p(x), x, \mathrm{id}_{p(x)})$. This recalls the comma replacement discussed at manuscript p. 20 ("Which comma construction repairs which variance"), but here its role is more demanding: it supplies the unit of a derived adjunction.

For $f : S' \longrightarrow S$, denote by L the functor induced by composition with f, and by R derived inverse image. If $[X]$ denotes $\mathrm{hot}_{S,W}(X)$, their formulas are

$$L[X'] = [X'/S], \qquad R[X] = [Q_S X \times_S S'].$$

The replacement in the second formula is over S. Even when $X' \longrightarrow S'$ is already a fibration, its composite with an arbitrary f need not be one. Replacing over S' would therefore solve the wrong problem. This is the reason for the otherwise rather insistent occurrences of X'/S in the argument. The occurrence of $Q_S(X'/S')$ in the square on manuscript page 139 is a slip already present in the edition; its intended meaning is $Q_S(X'/S)$.

The unit can be written before localization. Its component is the unique S'-functor

$$a_{X'} : X' \longrightarrow Q_S(X'/S) \times_S S'$$

whose first projection is $i_{X'/S}$ and whose second projection is the structure map of X'. Explicitly, it sends x' to the triple with base object $f(p'(x'))$ and identity arrow, together with $p'(x') \in S'$. The construction is natural in X'. Passing through the localization therefore gives $\alpha : \mathrm{id} \longrightarrow RL$.

The counit is slightly different. If $X \longrightarrow S$ is smooth, the projection $X \times_S S' \longrightarrow X$ represents $\beta_{[X]} : LR[X] \longrightarrow [X]$. For an arbitrary representative, the formula is instead

$$\beta_{[X]} = [i_X]^{-1}[\mathrm{pr}_1 : Q_S X \times_S S' \longrightarrow Q_S X].$$

Both arrows in this fraction lie over S, and the arrow inverted is one already known to belong to W_S^{d}. The forgetful functor $Q_S X \longrightarrow X$ on underlying categories does not generally lie over S: the two structure maps at (s, x, a) have values s and $p(x)$. The fraction is thus doing necessary work.

The formulas also explain why naturality survives the change of representatives. For an arrow $u : X \longrightarrow Y$ over S, the equalities $Q_S(u)i_X = i_Y u$ and $Q_S(u)\mathrm{pr}_1 = \mathrm{pr}_1(Q_S(u) \times_S S')$ give the naturality square for β after the i's have been inverted. The construction uses the localization universal property, rather than a choice of inverses in the original category. This is precisely the amount of structure needed for the adjunction proof that follows.

On peut décrire $\mathrm{HOT}_W(S)$ par $(\underline{\mathrm{Fib}}\, S)(W_S^{\mathrm{d}})^{-1}$ ou $(\underline{\mathrm{Liss}}\, S)(W_S^{\mathrm{d}})^{-1}$ par exemple, de sorte que f^* a une description simple par

$$f^*(\mathrm{hot}_{S,W}(X)) = \mathrm{hot}_{S',W}(X \times_S S')$$

(pour X lisse sur S). On a ensuite

$$f_! f^*(\mathrm{hot}_{S,W}(X)) = \mathrm{hot}_{S,W}(X \times_S S'),$$

mais attention, $X \times_S S'$ n'est pas a priori dans $\underline{\mathrm{Liss}}\, S$, seulement dans Cat/S sans plus. Mais cela n'empêche qu'il donne ce qu'il faut, par localisation $(W_S^{\mathrm{d}})^{-1}$ dans Cat/S. Pour définir β_X, il suffit donc de trouver une flèche

$$\beta_X : X \longleftarrow X \times_S S'$$

dans Cat/S, et on voit bien pr_1^X ([68]). On a donc

$$\begin{cases} \alpha : \mathrm{id} & \longrightarrow & f^* f_! \\ \beta : \mathrm{id} & \longleftarrow & f_! f^* \end{cases}$$

68. quand $\xi \in \mathrm{HOT}_W(S)$ est défini par X dans Cat/S non nécessairement lisse, on doit trouver $\Phi_S(X) \times_S S' \longrightarrow X$ dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$, on prend $(i_X)^{-1}\mathrm{pr}_1^{\Phi_S(X)}$ (cf. page 143).

3) *La compatibilité*

$$f_! \xrightarrow{f_!*\alpha} f_!f^*f_! \xrightarrow{\beta*f_!} f_!.$$
$$\text{id}$$

On doit donc prendre X' sur S', et expliciter les flèches à partir de l'objet

$$\xi' = \mathrm{hot}_{S',W}(X').$$

On a p. 86

$$f_!(\xi') = \mathrm{hot}_{S,W}(X'/S), \qquad \text{[page 141]}$$

et pour calculer $f^*f_!(\xi')$, il faut comme tantôt prendre $\Phi_S(X')$ et on trouve

$$f^*f_!(\xi') = \mathrm{hot}_{S',W}(\Phi_S(X') \times_S S').$$

Enfin,

$$f_!f^*f_!(\xi') = \mathrm{hot}_{S,W}(\Phi_S(X') \times_S S').$$

Il faut expliciter les flèches

$$\underbrace{f_!(\xi')} \xrightarrow{f_!(\alpha_{\xi'})} \underbrace{f_!f^*f_!(\xi')} \xrightarrow{\beta_{f_!(\xi')}} \underbrace{f_!(\xi')}.$$

(∗)
$$X'/S \xrightarrow[\text{déduit de } i_{X'}]{\alpha_{X'}} \Phi_S(X') \times_S S' \xrightarrow{\beta_{X'}} X'/S$$

sur S

$\alpha_{X'}$ est déduit de $i_{X'} : X' \longrightarrow \Phi_S(X')$ comme l'unique S'-morphisme rendant commutatif le diagramme

(∗∗)
$$\begin{array}{ccccc} X' & \xrightarrow{\alpha_{X'}} & \Phi_S(X') \times_S S' & \xrightarrow{\mathrm{pr}_1} & \Phi_S(X') \\ \downarrow & \overset{i_{X'}}{\nearrow} & & & \downarrow \\ S' & & \xrightarrow{\qquad\qquad} & & S. \end{array}$$

Pour décrire $\beta_{f_!(\xi')}$, où $f_!(\xi') = \mathrm{hot}_{S,W}(X')$, il faut donner une description générale de β_ξ qui soit valable pour *tout* représentant X de ξ, pas seulement dans le cas X lisse sur S. Pour calculer $f^*(\xi)$, il faut donc prendre le $\mathrm{hot}_{S',W}$ de $\Phi(X) \times_S S'$, puis pour $f_!f^*(\xi)$, il faut prendre le $\mathrm{hot}_{S,W}$ du même $\Phi_S(X) \times_S S'$. Il faut définir, si on peut, une flèche [page 142]

$$\Phi_S(X) \times_S S' \longrightarrow X \qquad \text{dans } \mathrm{Cat}/S,$$

ou du moins dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$. Mais on a

$$i_X : X \longrightarrow \Phi_S(X)$$

qui est dans W_S^{d}, et qui par produit cartésien définit

$$i_X \times_S \mathrm{id}_{S'} : X \times_S S' \longrightarrow \Phi_S(X) \times_S S'$$

(en d'autres termes on a pris l'image inverse de i_X par $S' \longrightarrow S$). Cette flèche est-elle encore dans W_S^{d}? ([69]). Si oui, on a le diagramme

69. Non, elle ne l'est pas, car si $S' = \{s\}$, cela signifierait que $X'_s \longrightarrow s\backslash X$ est dans W, ce qui est faux en général. p. 87

$$\begin{array}{ccc} \Phi_S(X) \times_S S' & \xrightarrow{\beta_X ?} & X \\ {\scriptstyle i_X \times_S \mathrm{id}_{S'}}\uparrow & \nearrow_{\mathrm{pr}_1^X} & \\ X \times_S S' & & \end{array} \quad = \pi_X$$

et on définit la flèche cherchée β_X *dans* $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$ par la commutativité de ce triangle, donc comme

$$\beta_X = \mathrm{pr}_1^X \circ \underbrace{\pi_X^{-1}}_{\text{inverse dans } (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}} .$$

Mais ça ne marche pas - cf. annotation! On va faire alors l'inverse [page 143]

$$\begin{array}{ccc} \Phi_S(X) \times_S S' & \xrightarrow{\mathrm{pr}_1^{\Phi_S(X)}} & \Phi_S(X) \\ & \searrow^{\beta_X ?} & \uparrow{\scriptstyle i_X} \quad \text{dans } W_S^{\mathrm{d}} \\ & & X \end{array}$$

Commentary · Examples [ms. 142]

A pullback can destroy the replacement equivalence

Grothendieck's first attempt to construct the counit asks whether the map i_X can be inverted after an arbitrary pullback. The walking arrow shows exactly where that attempt breaks. We work with ordinary weak homotopy equivalences, $W = W_\infty$, so that an empty category cannot be equivalent to a point.

Let $S = [1] = (0 \longrightarrow 1)$ and let $X = \{1\} \longrightarrow S$. An object of $\Phi_S X$ is an arrow of S with target 1. There are two such objects, $0 \longrightarrow 1$ and id_1, and one nonidentity morphism between them. The projection identifies $\Phi_S X$ with S over itself. Consequently

$$i_X : \{1\} \longrightarrow S$$

is right-fine: for $s = 0$ and $s = 1$, the functor $s\backslash X \longrightarrow s\backslash S$ is a weak equivalence between contractible categories.

Now pull back along $j : \{0\} \longrightarrow S$. The resulting map is

$$X \times_S \{0\} = \varnothing \longrightarrow \Phi_S X \times_S \{0\} = \{0\}.$$

It is not in W, nor is it a right-fine equivalence over the point. Regarded again as a map over S, it still fails the right-fine test at 0. Thus the proposed inverse of $\pi_X = i_X \times_S \mathrm{id}_{S'}$ need not exist in either localization relevant to the attempted argument.

The calculation also distinguishes the two inverse images without any abstract machinery. Strict pullback of X to 0 is empty, whereas derived pullback of $[X]$ to 0 is a point. The missing object records the arrow $0 \longrightarrow 1$. A comma fibre retains that arrow; a strict fibre does not.

There is no defect in the replacement itself. The map i_X becomes an isomorphism over S, exactly as intended. The invalid move was to apply a functor which had not been shown to preserve that class of equivalences on all of Cat/S. On manuscript page 143 Grothendieck repairs the argument himself: he first projects to $\Phi_S X$, and then inverts i_X in the localization over S. No pullback of an arbitrary denominator is required.

([70]), on définit β_X comme $(i_X)^{-1}\mathrm{pr}_1^{\Phi_S(X)}$, où $(i_X)^{-1}$ est défini dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$.

Pour prouver la commutativité de $(*)$ (p. 141), comme $i_{X'} : X' \longrightarrow \Phi_S(X')$ est dans W_S^{d}, il suffit de prouver, au lieu de $\beta_{X'}\alpha_{X'} = \mathrm{id}_{X'}$, la relation déduite en composant avec $i_{X'} : X' \longrightarrow \Phi_S(X')$

$$\underbrace{i_{X'}\beta_{X'}}_{\mathrm{pr}_1^{\Phi_S(X')}} \alpha_{X'} = i_{X'},$$

70. Description de β_ξ pour $\xi = \mathrm{hot}_{S,W}(X)$, avec X quelconque dans Cat/S, à expliciter dans définition en forme.

i.e.

$$\mathrm{pr}_1^{\Phi_S(X')} \circ \alpha_{X'} = i_{X'},$$

ce qui n'est autre que la relation de définition de $\alpha_{X'}$ (cf. (∗∗) p. 141), on gagne!

4) *Compatibilité*

$$f^* \xrightarrow{\alpha * f^*} f^* f_! f^* \xrightarrow{f^* * \beta} f^*.$$
$$\text{id}$$

Partons donc d'un $\xi \in \mathrm{ObHOT}_W(S)$, qu'on peut supposer défini par $X \in \mathrm{Ob}\underline{\mathrm{Fib}}\, S$. Alors p. 88 [page 144]

$$\begin{aligned} f^*(\xi) &= \mathrm{hot}_{S',W}(X \times_S S'), \\ f_! f^*(\xi) &= \mathrm{hot}_{S,W}(X \times_S S'), \\ f^* f_! f^*(\xi) &= \mathrm{hot}_{S',W}(\Phi_S(X \times_S S') \times_S S'). \end{aligned}$$

Il faut expliciter maintenant

$$\underbrace{f^*(\xi)}_{\mathrm{hot}_{S',W}(X')} \xrightarrow{\alpha_{f^*(\xi)}} \underbrace{f^* f_! f^*(\xi)}_{\mathrm{hot}_{S',W}(\Phi_S(X') \times_S S')} \xrightarrow{f^*(\beta_\xi)} \underbrace{f^*(\xi)}_{\mathrm{hot}_{S',W}(X')},$$

et vérifier que le composé est l'identité. On a posé

$$X' = X \times_S S',$$

et le diagramme est donc aussi

$$X' \xrightarrow{\alpha_{X'}} \Phi_S(X') \times_S S' \xrightarrow{f^*(\beta_\xi)} X', \qquad \mathrm{id}_{X'} : X' \to X'$$

dans $(\mathrm{Cat}/S')(W_{S'}^{\mathrm{d}})^{-1}$. Pour vérifier la commutativité, on peut composer avec

$$X \times_S S' = X' \xrightarrow{i_X \times_S \mathrm{id}_{S'}} \Phi_S(X') \times_S S' \qquad (\text{où } i_X : X \longrightarrow \Phi_S(X))$$

qui est dans $W_{S'}^{\mathrm{d}}$ ([71]), or on vérifie, sur la construction générale de $\beta_\xi = \beta_X$ (page précédente), que l'on a commutativité dans

$$\begin{array}{ccc} \Phi_S(X') \times_S S' & \xrightarrow{f^*(\beta_\xi)} & X' \\ & \searrow^{\Phi_S(\mathrm{pr}_1^X) \times_S S'} & \downarrow{\scriptstyle i_X \times_S S'} \\ & & \Phi_S(X) \times_S S'. \end{array}$$

Commentary · Exposition [ms. 143]

The counit is a fraction over the original base

Grothendieck's first formula for the counit is correct when the representative $X \to S$ is smooth: strict pullback represents derived inverse image, and projection

$$X \times_S S' \longrightarrow X$$

represents $f_! f^* q_S(X) \to q_S(X)$. To check the first triangle identity, however, one needs the counit on $f_! q_{S'}(X')$, whose natural representative need not be smooth over S. The extension to arbitrary representatives is the small but essential issue being worked out on ms. 141–143.

71. **NB** Comme X est lisse/S, et $\Phi_S(X)$ aussi, $X \longrightarrow \Phi_S(X)$ reste une W-équivalence colocale par tout changement de base.

For arbitrary X, put $R(X) = \Phi_S(X) \times_S S'$. The replacement map $i_X : X \to \Phi_S(X)$ is invertible in $\mathrm{HOT}_W(S)$, so the valid formula is

$$\beta_X = [i_X]^{-1}[\mathrm{pr}_1] : q_S(R(X)) \longrightarrow q_S(X).$$

Both arrows in this fraction are considered over S. Their naturality follows from the naturality of i and of projection. If X is smooth, the map $i_X \times_S S'$ is a right-fine equivalence over S', and the natural square with the two projections identifies this general formula with the simple projection formula above.

The abandoned attempt instead inverts $i_X \times_S S'$ without a hypothesis making that pullback a weak equivalence. A different interval calculation shows the problem directly. Take $S = (0 \to 1)$, $X = \{1\} \to S$, and $S' = \{0\}$. The strict fibre of X over 0 is empty, while the fibre of $\Phi_S(X)$ is $0\backslash X \simeq e$. The pullback of i_X is therefore $\varnothing \to e$. It is not a weak equivalence, either over S' or after regarding it over S; its comma fibre at 0 already fails. There is no inverse with which to form the proposed fraction.

The distinction is between an inverse in the localization over S, which is available, and the pullback of that inverse on arbitrary representatives, which is not represented by pulling back its denominator. The corrected roof leaves the denominator over S and uses projection from a replacement on which inverse image can be computed. This is the same discipline that governs total derived functors: apply the operation to a suitable replacement, then use the comparison isomorphism in the category where it is known to exist.

On est ramené à la commutativité de [page 145]

(∗)
$$\begin{array}{ccc} X \times_S S' = X' & \xrightarrow{\alpha_{X'}} & \Phi_S(X') \times_S S' \\ & \overset{?}{\searrow}_{i_X \times_S S'} & \downarrow{\scriptstyle \Phi_S(\mathrm{pr}_1^X) \times_S S'} \\ & & \Phi_S(X) \times_S S' \end{array}$$

Commentary · Exposition [ms. 145]

The last square is naturality

The argument has reached the last square before the second triangle identity. No new homotopical input is required. The remaining equality is the naturality of the comma-replacement map, and making that equality explicit finishes the adjunction on these pages.

For the first triangle, start with $X' \to S'$, regarded over S after composition. The defining relation for the unit is

$$\mathrm{pr}_1 \alpha_{X'} = i_{X'}.$$

The general formula for the counit gives $\beta_{X'} = i_{X'}^{-1} \mathrm{pr}_1$ in the localization over S. Consequently $\beta_{X'} \alpha_{X'} = \mathrm{id}_{X'}$. This is the identity $\beta f_! \circ f_! \alpha = \mathrm{id}_{f_!}$, and its proof applies without any smoothness hypothesis on X' over S.

For the second triangle we may represent ξ by a fibration $X \to S$. Put $X' = X \times_S S'$ and $r = \mathrm{pr}_1 : X' \to X$. Since X is smooth, the counit at ξ is represented by r. To calculate its derived inverse image on the possibly nonsmooth source $X' \to S$, replace that source by $\Phi_S(X')$. Functoriality of Φ_S then gives the relation

$$(i_X \times_S S')\, f^*(\beta_\xi) = \Phi_S(r) \times_S S'$$

in the localization over S'. Here $i_X \times_S S'$ is invertible because both X and $\Phi_S(X)$ are smooth over S.

It remains to prove

$$(\Phi_S(r) \times_S S') \alpha_{X'} = i_X \times_S S'.$$

These are maps $X' \to \Phi_S(X) \times_S S'$. Their second projections both equal the structure map $X' \to S'$. Their first projections are respectively

$$\Phi_S(r) i_{X'} \qquad \text{and} \qquad i_X r,$$

which are equal by the naturality of $i : \mathrm{id} \to \Phi_S$. The universal property of the pullback proves the displayed equality already in Cat/S'. Composing the preceding relation with $\alpha_{X'}$ and cancelling $i_X \times_S S'$ now gives

$$f^*(\beta_\xi)\alpha_{f^*\xi} = \mathrm{id}_{f^*\xi}.$$

The two triangle identities establish $f_! \dashv f^*$.

There is a minor but consequential printed index in the intervening display on ms. 144. The map labelled $i_X \times_S \mathrm{id}_{S'}$ has target $\Phi_S(X) \times_S S'$, as in the next triangle, rather than $\Phi_S(X') \times_S S'$. The latter is the target of $\alpha_{X'}$ and the source of $f^*(\beta_\xi)$; identifying them would obscure the naturality square just used. The edition prints the prime, so it is preserved as a source slip. The proof given here completes this last square and makes no claim of originality.

Overview · VI-b

Relative homotopy types, reflection, and integration.

These pages occupy a hinge in the construction of HOT. Grothendieck has accumulated several ways of representing a homotopy type over a small category S: a presheaf of categories, a split or unsplit fibration, a smooth category over S, or simply an arbitrary functor $X \to S$. He now wants to know exactly which localizations make these presentations interchangeable. Once that question is settled, the base may vary and the categories so obtained can begin to carry the operations of a derivator. The movement from a comparison at fixed S to inverse and direct images explains both the long abstract digression and the care devoted to the two triangular identities of an adjunction.

The indispensable distinction is between forgetting weak equivalences in the total category and testing them relative to the base. For a map $u : X \to Y$ over S, write

$$\begin{aligned} u \in W_S &\iff u \in W, \\ u \in W_S^{\mathrm{d}} &\iff (s\backslash u) \in W \quad \text{for every } s \in S, \\ u \in W_S^{\mathrm{g}} &\iff (u/s) \in W \quad \text{for every } s \in S. \end{aligned}$$

Here $s\backslash X = (s \downarrow X)$ and $X/s = (X \downarrow s)$ are comma categories, not strict fibres. The two fine classes retain respectively contravariant and covariant variation along arrows of S. On suitably smooth or proper representatives, the corresponding comma categories may be replaced by strict fibres. On homotopically locally constant representatives, the coarse and both fine tests coincide under the additional fibration hypothesis used in this part of the manuscript. The names of the fifteen categories in the large diagram serve this comparison; they do not describe fifteen different homotopy theories.

Two replacements organize the whole argument. The comma replacement $\Phi_S X$ is a split fibration with fibre $s\backslash X$; its natural map from X is a right-fine equivalence. It therefore changes the representative while retaining the relative homotopy type. The path replacement $C_S X$ has locally constant fibres and is connected to X by a coarse equivalence. It retains the total homotopy type but generally changes the relative one. The distinction is expressed by a reflective localization

$$\rho_S : \mathrm{HOT}_W(S) \rightleftarrows \mathrm{HOT}_W^{\mathrm{lc}}(S) : i_S, \qquad \rho_S \dashv i_S, \qquad \rho_S i_S \simeq \mathrm{id}.$$

The unit $X \to C_S X$ need not be invertible in $\mathrm{HOT}_W(S)$. This is why the second equivalence in Corollary 2 on manuscript page 120, which offers C_S as an alternative to Φ_S for computing the inverse image of an arbitrary relative type, must be corrected. Its C_S expression computes the inverse image after locally constant reflection. The commentary on the first part of Chapter VI already explains the basic distinction; the present commentary applies it precisely where the manuscript temporarily loses it.

The opening overlap with VI-a completes the adjunction by comparing $i_{C(X)}$ with $C(i_X)$. Concatenation of paths gives a common retraction, and hence equality after localization. There is also a formal reason: for a coaugmented endofunctor, invertibility of both iterated units forces their compatibility and identifies the essential image as a reflective subcategory. This familiar recognition principle is stated in higher categorical form by Lurie (2009, Proposition 5.2.7.4). Thus the path construction supplies particularly useful representatives, but its composition law is stronger data than the adjunction itself needs.

The abstract discussion beginning on manuscript page 85 isolates precisely this point. In a category $\mathcal{M}$ with weak equivalences W and a class of fibrations, Grothendieck compares the localization of $\mathcal{M}/S$ with that of its full subcategory of fibrant objects. A functorial replacement gives the equivalence directly. A replacement obtained only by lifting properties requires a separate argument: two choices of lift are compared through a factorization of a

relative diagonal, and become equal after localization. The manuscript proves this comparison, rather than merely assuming that choices disappear. Theorem–Scholie 2 then introduces a finer class $W_S^0 \subseteq W_S$ agreeing with W_S between fibrant objects and constructs the associated reflection. Our exposition writes out the naturality checks and the independence of choices, and explains why the functorial-replacement case already yields the adjunction without the additional path-composition hypothesis A'. This is an application of established deformation theory, not a new localization theorem; compare Riehl (2014, Theorem 2.2.11).

There are several distinct uses of the word fibration here. A Grothendieck fibration describes transport of objects in a category. A homotopical fibration controls comma categories and strict fibres. A fibration in a Quillen model structure is part of a lifting and factorization system. They interact, but the manuscript's abstract argument does not identify them. In particular, invoking Thomason's model structure gives a method for ordinary nerve weak equivalences on categories; it does not by itself establish every assertion for every proposed fundamental localizer. Likewise, weak saturation, meaning the formal closure axioms initially imposed on W, must be distinguished from strong saturation, which detects membership in W by invertibility in $\mathrm{Cat}[W^{-1}]$. The latter is supplied for fundamental localizers by Cisinski (2006c, Proposition 4.2.4 in the cited author version). It closes the explicit saturation reservation in the converse of Proposition 2 on manuscript pages 124–126.

Once the base varies, raw pullback of an arbitrary $X \to S$ is insufficient. To calculate f^* one first takes a representative, such as $\Phi_S X$, on which strict pullback respects the relevant weak equivalences. Smoothness of $X \to S$ supplies one sufficient condition; properness of the change of base supplies another. The "sure conjecture" on manuscript page 122 is not left open in the work: Grothendieck proves it on manuscript pages 168–169 of the same chapter. The commentary separates this later proof from what has actually been established in these pages. For ordinary weak homotopy equivalences, testing the comma replacement of a point also proves the converse: preservation of right-fine equivalences by strict pullback characterizes properness. A three-object span gives the nonproper homotopy fibration requested on manuscript page 126; it preserves coarse equivalences but fails to preserve a particular fine equivalence. These computations make the difference between the two base-change conditions explicit.

A natural transformation $f \Rightarrow g$ also requires attention: it induces $g^* \Rightarrow f^*$ in the presheaf convention, but a literal functor between arbitrary strict fibres need not exist. Split fibrations make that action explicit; localization then removes the dependence on the chosen splitting.

The questions about the locally constant theory lead to a useful distinction in the modern answer. Restriction between categories of locally constant diagrams has both adjoints; this holds for arbitrary derivator coefficients by Cisinski (2009, Corollary 3.11). Nevertheless, the varying-base assignment $S \mapsto \mathrm{HOT}^{\mathrm{lc}}(S)$ does not form a derivator for ordinary homotopy types. The pointwise Kan extension formula already fails for a point included in the walking arrow. Fixing a base S and varying an additional diagram category is a different operation: that construction does give the derivator of locally constant coefficients, as established in the same paper's Theorem 3.13. The distinction is visible without any higher machinery and prevents an attractive but incorrect explanation of Grothendieck's hesitation on manuscript page 128.

Another reservation concerns infinite disjoint unions of indexing categories. The corresponding product statement for arbitrary localizations is false. The bounded-length obstruction that Grothendieck notices can be realized by a countable family of finite fence categories: each factor becomes the terminal groupoid when all arrows are inverted, while the product has objects that no finite zigzag can connect. A refinement using finite categories inside a product with the walking retraction also answers footnote 66: strong saturation alone does not ensure that evaluation detects isomorphisms in localized diagram categories. A uniform three-arrow morphism is invertible at every coordinate, but its coordinate inverses require unbounded word lengths. The diagram shape in this counterexample is countably discrete; no

finite-shape conclusion is asserted. The space derivator nevertheless satisfies both pointwise detection and the unrestricted disjoint-union axiom. Model structures and controlled fraction presentations supply the additional uniformity that the abstract questions lack.

The final pages construct integration. Postcomposition with $f : S' \to S$ sends $X' \to S'$ to the same total category over S, and preserves the fine weak equivalences. This yields $f_!$ before any choice of fibrant replacement. The unit uses the comma replacement over the new base; the counit for arbitrary X is the localized composite

$$\Phi_S X \times_S S' \longrightarrow \Phi_S X \xrightarrow{i_X^{-1}} X.$$

The order matters. Pulling back i_X and then trying to invert it can fail, because strict pullback need not preserve a fine equivalence between arbitrary representatives. Grothendieck notices and repairs that attempt on manuscript pages 142–143. At manuscript page 145 the argument has reached the last square in the second triangle; the commentary completes its verification from naturality. In the case of spaces this integration is homotopy left Kan extension, and for the structural map it recovers homotopy colimit. The present derivator formalism provides its axiomatic setting; see Groth (2013).

The modern picture may be expressed as coherent diagrams of spaces on S^{op}, with locally constant objects corresponding to diagrams on the homotopy type of S. It is the entire homotopy type, not just the ordinary fundamental groupoid together with a functor into the homotopy category, that retains all the coherence. In particular, factoring the underlying diagram through ΠS detects local constancy but does not reconstruct its coherent object. The comma replacements and their categories of elements retain the additional data needed to form the homotopy colimit and to calculate its maps.

dans $(\mathrm{Cat}/S')(W^{\mathrm{d}}_{S'})^{-1}$. Essayons de prouver que c'est commutatif dans Cat/S', pas seulement dans le localisé par $W^{\mathrm{d}}_{S'}$. On peut le regarder comme diagramme dans Cat/S et prouver la commutativité à ce titre. Cette relation de commutativité $vu = w$ se décompose alors en deux, suivant les deux facteurs $\Phi_S(X)$ et S' de l'objet but $\Phi_S(X) \times_S S'$. Suivant le facteur S', la relation signifie simplement que $\alpha_{X'}$ est un S'-morphisme, c'est OK. Pour le facteur $\Phi_S(X)$, on prolonge le diagramme $(*)$ à droite par le carré p. 89

$$\begin{array}{ccc} X' & \xrightarrow{\alpha_{X'}} & \Phi_S(X') \times_S S' \xrightarrow{\mathrm{pr}_1^{\Phi_S(X')}} \Phi_S(X') \\ & \searrow & \downarrow{\scriptstyle \Phi_S(\mathrm{pr}_1 X)\times_S S'} \qquad \downarrow{\scriptstyle \Phi_S(\mathrm{pr}_1^X)} \\ & & \Phi_S(X) \times_S S' \xrightarrow{\mathrm{pr}_1^{\Phi_S(X)}} \Phi_S(X), \end{array}$$

et compte tenu que le composé de la première ligne horizontale est $i_{X'}$, par construction de $\alpha_{X'}$, on est ramené à la commutativité de [page 146]

$$(*) \qquad \begin{array}{ccc} X \times_S S' = X' & \xrightarrow{i_{X'}} & \Phi_S(X') \\ {\scriptstyle i_X \times_S S'}\downarrow & & \downarrow{\scriptstyle \Phi_S(\mathrm{pr}_1^X)} \\ \Phi_S(X) \times_S S' & \xrightarrow{\mathrm{pr}_1^{\Phi_S(X)}} & \Phi_S(X). \end{array}$$

Or le morphisme $i_X : X \longrightarrow \Phi_S(X)$ dans Cat/S donne lieu au carré commutatif (comme toute flèche $i : X \longrightarrow Y$)

$$\begin{array}{ccc} X \times_S S' & \xrightarrow{\mathrm{pr}_1^X} & X \\ {\scriptstyle i_X \times_S S'}\downarrow & & \downarrow{\scriptstyle i_X} \\ \Phi_S(X) \times_S S' & \xrightarrow{\mathrm{pr}_1^{\Phi_S(X)}} & \Phi_S(X), \end{array}$$

de sorte que le composé inférieur de $(*)$ n'est autre que celui de $(**)$, donc égal au composé supérieur de ce dernier, et la commutativité de $(*)$ revient à celle de

$$\begin{array}{ccc} X \times_S S' = X' & \xrightarrow{i_{X'}} & \Phi_S(X') \\ {\scriptstyle \mathrm{pr}_1^X}\downarrow & & \downarrow{\scriptstyle \Phi_S(\mathrm{pr}_1^X)} \\ X & \xrightarrow{i_X} & \Phi_S(X), \end{array}$$

qui est évidente par fonctorialité de $Z \xrightarrow{i_Z} \Phi_S(Z)$, appliquée à la flèche $\mathrm{pr}_1^X : X' \longrightarrow X$ de Cat/S.

On a ainsi prouvé que les foncteurs

p. 90

$$(*) \qquad \mathrm{HOT}_W(S') \underset{f^*}{\overset{f_!}{\rightleftarrows}} \mathrm{HOT}_W(S) \qquad \text{[page 147]}$$

sont adjoints l'un de l'autre, avec des morphismes d'adjonction

$$\begin{cases} \mathrm{id} & \xrightarrow{\alpha} & f^* f_! \\ \mathrm{id} & \xleftarrow{\beta} & f_! f^* \end{cases}$$

précisés plus haut. Je présume que la même démonstration, en travaillant avec les localiseurs grossiers W_S, $W_{S'}$, au lieu de W^{d}_S, $W^{\mathrm{d}}_{S'}$, donnerait que les foncteurs correspondants

$$(**) \qquad \mathrm{HOT}^{\mathrm{lc}}_W(S') \underset{f^*_{\mathrm{lc}}}{\overset{f^{\mathrm{lc}}_!}{\rightleftarrows}} \mathrm{HOT}^{\mathrm{lc}}_W(S)$$

sont adjoints l'un de l'autre, avec essentiellement 'les mêmes' morphismes d'adjonction α, β. Je n'ai pas envie de reprendre les raisonnements précédents et préfère le *déduire* de l'adjonction dans la situation $(*)$. Cela me donnera l'occasion de mieux comprendre les traits formels essentiels de la situation. Je poserai pour simplifier [page 148]

$$\begin{array}{rclcrcl} \mathrm{HOT}_W(S) & = & \mathcal{A}, & & \mathrm{HOT}_W(S') & = & \mathcal{A}', \\ \mathrm{HOT}^{\mathrm{lc}}_W(S) & = & \mathcal{A}_0, & & \mathrm{HOT}^{\mathrm{lc}}_W(S') & = & \mathcal{A}'_0, \end{array}$$

et j'utilise les couples de foncteurs adjoints

$$\mathcal{A} \underset{i}{\overset{\rho}{\rightleftarrows}} \mathcal{A}_0, \qquad \mathcal{A}' \underset{i'}{\overset{\rho'}{\rightleftarrows}} \mathcal{A}'_0,$$

où ρ, ρ' sont des foncteurs de localisation, i.e. i, i' des foncteurs pleinement fidèles. Je dispose d'un couple de foncteurs adjoints

$$\mathcal{A}' \underset{f^*}{\overset{f_!}{\rightleftarrows}} \mathcal{A},$$

et je suppose de plus

Commentary · Exposition [ms. 146]

The two triangles reduce to ordinary naturality

The adjunction proof is complete, although the second triangle occupies several diagrams. Its purpose is to turn the chosen representative formulas into a genuine universal property. We give both checks together, keeping the distinction between identities in a category of categories and identities after localization.

For X' over S', put $Z = \Phi_S(X'/S)$ and let $a : X' \longrightarrow Z \times_S S'$ be the unit representative. The first triangle is immediate from the defining equality $\mathrm{pr}_1 a = i_{X'/S}$:

$$\beta_{L[X']} L(\alpha_{[X']}) = [i_{X'/S}]^{-1}[\mathrm{pr}_1][a] = \mathrm{id}_{L[X']}.$$

This calculation uses a denominator over S, where its invertibility was established. In particular, it does not revive the failed pullback argument of page 142.

For the second triangle we may represent an arbitrary object of $\mathrm{HOT}_W(S)$ by a smooth $X \longrightarrow S$. Put $X' = X \times_S S'$ and $p = \mathrm{pr}_1 : X' \longrightarrow X$. The map

$$r_X = i_X \times_S \mathrm{id}_{S'} : X' \longrightarrow \Phi_S X \times_S S'$$

is now right-fine over S'. Here the smoothness of both X and $\Phi_S X$ is essential: right-fine equivalences between these good representatives are preserved by arbitrary base change. This is a property of the representatives, not a property of arbitrary arrows in Cat/S.

Under these identifications, the description of the derived counit says

$$[r_X] \circ R(\beta_{[X]}) = [\Phi_S(p) \times_S \mathrm{id}_{S'}].$$

The unit $a_{X'} : X' \longrightarrow \Phi_S X' \times_S S'$ therefore satisfies

$$[r_X] \circ R(\beta_{[X]})\alpha_{R[X]} = [\Phi_S(p) \times_S \mathrm{id}_{S'}][a_{X'}].$$

The right side is $[r_X]$. To see this before localization, compare its two projections. Projection to S' is the structure map of X'. Projection to $\Phi_S X$ gives $\Phi_S(p) i_{X'}$, which equals $i_X p$ by naturality of i. These are exactly the projections of r_X. Since $[r_X]$ is invertible, cancellation proves

$$R(\beta_{[X]})\alpha_{R[X]} = \mathrm{id}_{R[X]}.$$

The target of r_X is $\Phi_S(X) \times_S S'$. In the displayed line immediately preceding the first triangle on manuscript page 144 the edition prints $\Phi_S(X') \times_S S'$ instead. The adjacent diagram and the expression $i_X \times_S \mathrm{id}_{S'}$ determine the intended target unambiguously. This is a typographical slip, not a gap in the naturality argument.

We can now use $L \dashv R$ without further representative choices. Its Hom bijection sends $h : L\xi' \longrightarrow \eta$ to $R(h)\alpha_{\xi'}$, and its inverse sends $k : \xi' \longrightarrow R\eta$ to $\beta_\eta L(k)$. The two equations just proved say exactly that these transformations are inverse. They also make the construction independent of an accidental presentation of a morphism by a fraction. The result is stronger than the assertion that direct and inverse image have compatible formulas on objects.

Commentary · Context [ms. 147]

Adjunction is the organizing operation

Grothendieck's insistence on constructing both adjunction arrows belongs to the original motivation of derivators. In *Pursuing Stacks*, §69, printed pp. 1–2, he describes the diagram categories as a way to recover structure lost by a single derived category, and identifies the two adjoints to restriction as the operations replacing direct and inverse limits (Grothendieck, 1983). The present calculation supplies one of those adjoints in the categorical model of homotopy types.

Its immediate use is already visible. Once the unit and counit exist, a natural transformation between diagrams of indexing categories can be transported across adjunctions. This produces the comparison maps for Kan extensions, rather than merely plausible isomorphisms between their values. The commentary on Chapter I, manuscript p. 31 ("The base-change map as a mate") explained that formal operation; manuscript pages 138–146 have now constructed the particular adjunction to which it will be applied.

There is a further gain. An adjunction may pass to a reflective subcategory even when its two functors are not constructed there in the same manner. Direct image descends through a localization, while inverse image restricts to local objects. The next argument separates these two mechanisms. That separation will become decisive when the chapter later distinguishes $\mathrm{HOT}^{\mathrm{lc}}_{W}$ from $\mathrm{HOT}^{\mathrm{lc!}}_{W}$.

a) $f_!$ est compatible avec les localiseurs de $\mathcal{A}'$, $\mathcal{A}$ définis par ρ', ρ respectivement, donc définit un foncteur (bien déterminé à isomorphisme unique près)

$$f_!^0 : \mathcal{A}'_0 \longrightarrow \mathcal{A}_0,$$

donnant donc lieu à un diagramme commutatif (à isomorphisme fonctoriel près)

p. 91

(I)
$$\begin{array}{ccc} \mathcal{A}' & \xrightarrow{\rho'} & \mathcal{A}'_0 \\ {\scriptstyle f_!}\downarrow & & \downarrow{\scriptstyle f_!^0} \\ \mathcal{A} & \longrightarrow & \mathcal{A}_0. \end{array}$$

[plutôt $\mathcal{A} \xrightarrow{\rho} \mathcal{A}_0$]

b) 'Dualement', $f^* : \mathcal{A} \longrightarrow \mathcal{A}'$ est compatible avec les sous-catégories pleines images essentielles des foncteurs pleinement fidèles i, i', et induit alors un foncteur, défini à isomorphisme unique près : [page 149]

$$f_0^* : \mathcal{A}_0 \longrightarrow \mathcal{A}'_0,$$

donnant lieu à un carré de foncteurs, commutatif à isomorphisme fonctoriel canonique près

(II)
$$\begin{array}{ccc} \mathcal{A}_0 & \xrightarrow{i} & \mathcal{A} \\ {\scriptstyle f_0^*}\downarrow & & \downarrow{\scriptstyle f^*} \\ \mathcal{A}'_0 & \xrightarrow{i'} & \mathcal{A}'. \end{array}$$

Sous ces conditions, le couple de foncteurs

$$\mathcal{A}_0 \underset{f_0^*}{\overset{f_!^0}{\rightleftarrows}} \mathcal{A}'_0, \qquad [\text{plutôt } \mathcal{A}'_0 \underset{f_0^*}{\overset{f_!^0}{\rightleftarrows}} \mathcal{A}_0,]$$

est un couple de foncteurs adjoints. (NB quand je parle de couples de foncteurs adjoints, celui écrit au-dessus de l'autre est l'adjoint à gauche.)

Démonstration. Soient

$$\eta_0 \in \mathrm{Ob}\mathcal{A}_0, \qquad \xi'_0 \in \mathrm{Ob}\mathcal{A}'_0,$$

il faut définir une bijection bifonctorielle

$$\mathrm{Hom}_{\mathcal{A}_0}(f_!^0(\xi_0'), \eta_0) \simeq \mathrm{Hom}_{\mathcal{A}_0'}(\xi_0', f_0^*(\eta_0))$$

Pour cela, on va écrire ξ_0' sous la forme

$$\xi_0' = \rho'(\xi')\,, \qquad \xi' \in \mathrm{Ob}\mathcal{A}',$$

il suffira d'établir la bijection bifonctorielle en remplaçant ξ_0' par $\rho'(\xi')$, i.e.

$$\mathrm{Hom}_{\mathcal{A}_0}(f_!^0(\rho'(\xi')), \eta_0) \simeq \mathrm{Hom}_{\mathcal{A}_0'}(\rho'(\xi'), f_0^*(\eta_0))$$

(En effet, la formule d'adjonction s'interprète comme un isomorphisme de bifoncteurs, ou, ce qui revient au même, de foncteurs $\mathcal{A}_0' \underset{\psi}{\overset{\varphi}{\rightrightarrows}} \mathcal{A}_0^\wedge$, or p. 92 [page 150]

$$\begin{array}{ccc} \underline{\mathrm{Hom}}(\mathcal{A}_0', \mathcal{A}_0^\wedge) & \longrightarrow & \underline{\mathrm{Hom}}(\mathcal{A}', \mathcal{A}_0^\wedge) \\ \varphi & \longmapsto & \varphi \circ \rho' \end{array}$$

est pleinement fidèle, puisque ρ' est un foncteur de localisation, donc il revient au même de se donner un isomorphisme $\varphi \simeq \psi$, ou $\varphi \circ \rho' \simeq \psi \circ \rho'$.) On doit donc transformer l'expression

$$\begin{array}{ccccc} & \mathrm{Hom}_{\mathcal{A}_0}(\underbrace{f_!^0(\rho'(\xi'))}_{\rho f_!(\xi')}, \eta_0) & \underbrace{\simeq}_{\text{commutativité de (I)}} & \mathrm{Hom}_{\mathcal{A}_0}(\rho f_!(\xi'), \eta_0) & \\ \underbrace{\simeq}_{\text{adjonction } \rho,\, i} & \mathrm{Hom}_{\mathcal{A}}(f_!(\xi'), i(\eta_0)) & \underbrace{\simeq}_{\text{adjonction } f_!,\, f^*} & \mathrm{Hom}_{\mathcal{A}'}(\xi', \underbrace{f^* i(\eta_0)}_{i'(f_0^*(\eta_0))}) & \\ \underbrace{\simeq}_{\text{commutativité de (II)}} & \mathrm{Hom}_{\mathcal{A}'}(\xi', i'(f_0^*(\eta_0))) & \underbrace{\simeq}_{\text{adjonction } \rho',\, i'} & \mathrm{Hom}_{\mathcal{A}_0'}(\underbrace{\rho'(\xi')}_{\xi_0'}, f_0^*(\eta_0)), & \end{array}$$

ce qui est la bijection annoncée.

Je résume l'essentiel des résultats obtenus sur $f_!$, $f_!^{\mathrm{lc}}$:

Théorème 2. *Soit $f : S' \longrightarrow S$ une flèche dans* Cat*, considérons les foncteurs*

$$\mathrm{HOT}_W(S') \underset{f^*}{\overset{f_!}{\rightleftarrows}} \mathrm{HOT}_W(S)$$

$$\mathrm{HOT}_W^{\mathrm{lc}}(S') \underset{f_{\mathrm{lc}}^*}{\overset{f_!^{\mathrm{lc}}}{\rightleftarrows}} \mathrm{HOT}_W^{\mathrm{lc}}(S),$$

où les foncteurs $f_!$, $f_!^{\mathrm{lc}}$ sont décrits dans le théorème 1 *(p. 136). Les morphismes d'adjonction* [page 151]

$$\begin{cases} \mathrm{id} & \longrightarrow & f^* f_! \\ \mathrm{id} & \longleftarrow & f_! f^* \end{cases}$$

sont décrits p. 138 à 140.

Commentary · Exposition [ms. 150]

Passing an adjunction through two reflections

Grothendieck wants the locally constant adjunction without repeating the categorical calculations. The abstract argument is correct, and it is useful to state its hypotheses independently of any identification of local homotopy theories. Suppose

$$\rho : \mathcal{A} \rightleftarrows \mathcal{A}_0 : i, \qquad \rho' : \mathcal{A}' \rightleftarrows \mathcal{A}_0' : i'$$

are adjunctions with i, i' fully faithful, and $L : \mathcal{A}' \rightleftarrows \mathcal{A} : R$ is an adjunction. Let Σ and Σ' be the classes inverted by ρ and ρ'. Assume that $L(\Sigma') \subseteq \Sigma$ and that R carries the essential image of i into that of i'. We then have functors $\bar{L}$ and $\bar{R}$, with natural isomorphisms

$$\bar{L}\rho' \simeq \rho L, \qquad i'\bar{R} \simeq Ri.$$

The desired adjunction follows from the natural chain

$$\begin{aligned} \mathrm{Hom}_{\mathcal{A}_0}(\bar{L}\rho' x', y) &\simeq \mathrm{Hom}_{\mathcal{A}_0}(\rho L x', y) \\ &\simeq \mathrm{Hom}_{\mathcal{A}}(Lx', iy) \\ &\simeq \mathrm{Hom}_{\mathcal{A}'}(x', Riy) \\ &\simeq \mathrm{Hom}_{\mathcal{A}'}(x', i'\bar{R}y) \\ &\simeq \mathrm{Hom}_{\mathcal{A}'_0}(\rho' x', \bar{R}y). \end{aligned}$$

Every object of $\mathcal{A}'_0$ is isomorphic to one of the form $\rho' x'$. The resulting bijection also descends naturally in that object. Precomposition with a localization is fully faithful on functor categories: a naturality square for an inverted arrow is obtained from the original square by inversion, and then naturality holds for every composite of ordinary arrows and formal inverses. This supplies the step which cannot be replaced by essential surjectivity alone. If one wishes to avoid conventions about the notation $\mathcal{A}_0^{\wedge}$ in the text, the relevant object is simply the bifunctor on $(\mathcal{A}'_0)^{\mathrm{op}} \times \mathcal{A}_0$ appearing in this display.

The two compatibility assumptions actually describe the same condition. This standard observation clarifies why Grothendieck calls them dual. An object $z \in \mathcal{A}$ belongs to the reflective subcategory if and only if

$$\mathrm{Hom}(b, z) \longrightarrow \mathrm{Hom}(a, z)$$

is bijective for every $a \longrightarrow b$ in Σ. One direction follows from adjunction. For the converse, apply the condition to the unit $z \longrightarrow i\rho z$. It gives a retraction $i\rho z \longrightarrow z$. Since $i\rho z$ is already local, the same orthogonality shows that the other composite is the identity. Thus the unit is invertible.

If L preserves localization equivalences and y is local, the adjunction identifies

$$\mathrm{Hom}(b', Ry) \longrightarrow \mathrm{Hom}(a', Ry)$$

with $\mathrm{Hom}(Lb', y) \longrightarrow \mathrm{Hom}(La', y)$. This is a bijection for every $a' \longrightarrow b' \in \Sigma'$, so Ry is local. Conversely, if R preserves local objects, the same argument shows that $\rho L(a' \longrightarrow b')$ induces bijections into every object of $\mathcal{A}_0$. Yoneda then makes it invertible. In particular, one need not verify two unrelated conditions in applications. The basic facts about reflections and fully faithful adjoints are recorded in Riehl (n.d., Lemma 4.5.11 and Definition 4.5.12); the displayed Hom calculations give the particular descent argument needed here.

This formal lemma should be carried unchanged into the later revision of the chapter. What changes there is its application. A coarse localization of categories over S does not automatically identify with the full subcategory of locally constant objects. The latter comparison requires the additional hypotheses examined on manuscript pages 171–204. Theorem 2 therefore gives the fine adjunction without that difficulty, and gives the locally constant adjunction whenever the asserted reflections and their compatibility have been established. A correct formal argument does not supply a missing identification of its input categories.

On voudrait expliciter la formule sympathique, obtenue en passant

$$\boxed{f_! f^*(\xi) = \mathrm{hot}_{S,W}(S'/S) \times_S \xi}\ ,$$

pour ceci il faut expliciter le deuxième membre. Notons la

Proposition 4. *Il existe un unique foncteur*

$$(\xi, \eta) \longmapsto \xi \times_S \eta : \mathrm{HOT}_W(S) \times \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S)$$

avec la propriété que pour X, Y variables dans $\underline{\mathrm{Liss}}\, S$, on ait un isomorphisme bifonctoriel en X, Y

p. 93

$$(*) \qquad \mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y) \simeq \mathrm{hot}_{S,W}(X \times_S Y)$$

([72]).

C'est formel, en utilisant seulement que sur $\underline{\mathrm{Liss}}\, S$, le bifoncteur

$$(X, Y) \longrightarrow X \times_S Y$$

est compatible avec les localiseurs $W_S^{\mathrm{d}} \times W_S^{\mathrm{d}}$ et W_S^{d}. Pour le voir, on est ramené à voir que si $X \xrightarrow{u} X'$ dans $\underline{\mathrm{Liss}}\, S$ est dans W_S^{d}, alors il en est de même de $X \times_S Y \xrightarrow{u \times_S \mathrm{id}_Y} X' \times_S Y$, pour tout Y dans $\underline{\mathrm{Liss}}\, S$. En fait, on n'utilise que la lissité de X, X', pas celle de Y, et c'est immédiat, car si $X \longrightarrow X'$ est dans W_S^{d}, $X \times_S Y \longrightarrow X' \times_S Y$ est dans W_Y^{d}, donc aussi dans W_S^{d} (cf. théorème 1 appliqué à $Y \longrightarrow S$). Cette remarque suggère en même temps : [page 152]

Commentary · Exposition [ms. 151]

Deriving the product in both variables

The product appears because Grothendieck wants to understand the endofunctor $f_! f^*$. Before identifying it with multiplication by a relative homotopy type, he has to decide which fibre products survive localization. Proposition 4 makes the safe construction: take both representatives smooth over the base.

For smooth $X, Y \longrightarrow S$, their fibre product is again smooth. If $u : X \longrightarrow X_1$ is a right-fine equivalence between smooth objects, pulling it back along an arbitrary $Y \longrightarrow S$ gives a right-fine equivalence over Y. Forgetting from Y to S preserves that class. Hence

$$X \times_S Y \longrightarrow X_1 \times_S Y$$

is right-fine over S. The same assertion holds in the other variable when the objects varied are smooth. Localizing separately in the two variables therefore produces a bifunctor on $\mathrm{HOT}_W(S)$. The uniqueness asserted in the proposition is uniqueness with its comparison isomorphisms, rather than literal equality of all choices of localized categories.

For arbitrary representatives its value is

$$[X] \times_S [Y] \simeq [\Phi_S X \times_S \Phi_S Y].$$

If X is smooth, $\Phi_S X$ may be replaced by X in this expression. That fact does not yet allow $\Phi_S Y$ to be replaced by Y. The two replacements concern different maps. The first is an equivalence between smooth objects, to which the base-change statement applies. The second would require arbitrary pullback along $X \longrightarrow S$ to preserve all right-fine equivalences. Smoothness of X alone does not say this.

Associativity, symmetry and the unit are transported with their coherence maps. Their diagrams commute already for strict fibre products of categories; localization preserves those equalities. The unit is the class of $S \longrightarrow S$. Equivalently, the diagonal–product adjunction and the terminal-object adjunction descend, so the multiplication is the categorical product in the localized category. In the usual homotopy theory its diagram interpretation is simply the pointwise product of space-valued presheaves.

The boxed formula preceding the proposition must consequently be read provisionally. A formula

$$f_! f^*(\xi) \simeq [S'/S] \times_S \xi$$

for arbitrary f would identify a construction deriving only the varying input with one deriving both factors. Grothendieck notices the discrepancy almost immediately. The following counterexample is therefore part of the proof's development, and the corrected corollary is its actual conclusion. Treating the crossed-out assertion as a theorem would obscure the main mathematical distinction these pages establish.

Corollaire 1. (Faux) *La formule bifonctorielle* $(*)$ *reste valable pour* X *dans* $\underline{\mathrm{Liss}}\, S$, Y *quelconque dans* Cat/S, *et aussi dans le cas inverse.* ([73])

72. **NB** La multiplication $\times_S$ dans $\mathrm{HOT}_W(S)$ est associative, commutative, unitaire *etc., etc.*, puisque c'est le cas dans $\underline{\mathrm{Liss}}\, S$.

73. Cet énoncé est sûrement *faux!* Contrexemple p. 153, cf. corollaire 1 rectifié page 154-156.

Dans le premier cas, considérons

$$Y \xrightarrow{i_Y} \Phi(Y)$$

dans W_S^{d}, donc un isomorphisme dans $(\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}$, on aura donc

$$\begin{array}{ccc} \mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y) & \xrightarrow{\sim} & \mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(\Phi(Y)) \\ & \underbrace{\xrightarrow{\sim}}_{\text{car } X \text{ et } \Phi(Y) \text{ lisses sur } S} & \mathrm{hot}_{S,W}(X \times_S \Phi(Y)), \end{array}$$

or je dis que

$$X \times_S Y \xrightarrow{X \times_S i_Y} X \times_S \Phi(Y)$$

est encore dans W_S^{d}. Il suffit de voir que c'est dans W_X^{d} (cf. théorème 1), et pour ceci, que le changement de base lisse $X \longrightarrow S$ induit $\mathrm{Cat}/S \longrightarrow \mathrm{Cat}/X$ compatible avec les localiseurs W_S^{d}, W_X^{d}. Mais c'est *faux* (prendre $X = \{s\}$).

Montrons que les corollaire est faux. Je vais prendre $Y = \{s\}$, catégorie ponctuelle en s, alors $\Phi(Y)$ est la catégorie fibrée à fibres discrètes définie par le foncteur représentable F [page 153]
défini par s, donc c'est S/F et, en l'occurence S/s:

$$\Phi(\{s\}) \simeq S/s \qquad \text{comme catégorie sur } S.$$

Si p.ex. s est élément final e de S, on trouve

$$\Phi(\underset{S}{e}) \simeq S, \qquad \text{p. 94}$$

donc

$$\mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(e) = \mathrm{hot}_{S,W}(X),$$

d'autre part

$$\mathrm{hot}_{S,W}(X \times_S e) = \mathrm{hot}_{S,W}(X_e).$$

Si les deux étaient isomorphes dans $\mathrm{HOT}_W(S)$ par la flèche canonique

$$X_e \longrightarrow X,$$

en appliquant le foncteur $p_!$ (où $p : S \longrightarrow e$), il s'ensuiverait que $X_e \longrightarrow X$ est dans W. Si par [154]
exemple $S = \mathbf{\Delta}^1$, cela impliquerait que pour tout X lisse sur S, $X_1 \longrightarrow X$ est dans W, alors que normalement la lissité implique que $X_0 \longrightarrow X$ est dans W. Donc ça reviendrait à dire que $\underline{\mathrm{Liss}}\ \mathbf{\Delta}^1 = \underline{\mathrm{Liss}}_0 \mathbf{\Delta}^1$, d'où aussitôt $\underline{\mathrm{Liss}}\ S = \underline{\mathrm{Liss}}_0 S$, pour tout S dans Cat, ça se saurait! Le contrexemple le plus trivial est de prendre $X = \{0\} \hookrightarrow S = \mathbf{\Delta}^1$, l'inclusion de l'ouvert 'générique', immersion ouverte, donc lisse, la fibre X_1 est vide!

Corollaire 1 rectifié. *Si X est dans Cat/S, pas nécessairement lisse sur S, alors le foncteur*

$$\mathrm{mult}_{X/S} : Y \longmapsto Y \times_S X : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S$$

induit un foncteur

$$\underline{\mathrm{Liss}}\ S \longrightarrow \mathrm{Cat}/S$$

compatible avec les localiseurs W_S^{d}, W_S^{d}, donc induit un foncteur

$$(\underline{\mathrm{Liss}}\ S)(W_S^{\mathrm{d}})^{-1} \longrightarrow (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1},$$

ou encore (compte tenu de l'équivalence induite par l'inclusion

$$(\underline{\mathrm{Liss}}\, S)(W_S^{\mathrm{d}})^{-1} \xrightarrow{\sim} (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1} \quad),$$

un foncteur, encore noté $\mathrm{multhot}_{X/S}$,

$$\mathrm{multhot}_{X/S} : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S). \qquad [155]$$

Commentary · Examples [ms. 154]

The false corollary on every fibre

Grothendieck chooses the smallest base on which the two product constructions can differ. We expand his example because it also identifies the endofunctor which replaces the false formula. Let $S = [1] = (0 \longrightarrow 1)$, let $X = \{0\} \longrightarrow S$, and let $Y = \{1\} \longrightarrow S$.

The inclusion of 0 is a discrete fibration: an arrow into 0 can only be its identity. Thus X is smooth. Its comma fibres are

$$0\backslash X = e, \qquad 1\backslash X = \varnothing.$$

For Y both comma fibres are points, and $\Phi_S Y \cong S$. The relative homotopy type $[Y]$ is therefore the terminal object of $\mathrm{HOT}(S)$. It follows that

$$[X] \times_S [Y] \simeq [X].$$

On the other hand, $X \times_S Y = \varnothing$, so

$$[X \times_S Y] = [\varnothing].$$

Evaluation at 0 distinguishes the two objects: it gives a point on the first side and the empty homotopy type on the second. One smooth factor has not made the strict fibre product into the derived product.

There is a useful computation for an arbitrary coefficient. Write a space-valued presheaf on $[1]$ as a map $b : B \longrightarrow A$, with values $F(1) = B$ and $F(0) = A$. It may be represented by a smooth category over S, or calculated in the usual space-valued diagram model. For the inclusion $j_1 : \{1\} \longrightarrow S$, restriction gives B, and left Kan extension returns the constant diagram on B. Thus

$$j_{1!}j_1^* F = (B \xrightarrow{\mathrm{id}} B), \qquad [Y] \times_S F = F = (B \xrightarrow{b} A).$$

The counit has components id_B at 1 and b at 0. The candidate product formula is an equivalence precisely when b is a weak equivalence. For $F = [X]$, this is the map $\varnothing \longrightarrow e$.

For comparison, the inclusion $j_0 : \{0\} \longrightarrow S$ gives

$$j_{0!}j_0^* F = (\varnothing \longrightarrow A) \simeq [X] \times_S F.$$

The difference between the endpoints has a categorical explanation. The object 0 defines a sieve, so left Kan extension of presheaves from it is extension by the empty object. The object 1 instead has an incoming arrow from outside its image, and that arrow transports B into the value at 0.

This also proves a sharper warning contained in the corrected corollary. The map $Y \longrightarrow S$ is a right-fine equivalence, so $[Y] \simeq [S]$. Nevertheless the two fixed-factor endofunctors are different: multiplication by the category S/S is the identity, whereas $\mathrm{multhot}_{Y/S}$ sends $B \longrightarrow A$ to the constant diagram on B. Thus $\mathrm{multhot}_{Y/S}$ depends on the chosen category Y over S, not only on its class in $\mathrm{HOT}(S)$.

Ce foncteur satisfait donc à la relation

$$\mathrm{multhot}_{X/S}(\mathrm{hot}_{S,W}(Y)) \underbrace{\simeq}_{\text{isomorphisme canonique}} \mathrm{hot}_{S,W}(X \times_S Y)$$

pour Y *lisse sur* S, et pour Y quelconque dans Cat/S,

$$\mathrm{multhot}_{X/S}(\mathrm{hot}_{S,W}(Y)) \underbrace{\simeq}_{\text{isomorphisme canonique}} \mathrm{hot}_{S,W}(X \times_S \Phi_S(Y)).$$

p. 95

Quand X est lui-même lisse sur S, ce foncteur n'est autre que la multiplication par $\mathrm{hot}_{S,W}(X)$:

$$\mathrm{multhot}_{X/S} = \mathrm{mult}_{\mathrm{hot}_{S,W}(X)} \qquad \text{si } X \textit{ lisse sur } S.$$

Mais sa valeur pour $\mathrm{hot}_{S,W}(Y)$, quand Y n'est *pas* lisse sur S, ne doit pas être confondue avec $\mathrm{hot}_{S,W}(X \times_S Y)$.

Ainsi, si X et Y sont dans Cat/S, considérons

$$X \times_S Y \qquad \text{et} \qquad \boxed{\mathrm{hot}_{S,W}(X \times_S Y).}$$

a) Si ni X ni Y ne sont supposés lisses sur S, cet élément 'n'a aucune interprétation naturelle en termes d'opérations sur les catégories $\mathrm{HOT}_W(S)$' ([74]).

[156]

Commentary · Development (commentators') [ms. 155]

A precise boundary for the product formula on finite posets

The walking-arrow example suggests asking which inclusions permit the formula for every coefficient. In a finite poset the answer can be read directly from the order. The following elementary development extends Grothendieck's example to a complete criterion in that setting. We use ordinary homotopy types throughout, so $W = W_\infty$.

Proposition (full subposets and the universal product formula). [ours] Let S be a finite poset, regarded as a category, and let $u : U \hookrightarrow S$ be the inclusion of a full subposet. In space-valued presheaves put $P_U = u_!1$, where 1 is the terminal presheaf on U. The canonical map

$$\theta_F : u_!u^*F \longrightarrow P_U \times F$$

is an equivalence for every $F : S^{\mathrm{op}} \longrightarrow \mathsf{Spaces}$ if and only if U is a lower ideal: whenever $s \leq t$ and $t \in U$, one has $s \in U$.

Here $u_!$ means homotopy left Kan extension along u^{op}. The two components defining θ_F are $u_!u^*F \longrightarrow u_!1$, induced by the terminal map, and the counit $u_!u^*F \longrightarrow F$. This specifies the comparison whose invertibility is claimed.

Proof. For $s \in S$, write

$$U_{\geq s} = \{t \in U \mid s \leq t\}.$$

The pointwise formula gives

$$(u_!G)(s) \simeq \operatorname*{hocolim}_{(U_{\geq s})^{\mathrm{op}}} G(t), \qquad P_U(s) \simeq B(U_{\geq s}),$$

where B denotes the nerve's homotopy type. Replacing a category by its opposite does not change this homotopy type.

Suppose first that U is a lower ideal. If $s \notin U$, the category $U_{\geq s}$ is empty, so both $(u_!u^*F)(s)$ and $(P_U \times F)(s)$ are empty. If $s \in U$, the poset $U_{\geq s}$ has initial object s, and its opposite has terminal object s. The homotopy colimit is therefore $F(s)$; the same argument with constant value e gives $P_U(s) \simeq e$. Under these identifications $\theta_F(s)$ is the identity of $F(s)$. This proves the sufficiency, including the comparison map, at every object of S.

For necessity, suppose that $s \notin U$ but $s \leq t_0$ for some $t_0 \in U$. Take the representable discrete presheaf

$$F = h_s, \qquad h_s(t) = \mathrm{Hom}_S(t, s).$$

For every $t \in U_{\geq s}$, one has $s \leq t$ and $t \neq s$. Antisymmetry then excludes $t \leq s$, so $h_s(t) = \varnothing$. The diagram computing $(u_!u^*h_s)(s)$ is constantly empty, and its homotopy colimit is empty. By contrast,

$$(P_U \times h_s)(s) \simeq B(U_{\geq s}) \times e$$

is nonempty, since t_0 is an object of $U_{\geq s}$. Hence $\theta_{h_s}(s)$ is not an equivalence. This contradicts the asserted universal formula and proves necessity. □

The test uses only a representable presheaf. Consequently, in this finite-poset setting the universal formula can already be tested on the collection of representables h_s. For a point inclusion $\{t\} \hookrightarrow S$, it holds for every coefficient exactly when t is minimal. It holds for every point inclusion exactly when S is discrete.

There is also a distinction from absolute weak equivalence. In the chain $0 < 1 < 2$, take $U = \{1, 2\}$. Both U and S have contractible nerves, and $P_U \simeq 1$: each nonempty upper intersection $U_{\geq s}$ has a least element. Nevertheless u^*h_0 is empty, so $u_!u^*h_0$ is empty while $P_U \times h_0 \simeq h_0$ is not. Equivalence of the total homotopy types of the indexing categories does not remove the variation of an arbitrary coefficient diagram.

The positive sieve calculation is standard Kan-extension calculus; compare Groth (2013, Proposition 1.23, with the indexing categories replaced by their opposites). We checked the pointwise and sieve formulations in the cited derivator literature and searched for the

74. Sauf dans le cas où l'un des deux soit dans Fibhot S, cf. annotation page suivante.

> corresponding finite-poset converse under projection formula and Frobenius reciprocity. We did not locate this exact elementary criterion there. The proof is included as a continuation of the example, without a claim of priority or of a new general projection-formula theorem.

b) Si X et Y sont lisses sur S, cet élément s'interprète comme

$$\mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y)$$

([75]).

c) Si l'un des deux X, Y est lisse sur S, sans rien supposer sur l'autre, on a une interprétation en termes de mult_X (si Y lisse), ou mult_Y (si X lisse), notamment

$$\begin{aligned} \mathrm{hot}_{S,W}(X \times_S Y) &\simeq \mathrm{multhot}_X(\mathrm{hot}_{S,W}(Y)) \quad \text{si } Y \text{ lisse sur } S \\ &\simeq \mathrm{multhot}_Y(\mathrm{hot}_{S,W}(X)) \quad \text{si } X \text{ lisse sur } S. \end{aligned}$$

Corollaire 2. *Soit $f : S' \longrightarrow S$ une flèche dans* Cat*, d'où $f_!$, f^* entre* $\mathrm{HOT}_W(S')$ *et* $\mathrm{HOT}_W(S)$*. On a la relation*

$$f_! f^*(\xi) \simeq \mathrm{multhot}_{S'}(\xi),$$

donc si S' est lisse sur S,

$$f_! f^*(\xi) \simeq \mathrm{hot}_{S,W}(S') \times_S \xi.$$

Nous sommes maintenant en mesure de vérifier les axiomes Der 4′b, Der 5′ relatifs aux images directes (I, p. 67, 68), et de plus Der 3b (I, p. 111). L'axiome Der 4′ n'est autre que l'existence des adjoints à gauche $f_!$ des f^*. L'axiome Der 5′ permet le 'calcul' des fibres d'un objet $f_!(\xi)$. Il dit qu'une certaine flèche du changement de base, relatif au diagramme commutatif dans Cat

$$\begin{array}{ccc} S' & \xleftarrow{q} & s\backslash S' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow{p} & e \simeq \{s\} \end{array} \qquad (s \in \mathrm{Ob}\, S),$$

p. 96 [157]

savoir

$$p^*(f_!(\xi')) \longrightarrow f'_!(q^*(\xi'))$$

est un isomorphisme (pour $\xi' \in \mathbf{D}(S')$). Soit donc

$$\xi' \in \mathrm{Ob}\,\mathrm{HOT}_W(S'), \qquad \xi' = \mathrm{hot}_{S',W}(X')$$

avec X' dans Cat/S'. Comme

$$f_!(\xi') = \mathrm{hot}_{S,W}(X'),$$

et que X' n'a aucune raison d'être lisse sur S (si on ne suppose pas S' lui-même lisse sur S, auquel cas il pourrait être utile de prendre X' lisse sur S', donc aussi sur S), pour calculer $p^*(f_!(\xi'))$ il n'est pas question de prendre la fibre X'_s, mais il faut prendre $s\backslash X' = \Phi_S(X')_s$:

$$p^*(f_!(\xi')) \simeq \mathrm{hot}_W(s\backslash X').$$

$$\begin{array}{ccc} X' & \longleftarrow & s\backslash X' \\ \downarrow & & \downarrow \\ S' & \xleftarrow{q} & s\backslash S' \\ \downarrow & & \downarrow \\ S & \longleftarrow & s\backslash S \end{array}$$

75. Mais aussi si l'*un* des deux éléments est dans $\underline{\mathrm{Fibhot}}\, S$ (et moyennant l'axiome L6 bis sur W).

Commentary · Exposition [ms. 156]

Fixed-factor multiplication is a direct-image composite

The corrected corollary does more than impose an extra hypothesis on the false formula. It isolates an operation which remains available for every category $x : X \longrightarrow S$. Its varying argument is derived, while the category X is held fixed:

$$M_X([Y]) = [X \times_S \Phi_S Y].$$

The base-change assertion used in Proposition 4 makes this independent of the chosen smooth representative of $[Y]$. The example just calculated shows why it is not generally independent of the representative of $[X]$.

This operation has a direct adjunction-theoretic description:

$$M_X \simeq x_! x^*.$$

Indeed, for smooth Y the inverse image $x^*[Y]$ is represented over X by $Y \times_S X$. Direct image along x regards the same total category as lying over S. Thus both sides give $[Y \times_S X]$, naturally in Y. Since smooth objects present the localization, the identification holds on all of $\mathrm{HOT}_W(S)$. Corollary 2 is the special case $X = S'$.

There is a canonical comparison with the derived product. The map $i_X : X \longrightarrow \Phi_S X$ induces, for smooth Y,

$$[X \times_S Y] \longrightarrow [\Phi_S X \times_S Y] \simeq [X] \times_S [Y].$$

The right side derives both inputs; the left side has only derived the varying input. If X is smooth, the comparison is invertible, because it is the pullback of a right-fine equivalence between smooth representatives. Without that hypothesis the comparison can fail, as it does for $X = \{1\}$ over the walking arrow. The later discussion of homotopical fibrations and properness will supply further sufficient hypotheses. Nothing in the present corollary establishes those extensions in advance.

The identity $M_X \simeq x_! x^*$ also supplies structure which is easy to miss if one sees only the fibre-product formula. It is the underlying endofunctor of a comonad. Its counit is the projection map already used in the adjunction proof, and its comultiplication is

$$x_! x^* \xrightarrow{x_! \alpha x^*} x_! x^* x_! x^*.$$

The comonad laws follow from the triangle identities. When X is smooth, this is multiplication by $[X]$ with the diagonal coalgebra structure coming from the cartesian product. This interpretation explains the order of the argument: the adjunction is established first, and the formula for its composite is then refined according to the geometry of the fixed factor.

Thus the three cases listed on manuscript pages 155–156 have different information content. With two smooth factors, one obtains the product of two objects of the homotopy category. With only the varying factor smooth, one obtains the value of M_X. For two arbitrary strict representatives, their strict fibre product need not be determined by either localized class. These are statements about the operations available from particular representatives, rather than about different possible definitions of the same product.

Considérons le diagramme de changement de base par $s\backslash S \longrightarrow S$ ci-contre `[i.e. ci-dessus]`, à carrés cartésiens. On voit d'abord que $q^*(\xi')$ n'est autre que la classe dans $\mathrm{HOT}_W(s\backslash S')$ de l'image inverse de X' par le changement de base $s\backslash S' \longrightarrow S'$. Pour l'assurer, il suffirait de prendre X' lisse sur S' (ce qui est licite) - alors la description de l'image inverse [158]
est OK pour tout changement de base. Mais on a vu que dans le cas d'un co-isomorphisme local comme $s\backslash S' \longrightarrow S'$, il n'y a pas même besoin de cet artifice - la formule est OK sans restriction de lissité. Ainsi

$$q^*(\xi') = \mathrm{hot}_{s\backslash S', W}(s\backslash X'),$$

d'où p. 97

$$f'_!(q^*(\xi')) \simeq \mathrm{hot}_{S,W}(s\backslash X') = \mathrm{hot}_W(s\backslash X').$$

Donc on a bien trouvé

$$p^* f_! \simeq f'_! q^*.$$

Commentary · Exposition [ms. 157]

The comma square and its actual comparison map

Grothendieck now verifies the pointwise formula for direct image. This is where the construction becomes a derivator calculation: evaluation at an object of the base is expressed by a homotopy colimit over a category of arrows. The comma replacement makes the formula almost tautological, but the comparison map and the variance deserve to be stated.

Fix $s \in S$ and write $C = s\backslash S'$. Its objects are pairs $(s', a : s \longrightarrow f(s'))$, and a morphism from (s', a) to (t', b) is $v : s' \longrightarrow t'$ such that $f(v)a = b$. Let $q : C \longrightarrow S'$ forget a, let $r : C \longrightarrow e$, and let $p : e \longrightarrow S$ select s. The square drawn in the text is not strictly commutative. It carries the canonical natural transformation

$$\tau : pr \Longrightarrow fq, \qquad \tau_{(s',a)} = a.$$

The two cartesian squares in the larger diagram involving $s\backslash S$ are, by contrast, strict pullback squares. These two kinds of square should not be identified.

With the presheaf convention $\mathrm{HOT}(S) = \mathrm{Ho}(\mathsf{Spaces}^{S^{\mathrm{op}}})$, τ gives $q^*f^* \longrightarrow r^*p^*$. The standard left-adjoint mate is

$$r_!q^* \xrightarrow{r_!q^*\alpha} r_!q^*f^*f_! \longrightarrow r_!r^*p^*f_! \xrightarrow{\beta} p^*f_!.$$

It points in the reverse direction to the arrow displayed on manuscript page 157. Once exactness is proved, that displayed arrow can be read as its inverse. The direction is fixed by the units, counits and structural 2-cell; it is not a further hypothesis on W. For the general mate construction, see Riehl (n.d., Proposition 4.3.8).

Let $X' \longrightarrow S'$ represent ξ'. The right side $p^*f_!\xi'$ is represented by $s\backslash X'$. On the left, q is a discrete opfibration: an arrow $v : s' \longrightarrow t'$ has the unique lift taking (s', a) to $(t', f(v)a)$. The pullback rule for these co-isomorphisms permits us to compute $q^*\xi'$ by strict pullback even for arbitrary X'. That pullback has objects $(a : s \longrightarrow f(s'), x')$ with $p'(x') = s'$, and is canonically isomorphic to $s\backslash X'$. Applying $r_!$ then forgets its map to C, so

$$r_!q^*\xi' \simeq \mathrm{hot}_W(s\backslash X') \simeq p^*f_!\xi'.$$

These identifications also calculate the mate. An object represented by (a, x') is carried by the unit into the comma replacement with its identity arrow; the structural transformation then supplies a; the counit forgets the redundant intermediate object. The resulting object is precisely (a, x') in $s\backslash X'$, and the same description sends a morphism to itself. Thus the mate is the identity under these categorical identifications. This proves the canonical comparison is invertible, rather than merely exhibiting an unspecified isomorphism between its source and target.

In modern diagram notation the formula reads

$$(f_!F)(s) \simeq \operatorname*{hocolim}_{(s\backslash f)^{\mathrm{op}}} F(s').$$

The opposite is forced by the presheaf convention. Modern presentations using covariant diagrams write the corresponding over-category formula instead. The pointwise axiom and its comma-square formulation appear in Groth (2013, Definition 1.5 and Proposition 1.26); the calculation here supplies them concretely for the categorical model.

On peut maintenant prouver aussi Der 3b. On a vu qu'une fois qu'on dispose des adjoints à gauche $f_!$ des f^*, cet axiome s'énonce sous *forme homologique* ainsi : Si

$$f : S' \longrightarrow S$$

est dans W, il faut prouver que pour tout

$$\xi \in \mathrm{HOT}_W(e) \overset{\text{déf}}{=} \mathrm{Hot}_W,$$

la flèche correspondante

$$(*) \qquad p'_!p'^*(\xi) \longrightarrow p_!p^*(\xi)$$

est [un] isomorphisme dans Hot_W, où $p : S \longrightarrow e$, $p' : S' \longrightarrow e$ sont les flèches structurales. Or comme tout objet de Cat est lisse sur e, le corollaire 2 précédent permet d'identifier cette flèche $(*)$ à

$$\eta' \times_S \xi \longrightarrow \eta \times_S \xi$$

déduite de [159]

$$\mathrm{hot}_W(f) : \underbrace{\eta'}_{\overset{\text{déf}}{=} \mathrm{hot}_W(S')} \longrightarrow \underbrace{\eta}_{\overset{\text{déf}}{=} \mathrm{hot}_W(S)} .$$

Comme celle-ci est [un] isomorphisme par hypothèse, on gagne.

Commentary · Exposition [ms. 158]

Constant coefficients detect the total homotopy type

Having obtained direct images, Grothendieck can express an equivalence of indexing categories by its effect on homology with constant coefficients. This assertion concerns the total homotopy type of the base. It should be kept separate from equivalence of all categories of diagrams over the base.

Let $p : S \longrightarrow e$ and represent $\xi \in \mathrm{Hot}_W$ by a category T. Since every category is smooth over a point, the preceding product computation gives

$$p_! p^*(\xi) \simeq \mathrm{hot}_W(S) \times \xi.$$

For $f : S' \longrightarrow S$, with $p' = pf$, the induced comparison is therefore

$$\mathrm{hot}_W(S') \times \xi \longrightarrow \mathrm{hot}_W(S) \times \xi.$$

The subscript S on the multiplication signs in the edition's display on page 158 is a slip: both objects belong to $\mathrm{Hot}_W = \mathrm{HOT}_W(e)$, so this is the product over e.

If $f \in W$, its image in Hot_W is invertible; applying the product functor proves the desired comparison is invertible for every ξ. Conversely, if every such comparison is invertible, take $\xi = e$, the product unit. Then $\mathrm{hot}_W(f)$ itself is invertible. Thus the precise condition detected is membership in the strong saturation $\overline{W}$, the class of arrows inverted by $\mathrm{Cat} \longrightarrow \mathrm{Hot}_W$. When W is already strongly saturated this is simply $f \in W$. The later restatement on manuscript page 204 makes this distinction explicit.

The walking arrow again illustrates the scope. The inclusion $\{1\} \longrightarrow [1]$ is a weak equivalence of nerves. It therefore gives the same homology of constant coefficients as $[1] \longrightarrow e$. Restriction of arbitrary presheaves along that inclusion, however, remembers only B from a diagram $B \longrightarrow A$. It cannot be an equivalence of all diagram categories: the diagrams $\varnothing \longrightarrow e$ and $\varnothing \longrightarrow \varnothing$ have the same restriction but are distinguished at 0.

The stronger statement about *locally constant* diagrams is different. On [1], local constancy requires $B \longrightarrow A$ to be an equivalence, so evaluation at either endpoint loses no information up to coherent equivalence. This small example explains why the next page strengthens the conclusion only on $\mathrm{HOT}^{\mathrm{lc}}_W$. It also explains why the axiom controlling the relation between coarse equivalence and fibrewise equivalence will enter that proof. The elementary product argument for constant coefficients does not itself establish that stronger assertion.

Donc on a prouvé

Théorème 3. *Le prédérivateur* HOT *satisfait aux axiomes* Der 1, Der 2 ([76]) *(pour mémoire), et* Der 3b ([77]), Der $4'$, Der $5'$.

On a envie de prouver aussi les variantes renforcées de Der 3, la forme la plus forte étant celle-ci (Der $3b'_2$) : si $f \in W$, alors f^* induit une *équivalence* de catégories

$$f_0^* : \mathrm{HOT}^{\mathrm{lc}}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_W(S').$$

76. *pas prouvé*, le 'résultat' auquel je pensais est canulé, cf. complément proposition 5, page 164.

77. Et même la variante la plus forte Der $3b'_2$ de Der 3, cf. démonstration page suivante. **NB** Pour Der $3b'_2$, on a utilisé l'axiome L6 sur W - et c'est essentiel. On voit que la validité de Der $3b'_2$ implique L6, et même la forme plus forte L6 bis, et même si on suppose seulement Der $3b'_1$, i.e. f_0^* pleinement fidèle.

La pleine fidélité du foncteur f_0^* doit résulter de la variante naturelle Der $3b''_{coh}$ de Der 3b, une fois qu'on aura développé le formalisme des Hom internes dans les $\mathrm{HOT}_W(S)$. Mais pour donner un sens à Der $3b''_{coh}$, on a besoin des foncteurs *cohomologie,* i.e. de p_* et p'_* (au lieu de $p_!$, $p'_!$) pour HOT, donc c'est encore prématuré pour l'instant. La construction des f_* et celle des Hom internes se fera d'ailleurs sûrement ± conjointement.

Mais je m'aperçois à l'instant qu'on trouve quasiment 'à l'œil' le fait que f_0^* soit bien une *équivalence* de catégories, et que $f_!^0$ soit l'équivalence quasi-inverse, en utilisant l'adjonction des foncteurs $f_!^0$, f_0^*, et se rappelant que pour prouver que ce sont des équivalences quasi-inverses l'une de l'autre, il revient au même de montrer que les morphismes d'adjonction p. 98 [160]

$$\begin{array}{ccc} \mathrm{id} & \xrightarrow{\alpha_0} & f_0^* f_!^0 \\ \mathrm{id} & \xleftarrow{\beta_0} & f_!^0 f_0^* \end{array}$$

sont [des] isomorphismes. Je vais essayer de décrire ces flèches d'adjonction dans le cas général (sans supposer $f \in W$), puis de montrer qu'elles sont dans W si f l'est.

Commentary · Present state [ms. 159]

What Theorem 3 establishes at this point

Grothendieck has proved the left-adjoint and pointwise formulas, and has checked homological invariance for constant coefficients. These are substantial conclusions. The annotations to Theorem 3 also record two separate qualifications which must remain part of its statement.

First, the claim of Der 2 is withdrawn in footnote 76. A family of evaluations is conservative if a morphism in the localized diagram category is invertible whenever all its evaluations are invertible. Defining weak equivalences objectwise does not, by itself, prove this statement for arbitrary morphisms of a localization. One still has to control how such morphisms are represented, or compare the localization with a model in which objectwise detection can be proved. The supplement on manuscript page 164 belongs to that unfinished part of the argument. It would be inaccurate either to count the parenthetical "pour mémoire" as a proof or to infer that conservativity is false in ordinary homotopy theory.

For the standard model the question is settled. Cisinski (2003, Theorem 6.11, including its proof of Der 2) constructs homotopy right Kan extensions for model categories with small limits and proves the corresponding derivator axioms; his Proposition 6.13 constructs the space-valued external Hom. For combinatorial model categories, Groth (2013, Proposition 1.30) gives a strong derivator. These results justify the usual space-valued diagram interpretation used in the examples above.

For every basic localizer, Der 2 now follows from Cisinski (2006a, Propositions 3.1.30 and 4.2.7): conservativity for presheaf localizers transfers through a diagramwise equivalence using Δ (4.1.29). Thus the revised relative $\mathrm{W}(1,2,3)$ suffice, without accessibility or $\mathrm{W}(4)$. This later repair preserves the historical withdrawal; it makes no assertion for arbitrary weak basic localizers.

Second, the strengthened assertion that a W-equivalence of bases induces an equivalence of locally constant categories uses additional control of fibres. The annotation names the earlier axiom L6, and the following pages examine exactly where it is needed. For ordinary weak equivalences, homotopy invariance of locally constant model-category diagrams is proved by Cisinski (2009, Theorem 1.3).

The final paragraph about constructing f_* together with internal Hom is therefore a programme at this place in the text. The adjunction proved above supplies $f_!$, but it supplies no right adjoint to f^* by formal symmetry: taking opposites of indexing categories is not the same as changing a left adjoint into a right adjoint in the same coefficient theory. The later model-category constructions give both operations in their stated settings. The localizer-by-localizer analysis in the remainder of this chapter remains necessary to determine what follows from Grothendieck's chosen axioms alone.

[1) Soit] $\xi = \mathrm{hot}^{\mathrm{lc}}_{S,W}(X)$ dans $\mathrm{HOT}_W(S)$. On peut supposer $X \in \mathrm{Ob}\,\underline{\mathrm{Parf}}\,S$. Comme ['Comme' barré] X lisse sur S, on a

$$f_0^*(\xi) = \mathrm{hot}^{\mathrm{lc}}_{S',W}(X \times_S S'), \qquad f_!^0 f_0^*(\xi) = \mathrm{hot}^{\mathrm{lc}}_{S,W}(X \times_S S').$$

Donc

$$\beta_{0,\xi} : f_!^0 f_0^*(\xi) \longrightarrow \xi$$

est une flèche

$$X \times_S S' \longrightarrow X \qquad \text{dans } (\mathrm{Cat}/S)(W_S)^{-1}$$

et je présume que c'est pr_1 ([78]). Est-ce dans W si $f : S' \longrightarrow S$ l'est? Oui (car X est parfait
sur S), sous réserve que W satisfait l'axiome L6 (cf. page 43). [161]

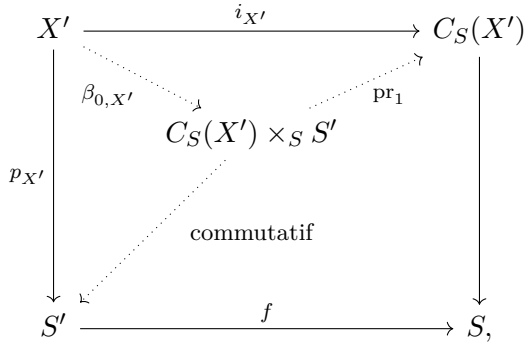
2) Soit

$$\xi' = \mathrm{hot}^{\mathrm{lc}}_{S',W}(X') \qquad \text{dans } \mathrm{HOT}_W(S'),$$

on a

$$f^0_!(\xi') = \mathrm{hot}^{\mathrm{lc}}_{S,W}(X'),$$

mais pour expliciter f_0^* de cet élément, comme X' n'a aucune raison d'être un Hot-fibré sur S (auquel cas il suffirait de prendre $f^*(X') \overset{\text{déf}}{=} X \times_S S'$), il faut d'abord prendre $C_S(X')$, puis appliquer f^* :



$$f_0^* f^0_!(X') = \mathrm{hot}^{\mathrm{lc}}_{S',W}(C_S(X') \times_S S').$$

Il faut donc définir

$$X' \xrightarrow{\beta_{0,X'}} C_S(X') \times_S S' \qquad \text{dans } (\mathrm{Cat}/S')W^{-1}_{S'}.$$

Or on trouve une flèche canonique dans Cat/S', déduite du S-morphisme $i_{X'} : X' \longrightarrow C_S(X')$, i.e. du carré commutatif en traits pleins

p. 99

comme l'unique flèche pointillée $\beta_{0,X'}$ qui soit un S'-morphisme (triangle gauche commutatif) et qui rende commutatif le triangle supérieur.

Si $f \in W$, alors pr_1, déduit de f par changement de base $C_S(X') \longrightarrow S$, qui est parfait, est dans W par L6, on sait qu'il en est de même de $i_{X'}$, donc aussi de $\beta_{0,X'}$, on gagne.

Pour terminer les propriétés générales des foncteurs $f_!$ pour HOT_W, je voudrais donner les énoncés raisonnables de changement de base. Ce serait un [page 162]

Commentary · Exposition [ms. 161]

When a change of base becomes an equivalence

Grothendieck now wants to know how much of the base a locally constant coefficient can remember. The adjunction is already available; the task is to determine when its two comparison maps become invertible. This is a stronger assertion than the agreement of cohomology with constant coefficients discussed just before it. A locally constant family has transport, and changing the base must preserve the whole family if restriction is to be an equivalence.

Write $f : S' \to S$, and retain the hypotheses under which the locally constant adjunction was constructed. For a perfect representative $X \to S$, the counit is the projection

$$\varepsilon_X : X \times_S S' \longrightarrow X.$$

78. **NB** On voit que l'axiome L6 est ± *nécessaire* pour que le résultat sur f_0^*, $f^0_!$ soit valable.

The notation β_0 used for this map agrees with the preceding adjunction. To prove that ε_X is a W-equivalence from the hypothesis $f \in W$, one must know that this particular change of base preserves W. This is the role of L6. The fact that a product with a fixed category preserves W is insufficient: $X \to S$ need not be a product projection.

The unit has a different presentation because an arbitrary $X' \to S'$ need not remain a good representative after composition with f. Put $P = C_S(X')$. The structural map $P \to S$ is perfect, and the natural map $j : X' \to P$ is a total W-equivalence. The map

$$a : X' \longrightarrow P \times_S S', \qquad \mathrm{pr}_1\, a = j,$$

is the unit on the chosen representative. If $f \in W$, L6 gives $\mathrm{pr}_1 \in W$, and two-out-of-three gives $a \in W$. Thus both the unit and the counit are inverted. The triangle identities then make $f^0_!$ and f^*_0 mutually quasi-inverse equivalences. The label $\beta_{0,X'}$ in the edition is a slip: this second comparison is $\alpha_{0,X'}$. The same pages twice place $\mathrm{hot}^{\mathrm{lc}}$ in an ambient category without the superscript lc; the locally constant category is intended.

The footnote about necessity also has a precise reading. Suppose that the adjunction on locally constant objects is an equivalence for every $f \in W$. Its counit then shows that $X \times_S S' \to X$ is inverted by the relevant localization for every perfect $X \to S$. Applying the total-space functor shows that it is inverted in Hot_W. If W is strongly saturated, it belongs to W. Consequently the asserted invariance forces the perfect-pullback stability used in the proof. Without strong saturation the same argument gives membership in the strong saturation of W, which explains why the manuscript cautiously writes "± nécessaire".

This argument will remain useful after the axioms are reorganized on manuscript p. 171. It identifies exactly the property needed at this point, without treating an earlier choice of notation for that property as permanent. It also distinguishes two operations which the succeeding pages repeatedly separate: replacing the total category by a better object over S, and testing whether that replacement is still an equivalence on each fibre.

Théorème 4. *Soit*

$$\begin{array}{ccc} X & \xleftarrow{\ q\ } & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow{\ p\ } & S' \end{array}$$

un diagramme cartésien dans Cat*, considérons la flèche de changement de base (dans* $\underline{\mathrm{Hom}}(\mathrm{HOT}_W(X), \mathrm{HOT}_W(S'))$*) :*

$$p^* f_! \longleftarrow f'_! q^*.$$

C'est un isomorphisme dans chacun des deux cas suivants.

a) f est lisse.

b) p est propre.

Démonstration. *Cas a).* On teste avec ξ dans $\mathrm{HOT}_W(X)$, on peut supposer ξ de la forme

$$\xi = \mathrm{hot}_{X,W}(Z) \qquad \text{avec } Z \in \mathrm{Ob}\,\underline{\mathrm{Liss}}\, X.$$

Notons que Z est alors aussi lisse sur S, puisque f est lisse.

$$f_!(\xi) = \mathrm{hot}_{S,W}(Z), \qquad p^* f_!(\xi) = \mathrm{hot}_{S',W}(\underbrace{Z \times_S S'}_{Z',\ \text{cf. diagramme}})$$

$$q^*(\xi) = \mathrm{hot}_{X',W}(Z'), \qquad f'_! q^*(\xi) = \mathrm{hot}_{S',W}(Z'),$$

OK!

$$\begin{array}{ccc} Z & \longleftarrow & Z' \\ \downarrow & & \downarrow \\ X & \xleftarrow[q]{} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow[p]{} & S' \end{array}$$

Cas b). Il faut admettre que le foncteur changement de base par p : [page 163]

$$Z \longmapsto Z \times_S S' : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S'$$

est compatible avec les localiseurs W_S^{d}, $W_{S'}^{\mathrm{d}}$ (cf. plus bas) - c'est ça, formellemet, la propriété pertinente pour p ([79]). Il en résultera que

$$p^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S')$$

se calcule, pour un élément dans $\mathrm{HOT}_W(S)$ donné par un Z *quelconque* dans Cat/S (pas nécessairement lisse sur S), par

$$p^*(\mathrm{hot}_{S,W}(Z)) = \mathrm{hot}_{S',W}(Z \times_S S').$$

Partons alors, comme dans a), d'un élément ξ de $\mathrm{HOT}_W(X)$ donné par un Z de Cat/X (inutile cette fois de supposer Z lisse), le calcul immédiat précédent établit encore la formule de commutation.

Mais il ne semble pas que la propriété de compatibilité de $X \longmapsto X \times_S S'$, avec l'équivalence colocale sur S et sur S', résulte de façon ± évidente de la condition que $p : S' \longrightarrow S$ soit propre ([80]). J'ai envie de le déduire de fourbis généraux sur le formalisme des dérivateurs, à savoir du théorème de changement de base des $f_!^{\mathbf{D}}$ pour un morphisme $\mathbf{D}$-propre.

Sous forme duale d'un théorème de changement de base pour $f_*^{\mathbf{D}}$, par changement de [page 164] base $\mathbf{D}$-lisse, c'est fait dans I, p. 56 à 58, et on doit pouvoir l'appliquer ici. Notons que dans la démonstration du théorème loc. cit., on n'utilise que L4 [plutôt Der 4], i.e. l'existence des $f_*^{\mathbf{D}}$, à l'exclusion des $f_!^{\mathbf{D}}$ (L4′ [plutôt Der 4′]), plus L5 [plutôt Der 5] bien sûr, donc la forme duale ne fait appel à l'existence des $f_*^{\mathbf{D}}$, seulement des $f_!^{\mathbf{D}}$. On a donc une bonne chance de pouvoir l'appliquer à HOT_W (où je n'ai pas encore établi l'existence des f_*^{HOT}).

Commentary · Exposition [ms. 163]

The canonical map in the base-change theorem

The purpose of Theorem 4 is to turn the concrete model for $f_!$ into a calculational rule. A pullback square of categories gives two ways of transporting a coefficient from X to S'. An isomorphism between their values would not by itself suffice: one needs the particular comparison determined by the adjunction, since subsequent compositions of squares use its compatibility with pasting.

For the square in the text, the comparison is the composite

$$f'_! q^* \xrightarrow{f'_! q^* \eta_f} f'_! q^* f^* f_! \cong f'_! f'^* p^* f_! \xrightarrow{\varepsilon_{f'} p^* f_!} p^* f_!.$$

Here $q^* f^* \cong f'^* p^*$ is induced by the equality $fq = pf'$. This formula fixes the orientation. In the smooth case choose $Z \to X$ smooth. Then $Z \to S$ is smooth, and all inverse images in this expression can be computed literally. The unit introduces the relevant pullback and the counit projects from it; their composite is the canonical identification between the two copies of $Z \times_S S'$. Thus the calculation on p. 162 proves that the canonical map is invertible, and not merely that its source and target happen to be isomorphic.

79. Ça doit être *équivalent* à p propre. Comparer avec le corollaire 1, page 166.

80. Mais si, cf. démonstration page 168. Les développements des quatre pages qui suivent sont inutiles par cette démonstration.

The proper case uses a different good feature. If literal pullback along p carries W^{d}_S into $W^{\mathrm{d}}_{S'}$, then for every $Z \to S$ the comparison

$$Z \times_S S' \longrightarrow \Phi_S(Z) \times_S S'$$

is right-fine. Hence literal pullback computes p^* even for a representative which is not smooth over S. To finish, one may still choose $Z \to X$ smooth in order to compute q^*; this costs nothing, because every coefficient has such a representative. Both sides of base change are again represented by $Z \times_S S'$, and the displayed mate gives its identity after the canonical comparisons. The direct argument on pp. 168–169 proves precisely the preservation statement needed here.

A small example shows why smoothness concerns transport rather than constancy. Let $S = (0 \to 1)$ and take the presheaf of sets F with

$$F(0) = \{a, b\}, \qquad F(1) = \{c\}, \qquad c \longmapsto a.$$

Its category of elements X has the arrow $a \to c$ and the isolated object b, with the evident map $f : X \to S$. This is a discrete Grothendieck fibration, hence smooth. For the terminal coefficient on X, the object $f_!1_X$ is represented by $X \to S$. Pullback to 0 is the two-point category, whereas pullback to 1 is the one-point category. Both values agree with base change along the corresponding point inclusion. The transition between the fibres is not a weak equivalence, and no local constancy has been used.

The terminology is inherited from the base-change theorems of algebraic geometry, but the hypotheses here are conditions on categories of lifts. The precise categorical characterization is recorded by Maltsiniotis (2005, Theorem 1.2); its proper version follows by opposites. In the modern derivator formalism, Groth (2013, Propositions 1.24 and 1.26) treats the corresponding exact squares for Grothendieck fibrations, opfibrations and comma categories. These references clarify the later language without supplying the missing Der 2 argument in the manuscript's first attempted proof.

Notons d'abord p. 101

Proposition 5. *Soit $f : S' \longrightarrow S$ une flèche dans* Cat. *Alors f est une* HOT_W*-équivalence* si et seulement si $\mathrm{hot}_W(f)$ *est* `[un]` *isomorphisme. Si W est fortement saturé, cela signifie donc que $f \in W$ (et en tous cas $f \in W \Longrightarrow f$* `[est]` *une* HOT_W*-équivalence)* ([81]).

C'est contenu dans la démonstration de Der 3b tantôt. Je rappelle que f est une HOT-équivalence, par définition, si et seulement si pour $a, b \in \mathrm{Hot}_W (= \mathrm{HOT}_W(e))$,

$$(*) \qquad \mathrm{Hom}_{\mathrm{HOT}_W(S)}(a_S, b_S) \longrightarrow \mathrm{Hom}_{\mathrm{HOT}_W(S')}(a_{S'}, b_{S'})$$

est `[un]` isomorphisme, où a_S etc. désigne $p_S^*(a)$ etc. ($p_S : S \longrightarrow e$). Les formules d'adjonction de $p_{S!}$, p_S^* et de $p_{S'!}$, $p_{S'}^*$ permettent d'interpréter la flèche $(*)$ comme

$$\mathrm{Hom}_{\mathrm{HOT}_W(S)}(p_{S!}(a_S), b) \longrightarrow \mathrm{Hom}_{\mathrm{HOT}_W(S')}(p_{S'!}(a_{S'}), b),$$

déduit par 'transposition' $\mathrm{Hom}(-, b)$ de la flèche

[page 165]

$$p_{S'!}(a_{S'}) \longrightarrow p_{S!}(a_S)$$

induite par f - donc il faut prouver que celle-ci est un isomorphisme (c'est la forme que nous avions utilisé tantôt). Or cette flèche s'identifie à

$$\eta' \times a \longrightarrow \eta \times a$$

induite par

$$\mathrm{hot}_W(f) : \underbrace{\eta'}_{=\mathrm{hot}_W(S')} \longrightarrow \underbrace{\eta}_{=\mathrm{hot}_W(S)},$$

et dire que c'est `[un]` isomorphisme quel que soit a dans Hot_W revient à dire que $\eta' \longrightarrow \eta$ l'est (puisque la multiplication dans Hot_W a une élément unité …).

81. devrait remonter vers le théorème 3, p. 159.

Maintenant je me rappelle que pour avoir l'axiome Der 2 des dérivateurs, je devrais également supposer W *fortement* saturé (i.e. égal au localiseur défini par le foncteur canonique $\mathrm{Cat} \longrightarrow (\mathrm{Cat})W^{-1} \overset{\text{déf}}{=} \mathrm{Hot}_W$). (C'est ce que je supposais d'emblée, en partant d'un $(\mathcal{M}, W)$ général pour définir un prédérivateur, pour avoir l'axiome Der 2.)

En appliquant le dual du théorème de I, p. 56, on trouve donc le théorème de changement de base pour $f_!$, pour changement de base $f : S' \longrightarrow S$ *W-propre.*

Mais la démonstration utilise sûrement Der 2 (critère d'isomorphisme par fibres, dans $\mathrm{HOT}_W(S)$), que je n'ai pas prouvé encore. Elle est incomplète pour le moment. Mais je peux noter dès maintenant le [page 166] ‖

Commentary · Exposition [ms. 165]

What constant coefficients detect

Grothendieck interrupts the base-change argument to identify the absolute equivalences detected by HOT_W. This is a useful move: it prevents the phrase "HOT_W-equivalence" from concealing a new, unexplained class of maps. The proof uses the adjunction just established and the already available product formula for a constant coefficient.

Let $p_S : S \to e$ and put $\eta = \mathrm{hot}_W(S)$. For $a \in \mathrm{Hot}_W$, write $a_S = p_S^* a$. The representing-category description gives a natural isomorphism

$$p_{S!}(a_S) \cong \eta \times a.$$

Indeed, if $a = \mathrm{hot}_W(T)$, then a_S is represented by $S \times T \to S$ and its left direct image is represented by $S \times T$. This also identifies the morphism induced by $f : S' \to S$: it is $\mathrm{hot}_W(f) \times \mathrm{id}_a$.

Adjunction therefore turns the defining map for a HOT_W-equivalence into

$$\mathrm{Hom}_{\mathrm{Hot}_W}(\eta \times a, b) \longrightarrow \mathrm{Hom}_{\mathrm{Hot}_W}(\eta' \times a, b), \qquad \eta' = \mathrm{hot}_W(S').$$

The base-dependent subscripts in the edition's displayed Hom formula are slips; both Hom sets here are in Hot_W. If $\mathrm{hot}_W(f)$ is an isomorphism, every displayed map is a bijection. Conversely, assume these maps are bijections for all a, b, and take a to be the terminal object 1. The product identifications $\eta \times 1 \cong \eta$ and $\eta' \times 1 \cong \eta'$ reduce the assertion to bijectivity of

$$\mathrm{Hom}_{\mathrm{Hot}_W}(\eta, b) \longrightarrow \mathrm{Hom}_{\mathrm{Hot}_W}(\eta', b) \quad \text{for every } b.$$

Yoneda gives invertibility of $\mathrm{hot}_W(f)$. More explicitly, taking $b = \eta'$ supplies a left inverse of $\mathrm{hot}_W(f)$, and injectivity for $b = \eta$ forces it to be a right inverse. This proves Proposition 5.

Strong saturation enters only when the result is translated back from the localized category to the original class W. The proposition without saturation says that the detected maps form $\overline{W}$, the class inverted by $\mathrm{Cat} \to \mathrm{Hot}_W$. If $W = \overline{W}$, this is exactly W. The proof does not require the detection of all isomorphisms in $\mathrm{HOT}_W(S)$ by point evaluations. In particular, it must not be counted as a proof of Der 2. That latter statement concerns arbitrary arrows of a localized category, including zigzags, whereas Proposition 5 identifies the image of a given functor of indexing categories.

The source itself recognizes the distinction on p. 166. The intended appeal to the abstract proper-base-change theorem still needs Der 2, so the proof by that route is incomplete. Nothing is wrong with Proposition 5, and nothing forces Theorem 4 to wait for a global repair of the derivator axioms: the direct proof on pp. 168–169 works before that repair. Keeping this order of dependence is the reason to retain both the interrupted argument and the author's later replacement of it.

Corollaire 1 (du théorème 4, p. 162). *Si la flèche $S' \xrightarrow{p} S$ dans* Cat *donne lieu (pour tout $f : X \longrightarrow S$ dans* Cat/S*) à la formule de changement de base pour* p. 102

$$f_! : \mathrm{HOT}_W(X) \longrightarrow \mathrm{HOT}_W(S),$$

alors le foncteur $p^* : X \longmapsto X \times_S S'$ de Cat/S *dans* Cat/S' *est compatible avec les localiseurs W_S^{d}, $W_{S'}^{\mathrm{d}}$.* (L'implication inverse a été vue déjà, cf. pages 161-163.)

Cela résultera du

Lemme. *Soit $u : X' \longrightarrow X$ une flèche dans* Cat/S*. Pour que $u \in W_S^{\mathrm{d}}$, il faut et il suffit (si W* `[est]` *fortement saturé) que pour tout $\xi \in \mathrm{Hot}_W$, la flèche correspondante*

$$u_* : p'_!(\xi_{X'}) \longrightarrow p_!(\xi_X)$$

soit `[un]` *isomorphisme dans* $\mathrm{HOT}_W(S)$*.*

C'est suffisant, sous réserve de saturation forte de W, car si u_* est `[un]` isomorphisme, passant aux fibres, on trouve par Der $5'$

$$H_\bullet^{\mathrm{HOT}_W}(s\backslash X', \xi) \longrightarrow H_\bullet^{\mathrm{HOT}_W}(s\backslash X, \xi),$$

si c'est `[un]` isomorphisme, alors $s\backslash X' \longrightarrow s\backslash X$ est par définition une HOT-équivalence, ce qui implique que c'est dans W (proposition 5).

C'est nécessaire, car si $\xi = \mathrm{hot}_W(T)$, donc $\xi_S = \mathrm{hot}_{S,W}(T_S)$ (où $T_S = T \times S/S$), et on a donc [page 167]

$$p'_!(\xi_{X'}) = \mathrm{hot}_{S,W}(X' \times T), \qquad p_!(\xi_X) = \mathrm{hot}_{S,W}(X \times T),$$

et il faut prouver que si $u : X' \longrightarrow X$ est dans W_S^{d}, alors $\underbrace{X' \times T}_{X' \times_S T_S} \longrightarrow \underbrace{X \times T}_{X \times_S T_S}$ aussi, ce qui signifie simplement que

$$(*) \qquad s\backslash(X' \times T) \longrightarrow s\backslash(X \times T)$$

est dans W pour tout $s \in S$. Mais le changement de base $s\backslash S \longrightarrow S$ commute aux produits fibrés, donc transforme $X \times T = X \times_S T_S$ en $(s\backslash X) \times_{s\backslash S} T_{(s\backslash S)} = s\backslash X \times T$, et de même pour X'. Donc la flèche s'identifie à

$$(s\backslash X') \times T \longrightarrow (s\backslash X) \times T,$$

déduite de

$$s\backslash X' \longrightarrow s\backslash X$$

par le foncteur $? \times T$. Comme ce foncteur transforme W en W, on gagne.

Commentary · Exposition [ms. 167]

A single coefficient already tests right-fine maps

The lemma on pp. 166–167 is meant to extract a statement about actual functors from a base-change isomorphism. Its family of constant coefficients is natural from the cohomological viewpoint. Once the pointwise formula for $f_!$ is known, however, the terminal coefficient already detects the maps under consideration. This observation shortens the proof and makes its independence from Der 2 explicit.

Assume W is strongly saturated, and let $u : X' \to X$ be a morphism over S. Then

$$u \in W_S^{\mathrm{d}} \quad \Longleftrightarrow \quad \mathrm{hot}_{S,W}(u) \text{ is an isomorphism.}$$

The forward implication is the definition of the localization. For the converse, apply the evaluation functor s^* to the asserted isomorphism. The pointwise formula identifies its value with

$$\mathrm{hot}_W(s\backslash X') \longrightarrow \mathrm{hot}_W(s\backslash X).$$

Strong saturation makes $s\backslash u$ a member of W for every s, which is exactly the definition of W_S^{d}. This argument applies evaluation to an isomorphism already known to exist; it does not infer a global isomorphism from a family of pointwise isomorphisms. Consequently it uses no unproved conservativity axiom.

Now let $p : X \to S$ and $p' : X' \to S$. The image of the terminal coefficient under left direct image is $p_! 1_X = \mathrm{hot}_{S,W}(X)$, and the map induced by u is $\mathrm{hot}_{S,W}(u)$. Thus the preceding equivalence is

precisely the manuscript's test with $\xi = 1$. For a general constant coefficient represented by T, the induced map is represented by $u \times \mathrm{id}_T$. Since

$$s\backslash(X \times T) \cong (s\backslash X) \times T,$$

product stability of W proves the implication from $u \in W_S^{\mathrm{d}}$ to the test for every ξ. The larger family of tests is therefore equivalent to the single one, rather than an additional hypothesis.

This gives Corollary 1 with its quantifiers visible. Suppose that base change along $p : S' \to S$ is valid for left direct image along every $X \to S$. If $u : X_1 \to X_2$ belongs to W_S^{d}, its map of pushed-forward terminal coefficients is invertible. Pulling that map back along p preserves invertibility. Naturality of base change identifies the resulting map with the left direct image of the terminal-coefficient map induced by

$$u' : X_1 \times_S S' \longrightarrow X_2 \times_S S'.$$

The single-coefficient test over S' implies $u' \in W_{S'}^{\mathrm{d}}$. Strong saturation is used at this last conversion to membership in W; without it the argument establishes the corresponding statement for the class detected in the localization.

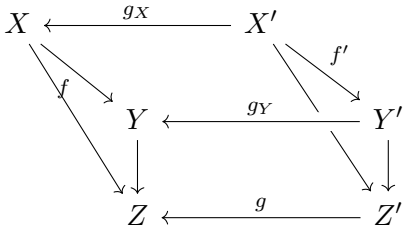
This is a useful instance of the distinction between a criterion for a representative and a criterion for an arbitrary localized morphism. The former is enough for the present base-change theorem. The latter is the broader problem of Der 2, which remains separate.

Finalement, je m'aperçois que j'ai eu un blocage stupide, pour la question que le changement de base propre soit compatible à la W-équivalence colocale. Soit p. 103 [page 168]

$$\begin{array}{ccccc} X & \xrightarrow{\ f\ } & Y & & \\ & \searrow & \swarrow & & \\ & & S & \xleftarrow{\ g\ } & S', \end{array}$$

avec $f \in W_S^{\mathrm{d}}$ et g propre, il faut voir que $f' : X' \longrightarrow Y'$ déduit de f par changement de base $S' \longrightarrow S$ est encore dans $W_{S'}^{\mathrm{d}}$. Cela signifie que tout changement de base de la forme $s'\backslash S' \longrightarrow S'$ le transforme en $\in W$. Mais soit $s = g(s')$, on a le carré commutatif

$$\begin{array}{ccc} S & \longleftarrow & S' \\ \uparrow & & \uparrow \\ \underbrace{s\backslash S}_{=Z} & \longleftarrow & \underbrace{s'\backslash S'}_{=Z'}, \end{array}$$



et il suffit de voir que pour toute flèche $\varphi : \mathcal{X} \longrightarrow \mathcal{Y}$ dans Cat/Z qui est dans W, son image inverse par changement de base $Z' \longrightarrow Z$ est itou. (En appliquant ceci au cas $\mathcal{X} = X \times_S (s\backslash S)$, $\mathcal{Y} = Y \times_S (s\backslash S)$, $\varphi = s\backslash f$.) Or ceci résulte du fait que, par hypothèse de propreté, $Z' \longrightarrow Z$ est propre et à fibres Hot-asphériques, donc c'est une Hot-équivalence universelle. Il suffirait même que g soit W-propre, pour impliquer que $Z' \longrightarrow Z$ est une W-équivalence universelle, i.e. qui reste telle après tout changement de base. Or on a le [page 169]

Lemme. Si $g : Z' \longrightarrow Z$ est une W-équivalence universelle, alors le foncteur

$$g^* : X \longmapsto X \times_Z Z' : \mathrm{Cat}/Z \longrightarrow \mathrm{Cat}/Z'$$

est compatible avec les localiseurs W_Z, $W_{Z'}$, i.e. si $f : X \longrightarrow Y$ dans Cat/Z est dans W, de

même $f' : X' \longrightarrow Y'$ dans Cat/Z'.

Cela est évident sur le carré supérieur du diagramme ci-dessus, où g_X, g_Y sont dans W par l'hypthèse sur g, donc f est dans W si et seulement si f' l'est, cqfd.

Commentary · Exposition [ms. 169]

Proper base change without a pointwise conservativity axiom

The short proof on pp. 168–169 succeeds because it turns a relative question into an absolute one over a suitable comma category. Properness supplies a comparison of bases which remains a W-equivalence after every pullback. Two-out-of-three can then transport the desired equivalence across that comparison.

We first isolate the elementary part. Let $v : T' \to T$ be a universal W-equivalence, meaning that for every $A \to T$ the projection $A \times_T T' \to A$ belongs to W. If $h : A \to B$ is a map over T, the commutative square

$$\begin{array}{ccc} A \times_T T' & \xrightarrow{h'} & B \times_T T' \\ {\scriptstyle v_A}\downarrow & & \downarrow{\scriptstyle v_B} \\ A & \xrightarrow[h]{} & B \end{array}$$

has both vertical arrows in W. If $h \in W$, then $hv_A \in W$ and $v_B h' = hv_A$ forces $h' \in W$. The reverse implication is the same calculation in the other direction. Literal pullback along a universal equivalence therefore preserves and reflects W. No localization, no adjunction and no pointwise detection is involved in this lemma.

Take now $g : S' \to S$ proper, or more generally W-proper, and fix $s' \in S'$ with $s = g(s')$. Properness gives a universal W-equivalence

$$v : s'\backslash S' \longrightarrow s\backslash S.$$

Its fibre over an arrow $s \to t$ is the category of its lifts starting at s'. The defining asphericity conditions for properness, together with their stability after base change, give the stated universality. This is the geometric content of the proof; it is not a consequence of the existence of initial objects in the two comma categories alone. Two contractible categories can be connected by a functor which fails to be a universal equivalence.

For $u : X \to Y$ over S, form $u_s : s\backslash X \to s\backslash Y$, a map over $s\backslash S$. If $u \in W_S^{\mathrm{d}}$, then $u_s \in W$. Pullback along v identifies u_s with

$$s'\backslash(X \times_S S') \longrightarrow s'\backslash(Y \times_S S').$$

The elementary lemma makes this map a member of W. Since s' was arbitrary, literal pullback along g preserves right-fine equivalences. This completes the proper case of Theorem 4 by the model calculation explained above.

For a discrete opfibration, the role of the lift categories is especially transparent. An arrow $g(s') \to t$ has a unique lift with prescribed source s'. Hence the induced functor on undercategories is an isomorphism; the preceding comparison needs no homotopy argument at all. For an ordinary Grothendieck opfibration, a chosen cocartesian lift is initial in the corresponding category of lifts, so its nerve is contractible. The general proper case replaces this initial object by the weaker asphericity condition required by W.

The manuscript calls the earlier obstruction a "blocage". Mathematically, the change is a change of test objects: the universal comparison over $s\backslash S$ carries exactly the information needed for right-fine equivalence. The abandoned four-page route is not a counterexample to proper base change, nor does it expose a defect in the construction of $f_!$.

Nouvelle version de la théorie de HOT_W.

Je me suis aperçu que l'hypothèse $W \supseteq W_\infty$ (L3 quater, p. 1), que j'avais fini par mettre sur W, est artificielle, et que l'hypothèse L5 (p. 43), voire L6, L6 bis (p. 43-44), est inutile pour une grande partie de la théorie de HOT_W. J'ai été ainsi amené à revoir la théorie (i.e. ce que j'en ai fait jusqu'à présent) sous les hypothèses suivantes sur W (cf. XII) :

W(1) (*Saturation* de W) : comme avant (L1 page 1)

W(2) (localisation) : c'est l'ancien L4 bis ([82]).

W(3) (objet final) : Si X a un objet final, X est W-asphérique (ancien L3).

Ces trois axiomes sont suffisants pout tout ce que j'avais fait dans Pursuing Stacks, et dans une grande partie de ce qui a été fait ici sur HOT. Parfois cependant il faut l'ancien L 5, que je réénonce ici (comparer XII, théorème `[numéro du théorème manque]`) :

Commentary · Exposition [ms. 171]

Axioms for the localization and axioms for its fibres

Grothendieck's new beginning separates the construction of a homotopy theory from the stronger rules which make its total spaces determine its fibres. Much of the preceding work survives under three localizer axioms. The extra fibration axiom enters at identifiable comparison maps, and the next ten pages are an effort to locate those maps rather than to replace the entire construction.

The localization axiom W(2) is a relative Theorem A statement. For a triangle $X \to Y \to S$, it says that membership of $X/s \to Y/s$ in W for every s implies membership of $X \to Y$ in W. Together with the terminal-object axiom and the saturation rules, it gives the familiar local-to-global mechanism. The weakened W(2 bis) keeps only the case in which all the relevant comma categories are W-aspherical. The distinction matters when the minimum class W_ω is introduced: it is defined using this weaker axiom, not by simply repeating the complete list W(1,2,3).

There is a second distinction in the word "fibration". The ordinary category $\underline{\mathrm{Fib}}S$ consists of Grothendieck fibrations over S. The category $\underline{\mathrm{Fib}}_W S$ in the revised diagram consists of weak W-fibrations and is defined by a homotopical condition. One equivalent test is this: for every categorically contractible $T \to S$ and every $t \in T$, the inclusion

$$X_t \longrightarrow X \times_S T$$

belongs to W. This is the formulation of Chapter XII, Theorem 3, manuscript pp. 51–52, to which Grothendieck refers here (Grothendieck, 1990–1991f). The word "contractible" in this test cannot be replaced silently by "W-aspherical". Doing that asks for a stronger condition, whose relation to the weak condition is precisely part of the fibration-axiom problem.

For an ordinary Grothendieck fibration, the weak condition has a concrete interpretation: each transport functor $u^* : X_{s'} \to X_s$ must belong to W. Thus an ordinary fibration can be smooth without being weakly W-fibred, as in the two-fibre example above. Conversely, a weak W-fibration need not possess chosen cartesian lifts. The comma replacement Φ is what supplies an ordinary split fibration representing its homotopical data.

W(4b) compares two tests for a morphism between such weakly fibred objects. The global test asks whether $X \to Y$ lies in W as a functor of total categories. The fibre test asks whether each $X_s \to Y_s$ lies in W. The implication from the fibre test to the global test already follows from W(2), after comparing fibres with comma fibres. W(4b) asserts the converse. It is therefore a cancellation rule for total spaces over a fixed base, not merely a restatement of two-out-of-three.

The first version of W(4b′) restricts that rule to W_ω-perfect objects. This does prove equality of the two tests inside that smaller category. It does not yet compare an arbitrary weakly fibred X with its perfect replacement $C(X)$, because X need not belong to the smaller category. The footnote retracting the claimed sufficiency points to exactly this missing scope in the available argument. The retraction does not establish that the implication is false. With the later minimality and filtered-colimit results explained below, the alternating replacement on pp. 192–195 supplies the missing fine unit; the original restricted condition does then imply W(4b). The commentary at p. 195 gives the transfer argument. Later a different condition receives the same label W(4b′); the two formulations must be kept separate throughout the audit.

82. i.e. le L5 de la page 2. L'axiome est repris (sous une forme voisine et équivalente) au bas de la page 43.

W(4b) Soient X, Y W-fibrés sur S, $f : X \longrightarrow Y$ un S-morphisme. Si $f \in W$, alors $\forall s \in \mathrm{Ob}\, S$, $f_s : X_s \longrightarrow Y_s$ est dans W.

Pour la notion de W-fibré (*faible*), j'ai été long à trouver enfin *la* bonne notion, bonne pour un W ne satisfaisant que W(1, 2, 3) (et même seulement W(1, 2 bis, 3), où W(2 bis) est l'ancien L4). Je renvoie pour cela à (XII, théorème 3, p. 51), où la notion est bien cernée à coups de conditions équivalentes. En fait, pour les applications principales à HOT_W, vues jusqu'à présent, il suffit ([83]) d'une variante affaiblie de W(4b) :

W(4b′) Comme W(4b), mais en exigeant de plus que X, Y soient dans $\underline{\mathrm{Parf}}_\omega\, S$.

Pour la notion de morphismes W-propres, W-lisses, W-parfaits dans Cat, je renvoie à XII, partie III (p. 22-52), et les notations $\underline{\mathrm{Liss}}_W S$, $\underline{\mathrm{Prop}}_W S$, $\underline{\mathrm{Parf}}_W S$ (sous-catégories de Cat/S), et $\mathrm{Parf}_W \subseteq \mathrm{Fl(Cat)}$. Dans l'énoncé de W(4b′) on a posé [page 172]

$$\underline{\mathrm{Parf}}_\omega S = \underline{\mathrm{Parf}}_{W_\omega} S, \qquad \text{où } W_\omega \subseteq \mathrm{Fl(Cat)} \text{ est la plus petite partie de Fl(Cat) satisfaisant W}(1, 2\text{bis}, 3).$$

Je note de même

$$W'_\omega \subseteq \mathrm{Fl(Cat)}, \qquad \text{plus petite partie de Fl(Cat) satifaisant W}(1, 2, 3, 4\text{b}).$$

L'hypothèse $W \supseteq W_\infty$ que nous avions fini par imposer sur W, et qui est apparu artificielle au cours de la réflexion du XII, a avantage à être remplacée par p. 105

$$W \supseteq W'_\omega \qquad (\text{ou par } W \supseteq \overline{W'_\omega},\ \text{où } \overline{W'_\omega} \text{ est le saturé fort de } W'_\omega)$$

([84]). Mais nous ne l'imposons pas comme condition impérative, au même titre que W(1, 2, 3), pas plus que W(4b). Le rôle que j'ai fait jouer à W_∞ dans les semaines passées, semble revenir plus naturellement à W'_ω ou $\overline{W'_\omega}$. Il en est ainsi notamment aussi, il me semble, dans l'énoncé des conditions du type Der 3 sur un dérivateur (I, p. 111-112), qu'il faudrait revoir dans cette lumière. Mais tout dépend, si (comme j'en ai l'impression) on peut faire vraiment de l'algèbre homotopique substantielle, avec notamment les suites exactes longues de fibration et de suspension, pour HOT_W, avec des W qui sont *strictement* contenus dans W_∞. Avant de même être assuré, il est trop tôt encore pour me prononcer sur la 'bonne' formulation de Der 3,

Commentary · Later developments [ms. 172]

The proposed theory below ordinary weak equivalence

Grothendieck is trying to remove an externally imposed reference to classical homotopy. His question about a localizer strictly smaller than W_∞ concerns the strength of the axioms themselves: perhaps their formal consequences already contain more classical homotopy theory than he has yet extracted.

For the modern basic-localizer axioms, this question is settled. Cisinski (2004, Definition 1.1.3 and Theorem 2.2.11) proves that every basic localizer contains the nerve weak equivalences W_∞. Thus no strictly smaller basic localizer satisfies that complete package. The weaker list defining W_ω requires a further theorem. Cisinski (2009, Theorem 1.10 and Remark 1.11) proves the corresponding minimality among weak basic localizers, using the absolute Theorem A condition. It follows that $W_\omega = W_\infty$ as well. To check the saturation hypothesis, if $ri = \mathrm{id}$ and $ir \in W$, the manuscript's condition on the two composites ri, ir gives $i, r \in W$; this is the retract clause in the weak-basic-localizer formulation. W(2 bis) and W(3) supply its other two clauses. The two axiom lists remain different even though their minimum classes now have the same description.

83. C'est finalement une erreur, semble-t-il à présent. Je crois que l'axiome W(4b′) ne sert finalement à strictement rien (si ce n'est en fait à entretenir des idées fausses.)

84. $\overline{W'_\omega}$ est le plus petit sous-ensemble *fortement saturé* de Fl(Cat), satisfaisant W(4b), et il satisfait même la condition W′(4a), variante la plus forte des axiomes du type W(4).

This result changes the status of the proposed example, but it leaves the reason for the revision intact. Removing an explicit hypothesis $W_\infty \subseteq W$ can still clarify which finite arguments use only the localizer axioms and which use a separate fibre-detection condition. Indeed, a class larger than W_∞ can satisfy the basic axioms while failing W(4b). The connected-components localizer used below gives an elementary instance. The ordinary theory is minimal in the order of classes of equivalences; further localization is entirely possible, and it can forget information that a fibrewise test retains.

The same minimum is obtained after adjoining W(4b): $W'_\omega = W_\infty$. Indeed, Quillen's Theorem B identifies the fibres of a weak W_∞-fibration with its homotopy fibres (Cisinski, 2004, Theorem 2.3.2). A total weak equivalence over a fixed base therefore induces weak equivalences on the fibres. Thus W_∞ satisfies W(4b) and is an admissible candidate for W'_ω; basic minimality gives the reverse inclusion. Its strong saturation is the same class. The homotopy-pullback description also supplies the strongest base-change property intended in footnote 84.

This identifies the minimum within the standing W(1,2,3) framework. The inclusion $W'_\omega \subseteq W$ does not, by itself, imply that W inherits every closure property appearing in the defining list: the notion of weak W-fibration changes when W changes. The fibre-cancellation axiom is not simply an upward-closed property of subsets of Fl(Cat). This explains why Grothendieck treats the suggested containment and the assertion W(4b) as different conditions in the paragraph itself.

By Cisinski (2006a, Corollary 4.2.22), W(6 bis) is automatic for basic localizers; the theorem assumes relative W(2).

[page 173]

qui est l'axiome mettant en relation le dérivateur **D** avec W_∞, ou avec quelque autre localiseur fondamental.

Je vais faire à présent un résumé de la théorie de HOT_W, revue dans l'optique que je viens de dire : on suppose pour W *les conditions* $\mathrm{W}(1,2,3)$ *sans plus,* sauf mention explicite.

① **Localiseurs principaux** sur Cat/S et sur les principales catégories de S-catégories (cf. diagramme p. 76).

Ils seront tous induits par les trois localiseurs familiers

$$W_S^{\mathrm{d}} \qquad W_S^{\mathrm{g}}$$
$$\searrow \quad \swarrow$$
$$W_S$$

sur Cat/S. Il y a lieu aussi de regarder W_S^{f}, mais jamais sur Cat/S tout entier, mais sur d'autres catégories du diagramme, et toujours dans des cas où W_S^{f} coïncide soit avec W_S^{d}, soit avec W_S^{g}. Mais le point de vue W_S^{f} est souvent plus directement commode, et a l'avantage de plus d'être symétrique.

ⓐ Dans $\underline{\mathrm{Liss}}_W S$, on a

p. 106

$$\begin{array}{l} W_S^{\mathrm{f}} \quad = W_S^{\mathrm{d}} = W_S^{\mathrm{univ}} \\ \Downarrow \\ W_S^{\mathrm{g}} \\ \Downarrow \\ W_S \end{array}$$

Dualement,

ⓑ dans $\underline{\mathrm{Prop}}_W S$, on a

$$\begin{array}{ccc} W_S^{\mathrm{f}} & = W_S^{\mathrm{g}} = W_S^{\mathrm{univ}} & \\ \Downarrow & & \\ W_S^{\mathrm{d}} & & \\ \Downarrow & & \\ W_S, & & \end{array}$$

enfin, [page 174]

ⓒ dans $\underline{\mathrm{Fib}}_W S$, on a

$$\begin{array}{ccccccc} W_S^{\mathrm{f}} & \Longleftrightarrow & W_S^{\mathrm{d}} & \Longleftrightarrow & W_S^{\mathrm{g}} & \Longleftrightarrow & W_S^{\mathrm{univ}} \\ \Downarrow & & & & & & \\ W_S. & & & & & & \end{array}$$

Cette implication $W_S^{\mathrm{f}} \Longrightarrow W_S$ est stricte si on ne fait pas sur W l'axiome W(4b), dont l'utilité ici est exactement d'assurer

> $W_S^{\mathrm{f}} \Longleftrightarrow W_S$ dans $\underline{\mathrm{Fib}}_W S$ *si* W(4b) `[est]` satisfait
>
> et alors les cinq localiseurs envisagés ci-dessus
>
> dans $\underline{\mathrm{Fib}}_W S$ sont tous égaux.

Les relations entre [?] localiseurs dans $\underline{\mathrm{Liss}}_W S$, $\underline{\mathrm{Prop}}_W S$, $\underline{\mathrm{Fib}}_W S$ se transportent automatiquement aux sous-catégories de celles-ci, plus généralement à toutes celles qui s'envoient par un foncteur d'inclusion dans une de celles-ci. Dans le diagramme p. 76, toutes les catégories, à la seule exception de Cat/S tout entier, sont dans ce cas. p. 107

Commentary · Exposition [ms. 174]

Five tests and the role of good objects over the base

The diagram of localizers is the bookkeeping on which the revised theory depends. Grothendieck is distinguishing the information carried by a strict fibre, a comma fibre, and a total category. To read its equalities, every test must refer to the same map $u : X \to Y$ over the same base S.

The five conditions are

$$\begin{aligned} u \in W_S &\iff u \in W \text{ on total categories,} \\ u \in W_S^{\mathrm{f}} &\iff u_s : X_s \to Y_s \in W \quad (s \in S), \\ u \in W_S^{\mathrm{d}} &\iff s\backslash X \to s\backslash Y \in W \quad (s \in S), \\ u \in W_S^{\mathrm{g}} &\iff X/s \to Y/s \in W \quad (s \in S), \\ u \in W_S^{\mathrm{univ}} &\iff X \times_S T \to Y \times_S T \in W \quad (T \to S). \end{aligned}$$

In the last line universality is relative to S. It is not the assertion that $u : X \to Y$ remains a W-equivalence after every map into its total target Y. The difference is already visible when $S = e$.

If X and Y are W-smooth over S, the inclusions of strict fibres into under-comma fibres give a commutative square

$$\begin{array}{ccc} X_s & \xrightarrow{u_s} & Y_s \\ \downarrow & & \downarrow \\ s\backslash X & \xrightarrow[s\backslash u]{} & s\backslash Y \end{array}$$

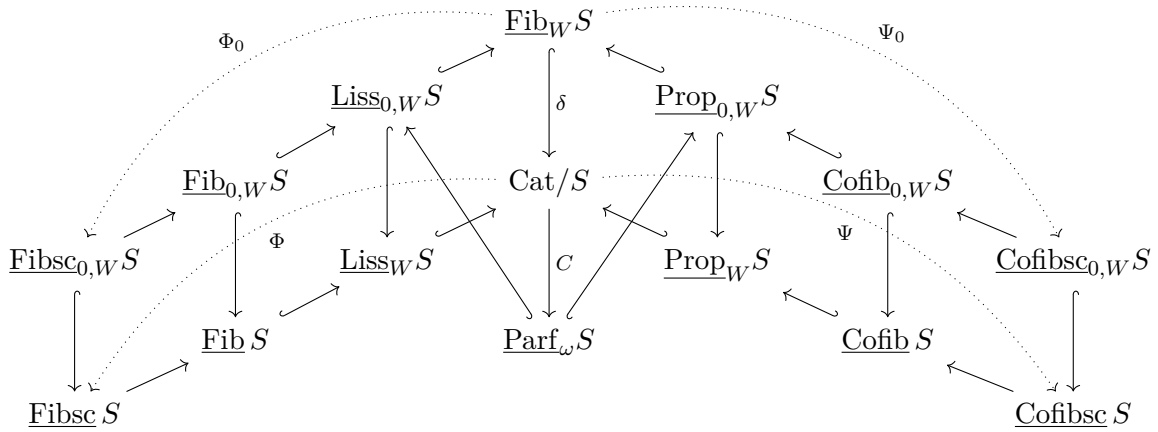
whose vertical arrows lie in W. Two-out-of-three identifies the fibre and right-fine tests. Smoothness survives change of base. Thus the fibre test, applied after every $T \to S$, gives a right-fine map over

T and hence a total W-equivalence by W(2). This proves $W_S^{\mathrm{f}} \subseteq W_S^{\mathrm{univ}}$ on smooth objects. The reverse inclusion follows by taking $T = \{s\}$. Finally, taking $T = S/s$ gives $W_S^{\mathrm{univ}} \subseteq W_S^{\mathrm{g}}$, and the relative localizer axiom gives $W_S^{\mathrm{g}} \subseteq W_S$. These are exactly the first chain of implications in the text. Opposites give the proper chain.

For weak W-fibrations, the defining universal comparisons apply to both the initial and the terminal comma categories. Hence both vertical comparisons, for $s\backslash X$ and for X/s, are in W, and remain so after changing the base. The same proof identifies all four fine or universal tests. W(4b) adds the reverse implication from the total test. Its statement is equivalent to equality of all five classes on $\underline{\mathrm{Fib}}_W S$ for every S.

A two-object example explains the restriction to good objects. Let $S = (0 \to 1)$, let X be the discrete category on $0, 1$ mapped identically on objects to S, and let $Y = S$ with its identity structural map. The functor $u : X \to Y$ is the identity on objects. Every strict fibre map is the identity of a point, so $u \in W_S^{\mathrm{f}}$ for ordinary weak equivalences. But X has two connected components and Y has one, so $u \notin W_S$. At 0, the under-comma category $0\backslash X$ consists of two isolated objects, whereas $0\backslash Y$ is an interval. The right-fine test detects exactly the missing arrow. This is why the text avoids using the strict-fibre localizer on all of Cat/S.

The phrase that the inclusion is strict "si on ne fait pas" W(4b) should be read as a statement about what the basic axioms do not force. For a fixed W and a fixed S, absence of an additional assumption is not a proof that the classes differ. The exact universal assertion is the equivalence with W(4b); the example below supplies a localizer and a base where the difference is real.



Pour les résultats principaux développés jusqu'à présent sur HOT_W, quand l'axiome W(4b) est utilisé, la forme faible W(4b′) suffit. On a

> $W_S^{\mathrm{f}} \Longleftrightarrow W_S$ dans $\underline{\mathrm{Parf}}_\omega S$ *si* W(4b′) `[est]` satisfait
>
> et alors les cinq localiseurs W_S^{f}, W_S^{d}, W_S^{g}, W_S^{univ}, W_S
>
> sont égaux dans $\underline{\mathrm{Parf}}_\omega S$.

② **Principales catégories de catégories sur S.**

Ce sont, à des modifications d'éclairage près, celles du diagramme p. 76. Les catégories $\underline{\mathrm{Fibsc}}\, S$, $\underline{\mathrm{Fib}}\, S$, $\underline{\mathrm{Cofibsc}}\, S$, $\underline{\mathrm{Cofib}}\, S$ et leurs variantes à indice 0, sont inchangées - leur rôle est d'être aussi petites

que possible pour remplir leur fonction (de description de $\mathrm{HOT}_W(S)$, $\mathrm{HOT}^o_W(S)$, $\mathrm{HOT}^{\mathrm{lc}}_W(S)$, ou $\mathrm{HOT}^{\mathrm{lc!}}_W(S)$ ci-dessous). La catégorie $\underline{\mathrm{Parf}}\, S$ du diagramme remplissait une fonction du même type, c'est pourquoi nous la remplaçons à présent (en surenchérissant) par $\underline{\mathrm{Parf}}_\omega S$. Les autres catégories du diagramme sont, en plus de Cat/S, $\underline{\mathrm{Liss}}\, S$ et $\underline{\mathrm{Prop}}\, S$ et leurs variantes à indice 0, ainsi que $\underline{\mathrm{Fibhot}}\, S$. (Toutes ces catégories, ainsi que $\underline{\mathrm{Parf}}\, S$, étaient donc construites par référence à W_∞, non pas à W.) Leur rôle est d'être aussi grandes que possible pour donner lieu à certaines propiétés et relations. Or il se trouve qu'ici la référence à W_∞ était artificielle, et il y a lieu de mettre plutôt les catégories $\underline{\mathrm{Liss}}_W S$, $\underline{\mathrm{Prop}}_W S$, $\underline{\mathrm{Fib}}_W S$, et en plus les variantes $\underline{\mathrm{Liss}}_{0,W} S$, $\underline{\mathrm{Prop}}_{0,W} S$. Ainsi le diagramme devient [page 175]

([85]) (tous les carrés [sont] cartésiens, les foncteurs notés $\hookrightarrow$ sont pleinement fidèles),

où j'ai encore marqué en vert [dans l'original seulement] les cinq *'foncteurs d'inversion'* p. 108 [page 176]

$$\Phi,\ \Psi,\ \Phi_0,\ \Psi_0,\ C,$$

qui fournissent des quasi-inverses des foncteurs sur les catégories localisées déduits par les *foncteurs d'inclusion.*

③ **Les quatre types de catégories** HOT_W**.**

Sur chacune des catégories de l'etage, il y a *deux* localiseurs à regarder,

$$\begin{array}{c} W_S^{\mathrm{f}} \quad = W_S^{\mathrm{g}} = W_S^{\mathrm{d}} = W_S^{\mathrm{univ}} \\ \Big\Downarrow \\ W_S, \end{array}$$

donnant lieu à deux localisés distincts, notés

$$\mathrm{HOT}_W^{\mathrm{lc}}(S) \qquad \text{et} \qquad \mathrm{HOT}_W^{\mathrm{lc!}}(S),$$

il se trouve que (grâce à Φ_0 et Ψ_0) ces localisés 'sont les mêmes' pour les 8 catégories de l'étage, à l'exception de $\underline{\mathrm{Parf}}_\omega S$; plus exactement, les foncteurs d'inclusion (à l'exception peut-être de ceux ayant pour source $\underline{\mathrm{Parf}}_\omega S$) induisent des équivalences sur les deux types de localisés, les équivalences quasi-inverses étant obtenues par Φ_0 (aile gauche) ou Ψ_0 (aile droite). Quand on localise *pour* W_S (à l'exclusion de W_S^{f}), on trouve aussi des quasi-inverses par $C|\underline{\mathrm{Liss}}_{0,W}S$ resp. $C|\underline{\mathrm{Prop}}_{0,W}S$, pour les deux inclusions

$$\underline{\mathrm{Liss}}_{0,W}S \longleftarrow \underline{\mathrm{Parf}}_\omega S \longhookrightarrow \underline{\mathrm{Prop}}_{0,W}S$$

([86]). Par raison de symétrie, le plus joli semble de définir

$$\left\{ \begin{array}{lcl} \mathrm{HOT}_W^{\mathrm{lc}}(S) & = & (\underline{\mathrm{Fib}}_W S)(W_S^{\mathrm{f}})^{-1} \\ \mathrm{HOT}_W^{\mathrm{lc!}}(S) & = & (\underline{\mathrm{Fib}}_W S)(W_S)^{-1}, \end{array} \right.$$

et on a un foncteur de localisation

$$\mathrm{HOT}_W^{\mathrm{lc}}(S) \xrightarrow{\lambda} \mathrm{HOT}_W^{\mathrm{lc!}}(S)$$

induit par l'inclusion

$$W_S^{\mathrm{f}} \subseteq W_S.$$

Commentary · Exposition [ms. 176]

Why four localizations appear

Grothendieck's large diagram organizes choices of representatives. The smaller categories make constructions explicit; the larger ones make stability properties easier to state. The object represented should not depend on a convenient replacement, but that independence must be proved for the particular class of arrows one inverts.

There are two first choices. Localizing all of Cat/S by the under-comma test gives $\mathrm{HOT}_W(S)$; using the over-comma test gives $\mathrm{HOT}_W^o(S)$. The replacements Φ and Ψ make these two categories

85. NB la nouvelle notation serait plutôt $\underline{\mathrm{Fibf}}_W S$, car il s'agit de W-fibrations qu'à présent j'appelle 'faibles' (et définies seulement dans Cat, à l'opposé des W-fibrations, définissables dans toute catégorie de modèles).

86. cf. plus bas, ce qu'on peut dire pour les localisés pour W_S^{f}.

accessible through smooth and proper models respectively. Their symmetry comes from taking opposite categories, not from an identification of the two comma tests on arbitrary objects over S.

The weakly fibred objects make a second pair of choices possible. On $\underline{\mathrm{Fib}}_W S$, all the fine tests agree, so one may form

$$\mathcal{L}_S = \underline{\mathrm{Fib}}_W S[(W_S^{\mathrm{f}})^{-1}].$$

This retains the homotopy type of each fibre together with its transport. One may instead invert every map of weakly fibred objects whose total functor belongs to W:

$$\mathcal{G}_S = \underline{\mathrm{Fib}}_W S[W_S^{-1}].$$

The notation in the text is $\mathcal{L}_S = \mathrm{HOT}_W^{\mathrm{lc}}(S)$ and $\mathcal{G}_S = \mathrm{HOT}_W^{\mathrm{lc!}}(S)$. The exclamation mark records that this second construction may identify more arrows. It does not add an extra adjunction or an additional kind of pointwise constancy.

Since $W_S^{\mathrm{f}} \subseteq W_S$ on weakly fibred objects, the identity functor induces $\lambda : \mathcal{L}_S \to \mathcal{G}_S$. This is a localization by its universal property. Namely, a functor out of $\mathcal{L}_S$ factors through λ precisely when it inverts the images of all total W-equivalences between weakly fibred objects. No full faithfulness of λ follows from this description.

The replacement C explains why the coarse category also has the presentation

$$\mathcal{G}_S \simeq (\mathrm{Cat}/S)[W_S^{-1}].$$

It sends every object into $\underline{\mathrm{Parf}}_\omega S \subseteq \underline{\mathrm{Fib}}_W S$, and its natural unit is a total W-equivalence. Therefore both composites of the inclusion and replacement become naturally isomorphic to the identity after coarse localization. The same proof applies to a full intermediate category containing the image of C. For fine localization, however, the proof requires a fibrewise unit; the coarse unit cannot be used in its place.

For Φ_0 and Ψ_0 the necessary finer comparison is available on $\underline{\mathrm{Fib}}_W S$. This is why the two wings of the upper diagram still describe $\mathcal{L}_S$, whereas the perfect vertex is temporarily excluded from that assertion. The pattern is not an arbitrary list of exceptions. Each exception records a precise natural transformation whose known class is too coarse for the desired localization.

The diamond on p. 178 consequently says $\rho i = \lambda = \sigma j$, up to the canonical identifications of presentations. Calling i and j inclusions expresses the intended role of locally constant objects inside the two directional theories. Their full faithfulness still requires an argument. The reflection formulas established after W(4b) is imposed provide such an argument; the shape of the diamond alone does not.

p. 109
[page 177]

Pour toute sous-catégorie pleine

$$\mathcal{F} \subseteq \underline{\mathrm{Fib}}_W S$$

qui contient l'une des trois sous-catégories

$$\underline{\mathrm{Fib}}_{0,W} S,\ \underline{\mathrm{Parf}}_\omega S,\ \underline{\mathrm{Prop}}_{0,W} S,$$

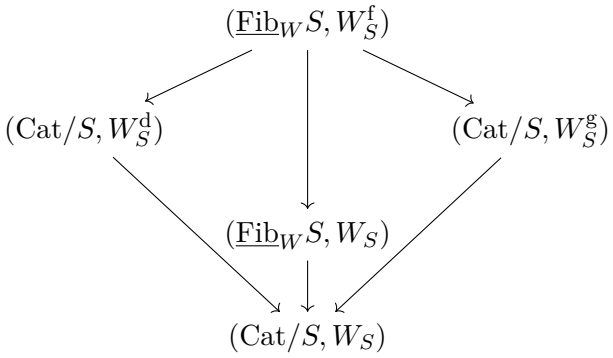
l'inclusion de $\mathcal{F}$ dans $\underline{\mathrm{Fib}}_W S$ définit des équivalences

$$\mathcal{F}(W_S)^{-1} \approx \mathrm{HOT}_W^{\mathrm{lc!}}(S),$$

et si $\mathcal{F}$ contient l'une des deux sous-catégories $\underline{\mathrm{Fib}}_{0,W} S$, $\underline{\mathrm{Prop}}_{0,W} S$ (à l'exclusion de $\underline{\mathrm{Parf}}_\omega S$), on trouve aussi

$$\mathcal{F}(W_S^{\mathrm{f}})^{-1} \approx \mathrm{HOT}_W^{\mathrm{lc}}(S).$$

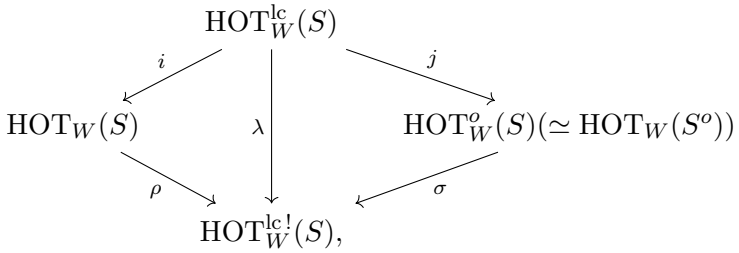
Le rez-de-chaussée contribue deux autres variantes de HOT, en localisant soit par W_S^{d} (aile gauche), soit par W_S^{g} (aile droite). Les foncteurs d'inclusion définissent des équivalences pour les localisées soit pour W_S^{d} (aile gauche), soit pour W_S^{g} (aile droite). Le plus joli (symétrie) semble de définir ces deux localisés par Cat/S



$$\mathrm{HOT}_W(S) = (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1}, \qquad \mathrm{HOT}_W^{o}(S) = (\mathrm{Cat}/S)(W_S^{\mathrm{g}})^{-1}.$$

Les quasi-inverses pour les équivalences de catégories localisées, induites par les foncteurs d'inclusion, sont donnés soit par Φ (aile gauche), soit par Ψ (aile droite).

Mais Φ et Ψ fournissent des quasi-inverses également quand on localise pour W_S, la W-équivalence grossière au lieu de la fine - pareil qu'à l'étage. On trouve donc au rez-de-chaussée un (unique) troisième localisé, qu'on peut décrire plus joliment par



$$(\mathrm{Cat}/S)(W_S)^{-1},$$

mais il est équivalent à $(\underline{\mathrm{Fib}}_W S)W_S^{-1}$ par le foncteur induit par l'inclusion. (Un quasi-inverse étant fourni par C.) C'est donc $\mathrm{HOT}_W^{\mathrm{lc}!}(S)$. On trouve ainsi, par le diagramme commutatif de catégories avec localiseurs [page 178]

(où la flèche verticale courte induit une équivalence sur les localisés), le diagramme commutatif entre les catégories HOT_W liées à S : p. 110

$(*)$

où ρ, σ, λ sont des foncteurs de localisation, et où i, j sont ressentis comme des foncteurs d'inclusion. Ce diagramme $(*)$ semble épuiser les foncteurs naturels qui relient entre elles les quatre catégories envisagées.

Les propriétés des foncteurs Φ, Ψ, C qui ont été utilisées, pour fournir tous les quasi-inverses voulus de foncteurs (entre catégories localisées) induits par les foncteurs d'inclusion du diagramme, sont les suivantes. [page 179]

Commentary · Development (commentators') [ms. 178]

An explicit failure of faithfulness for the coarse comparison

Grothendieck's four-category diagram raises a question about arrows, not only about which objects become isomorphic. The coarse localization can erase distinct automorphisms of a locally constant family. We make that loss explicit for the connected-components localizer. The covering obstruction discussed at manuscript p. 43 already distinguished a total equivalence from a fibre equivalence; the calculation here follows the comparison functor λ itself and determines the localization of a whole class of examples.

Let W_0 be the class of functors inducing bijections on connected components. It satisfies the basic localizer axioms. Saturation and the terminal-object condition follow directly from the functor $\pi_0 : \mathrm{Cat} \to \mathrm{Set}$. For the relative axiom, given $X \to S$, there is a natural bijection

$$\pi_0 X \cong \operatorname*{colim}_{s \in S} \pi_0(X/s).$$

To see this without a homotopy-colimit theorem, send the class of an object $(x, p(x) \to s)$ to the component of x. Every component occurs by using $(x, \mathrm{id}_{p(x)})$. The relations induced by morphisms in a slice, and by arrows of S, preserve that component. Conversely, every object $(x, p(x) \to s)$ is identified in the colimit with $(x, \mathrm{id}_{p(x)})$, and every arrow $x \to x'$ gives the corresponding identification through the slice over $p(x')$. These observations give inverse maps. A pointwise bijection of the slice-component diagrams therefore induces a bijection on total components, proving W(2).

Proposition (orbit collapse).[ours] Let G be a nontrivial group and $S = BG$. For $W = W_0$, the functor

$$\lambda : \mathrm{HOT}^{\mathrm{lc}}_{W_0}(BG) \longrightarrow \mathrm{HOT}^{\mathrm{lc!}}_{W_0}(BG)$$

is not faithful. On the full category of discrete fibrations over BG associated with right G-sets, its fine and coarse source presentations are respectively the category of right G-sets and the category of sets; the induced functor is the orbit functor.

Proof. For a right G-set E, let $\int E \to BG$ be its category of elements. Its objects are elements of E, and a morphism over $g \in G$ with target e' has source $e'g$. Unique lifting, and the invertibility of g, make the projection both a discrete fibration and a discrete opfibration. The categories of prescribed lifts are singletons, so these objects are W_ω-perfect and in particular weakly W_0-fibred. Functors over BG between them correspond exactly to equivariant maps of G-sets.

The strict fibre of $\int E$ is the discrete set E, while its set of total connected components is E/G. It follows that a map induced by $h : E \to F$ is fine precisely when h is a bijection, and coarse precisely when $E/G \to F/G$ is a bijection. A bijective equivariant map is already an isomorphism. Hence fine localization of this category changes nothing.

For the coarse localization, write $O(E) = E/G$, and give every set A the trivial G-action $T(A)$. The natural equivariant map

$$q_E : E \longrightarrow T(O(E))$$

induces the identity on orbit sets. Thus every q_E is inverted by coarse localization, while $OT = \mathrm{id}_{\mathrm{Set}}$. The induced functors O and T are consequently quasi-inverse equivalences after that localization: TO is naturally isomorphic to the identity through the inverted q_E. Under this equivalence the fine-to-coarse functor is exactly O.

It remains to verify that the loss of faithfulness persists in the full categories of the proposition, rather than only in the restricted example category. Take $E = G$ with its regular right action. For each $h \in G$, left multiplication $L_h(g) = hg$ is equivariant and defines an endomorphism of $\int G$ over BG. Evaluation on the strict fibre followed by π_0 is a functor

$$\underline{\mathrm{Fib}}_{W_0}(BG) \longrightarrow \mathrm{Set}$$

which inverts every fine equivalence. It therefore factors through $\mathrm{HOT}^{\mathrm{lc}}_{W_0}(BG)$. Its values on the L_h are distinct set maps, so these endomorphisms remain distinct in the fine localization. On the other hand, $q_G : G \to \{*\}$ is coarse, because both orbit sets are singletons. The equalities $q_G L_h = q_G$ and invertibility of q_G in the coarse localization imply that every $\lambda(L_h)$ is the identity. Thus λ is not faithful. □

This also gives a completely explicit failure of W(4b), even on the perfect objects used in its first weakened variant: $\int G \to BG$ is a total W_0-equivalence, whereas its fibre map $G \to \{*\}$ is not. The proposition does not assert that the full coarse category is always a category of sets. The equivalence with sets was proved for the displayed category of discrete fibrations; nonfaithfulness in the full category was established separately by fibre evaluation.

We checked the localizer discussion in (Cisinski, 2004) and the locally constant formalism in (Cisinski, 2009). We did not find this exact calculation of the manuscript's λ there. The argument is an elementary development of familiar action-groupoid and localization constructions, with no claim of priority.

ⓐ On a un homomorphisme fonctoriel dans Cat/S

$$X \xrightarrow{i_X} \Phi(X), \qquad \underline{i_X \in W_S^{\mathrm{d}}}.$$

Quand X est dans $\underline{\mathrm{Fib}}_W S$, $\Phi(X)$ est dans $\underline{\mathrm{Fibsc}}_0 S$ `[plutôt` $\underline{\mathrm{Fibsc}}_{0,W} S$`, cf. diag. p. 175]`, donc $i_X \in W_S^{\mathrm{f}}$ ($= W_S^{\mathrm{d}}$ sur $\underline{\mathrm{Fib}}_W S$). Ainsi Φ induit le foncteur Φ_0 du diagramme.

Dualement, on a

$$X \xrightarrow{i_X} \Psi(X), \qquad \underline{i_X \in W_S^{\mathrm{g}}},$$

et quand X est dans $\underline{\mathrm{Fib}}_W S$, $\Psi(X)$ est dans $\underline{\mathrm{Cofibsc}}_0 S$ [plutôt $\underline{\mathrm{Cofibsc}}_{0,W} S$], d'où le foncteur Ψ_0.

ⓑ On a un homomorphisme fonctoriel

$$\left|\begin{array}{l} X \xrightarrow{i_X} C(X), \qquad \underline{i_X \in W_S} \\ \text{et } C(X) \in \mathrm{Ob}\,\underline{\mathrm{Parf}}_\omega S. \end{array}\right.$$

||| Mais on fera attention qu'en l'absence de l'axiome W(4b) sur W, on ne peut *pas* affirmer $i_X \in W_S^{\mathrm{f}}$, même si X est dans $\underline{\mathrm{Fib}}_W S$ (voire, dans $\underline{\mathrm{Parf}}_\omega S$), seul cas (de toutes façons) où on est en droit de s'y attendre. Je note à ce propos le diagramme *cartésien,* pour $f : X \longrightarrow Y$ dans Cat/S p. 111

$$\begin{array}{ccc} C(Y)_s & \xleftarrow{C(f)_s} & C(X)_s \\ {\scriptstyle \pi^s_Y}\downarrow & & \downarrow{\scriptstyle \pi^s_X} \\ Y & \xleftarrow{\quad f \quad} & X, \end{array} \qquad \text{flèches verticales dans } \underline{\mathrm{Parf}}_\omega \subseteq \underline{\mathrm{Fib}}_W$$

qui montre par exemple que l'on ne peut pas s'attendre que $f \in W_S \implies C(f) \in W_S^{\mathrm{f}}$ sans [page 180] disposer de l'axiome W(4a′) [qu'est-ce que c'est?] (ou d'un axiome de force comparable, tel W(4b)).

Ce sont ces faits négatifs (en l'absence de W(4b)) qui sont cause que je ne peux rien dire de particulier sur les foncteurs induits par *localisation fine* $(W_S^{\mathrm{f}})^{-1}$ des deux foncteurs d'inclusion

$$\underline{\mathrm{Liss}}_0 S \longleftarrow \underline{\mathrm{Parf}}_\omega S \longrightarrow \underline{\mathrm{Prop}}_0 S,$$

ou, ce qui revient au même, de celui induit par le composé commun de ceux-là avec les inclusions dans $\underline{\mathrm{Fib}}_W S$

$$\begin{array}{ccccc} & & \underline{\mathrm{Parf}}_\omega S & & \\ & \swarrow & \downarrow & \searrow & \\ \underline{\mathrm{Liss}}_0 S & & & & \underline{\mathrm{Prop}}_0 S \\ & \searrow & \downarrow & \swarrow & \\ & & \underline{\mathrm{Fib}}_W S, & & \end{array}$$

en d'autres termes, je ne peux rien dire sur les propriétés de fidélité du foncteur

$$(\underline{\mathrm{Parf}}_\omega S)(W_S^{\mathrm{f}})^{-1} \longrightarrow (\underline{\mathrm{Fib}}_W S)(W_S^{\mathrm{f}})^{-1},$$

et encore moins que ce soit une équivalence de catégories. Donc, en l'absence de W(4b), pour les sous-catégories pleines $\mathcal{F}$ de $\underline{\mathrm{Fib}}_W S$ qui contiennent $\underline{\mathrm{Parf}}_\omega S$, sans contenir ni $\underline{\mathrm{Liss}}_0 S$ ni $\underline{\mathrm{Prop}}_0 S$, il se pourrait a priori que les localisées

$$\mathcal{F}(W_S^{\mathrm{f}})^{-1}$$

soient toutes différentes. Je pense notamment à $\underline{\mathrm{Parf}}_W S$, aussi intéressante en elle-même, après tout, que $\underline{\mathrm{Parf}}_\omega S$. Donc en plus des quatre localisées du diagramme (∗), p. 178, il y a toute une série infinie 'tératologique' de localisées qui refusent de se laisser 'boucler' [?] par [page 181] Φ_0 ou Ψ_0, et pour lesquelles même C n'est d'aucun secours, faute de l'axime W(4b).

Commentary · Exposition [ms. 180]

Which replacement actually gives a quasi-inverse

Grothendieck now tests the tools used to draw the preceding diagram. The decisive information is carried by the natural maps into the replacements. A replacement whose value belongs to a desirable subcategory gives an equivalence of localizations only when its comparison map lies in the localizer used on both sides.

For Φ the comparison $X \to \Phi(X)$ is right-fine on all objects. If X is weakly W-fibred, its value is a split locally constant fibration, and the equivalence of fine tests on weakly fibred objects makes the comparison fibrewise. The same reasoning for Ψ uses the left-fine comparison and the proper side. These statements explain why the upper wings remain equivalent after fine localization. They are applications of the localization comparison lemma already discussed in the commentary at manuscript p. 12, rather than a new assertion that localization preserves arbitrary full embeddings. At the split vertices one also uses the free split-fibration adjunction discussed in the commentary at manuscript pp. 53–59; the original unit need not preserve the chosen splitting.

The map $X \to C(X)$ comes with a weaker recorded guarantee: it belongs to W_S. Its target is perfect, but perfection of the target alone does not make the comparison fine. The Cartesian square displayed on p. 179 isolates the issue even more sharply. For a total W-equivalence $u : X \to Y$, the map $C(u)_s$ is obtained by pulling u back along the perfect map $C(Y)_s \to Y$. To conclude that $C(u)_s \in W$ one needs a suitable preservation theorem for that pullback. Two-out-of-three for the total units only proves $C(u) \in W_S$; it supplies no missing fibre comparison.

There are two different questions here. One asks whether C turns coarse equivalences into fine ones. The other asks whether the inclusion of perfect objects induces an equivalence after fine localization. Failure of the first proposed proof does not establish a negative answer to the second question. Another replacement, or an additional limit argument, could still produce the required fine comparisons. This is exactly what the alternating construction on pp. 192–197 is designed to investigate.

Accordingly, the "tératologique" family of localizations is a possibility recorded during the investigation, not a theorem that infinitely many pairwise inequivalent categories have been constructed. The source supplies no family of counterexamples on these pages. Modernly, the alternating replacement settles this particular question: the results explained at p. 172 make its values W_ω-perfect and its units fine on every weakly W-fibred input. Every full intermediate category containing $\underline{\mathrm{Parf}}_\omega S$ therefore has the same fine localization as $\underline{\mathrm{Fib}}_W S$, by the common replacement and its units. The proof is given at p. 195. This does not identify fine and coarse localization: the connected-components counterexample still applies to λ.

④ Cas où l'axiome W(4b) est satisfait.

Alors les perplexités que je viens de dire disparaissent. On a aussitôt, en vertu de W(4b) : p. 112

$$\Big|\Big| \qquad \text{Si } X \in \mathrm{Ob}\,\underline{\mathrm{Fib}}_W S, \text{ alors } i_X : X \longrightarrow C(X) \text{ est dans } W_S^{\mathrm{f}} \quad (\textit{en supposant l'axiome } \mathrm{W}(4\mathrm{b}))$$

et C fournit des quasi-inverses pour les foncteurs 'd'inclusion' entre localisés fins (pour W_S^{f}) envisagés à la page précédente. Il en fournit `['Il en fournit' barré]` un également pour le foncteur λ envisagé plus haut ((∗) page 178)

$$\underbrace{(\underline{\mathrm{Fib}}_W S)(W_S^{\mathrm{f}})^{-1}}_{\overset{\text{déf}}{=}\mathrm{HOT}^{\mathrm{lc}}_W(S)} \longrightarrow \underbrace{(\mathrm{Cat}/S)(W_S)^{-1}}_{\simeq \mathrm{HOT}^{\mathrm{lc}\,!}_W(S)},$$

lequel est donc une équivalence. Une autre façon, plus évidente, de dire la même chose, c'est que sur chacune des catégories de l'étage les deux localiseurs W_S^{f} et W_S sont désormais identiques (puisqu'elles sont toutes contenues dans $\underline{\mathrm{Fib}}_W S$, où elles `[plutôt ils]` le sont justement par l'axiome W(4b)), donc le foncteur λ entre ces deux localisés (définition originale de λ, dans le cas $\mathcal{F} = \underline{\mathrm{Fib}}_W S$, cf. page 176) est même le *foncteur identique,* les deux catégories localisées étant *égales :*

$$\mathrm{HOT}^{\mathrm{lc}}_W(S) = \mathrm{HOT}^{\mathrm{lc}\,!}_W(S) \qquad !$$

Ainsi le diagramme (∗) p. 178 prend la forme

(∗)
$$\begin{array}{ccccc} & & \mathrm{HOT}^{\mathrm{lc}}_W(S) & & \\ & \overset{\rho}{\nearrow}\!\!\underset{i}{\swarrow} & & \overset{\sigma}{\nwarrow}\!\!\underset{j}{\searrow} & \\ \mathrm{HOT}_W(S) & & & & \mathrm{HOT}^{o}_W(S). \end{array}$$

Commentary · Exposition [ms. 181]

The fibre axiom closes the comparison

The force of W(4b) is now visible in one line. For a weakly W-fibred object X, both X and $C(X)$ are in $\underline{\mathrm{Fib}}_W S$, and the natural map $i_X : X \to C(X)$ is a total W-equivalence. W(4b) makes it a fibrewise W-equivalence. This is the missing comparison in the preceding block.

It is useful to check that this gives a functor on the desired localizations, not only good objects. If $u : X \to Y$ is fine, naturality gives

$$C(u)i_X = i_Y u.$$

On each fibre, i_X and i_Y are W-equivalences. Two-out-of-three therefore makes $C(u)$ fine. The functor C thus descends to fine localizations. On the full category of weakly fibred objects and on every indicated intermediate full subcategory containing its perfect image, the two composites with inclusion are naturally isomorphic to the identity through the same units. This proves the claimed equivalences.

For λ an even shorter argument is available. The two presentations are localizations of the very same category $\underline{\mathrm{Fib}}_W S$, and W(4b) identifies their two classes of denominators. Choosing the same localization construction on each side makes λ literally the identity. Without that choice, the invariant conclusion is its canonical equivalence. Grothendieck's exclamation mark after the displayed equality expresses this formal simplification, not an additional theorem about particular models of localization.

The reduction from four categories to three consequently has an exact hypothesis. The connected-components example above shows that it cannot be asserted for every localizer satisfying only the basic axioms. The next step is to identify the remaining maps as adjoints and to prove that the locally constant category sits fully faithfully inside the two directional theories. Those assertions require the mapping-property calculation on pp. 182–183; they do not follow from drawing a triangle in place of the diamond.

Quand on interprète non seulement les deux catégories latérales $\mathrm{HOT}_W(S)$, $\mathrm{HOT}^o_W(S)$, mais aussi celle du milieu, comme des localisées de Cat/S, pour les localiseurs W^{d}_S, W^{g}_S et W_S respectivement, les foncteurs ρ, σ sont ceux déduits des deux inclusions [page 182]

$$\begin{array}{ccc} W^{\mathrm{d}}_S & & W^{\mathrm{g}}_S \\ & \searrow \quad \swarrow & \\ & W_S & \end{array} \qquad \text{comme parties de } \mathrm{Fl}(\mathrm{Cat}/S),$$

tandis que les foncteurs i, j sont déduits, par passage aux localisés, d'un seul et même foncteur

$$\mathrm{Cat}/S \xrightarrow{C} \mathrm{Cat}/S,$$

ce foncteur ayant la vertu d'appliquer W_S dans $W^{\mathrm{d}}_S \cap W^{\mathrm{g}}_S$,

$$f \in W_S \overset{\text{moyennant W(4b)}}{\Longrightarrow} C(f) \in W^{\mathrm{d}}_S \cap W^{\mathrm{g}}_S \qquad (\text{et même } \in W^{\mathrm{univ}}_S).$$

(Et pour cause, puisque C se factorise par $\underline{\mathrm{Fib}}_W S$ (et même par $\underline{\mathrm{Parf}}_\omega S$), où W_S est identique à W^{d}_S, W^{g}_S, W^{univ}_S. Que $f \in W_S$ implique $C(f) \in W$ est indépendant de l'axiome W(4b), et se voit sur le diagramme p. 113

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ {\scriptstyle i_X}\downarrow & & \downarrow{\scriptstyle i_Y} \\ C(X) & \xrightarrow{C(f)} & C(Y), \end{array}$$

où les flèches i_X, i_Y sont dans W_S.)

Ceci dit, il est vrai que les couples

$$(\rho, i),\ (\sigma, j)$$

sont des couples de foncteurs adjoints, donc (ρ et σ étant des foncteurs de localisation) que i et j sont *pleinement fidèles.* La formule d'adjonction peut se lire comme

$$(*) \qquad \boxed{\mathrm{Hom}_{W_S^{\mathrm{g}}}(X, CY) \simeq \mathrm{Hom}_{W_S^{\mathrm{d}}}(X, CY) \simeq \mathrm{Hom}_{W_S}(X, Y)}$$

pour X, Y dans Cat/S sans plus. Un Hom_Σ indique le Hom dans $(\mathrm{Cat}/S)\Sigma^{-1}$. [page 183]

Corollaire. *Si X dans Cat/S, Y dans $\underline{\mathrm{Fib}}_W S$, alors*

$$\begin{array}{ccc} \mathrm{Hom}_{W_S^{\mathrm{g}}}(X, Y) & & \mathrm{Hom}_{W_S^{\mathrm{d}}}(X, Y) \\ & \searrow^{\sim} \quad \swarrow_{\sim} & \\ & \mathrm{Hom}_{W_S}(X, Y) & \end{array}$$

sont bijectifs.

En effet, Y dans $\underline{\mathrm{Fib}}_W(S)$ implique que $Y \xrightarrow{i_Y} C(Y)$ est dans $W_S^{\mathrm{univ}} \subseteq W_S^{\mathrm{d}} \cap W_S^{\mathrm{g}}$, donc

$$\mathrm{Hom}_{W_S^{\mathrm{g}}}(X, Y) \xrightarrow{\sim} \mathrm{Hom}_{W_S^{\mathrm{g}}}(X, CY) \underbrace{\xrightarrow{\sim}}_{\text{adjonction}} \mathrm{Hom}_{W_S}(X, Y),$$

et itou pour $\mathrm{Hom}_{W_S^{\mathrm{d}}}(X, Y)$.

⑤ Perplexités sur les variantes affaiblies de l'axiome W(4b).

Que reste-t-il de toutes ces belles choses (plus que trois catégories HOT, au lieu de $4 + \infty$!) quand on ne suppose plus que W(4b′) au lieu de W(4b), i.e. l'égalité de W_S et W_S^{f} dans $\underline{\mathrm{Parf}}_\omega S$? Finalement, il me semble (contrairement à ce que j'avais cru voir) qu'il ne reste presque rien ([87]). On ne sait alors toujours pas, pour X dans $\underline{\mathrm{Fib}}_W S$, si p. 114

$$i_X : X \longrightarrow C(X)$$

n'est dans W_S^{f}, et non seulement dans W_S; on ne le sait que pour $X \in \underline{\mathrm{Parf}}_\omega S$, mais dans ce cas on n'en a pas besoin, car l'utilité du foncteur $C(X)$ et de l'inclusion $i_X : X \longrightarrow C(X)$, c'est 'd'améliorer' X et de le rendre parfait, voire même W-parfait. Mais s'il l'est déjà, c'est plus la peine. Il y aura, comme avant, 4 localisées essentiellement distinctes HOT_W, HOT_W^o, $\mathrm{HOT}_W^{\mathrm{lc}}$, $\mathrm{HOT}_W^{\mathrm{lc}!}$, plus une infinité d'autres $\mathcal{F}(W_S^{\mathrm{f}})^{-1}$ pour $\mathcal{F}$ entre $\underline{\mathrm{Parf}}_\omega S$ et $\underline{\mathrm{Fib}}_W S$ (cf. page 180), avec le seul bénéfice qu'on peut maintenant exclure le cas $\mathcal{F} = \underline{\mathrm{Parf}}_\omega S$, car dans ce cas $\mathcal{F}(W_S^{\mathrm{f}})^{-1} = \mathcal{F}(W_S)^{-1} = \mathrm{HOT}_W^{\mathrm{lc}!}(S)$ fait partie des quatre canoniques. La chose décisive, c'est qu'on n'a toujours aucun moyen de prouver que [page 184]

$$\lambda : \mathrm{HOT}_W^{\mathrm{lc}}(S) \longrightarrow \mathrm{HOT}_W^{\mathrm{lc}!}(S)$$

est une équivalence, et je doute que ce soit le cas. Il faudrait regarder avec $W = W_{\mathbf{D}}$ la $\mathbf{D}$-équivalence, où $\mathbf{D}$ est un dérivateur $\mathrm{Der}(k\text{-Mod})$, k un anneau donné (p.ex. $k = \mathbf{Z}$, ou k un corps $\mathbf{Z}/p\mathbf{Z}$ ou $\mathbf{Q}$ …). Je ne vais pas le faire maintenant cependant. (Il est vrai que l'axiome W(4b′) n'est pas non plus satisfait dans ce cas …)

87. **NB** Si W satisfait l'axiome des limites, alors W(4b′) implique W(4b), cf. théorème récapitulatif dans XVI 4.4.13 (p. 58-62), notamment 2°). La condition W(4b) est la condition B de cet énoncé, et W(4b′) la condition D. (Elle est impliquée par W(4a) = C, ce que je soupçonnais nullement en écrivant XII …)

Commentary · Exposition [ms. 183]

Local objects absorb the extra denominators

Grothendieck has reached the point where the three remaining homotopy categories can be compared by their maps, rather than by successive descriptions of their objects. This is the purpose of the boxed formula. Its force is that the source X is arbitrary: local constancy is imposed on the target, where it supplies the extension property needed to invert the additional arrows.

Write $\mathcal{H}_d(S) = (\mathrm{Cat}/S)[(W_S^{\mathrm{d}})^{-1}]$ and $\mathcal{H}_c(S) = (\mathrm{Cat}/S)[W_S^{-1}]$. Under W(4b), the functor C represents a fully faithful right adjoint i to the localization $\rho : \mathcal{H}_d(S) \to \mathcal{H}_c(S)$. For X, Y in Cat/S, the adjunction gives

$$\mathrm{Hom}_{\mathcal{H}_d(S)}(X, CY) \simeq \mathrm{Hom}_{\mathcal{H}_c(S)}(X, Y).$$

This formula is natural in both variables. In particular, it identifies the map induced by localization, after the canonical identification of CY with Y in $\mathcal{H}_c(S)$; it is not merely an abstract bijection between two sets of the same size. The dual localization gives the other bijection in the text.

To see what changes when Y is already W-fibred, use the comparison $i_Y : Y \to CY$. It belongs to W_S^{f}, and on the category of W-fibred objects this is also W_S^{d} and W_S^{g}. Thus postcomposition by i_Y is a bijection on Hom sets in either lateral category. Composing with the displayed adjunction proves the corollary exactly as stated. Notice that no replacement of the source is required. An arbitrary object can map into a local object, and this map already incorporates all the relations that the coarse localization would introduce.

There is a useful intrinsic reformulation. Let $v : A \to B$ be a coarse weak equivalence, and regard it as a map in $\mathcal{H}_d(S)$. For every W-fibred Y, precomposition induces a bijection

$$v^* : \mathrm{Hom}_{\mathcal{H}_d(S)}(B, Y) \longrightarrow \mathrm{Hom}_{\mathcal{H}_d(S)}(A, Y).$$

Indeed the two sides are the corresponding Hom sets in $\mathcal{H}_c(S)$, where v is invertible. This is the categorical meaning of being local for the additional denominators. It is this property, rather than the mere existence of a map $Y \to CY$, that makes a reflection useful. The distinction was prepared in the commentary at manuscript pp. 64–69; here it becomes an operational formula for computing morphisms.

The hypothesis W(4b) enters at a precise place. Naturality of $X \to CX$ and two-out-of-three show, without W(4b), that C preserves total W-equivalences. To conclude that $C(v)$ is also right-fine, one must pass from a total equivalence between fibred objects to equivalences on their fibres. That is exactly what W(4b) supplies. The following pages investigate whether a smaller family of test objects can supply the same passage.

Si dans l'énoncé de l'axiome, on remplaçait $\underline{\mathrm{Parf}}_\omega S$ par $\underline{\mathrm{Parf}}_W S$, rien d'essentiel ne serait changé - tout au plus je remplacerais $\underline{\mathrm{Parf}}_\omega S$ par $\underline{\mathrm{Parf}}_W S$ dans le brillant diagramme p. 175. Finalement, je suis à présent convaincu qu'il faut tout ou rien : ou bien *quatre* catégories $\mathrm{HOT}(S)$ pour W, en se contentant de W(1, 2, 3), ou bien rien que trois, i.e. pas de $\mathrm{HOT}_W^{\mathrm{lc}!}(S)$ - et pour ça, il ne semble pas qu'on puisse se contenter de moins de W(4b).

Il suffirait, il est vrai, de supposer que $W_S = W_S^{\mathrm{f}}$ sur l'une quelconque des sept catégories [page 185] de l'étage autres que $\underline{\mathrm{Parf}}_\omega S$. Cela impliquerait alors que dans les six autres, on aura $\overline{W_S} = \overline{W_S^{\mathrm{f}}}$ (mêmes saturés forts dans $\mathrm{Fl}(\mathcal{F})$). Un des deux les plus faibles des axiomes en question serait :

Commentary · Present state [ms. 184]

The later annotation changes the question

Grothendieck is asking how much fibre detection is needed to identify the two locally constant theories. The note added to this passage belongs to a later stage of the investigation. In Chapter XVI, Theorem 4.4.13, especially part 2°, he proves an equivalence of the relevant fibration conditions when the localizers concerned are stable under sequential colimits. Its conditions B, C, and D are the later counterparts of the fibre-detection condition, the base-change condition, and the restriction to perfect objects discussed here. The proof uses the alternating replacement of manuscript pages 192–195, together with a factorization argument (Grothendieck, 1991b, §4.4, especially Corollaries 4.4.10–4.4.12 and Theorem 4.4.13).

Thus the apparent weakness of a perfect-object test must be read together with the limit hypothesis. The test cannot be used on an arbitrary weak fibration until a suitable replacement

has been constructed and its unit has been proved fine. These are precisely the tasks undertaken later in the chapter. The annotation supplies a conditional resolution in its historical setting. The modern automatic-colimit result discussed after manuscript p. 195 supplies the limit hypothesis for the standing basic localizers, while the restricted fibre-detection test remains necessary. The references to "XVI 4.9" in notes 95–96 should be located through the statements: in the current electronic edition the relevant replacement results occur in §4.4.

Si $f : X \longrightarrow Y$ est un foncteur *cartésien* de catégories Cat-fibrées et W-fibrées ([88]) sur une autre S, si $f \in W$, alors $f_s \in W$ pour tout $s \in S$,

(et l'autre est la version duale, pour les foncteurs cocartésiens de catégories cofibrées). Sauf erreur, cet axiome doit déjà impliquer que $\overline{W}$ satisfait la version W(4a) la plus forte de toutes (a fortiori W(4b)) des axiomes W(4). Cet axiome me paraît donc à présent beaucoup plus raisonnable que W(4b′), et ceci d'autant plus qu'il se réfère directemment à la description de $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ en termes de foncteurs (ou de 'pseudofoncteurs', si on ne veut supposer les catégories scindées et les foncteurs compatibles aux scindages) $S^o \longrightarrow \mathrm{Cat}$. D'ailleurs, bien qu'il n'en ait pas l'air, cet axiome *est* autodual, puisque la version duale, pour S fixée, est la version directe pour S^o! Cela rend cet axiome encore plus appétissant. Donc pour formuler W(4a′), j'ai envie à présent de laisser tomber $\underline{\mathrm{Parf}}_\omega$, et de faire pareil. Si on garde deux versions W(4a′) (l'ancienne) et W(4a″) (la nouvelle), l'une et l'autre ont la vertu d'impliquer W(4b). Et W(4b′) (nouvelle version) doit impliquer W(4a) (version ultraforte), sinon pour W, du moins pour $\overline{W}$. p. 115

Mes idées étaient tenacement [?] embrouillées jusqu'à aujourd'hui même, car j'avais l'idée que, grâce au mirifique foncteur C, la catégorie $\underline{\mathrm{Parf}}_\omega S$, comme les sept autres catégories de l'étage, pourrait servir à définir $\mathrm{HOT}^{\mathrm{lc}}_W(S)$. Or il n'en est rien, semble-t-il, à moins de supposeer l'axiome W(4b), ou la variante W(4b′) (nouvelle version). L'ancienne version de W(4b′) s'avère parfaitement inutilisable. [page 186]

Commentary · Exposition [ms. 185]

A smaller test family must still contain replacements

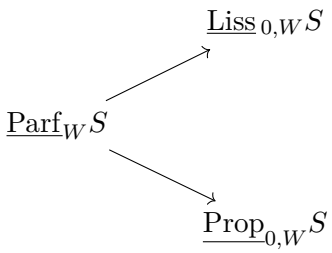
Grothendieck is trying to economize the fibre-detection axiom without losing the reflection. The difficulty is structural. Testing total equivalences only between perfect objects says nothing about the map which first makes a given fibred object perfect, unless that map is already known to be a fibrewise equivalence. This is why the first version of W(4b′) does not immediately do the work expected of it.

The issue can be stated without the changing notation. Let $\mathcal{F}$ be a category of objects over S, and let $E \subseteq V$ be two classes of arrows, thought of as fibrewise and total equivalences. Suppose $\mathcal{P} \subseteq \mathcal{F}$ is a full subcategory on which E and V agree. This equality alone does not identify $\mathcal{F}[E^{-1}]$ with $\mathcal{F}[V^{-1}]$. What is additionally needed is a functor $R : \mathcal{F} \to \mathcal{P}$ with a natural map $\eta : \mathrm{id} \to R$ whose components belong to E. Once such a functor exists, the conclusion follows, and in fact the argument proves more. For $u : X \to Y$ in V, naturality and two-out-of-three imply $R(u) \in V$. Since RX, RY lie in $\mathcal{P}$, it follows that $R(u) \in E$. In the square

$$\begin{array}{ccc} X & \xrightarrow{u} & Y \\ {\scriptstyle \eta_X}\downarrow & & \downarrow{\scriptstyle \eta_Y} \\ RX & \xrightarrow[R(u)]{} & RY \end{array}$$

the other three arrows therefore lie in E, so u does also. Thus $E = V$ throughout $\mathcal{F}$, provided these are the actual two-out-of-three classes under consideration; if only invertibility in the localization was assumed, the conclusion is equality of their strong saturations.

In the present application, $\mathcal{F} = \underline{\mathrm{Fib}}_W S$, $E = W^{\mathrm{f}}_S$, and $V = W_S$. The old perfect-object test does not initially provide the required fine unit. By contrast, a test on split fibrations with W-equivalent



88. 'W-fibrées' signifiant ici que pour $u \in \mathrm{Fl}\, S$, les foncteurs u^* de changement de base $X_{s'} \longrightarrow X_s$, $Y_{s'} \longrightarrow Y_s$ sont dans W.

transport does: the functor Φ takes a W-fibred object into that class, and its unit is fibrewise in W. The infinite alternating construction below provides another such replacement, now into $\underline{\mathrm{Parf}}_W S$, assuming the sequential-colimit axiom.

This explains both the frustration and the eventual simplification. There are two different statements to prove: enough good objects exist, and coarse equivalences between these objects are fine. The first is a replacement statement, the second a detection statement. Neither follows merely from writing down a localization. The proposition on manuscript p. 196 combines them; the omitted adjunction check on p. 197 can then be completed by transferring the already established reflector, as we shall do there.

À ce propos, je n'ai toujours pas répondu clairement pourtant, pas un 'oui' ou un 'non', à la question :

Question : *les inclusions*

induisent-elles, même en l'absence de W(4b) (ou de ses variantes affaiblies) des équivalences pour les localisées fines (par W_S^{f})? Même question pour $\underline{\mathrm{Parf}}_\omega S$ au lieu de $\underline{\mathrm{Parf}}_W S$ ([89]). Même question pour

$$\underline{\mathrm{Bifib}}\, S \subseteq \underline{\mathrm{Parf}}_\omega S,$$

la catégorie des catégories sur S qui sont à la fois Cat-*fibrées et* Cat-*cofibrées.*

Je ne me rends pas compte, même en admettant (cette fois) l'axiome W(4a), si $\underline{\mathrm{Bifib}}\, S$ est assez grosse pour pouvoir décrire tous le types d'homotopie relatifs localement constants sur S, i.e. si

$$(\underline{\mathrm{Bifib}}\, S)(W_S^{\mathrm{f}})^{-1} \longrightarrow (\underline{\mathrm{Fib}}_W S)(W_S^{\mathrm{f}})^{-1}$$

est au moins essentiellement surjectif, sinon une équivalence de catégories. Il manque un foncteur

$$\mathrm{Cat}/S \longrightarrow \underline{\mathrm{Bifib}}\, S \qquad \text{ou du moins} \qquad \underbrace{\underline{\mathrm{Fib}}_W S}_{\text{ou } \underline{\mathrm{Fib}}_\omega S\,?} \longrightarrow \underline{\mathrm{Bifib}}\, S,$$

qui puisse jouer le rôle de Φ et de Ψ *simultanément.* Je n'ai pas même vérifié que Φ ne transforme *pas* objets de $\underline{\mathrm{Prop}}_W S$ ou de $\underline{\mathrm{Prop}}_{0,W}(S)$ en objets W-propres (donc W-parfaits, étant de toutes façons W-lisse et même W_ω-lisse) sur S ([90]). Si c'était pourtant vrai sur $\underline{\mathrm{Prop}}_W S$, ça montrerait que l'image essentielle de $\underline{\mathrm{Prop}}_W S$ dans $\mathrm{HOT}_W(S)$ $(= (\mathrm{Cat}/S)(W_S^{\mathrm{d}})^{-1})$ est contenu dans $\mathrm{HOT}_W^{\mathrm{lc}}(S)$. Prenant $S = \mathbf{\Delta}^1$, cela signifierait que si dans X on a une sous-catégorie fermée X_1 telle que $X_1 \overset{i}{\hookrightarrow} X$ soit W_ω-asphérique, alors $1\backslash X \longrightarrow 0\backslash X$ est dans W - or $0\backslash X \simeq X$, $1\backslash X \simeq X_1$, la flèche est $X_1 \longrightarrow X$, qui est bien dans W étant W-asphérique! C'est étrange et quasiment immoral ([91]). Mais à force de gribouillis je viens de me convaincre que même si X est cofibrée sur S (donc aussi W-propre), $\Phi(X)$ n'est pas W-propre (ce qui impliquerait W-parfait), ni même un W-fibré, ce qui signifierait que

p. 116 [page 187] [page 188]

89. OK en présence de l'axiome W(6bis) sur les $\varinjlim$, cf. p. 192 ff.
90. Voir réponse à cette intéressante question page 192.
91. On observe plus bas que c'est ainsi chaque fois que S a un objet final.

$$s'\backslash X \longrightarrow s\backslash X \qquad \text{associé à } s \longrightarrow s' \text{ dans } S$$

serait toujours dans W. Posant $Z' = s'\backslash S$, $Z = s\backslash S$, cela signifierait que si on a un *co-isomorphisme local*

$$i : \underbrace{Z'}_{\simeq z_0\backslash Z} \longrightarrow Z,$$

où Z', Z ont des éléments initiaux, et si X est cofibrée sur Z, X' son image inverse sur Z', alors $X' \longrightarrow X$ est dans W. En fait, si Z a aussi un élément *final* e (comme c'était le cas tantôt pour $\mathbf{\Delta}^1$), alors $Z' \simeq z_0\backslash Z$ en a aussi en e', qui s'envoie sur e, et on aura le diagramme commutatif

$$\begin{array}{ccc} X' & \xrightarrow{\ j\ } & X \\ {\scriptstyle W}\uparrow & & \uparrow{\scriptstyle W} \\ X'_{e'} & \xrightarrow{\ \sim\ } & X_e, \end{array}$$

d'où $j \in W$. Donc pour faire un contrexemple, il faut prendre Z sans élément final. [page 189]

Commentary · Present state [ms. 186]

What the bifibration question asks

Grothendieck now asks for a replacement which has both kinds of categorical lifting at once. The question is stronger than the existence of a W-perfect replacement. A Grothendieck bifibration has actual Cartesian and coCartesian lifts. Smoothness and properness ask for suitable categories of lifts to be W-aspherical. The latter condition can hold without a distinguished universal lift, so an equivalence using $\underline{\mathrm{Parf}}_W S$ does not by itself answer the question about $\underline{\mathrm{Bifib}}S$.

One case admits a complete answer with the constructions already at hand. Suppose the base S is a groupoid. Every Grothendieck fibration $p : E \to S$ is then also an opfibration. To prove this, let $u : s \to t$ and $x \in E_s$. Choose a Cartesian lift of u^{-1} with codomain x. Its domain lies over t, and the lift is an isomorphism because its base arrow is invertible: Cartesian lifting of the inverse gives a two-sided inverse by the uniqueness in the Cartesian universal property. The inverse of this lift is therefore a coCartesian arrow over u with domain x. This supplies the required coCartesian lifts for all u and x.

Consequently $\Phi(X) \to S$ is a bifibration for every $X \to S$. If X is W-fibred, its unit $X \to \Phi(X)$ is in W_S^{f}. The functor Φ preserves fine equivalences between such objects: in each fibre it gives a comma functor, and the two fibre-inclusion equivalences identify this with the original fibre map. The same unit, restricted to bifibrations, stays inside that full subcategory. Passing to the fine localizations therefore gives mutually inverse equivalences

$$(\underline{\mathrm{Bifib}}S)[(W_S^{\mathrm{f}})^{-1}] \simeq (\underline{\mathrm{Fib}}_W S)[(W_S^{\mathrm{f}})^{-1}] \qquad (S \text{ a groupoid}).$$

No colimit axiom is used. This includes discrete bases, where the assertion is simply the independent comparison on every fibre.

For an arbitrary base, the proof breaks at exactly the attempted inversion of u. A fibration classified by $F : S^{\mathrm{op}} \to \mathrm{Cat}$ is a bifibration when its transport functors have the appropriate left adjoints, with the coherent structure coming from the liftings. Knowing only that these transport functors lie in W does not produce such adjoints. The sequential construction below proves the fine-localization comparison for $\underline{\mathrm{Parf}}_W S$; it does not equip its output with Cartesian and coCartesian lifts, and therefore does not establish the general $\underline{\mathrm{Bifib}}S$ comparison.

A relevant categorical construction is now available: Clarke et al. (2025, Theorem 1.17) constructs the free cloven bifibration on any functor $p : X \to S$, with a natural unit $X \to \mathrm{Bif}(p)$. Its universal property uses functors preserving the chosen lifts. Propositions 1.23–1.24 make the unit fully faithful and give it a left inverse on total categories. Those conclusions do not make the unit a fibrewise W-equivalence on weakly W-fibred inputs, which is the missing assertion for the present application. The antecedent path construction in Lamarche (2013, §4, pp. 22–23) explicitly distinguishes its own weak equivalences from ordinary nerve weak equivalences. Thus these free constructions cannot be cited as a verified homotopical replacement for this question, even at $W = W_\infty$.

We did not find the precise arbitrary-base, arbitrary-localizer bifibration comparison in the literature checked. This is a limit of the present audit, not an assertion that the problem is open.

> The modern theory of locally constant coefficients gives a homotopy invariant category of such coefficients; for example, Cisinski (2009, Theorem 1.3 and Corollary 1.28) proves invariance under nerve weak equivalences and its detection by locally constant coefficients. That theorem does not assert the strict bifibration presentation asked for here.

Mais prenons Z `[un]` ensemble ordonné, avec un objet initial 0, mais sans objet final, et prenons pour z_0 un élément *maximal* de Z, de sorte que $Z' = z_0\backslash Z$ soit isomorphe à $\{z_0\}$. Il faut donner dans Cat un exemple où l'inclusion de X_{z_0} dans X n'est pas dans W. On va prendre

p. 117

$$Z = \quad 0 \nearrow a \quad 0 \searrow b = z_0,$$

donc la donnée de X cofibrée coscindée sur Z équivaut à un diagramme dans Cat

$$X_0 \xrightarrow{\alpha} X_a, \qquad X_0 \xrightarrow{\beta} X_b.$$

Je pense que sous des conditions assez fortes (p.ex. si α, β sont des immersions ouvertes, ou des immersions fermées - à vérifier!), la catégorie X est isomorphe dans Hot à la somme amalgamée dans Cat

$$X_a \coprod_{X_0} X_b,$$

et il n'y `[a]` aucune raison (sauf si on suppose $\alpha \in W$, et encore …) que $X_b \longrightarrow X_a \coprod_{X_0} X_b$ soit dans W. Prenons $X_0 = X_b = e$, $\beta = \mathrm{id}_e$, donc α est donné par la donnée d'un élément t de $\mathrm{Ob}(X_a = T)$. La somme amalgamée est T, qui n'est pas isomorphe à e dans Hot_W, si T n'a pas été prise W-asphérique. Mais je vais essayer de montrer directement que l'inclusion

[page 190]

$$T = X_a \longrightarrow X$$

est $\in W$. Pour ceci je regarde la sous-catégorie ouverte Z'' de Z, complémentaire de la sous-catégorie pleine fermée Z', et je note que $X'' = X|Z''$ étant propre sur Z'' et a étant objet final de Z'', on a

$$X_a \longrightarrow X'' \qquad \text{dans } W,$$

il reste à voir qu'il en est de même de $X'' \longrightarrow X$. Or X'' est déduite de X en ajoutant un unique élément ξ (celui de X_b), lequel ne s'envoie dans aucun élément de X'', et qui ne reçoit aucun élément de X_a - par contre pour l'unique élément ξ_0 de X_0 il y a une unique flèche de celui-ci dans ξ. On a donc une rétraction de X sur X'', envoyant ξ sur ξ_0 et la flèche précédente sur id_{ξ_0}. Est-ce un homotopisme? Il suffit de `[montrer]` qu'en tant qu'endomorphisme φ de X, c'est $\sim \mathrm{id}_X$. Or on a bien $\mathrm{id}_X \longleftarrow \varphi$, dont la valeur sur X'' est l'identité, et la valeur sur ξ est l'unique $\varphi(\xi) = \xi_0 \longrightarrow \xi$. C'est un peu bref, mais ça doit être vrai. (De toutes façons, X est la réunion de deux ouverts X'', et de l'ouvert $X|\{0, b\} = X'''$, avec $X''' \simeq \mathbf{\Delta}^1$, et $X'' \cap X''' \simeq e$, donc au moins pour la cohomologie à coefficients localement constants de X je suis à l'aise par Mayer-Vietoris, et sais bien que c'est celle du morceau X'', donc celle de X_0 `[ou $X_a$, indice illisible]` nullement celle de e!)

On a donc vu au moins ceci : Si X est cofibrée donc W-propre sur S, il ne s'ensuit nullement que $\Phi(X)$ soit encore W-propre sur S ([92]), ni que ce soit un W-fibré. Mais que se passe-t-il si

p. 118
[page 191]

92. voir résultat plus précis page suivante!

$X \in \underline{\mathrm{Prop}}_{0,W} S$, par exemple s'il provient de $\underline{\mathrm{Cofibsc}}_0 S$? Alors X est dans $\underline{\mathrm{Fib}}_W S$, donc on sait déjà que $\Phi(X)$ est dans $\underline{\mathrm{Fibsc}}_{0,W} S$, donc ce n'est pas par là qu'on fera un contrexemple. Mais considérons encore X cofibrée sur

$$S = \quad \begin{array}{ccc} & & a \\ & \nearrow & \\ 0 & & \\ & \searrow & \\ & & b, \end{array}$$

donnée par le diagramme

$$\begin{array}{ccc} & & X_a \\ & \overset{u}{\nearrow} & \\ X_0 & & \\ & \underset{v}{\searrow} & \\ & & X_b \end{array}$$

dans Cat, en supposant cette fois $u, v \in W$ ($X \in \underline{\mathrm{Cofibsc}}_{0,W} S$). Alors $\Phi(X)$ est la catégorie fibrée scindée sur S définie par le diagramme contravariant sur S

$$\begin{array}{ccc} & & X_a \\ & \overset{i}{\swarrow} & \\ X_0 & & \\ & \underset{j}{\nwarrow} & \\ & & X_b, \end{array}$$

où i, j sont les inclusions (qui sont des immersions fermées). Dire que $\mathcal{X} = \Phi(X)$ est propre sur S signifie aussi que ses restrictions au dessus des sous-catégories ouvertes $\{0, a\}$ et $\{0, b\}$ de S le sont (car toute flèche $\mathbf{\Delta}^1 \longrightarrow S$ se factorise par l'une ou l'autre). Cela signifie donc aussi que l'inclusion des fibres fermées [page 192]

$$X_a \longrightarrow X, \qquad X_b \longrightarrow X$$

sont coasphériques. Mais $X_a \longrightarrow X$ ne peut être coasphérique que si $X_b = \emptyset$, car pour $x \in X_b \subseteq X$, $x \backslash X_a$ (ainsi que X_a / x) est vide, donc *pas* W-asphérique (si on ne suppose $W = \mathrm{Fl}(\mathrm{Cat})$, cas que nous excluons). Donc $\Phi(X)$ n'est propre sur S *que* si X_a et $X_b = \emptyset$ (résultat valable pour *toute* X sur S, qu'elle soit cofibrée sur S ou W-propre, ou non). Si on veut $u, v \in W$, cela implique donc que $X_0 = \emptyset$, donc on a prouvé :

Commentary · Examples [ms. 190]

A branching base defeats one-sided completion

Grothendieck needs a counterexample which separates transport in one direction from transport in the other. A base with a terminal object hides this distinction: an opfibration over such a base has the homotopy type of its terminal fibre. The branching poset $S = (0 \to a,\ 0 \to b)$ removes that shortcut.

Take a pointed category (T, t), and form the split opfibration classified by

$$e \xrightarrow{t} T, \qquad e \xrightarrow{\mathrm{id}} e.$$

Its total category X has the objects of T, together with objects ξ_0 over 0 and ξ_b over b. The additional arrows are a single arrow $\xi_0 \to \xi_b$ and, for every $z \in T$, arrows $\xi_0 \to z$ indexed by

$\mathrm{Hom}_T(t,z)$. Composition with arrows of T is the evident one. There are no arrows from T to ξ_0 or ξ_b, and none from ξ_b to the other objects.

Let X'' be the full subcategory obtained by deleting ξ_b. There is a retraction $r : X \to X''$ which sends ξ_b to ξ_0 and the arrow $\xi_0 \to \xi_b$ to an identity. If $j : X'' \hookrightarrow X$ denotes the inclusion, then $rj = \mathrm{id}$ and there is a natural transformation $jr \Rightarrow \mathrm{id}_X$, equal to the identity on X'' and to $\xi_0 \to \xi_b$ at ξ_b. Naturality needs checking only on the new arrow, where both composites are that arrow. Thus j is a categorical homotopy equivalence and belongs to every localizer in use here.

There is a second retraction $r_a : X'' \to T$, sending ξ_0 to t and fixing T. In fact r_a is left adjoint to the inclusion $j_a : T \hookrightarrow X''$: the only nontrivial adjunction formula is

$$\mathrm{Hom}_T(r_a\xi_0, z) = \mathrm{Hom}_T(t,z) = \mathrm{Hom}_{X''}(\xi_0, j_a z).$$

Hence $T \to X'' \to X$ belongs to W. The fibre over b is nevertheless e. If $T \to e$ is not in W, the map $X_b \to X$ is not in W, by two-out-of-three. Since $\Phi(X)_0 \simeq X$ and $\Phi(X)_b \simeq e$, transport along $0 \to b$ in the completed fibration is not a W-equivalence. This proves that $\Phi(X)$ need not even be W-fibred, although $X \to S$ is an opfibration and hence proper.

For the ordinary weak-homotopy localizer, a completely finite choice is $T = \{t, t'\}$ discrete. Then X is the disjoint union of the three-object poset $\xi_b \leftarrow \xi_0 \to t$ and the isolated object t'. Its nerve has two contractible components, whereas X_b has one. No homology calculation or pushout theorem is required. For a general W, the argument requires a pointed T which is not W-aspherical; the nondegeneracy assumption $W \neq \mathrm{Fl}(\mathrm{Cat})$ alone should not be substituted for that requirement in this particular example.

The parenthetical pushout question has a positive answer under the suggested symmetric hypotheses. If $A \hookrightarrow B$ and $A \hookrightarrow C$ are both full sieves, their pushout P contains no arrows from $B \setminus A$ to $C \setminus A$, or conversely. Every composable chain lies in one side, so $NP = NB \cup_{NA} NC$. The nerve inclusions are monomorphisms, and this union is the homotopy pushout of the two inclusions. Equivalently one can check the canonical functor from the total category of $B \leftarrow A \to C$ by comma categories: for $p \in B \setminus A$, retract the copy of A/p lying on the C-side onto the middle copy. The resulting category has terminal object p on the B-side. The case $p \in C \setminus A$ is symmetric, and for $p \in A$ the comma category contracts to the three copies of p joined by a span. Theorem A therefore proves the comparison is in W. For two cosieves, apply the dual argument. The special example above is simpler still, since the explicit retractions determine the homotopy type for every allowed W.

p. 119

||| Soit $X \in \mathrm{Cat}/S$, $S = \begin{array}{ccc} & & a \\ 0 & \nearrow & \\ & \searrow & \\ & & b \end{array}$. Si $\Phi(X)$ est propre sur S, alors $X = \emptyset$ (si on suppose $W \neq \mathrm{Fl}(\mathrm{Cat})$).

Mais chemin faisant est apparue une idée bizarre. Considérons le diagramme infini, pour X dans Cat/S :

$$X \longrightarrow \Phi(X) \longrightarrow \Psi\Phi(X) \longrightarrow \Phi\Psi\Phi(X) \longrightarrow \cdots$$

Si X est quelconque, ces flèches sont alternativement dans W_S^{d} et W_S^{g}, donc leurs composées sont dans W_S sans plus. Mais si X est dans $\underline{\mathrm{Fib}}_W S$, comme cette catégorie est *stable* par Φ, Ψ, et que sur $\underline{\mathrm{Fib}}_W S$ $W_S^{\mathrm{d}} = W_S^{\mathrm{g}} = W_S^{\mathrm{f}} = W_S^{\mathrm{univ}}$, on voit que dans ce cas les flèches sont toutes dans W_S^{f}. On a envie maintenant de poser

$$\Phi_\infty(X) = \varinjlim \text{ de tout ça}$$

et on définirait symétriquement [page 193]

$$\Psi_\infty(X) = \varinjlim(X \longrightarrow \Psi(X) \longrightarrow \Phi\Psi(X) \longrightarrow \cdots).$$

Commentary · Development (commentators') [ms. 192]

The obstruction persists on any base with two maximal branches

Grothendieck strengthens the preceding counterexample: over the three-object branching poset, a single application of Φ cannot be proper unless the original category is empty. The obstruction lies in the absence of arrows between the two maximal branches. We can isolate that reason and extend the statement without introducing additional homotopical machinery.

Branching obstruction. [ours] Let S be a poset with a least element 0 and two distinct maximal elements a, b. Let W be a localizer satisfying the standing axioms and suppose that $\varnothing \to e$ does not belong to W. For every $X \to S$, if $\Phi_S(X) \to S$ is W-proper, then $X = \varnothing$.

Proof. The fibre diagram of $\Phi_S(X)$ is $s \mapsto s\backslash X$. Since 0 is least, $0\backslash X$ identifies with X. Since a and b are maximal, $a\backslash X = X_a$ and $b\backslash X = X_b$. The two transport functors to the fibre at 0 are therefore the inclusions $X_a \hookrightarrow X$ and $X_b \hookrightarrow X$.

Properness forces each of these inclusions to be coaspherical. Here is the precise test being used. Pull the fibration back along the arrow $0 \to a$. For an object x of its fibre over 0, the category of arrows from x to the fibre over a is the comma category $x\backslash X_a$. Properness requires it to be W-aspherical. This is the elementary lifting-category criterion for properness, applied to this one arrow; the same statement holds for b.

If $x \in X$ existed, the category $x\backslash X_a$ would be W-aspherical and hence nonempty. Choose one of its objects, an arrow $x \to x_a$ with $x_a \in X_a$. Properness along $0 \to b$, applied now to the object x_a of X, would require $x_a\backslash X_b$ to be W-aspherical. But this category is empty: an arrow $x_a \to x_b$ would project to an arrow $a \to b$, impossible for distinct maximal elements of a poset. This contradicts the hypothesis on the empty category. Thus X has no objects. Conversely, the empty category over S is proper, since all the lifting tests with a specified source object are vacuous. □

For the standing localizers, the nondegeneracy condition in the text implies the displayed hypothesis on $\varnothing \to e$. Indeed, if $\varnothing \to e$ were in W, product stability would put $\varnothing \to A$ in W for every category A. Two-out-of-three would then put every functor in W.

This proof also fills the final step in the boxed assertion on manuscript p. 192. Showing that $X_a = X_b = \varnothing$ is not yet, by itself, a proof that $X_0 = \varnothing$ for an arbitrary $X \to S$. One must use coasphericity once more: $\varnothing \to X$ cannot be coaspherical when X has an object. The argument above incorporates this step directly. The preceding contravariant diagram prints X_0 at its centre; its mathematical value is $X = 0\backslash X$, as both the following inclusions and the proof require. That printed slip is retained in the source and recorded in the correction ledger.

We checked the lifting criteria in Maltsiniotis (2005, Proposition 4.3, Theorem 4.13, and Example 4.17); we did not find this particular branching formulation there. The proposition is an elementary extension of the present manuscript argument, with no claim of priority.

Pour que ce soit utilisable, il faut poser l'axiome W(6 bis) (comparer XII, pages 14, 15). La limite inductive d'une suite de morphismes $f_i : X_i \longrightarrow Y_i$, pour un morphisme de systèmes inductifs dans Cat indexés par $\mathbf{N}$, est dans W si les f_i le sont.

Cet axiome est voisin de W(6) de loc. cit., mais n'est impliqué par lui que moyennant W(4b). Il est plus fort dans le cas de systèmes inductifs indexés par $\mathbf{N}$ (donc aussi, plus généralement, de systèmes inductifs sur des ensembles ordonnés filtrants ayant un ensemble cofinal dénombrable), mais ne dit rien sur les systèmes inductifs sur des ensembles ordonnés d'indices plus généraux.

Cet axiome implique aussi qu'une limite inductive filtrante de morphismes f_i est W-lisse, resp. W-propre, si les f_i le sont. On trouve alors que $\Phi_\infty(X)$ est à la fois W-lisse (comme limite inductive des $\Phi(X)$, $\Phi\Psi\Phi(X)$, …, $\Phi(\Psi\Phi)^n(X)$, lesquelles sont W-lisses sur S) et W-propre (comme limite inductive des $\Psi\Phi(X)$, …, $(\Psi\Phi)^n(X)$ …). D'autre part, que $X \longrightarrow \Phi_\infty(X)$ est dans W_S^{f} - car W_S^{f} est stable par limites inductives filtrantes dénombrables dans Cat/S. On a donc trouvé un foncteur [page 194]

$$\Phi_\infty : \underline{\mathrm{Fib}}_W S \longrightarrow \underline{\mathrm{Parf}}_W S \subseteq \underline{\mathrm{Fib}}_W S$$

et un morphisme fonctoriel

$$i_X : X \longrightarrow \Phi_\infty(X), \qquad \boxed{i_X \in W_S^{\mathrm{f}}} \qquad \text{si } X \in \underline{\mathrm{Fib}}_W S.$$

Ce foncteur permet alors, en l'absence de W(4b), de faire ce que le foncteur C refusait absolument. Il est vrai que C a l'avantage d'être défini sur Cat/S tout entier, et d'y être raisonnable et même fort utile, quand on a W(4b). Mais Φ_∞ est, lui aussi, défini sur Cat/S tout entier, ainsi que i_X p. 120

$$\Phi_\infty : \mathrm{Cat}/S \longrightarrow \underline{\mathrm{Parf}}_W S$$
$$i : \mathrm{id} \longrightarrow \Phi_\infty \qquad \text{i.e.} \begin{cases} i_X : X \longrightarrow \Phi_\infty(X) \\ i_X \in W_S, \end{cases}$$

avec le seul handicap (inévitable) que si X n'est pas dans $\underline{\mathrm{Fib}}_W S$, on ne peut dire mieux que $i_X \in W_S$, à l'exclusion de $i_X \in W_S^{\mathrm{f}}$. Mais pour $C(X)$ c'était forcément pareil. Donc on a l'impression que Φ_∞, au choix, Ψ_∞, bonnet blanc, blanc bonnet, joue en présence de W(6 bis) le même rôle que C en présence de W(4b). Tout au plus (en présence des deux axiomes à la fois) le foncteur C a-t-il l'avantage esthétique de prendre ses valeurs dans $\underline{\mathrm{Parf}}_\omega S$, au lieu de $\underline{\mathrm{Parf}}_W S$ seulement ([93]). Mais il s'impose de se rendre compte à présent que Φ_∞ a un [page 195] avantage exactement du même ordre sur C, en introduisant

$$W''_\omega = \text{plus petite partie } \Sigma \text{ de } \mathrm{Fl}(\mathrm{Cat}) \text{ satisfaisant } \mathrm{W}(1, 2 \text{ bis}, 3, 6 \text{ bis})$$

et noter que

$$\Phi_\infty(X) \in \mathrm{Ob}\, \underline{\mathrm{Parf}}_{W''_\omega} S, \qquad i_x \in W''_\omega$$

- mais là je m'aperçois qu'on a

$$W_\omega \subseteq W''_\omega,$$

donc C est quand même un peu meilleur à cet égard …

Commentary · Exposition [ms. 194]

Why alternating completion works at the limit

The failure of one-sided completion suggests Grothendieck's next move. Instead of asking Φ to preserve properness, he restores properness with Ψ, then restores smoothness with Φ, and continues. No finite stage has to possess both properties. At the limit, the odd and even stages are cofinal and can establish the two properties separately.

Put $X_0 = X$, $X_1 = \Phi X$, $X_2 = \Psi\Phi X$, and continue alternately, with the canonical unit at each step. Let $RX = \varinjlim_n X_n$. W(6 bis) means that an objectwise W-equivalence between two sequential diagrams induces a W-equivalence on their ordinary colimits in Cat. Its quantifier is sequential. The unqualified words "limite inductive filtrante" in the next paragraph must be read with this restriction; an arbitrary filtered indexing category is not covered by the axiom as written.

The passage from this axiom to smoothness and properness of $RX \to S$ can be made explicit by the lifting-category criterion. For a functor $p : E \to S$, a base arrow $u : s \to t$, and $y \in E_t$, let $L_p(u, y)$ have objects arrows $v : x \to y$ with $p(v) = u$ and morphisms commuting triangles whose arrow between sources lies over id_s. Smoothness is equivalent to $L_p(u, y)$ being W-aspherical for every u, y. Properness is the dual condition on arrows with a specified source. These are the familiar fibre categories of $E/y \to S/t$ and their duals.

Suppose first that $E = \varinjlim_n E_n$ over the fixed base S, with every $E_n \to S$ smooth. An object y of E is represented by $y_n \in E_n$ at some stage. After restricting to that tail of the sequence, there is a canonical isomorphism

$$L_p(u, y) \simeq \varinjlim_{m \geq n} L_{p_m}(u, y_m).$$

To verify it, represent an arrow to y at a sufficiently late stage; its image in S is already the required fixed arrow u. A morphism of the lifting category is represented by one further arrow and one equality of composites, and that equality holds at a later stage. The same argument detects equality of two such morphisms. Thus the displayed functor is bijective on objects and arrows after taking

93. *En fait* $\Phi_\infty = C$, si C est défini via des chemins infinis d'un seul côté simplement. Si on définit C via les chemins *finis* de tous types c, alors il prend en effet ses valeurs dans $\underline{\mathrm{Parf}}_\omega S$.

the colimit. Every stage maps to e by a member of W, so W(6 bis) makes the colimit W-aspherical. This proves sequential stability of smoothness. Reversing arrows proves stability of properness.

Now the odd subsequence $X_1, X_3, \dots$ consists of smooth categories over S, and the even subsequence $X_2, X_4, \dots$ consists of proper ones. Both have colimit RX, because each is cofinal in the original sequence. Hence RX is W-perfect. Every transition $X_n \to X_{n+1}$ belongs to W_S, so every composite $X \to X_n$ does. Apply W(6 bis) to the natural transformation from the constant sequence at X to (X_n): its colimit is $X \to RX$, proving that this map lies in W_S for arbitrary X.

When X is W-fibred, all stages remain W-fibred and the transitions are fibrewise W-equivalences. Fibres over a fixed s commute with these colimits: their objects and arrows are defined by fixed equations in S, and any equality in a filtered colimit is witnessed at a later stage. Applying W(6 bis) in each fibre yields

$$X_s \longrightarrow (RX)_s \quad \text{in } W \qquad \text{for every } s \in S.$$

Thus the same construction supplies both kinds of unit advertised in the text: a total equivalence for arbitrary objects and a fine equivalence for fibred objects. It is the latter statement that was missing for the earlier proposed perfect-object replacement. Nothing in this argument asserts that $RX \to S$ is a Grothendieck bifibration: a sequential colimit of lifting categories known to be aspherical does not supply actual universal lifts.

Quand on dispose de Φ_∞ avec les propriétés qu'on vient d'expliciter, on trouve que l'inclusion

$$\underline{\mathrm{Parf}}_W S \longrightarrow \underline{\mathrm{Fib}}_W(S)$$

induit une équivalence non seulement pour les localisés pour W_S, mais aussi pour les localisés fins

$$(\underline{\mathrm{Parf}}_W S)(W_S^{\mathrm{f}})^{-1} \longrightarrow (\underline{\mathrm{Fib}}_W(S))(W_S^{\mathrm{f}})^{-1} \overset{\text{déf}}{=} \mathrm{HOT}^{\mathrm{lc}}_W(S)$$

([94]). Mais on ne peut pour autant réduire le nombre des localisés utiles à trois, en l'absence de W(4b). Tout au plus, ayant un foncteur Φ_∞ qui est plus simple que C, en l'absence de W(4b), du fait qu'on sait de toutes façons que

$$i_X : X \longrightarrow \Phi_\infty(X)$$

est dans W_S^{f} si X est dans $\underline{\mathrm{Fib}}_W S$, peut on espérer s'en tirer avec la variante affaiblie de W(4b) obtenue en se bornant dans l'énoncé de W(4b) (p. 171) au cas où X, Y sont dans $\underline{\mathrm{Parf}}_{W''_\omega} S$. Cette fois, ça suffit en effet à impliquer que le foncteur p. 121 [page 196]

$$\lambda : (\underline{\mathrm{Fib}}_W S)(W_S^{\mathrm{f}})^{-1} \longrightarrow (\underline{\mathrm{Fib}}_W S)(W_S)^{-1}$$

est une équivalence de catégories, puisque on peut le 'calculer' aussi bien en utilisant $\underline{\mathrm{Parf}}_{W''_\omega} S$ au lieu de $\underline{\mathrm{Fib}}_W S$, or l'hypothèse W(4b($\mathrm{W}''_\omega$)) implique que sur $\underline{\mathrm{Parf}}_{W''_\omega} S$ les deux localiseurs W_S^{f}, W_S sont *égaux.*

Commentary · Exposition [ms. 195]

Fine replacement gives an equivalence of localizations

Grothendieck can now return to the question on manuscript p. 186 with an actual construction in hand. The essential point is stronger than the existence of a perfect object with the right total homotopy type: for a fibred input, the comparison is an equivalence in every fibre. This is what allows the replacement to control morphisms as well as objects.

Today W(6 bis) is automatic: every basic localizer is closed under filtered colimits (Cisinski, 2006a, Corollary 4.2.22). This applies to the standing relative W(1, 2, 3), without accessibility; we do not extend it here to arbitrary weak basic localizers.

94. On peut y remplacer même $\underline{\mathrm{Parf}}_W S$ par $\underline{\mathrm{Parf}}_{W''_\omega} S$, *ou* par toute autre sous-catégorie pleine de $\underline{\mathrm{Fib}}_W S$ contenant $\underline{\mathrm{Parf}}_{W''_\omega} S$.

Let $R = \Phi_\infty$, let $\mathcal{F} = \underline{\mathrm{Fib}}_W S$, and let $\mathcal{P} = \underline{\mathrm{Parf}}_W S$. Under W(6 bis), the unit $\eta_X : X \to RX$ is fine for every $X \in \mathcal{F}$. The functor R preserves fine equivalences on $\mathcal{F}$. Indeed, if $u : X \to Y$ is fine, then in each fibre the equality

$$(Ru)_s(\eta_X)_s = (\eta_Y)_s u_s$$

and two-out-of-three show that $(Ru)_s$ lies in W. Thus both the inclusion $J : \mathcal{P} \hookrightarrow \mathcal{F}$ and R induce functors after fine localization. The units give natural isomorphisms

$$\mathrm{id} \xrightarrow{\sim} \overline{J}\,\overline{R} \quad \text{on } \mathcal{F}[(W_S^{\mathrm{f}})^{-1}], \qquad \mathrm{id} \xrightarrow{\sim} \overline{R}\,\overline{J} \quad \text{on } \mathcal{P}[(W_S^{\mathrm{f}})^{-1}].$$

For the second assertion, both endpoints of the unit belong to $\mathcal{P}$, and the subcategory is full. These two natural isomorphisms prove that the induced functors are quasi-inverse equivalences. In particular, full faithfulness is part of the result; there is no separate assumption about roofs or a calculus of fractions.

The same proof works with any full intermediate subcategory containing the image of R. The more precise claim in footnote 94 follows because the construction already lands in $\underline{\mathrm{Parf}}_{W''_\omega} S$. One must keep the two minimal classes distinct at this stage of the manuscript. The inclusion $W_\omega \subseteq W''_\omega$ does not, on its own, put the output in $\underline{\mathrm{Parf}}_\omega S$. It puts it in the class named in the footnote.

The minimality comparison above does, however, allow us to settle the stronger annotation in footnote 89. It identifies W_ω with the nerve weak-homotopy equivalences W_∞. This class is stable under sequential colimits. Indeed, the nerve commutes with filtered colimits because each finite ordinal category $[n]$ is finitely presented. Weak equivalences of simplicial sets are stable under such colimits: apply Ex^∞, which commutes with them since every subdivided simplex is finite; a filtered colimit of Kan complexes is Kan, and maps and homotopies from finite simplicial spheres are witnessed at finite stages, giving the required isomorphisms on all homotopy groups and on components. Thus W_∞ satisfies W(6 bis). Minimality gives

$$W_\omega \subseteq W''_\omega \subseteq W_\infty = W_\omega.$$

Consequently the replacement can indeed be taken in $\underline{\mathrm{Parf}}_\omega S$, with the fine unit just proved. This conclusion uses the modern identification of the minimal class; it was not a consequence of the single inclusion written on manuscript p. 195.

The original restricted W(4b′) now suffices as well. Given a total W-equivalence $u : X \to Y$ between weakly fibred objects, naturality of the unit makes Ru a total W-equivalence between $\underline{\mathrm{Parf}}_\omega$-objects. The restricted hypothesis makes Ru fine, and the two fine units then make u fine by two-out-of-three in each fibre. This proves full W(4b), and therefore the fine-to-coarse comparison. It explains precisely how the historical retraction acquires a positive answer once the later colimit and minimality theorems are available.

This replacement equivalence still does not identify the fine and coarse localizations. It allows either of them to be computed on a smaller category; it does not say that the two classes of denominators agree there. That remaining assertion is exactly the restricted W(4b) hypothesis in the following proposition. Grothendieck's distinction between replacing objects and comparing equivalences is therefore preserved even after the successful infinite construction.

Il faut une conclusion pratique utilisable de toutes ces perplexités et observations. Essayons

Proposition. *Supposons que l'on soit sous l'une des conditions suivantes.*

1°) *L'axiome* W(4b) *est satisfait dans le cas de catégories X, Y qui sont dans* $\underline{\mathrm{Fibsc}}_{0,W} S$ ([95]) *(cette condition sur W est en fait autoduale).*

2°) *L'axiome* W(4b) *est satisfait dans le cas de catégories X, Y qui sont dans* $\underline{\mathrm{Parf}}_{W''_\omega} S$*, où W''_ω est le plus petit ensemble $\Sigma \subseteq Fl(\mathrm{Cat})$ satisfaisant les conditions* W(1, 2 bis, 3, 6 bis). *(On peut aussi se contenter de la condition, plus forte mais plus compréhensible, que* W(4b) *est OK si X, Y sont dans* $\underline{\mathrm{Parf}}_W S$ ([96])*.) De plus, on suppose que W satisfait* W(6 bis).

95. mais c'est *équivalent* à W(4b)! Cf. XVI 4.9. loc. cit.

96. Mais cela implique aussi W(4b), cf. loc. cit.

Sous ces conditions, le foncteur correspondant [?] λ

$$\mathrm{HOT}^{\mathrm{lc}}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc!}}_W(S)$$

est une équivalence de catégories (cf. diagramme p. 178), donc (ρ, i), (σ, j) *peuvent être regardés comme des couples de foncteurs entre deux catégories (cf.* $(*)$ *p. 181).* Ce sont des couples de foncteurs adjoints, *donc* i, j *sont pleinement fidèles, et on a la formule d'adjonction* $(*)$*, page 182.*

Pour prouver l'adjonction de (ρ, i) (ou dualement de (σ, j)), on exprime encore les deux catégories en présence $\mathrm{HOT}_W(S)$, $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ comme $(\mathrm{Cat}/S)(W^{\mathrm{d}}_S)^{-1}$, $(\mathrm{Cat}/S)(W_S)^{-1}$, le foncteur ρ étant la localisation canonique allant du premier vers le second, et le foncteur i étant donné par un foncteur d'inversion [page 197]

$$\gamma : (\mathrm{Cat}/S, W_S) \longrightarrow (\mathrm{Cat}/S, \overline{W^{\mathrm{d}}_S})$$

qui est C dans le cas 1°, Φ_∞ dans le cas 2°. Les morphismes d'adjonction

$$\rho i \longrightarrow \mathrm{id}, \qquad i\rho \longleftarrow \mathrm{id}$$

doivent se décrire alors comme dans le cas où on suppose tout bonnement W(4b), et les compatibilités se voient de même : on est ramené à prouver que deux flèches p. 122

$$\gamma(X) \underset{\gamma(i_X)}{\overset{i_{\gamma(X)}}{\rightrightarrows}} \gamma(\gamma(X))$$

sont égales dans $(\mathrm{Cat}/S)(W^{\mathrm{d}}_S)^{-1}$. La vérification dans le cas 1°), où $\gamma = C$, ne doit pas être changée. Dans le cas 2°) où $\gamma = \Phi_\infty$, je ne l'ai pas fait. Je ne le ferai que sous la pression des besoins.

⑥ Loi contravariante de $\mathrm{HOT}_W(S)$, $\mathrm{HOT}^{\mathrm{lc}}_W(S)$.

Il y a pour

$$f : S' \longrightarrow S$$

un homomorphisme du diagramme

$$\begin{array}{ccc} \mathrm{HOT}^{\mathrm{lc}}_W(S') & & \\ \swarrow \quad \searrow & & \\ \mathrm{HOT}_W(S') & & \mathrm{HOT}^{o}_W(S') \end{array} \qquad \texttt{[Plutôt} \qquad \begin{array}{ccc} \mathrm{HOT}^{\mathrm{lc}}_W(S) & & \\ \swarrow \quad \searrow & & \\ \mathrm{HOT}_W(S) & & \mathrm{HOT}^{o}_W(S) \texttt{]} \end{array}$$

dans le diagramme similaire pour S `[plutôt` S'`]`, par des foncteurs f^* qui sont définis respectivement sur [page 198]

$$\begin{array}{rcccc} \underline{\mathrm{Liss}}_W S & \text{pour} & \mathrm{HOT}_W(S) & \longrightarrow & \mathrm{HOT}_W(S') \\ \underline{\mathrm{Prop}}_W S & \text{pour} & \mathrm{HOT}^{o}_W(S) & \longrightarrow & \mathrm{HOT}^{o}_W(S') \\ \underline{\mathrm{Fib}}_W S & \text{pour} & \mathrm{HOT}^{\mathrm{lc}}_W(S) & \longrightarrow & \mathrm{HOT}^{\mathrm{lc}}_W(S'), \end{array}$$

par l'intermédiaire des foncteurs

$$f^* : X \longmapsto X \times_S S' : \begin{cases} \underline{\mathrm{Liss}}_W S & \longrightarrow & \underline{\mathrm{Liss}}_W S' \\ \underline{\mathrm{Prop}}_W S & \longrightarrow & \underline{\mathrm{Prop}}_W S' \\ \underline{\mathrm{Fib}}_W S & \longrightarrow & \underline{\mathrm{Fib}}_W S', \end{cases}$$

lequel foncteur est compatible avec les localiseurs pretinents, qui sont W^{f}_S dans tous les cas. Par contre, en l'absence d'hypothèses draconiennes sur W ou sur S, on ne peut dire que

f^* soit compatible avec W_S, $W_{S'}$ sur une quelconque des catégories du diagramme p. 175, permettant de définir $\mathrm{HOT}^{\mathrm{lc!}}_W(S)$, de façon à nous donner un foncteur

$$\mathrm{HOT}^{\mathrm{lc!}}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc!}}_W(S').$$

En l'absence d'axiomes sur W, le seul cas qui me soit connu est celui où f est *une W-équivalence universelle,* i.e. une W-fibration à fibres W-asphériques, auquel cas il est évident que pour *toute* flèche $u : X \longrightarrow Y$ dans Cat/S, $u \in W_S$ si et seulement si $(u' : X' \longrightarrow Y') \in W_{S'}$. On trouve alors un homomorphisme du diagramme complet $(*)$ p. 176 `[plutôt p. 178]` pour S, dans le diagramme correspondant pour S'.

Commentary · Exposition [ms. 197]

Completing the omitted compatibility of the two units

Grothendieck has proved enough to compare the localizations, but deliberately leaves the triangle check for Φ_∞ unfinished. There is a short way to complete it which uses the fine replacement already constructed. It also explains the later annotation that the proposed weakened hypotheses recover the full fibre-detection axiom.

First consider any S-map $u : X \to Y$ between W-fibred categories, with $u \in W$. Under condition 1°, put $R = \Phi$; under condition 2°, put $R = \Phi_\infty$. In either case η_X and η_Y are fine equivalences. Naturality and two-out-of-three show $Ru \in W$. In the first case RX, RY are split fibrations with W-equivalent transports; in the second they lie in $\underline{\mathrm{Parf}}_{W''_\omega} S$. The restricted fibre-detection hypothesis therefore gives $Ru \in W^{\mathrm{f}}_S$. Applying two-out-of-three in each fibre to

$$(Ru)_s(\eta_X)_s = (\eta_Y)_s u_s$$

gives $u_s \in W$. Thus each displayed hypothesis implies W(4b) itself. In the first case, it is enough to impose the test only on Cartesian maps, since $\Phi(u)$ is Cartesian. This is the replacement argument formalized later in Grothendieck (1991b, Lemma 4.4.9 and Corollary 4.4.10); the calculation here uses only the constructions already present in Chapter VI.

Under condition 1°, the established reflector C already proves the proposition. We now work under condition 2°, retaining W(6 bis), and compare $R = \Phi_\infty$ with C. Write $\alpha_X : X \to CX$ for the unit of C. Work in $\mathcal{H}_d(S)$, where the established reflection gives $C \simeq i\rho$. Let $R = \Phi_\infty$ and retain $\eta_X : X \to RX$ for its unit. The object RX is W-fibred, so α_{RX} is an isomorphism in $\mathcal{H}_d(S)$. Also $\eta_X \in W_S$, hence $C(\eta_X)$ is right-fine under W(4b). We therefore have a natural isomorphism

$$\theta_X = (\alpha_{RX})^{-1} C(\eta_X) : CX \xrightarrow{\sim} RX.$$

Naturality of α gives the exact identity

$$C(\eta_X)\alpha_X = \alpha_{RX}\eta_X, \qquad \text{hence} \qquad \theta_X \alpha_X = \eta_X.$$

Thus R represents the same reflection, with its given unit. This is stronger than an unspecified isomorphism between the two endofunctors: it identifies the units, which are what determine the adjunction.

It remains to extract the equality Grothendieck asks for. Since R^2X is a local object, the universal property of the reflection says that precomposition by η_X is a bijection

$$\mathrm{Hom}_{\mathcal{H}_d(S)}(RX, R^2X) \xrightarrow{\sim} \mathrm{Hom}_{\mathcal{H}_d(S)}(X, R^2X).$$

The two maps η_{RX} and $R(\eta_X)$ have the same image under this bijection, because naturality of η gives

$$\eta_{RX}\eta_X = R(\eta_X)\eta_X.$$

Therefore $\eta_{RX} = R(\eta_X)$ in $\mathcal{H}_d(S)$, as required. Both maps are isomorphisms: the first because RX is fibred, the second because R sends coarse equivalences to fine ones after the fibre-detection argument. Inverting this common map supplies the multiplication of the idempotent reflector, and the triangle identities follow.

The missing verification is consequently a genuine omission in the written proof, but no additional axiom is needed to repair it. The repair is not the generally invalid cancellation of η_X from an equality of composites; η_X need not be invertible in the lateral category. Cancellation is justified here by its proven universal property against the local target R^2X.

Si on suppose W(4b), alors $W_S = W_S^{\mathrm{f}}$ sur $\underline{\mathrm{Fib}}_W S$, donc sur cette catégorie-là le foncteur f^* est compatible (sans mérite!) avec les localiseurs W_S, $W_{S'}$, mais ce n'est pas nouveau vraiment par rapport à ce qui a été dit plus haut, pour $\underline{\mathrm{Fib}}_W S$, $\underline{\mathrm{Fib}}_W S'$, et pour les $\mathrm{HOT}_W^{\mathrm{lc}}$. p. 123

Mais si on suppose W(4a), et $f \in \underline{\mathrm{Fib}}_W$, alors f^* sur Cat/S tout entier est compatible [page 199] avec les localiseurs W_S, $W_{S'}$, et on trouve un calcul de f^* sur $\mathrm{HOT}_W^{\mathrm{lc!}}(S) \approx \mathrm{HOT}_W^{\mathrm{lc}}(S)$ par

$$f^*(\mathrm{hot}_{S,W}^{\mathrm{lc}}(X)) = \mathrm{hot}_{S',W}^{\mathrm{lc}}(X \times_S S').$$

Donc c'est là un cas, exceptionellement, où les foncteurs f^* pour les HOT_W sont compatibles non seulement aux foncteurs d'inclusion i, j (de la page 176 [plutôt p. 178]), mais aussi aux foncteurs de localisation ρ, σ.

Oubli : Si $p : S' \longrightarrow S$ est W-propre, alors $p^* : \mathrm{Cat}/S \longrightarrow \mathrm{Cat}/S'$ est compatible avec W_S^{d}, $W_{S'}^{\mathrm{d}}$, et $p^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S')$ peut se 'calculer' par la formule

$$p^*(\mathrm{hot}_{S,W}(X)) = \mathrm{hot}_{S',W}(X \times_S S')$$

pour *tout* X dans Cat/S.

⑦ Produit dans $\mathrm{HOT}_W(S)$.

Le foncteur

$$(X, Y) \longmapsto X \times_S Y : \underline{\mathrm{Liss}}_W S \times \underline{\mathrm{Liss}}_W S \longrightarrow \underline{\mathrm{Liss}}_W S$$

est compatible avec les localiseurs $W_S^{\mathrm{f}} \times W_S^{\mathrm{f}}$ et W_S^{f}, donc passe aux localisés en

$$\begin{cases} \mathrm{HOT}_W(S) \times \mathrm{HOT}_W(S) & \longrightarrow & \mathrm{HOT}_W(S) \\ (\xi, \eta) & \longmapsto & \xi \times_S \eta \end{cases}$$

([97]). Ce produit est associatif, unitaire, commute avec toutes les compatibilités habituelles, comme il résulte du fait que c'est comme ça dans $\underline{\mathrm{Liss}}_S$. L'élément unité est la classe de $S \xrightarrow{\mathrm{id}} S$. La sous-catégorie $\mathrm{HOT}_W^{\mathrm{lc}}(S)$ est stable par le produit, qui induit [page 200]

$$\mathrm{HOT}_W^{\mathrm{lc}}(S) \times \mathrm{HOT}_W^{\mathrm{lc}}(S) \longrightarrow \mathrm{HOT}_W^{\mathrm{lc}}(S),$$

lui-même induit par le foncteur produit $(X, Y) \longrightarrow X \times_S Y$ dans $\underline{\mathrm{Fib}}_W S$.

Commentary · Exposition [ms. 199]

Restriction depends on the chosen equivalences

Grothendieck's three inverse-image functors are built from the same categorical pullback, but they are defined on different useful representatives. This is why the functorial diagram is more informative than an undifferentiated assertion that pullback preserves weak equivalences.

For a smooth representative $X \to S$, its pullback along $f : S' \to S$ is again smooth, and fibrewise equivalences remain fibrewise equivalences. Since fine and right-fine equivalences agree on smooth objects, this constructs f^* on HOT_W. The dual argument uses proper representatives for $\mathrm{HOT}_W^{\mathrm{o}}$. On $\underline{\mathrm{Fib}}_W S$, the same pullback preserves the class of objects and the fine equivalences, and therefore constructs f^* on $\mathrm{HOT}_W^{\mathrm{lc}}$. In each case the composition and identity constraints are those of categorical pullback, passed through localization. Their coherence is inherited from the coherent pullback identifications before localization.

For the coarse localization, this argument is unavailable until total equivalences are controlled. If f is universally in W, every projection $X \times_S S' \to X$ belongs to W. Given $u : X \to Y$, the natural square with these projections proves

$$u \in W \quad \Longleftrightarrow \quad u \times_S S' \in W$$

97. **NB** Si X, Y sont *quelconques* dans Cat/S, on a $\mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y) = \mathrm{hot}_{S,W}(\Phi_S(X) \times_S \Phi_S(Y))$. Si X ou Y est lisse sur S, on peut y remplacer $\Phi(X)$ resp. $\Phi(Y)$ par X resp. Y.

by two-out-of-three. This proves both preservation and reflection of total equivalences; no good-representative restriction is needed. Under W(4a), the same preservation statement holds when f is W-fibred, by the defining universal preservation property of that axiom. It then computes the coarse restriction directly on every $X \to S$.

There is a second, differently placed improvement. If $p : S' \to S$ is proper, pullback preserves right-fine equivalences on all of Cat/S. The displayed formula for p^* on an arbitrary representative is therefore legitimate. The condition is on the map changing the base, whereas the first construction required smoothness of the object being pulled back. Either condition can make the ordinary pullback compute the desired derived inverse image, but the two arguments test different arrows.

These distinctions also explain the compatibility claims. Restriction on fine representatives commutes with the inclusions of locally constant objects into the lateral theories. Commutation with the coarse localization requires preservation of the coarse denominators, and therefore the extra hypotheses just discussed. A diagram of functors cannot be promoted from one assertion to the other merely because the object formulas look identical.

Si X est quelconque dans Cat/S, le foncteur

$$\mathrm{mult}_{X/S} : Y \longmapsto X \times_S Y : \underline{\mathrm{Liss}}_W S \longrightarrow \mathrm{Cat}/S$$

est compatible avec les localiseurs W_S^{d}, car ce foncteur peut s'écrire comme le composé du foncteur correspondent *à valeurs dans* $\underline{\mathrm{Liss}}_W X$, lequel est compatible avec les localiseurs W_S^{d}, W_S^{d}, et le foncteur 'oubli de X' de $\underline{\mathrm{Liss}}_W X$ (même de Cat/X) dans Cat/S, lequel est compatible avec W_X^{d} et W_S^{d}. On trouve ainsi un foncteur p. 124

$$\begin{cases} \mathrm{mult}_{X/S} : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S) \\ \mathrm{mult}_{X/S}(\mathrm{hot}_{S,W}(Y)) \overset{\text{déf}}{=} \mathrm{hot}_{S,W}(X \times_S Y) \qquad \text{si } Y \textit{ lisse} \text{ sur } S \end{cases}$$

([98]), puisque $\mathrm{HOT}_W(S)$ peut s'obtenir comme localisé tant de $\underline{\mathrm{Liss}}_W S$ que de Cat/S, pour W_S^{d}. Quand X est lui-même W-lisse sur S, ce foncteur n'est autre que

$$\begin{cases} \mathrm{mult}_\xi : \eta \longmapsto \xi \times_S \eta, \\ \text{où} \quad \xi = \mathrm{hot}_{S,W}(X). \end{cases}$$

Mais il n'en est pas de même si X n'est pas lisse, i.e. il faut distinguer dans ce cas, même pour Y W-lisse sur S,

$$\mathrm{hot}_{S,W}(X \times_S Y) \qquad \text{et} \qquad \mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y).$$

Le deuxième terme peut s'expliciter comme $\mathrm{hot}_{S,W}(\Phi(X) \times_S Y)$ qui reçoit $\mathrm{hot}_{S,W}(X \times_S Y)$, i.e. on a un homomorphisme canonique [page 201]

$$\underbrace{\mathrm{hot}_{S,W}(X \times_S Y)}_{=\mathrm{mult}_{X/S}(Y)} \longrightarrow \underbrace{\mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y)}_{=\mathrm{hot}_{S,W}(\Phi(X) \times_S Y)},$$

induit par

$$X \times_S Y \longrightarrow \Phi(X) \times_S Y,$$

mais cette dernière flèche n'a aucune raison d'être dans W_S^{d}, et n'induit donc pas nécessairement un isomorphisme dans $\mathrm{HOT}_W(S)$. (Contrexemple page 154.)

98. Cette formule est également valable si Y est dans $\underline{\mathrm{Fib}}_W S$, cf. (∗), p. 202.

Commentary · Exposition [ms. 200]

Multiplication by a category over the base

Grothendieck introduces $\mathrm{mult}_{X/S}$ because an arbitrary category over the base still acts on relative homotopy types, even when its strict fibre product does not compute the internal product. The action remembers the map $X \to S$ before replacement.

Let $p : X \to S$. For a smooth representative $Y \to S$, pullback computes $p^*[Y]$ as $[X \times_S Y]$ over X. Postcomposition then gives

$$\mathrm{mult}_{X/S} = p_! p^*.$$

This identity already explains why the functor is well defined for arbitrary X: the right-fine equivalences are respected in the two stages where Grothendieck factors the construction. The repeated W_S^{d} at the start of printed p. 124 is a source slip; the pullback stage has source class W_S^{d} and target class W_X^{d}.

By contrast, the internal product is obtained by replacing both factors by smooth categories:

$$[X] \times_S [Y] = [\Phi X \times_S \Phi Y].$$

The map $X \to \Phi X$ induces a comparison from the action to multiplication by $[X]$. For smooth Y, it is represented by $X \times_S Y \to \Phi X \times_S Y$. Its failure to be right-fine in general is the counterexample already analyzed on manuscript pp. 153–156; there is no need to repeat it here. What changes in the present discussion is the proposed hypothesis that X is W-fibred.

The argument given on pp. 201–202 correctly proves the action formula when X is fibred. Indeed the unit $X \to \Phi X$ is fine; after arbitrary base change to Y it is fine between W-fibred objects over Y, hence right-fine there. Forgetting the intermediate base preserves right-fine equivalences. This proves that the action of Y/S on $[X]$ can be computed by the strict fibre product even for arbitrary Y.

There remains an apparent asymmetry: identifying that value with $[X] \times_S [Y]$ also requires replacing Y. Grothendieck proves this when X is proper and suspects that the extra condition is necessary. The next development supplies the missing comparison for a W-fibred X by using the transports in its split-fibration replacement. The argument will identify the canonical comparison map itself, so it also gives the natural compatibility needed for products and inverse images.

Il faut regarder à part le cas *où X est dans* $\underline{\mathrm{Fib}}_W S$, j'ai envie de dire que dans ce cas on a

$$(*) \qquad \mathrm{hot}_{S,W}(X \times_S Y) \xrightarrow{\sim} \underbrace{\mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y)}_{= \mathrm{hot}_{S,W}(\Phi(X) \times_S \Phi(Y))}$$

([99]) pour *tout* Y dans Cat/S (pas nécessairement W-lisse), a fortiori que dans ce cas

$$(**) \qquad \begin{cases} \mathrm{mult}_{X/S} = \mathrm{mult}_\xi & \text{dans } \mathrm{HOT}_W(S) \\ \text{où } \xi = \mathrm{hot}_{S/W}(X/S) \text{ (si } X \text{ dans } \underline{\mathrm{Fib}}_W S). \end{cases}$$

Dans le cas où Y est lisse sur S (ce qui suffit pour établir $(**)$), il suffit de se rappeler que $X \longrightarrow \Phi(X)$ est dans W_S^{f} (résulte du fait que X est W-fibré sur S ([100]), donc $X_s \longrightarrow s\backslash X$ est dans W, $\forall\ s \in S$), donc $\underbrace{X \times_S Y}_{X_Y} \longrightarrow \underbrace{\Phi(X) \times_S Y}_{\Phi(X)_Y}$ est aussi dans W_Y^{f}, donc (comme X_Y, $\Phi(X)_Y$ sont W-fibrés sur Y) dans W_Y^{d}, donc aussi dans W_S^{d}. En fait, même sans supposer Y lisse, ceci montre que l'on a p. 125

$$(*) \qquad \mathrm{hot}_{S,W}(X \times_S Y) \xrightarrow{\sim} \mathrm{mult}_{Y/S}(\mathrm{hot}_{S,W}(X)) \qquad \text{si } X \text{ est dans } \underline{\mathrm{Fib}}_W S. \qquad \text{[page 202]}$$

Pour avoir $(*)$ pour Y quelconque, on peut par ce qui précède supposer X lisse (quitte à le remplacer par $\Phi(X)$), donc X dans $\underline{\mathrm{Liss}}_{0,W} S$. Il faut voir que

$$X \times_S Y \longrightarrow X \times_S \Phi(Y)$$

99. Cette formule n'est établie qu'en supposant ou bien Y W-lisse (en plus de X W-fibré sur S), ou bien X W-propre, p.ex. X W-parfait.

100. il suffit même W-prélisse sur S

est encore dans W_S^{d}. Or si X est W-*propre* sur S, le changement de base $X \longrightarrow S$ est compatible avec W_S^{d}, W_X^{d} (sur Cat/S tout entier), et on gagne. (Ça doit être faux sans hypothèse de W-propreté sur X, *ou* de W-lissité sur Y …)

Quand on a

$$f : S' \longrightarrow S,$$

alors

$$f^* : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S')$$

est compatible avec les structures de produit.

⑧ Les foncteurs $f_!$: théorème d'adjonction, propriétés du dérivateur HOT_W.

Soit

$$f : S' \longrightarrow S$$

dans Cat, alors le foncteur induit

$$f_! : \mathrm{Cat}/S' \longrightarrow \mathrm{Cat}/S$$

est compatible avec les localiseurs $(W_{S'}^{\mathrm{d}}, W_S^{\mathrm{d}})$, ou $(W_{S'}^{\mathrm{g}}, W_S^{\mathrm{g}})$, ou $(W_{S'}, W_S)$. On trouve donc un foncteur induit pour les localisées, et `[un]` diagramme commutatif [page 203]

$$\begin{array}{ccccc}
\mathrm{HOT}_W(S') & & & & \mathrm{HOT}^o_W(S') \\
\downarrow{\scriptstyle f_!} & \searrow^{\rho'} & & \swarrow_{\sigma'} & \downarrow{\scriptstyle f^o_!} \\
\mathrm{HOT}_W(S) & & \mathrm{HOT}^{\mathrm{lc}\,!}_W(S') & & \mathrm{HOT}^o_W(S). \\
& \searrow_{\rho} & \downarrow{\scriptstyle f^{\mathrm{lc}\,!}_!} & \swarrow^{\sigma} & \\
& & \mathrm{HOT}^{\mathrm{lc}\,!}_W(S) & &
\end{array}$$

Commentary · Development (commentators') [ms. 202]

A fibred factor suffices for the product formula

Grothendieck's desired formula on manuscript p. 201 is stronger than the proof immediately following it. The remaining difficulty can be resolved by calculating over a comma category: the arrow from its fixed starting object trivializes the transport of a locally constant fibration. This gives the unrestricted second factor that the manuscript leaves undecided.

Product comparison for a fibred factor. [ours] Assume $\mathrm{W}(1,2,3)$. If $X \to S$ is W-fibred in the weak, universally stable sense used in this chapter, then for every $Y \to S$ the canonical map

$$[X \times_S Y] \longrightarrow [X] \times_S [Y] \quad \text{in } \mathrm{HOT}_W(S)$$

is an isomorphism. No properness assumption on X or smoothness assumption on Y is required.

Proof. We first treat a split Grothendieck fibration $X = \int_S F$ with $F : S^{\mathrm{op}} \to \mathrm{Cat}$ and $F(u) \in W$ for every arrow u of S. Fix $s \in S$ and put $B = s\backslash Y$. An object of B is (y, a), with $a : s \to q(y)$, where $q : Y \to S$ is the structure map. The projection

$$E = s\backslash(X \times_S Y) \longrightarrow B$$

is the split fibration classified by $(y, a) \mapsto F(qy)$. A morphism $(y, a) \to (y', a')$ is an arrow $h : y \to y'$ with $qh\, a = a'$, and its transport is $F(qh)$.

The maps $F(a) : F(qy) \to F(s)$ form a natural transformation to the constant diagram at $F(s)$, because

$$F(a)F(qh) = F(qh\, a) = F(a').$$

They therefore define a Cartesian functor

$$T : E \longrightarrow F(s) \times B, \qquad (x, y, a) \longmapsto (F(a)x, (y, a)).$$

Each fibre map of T belongs to W. Hence $T \in W$: a fibrewise W-equivalence between Grothendieck fibrations is right-fine, as seen by the fibre-to-comma adjunctions, and the relative localization axiom sends right-fine equivalences to total ones. This implication uses the fibrewise-to-total direction; it does not invoke W(4b).

We check that this proves the canonical comparison, not just an equivalence between its endpoints. Since X is smooth, $[X] \times_S [Y]$ is represented by $X \times_S \Phi Y$. Let

$$k_s : s\backslash(X \times_S Y) \longrightarrow s\backslash(X \times_S \Phi Y)$$

be induced by the unit of Y. The target is a comma category of a split fibration, so pullback to its fibre at s defines a functor

$$r_s : s\backslash(X \times_S \Phi Y) \longrightarrow F(s) \times (s\backslash Y).$$

The inclusion of that fibre is left adjoint to r_s: an arrow from a fibre object to an object over t, lying over $c : s \to t$, is uniquely an arrow in the fibre to its Cartesian pullback. Thus $r_s \in W$. On an object (x, y, a) of the source of k_s, the unit of Y introduces the identity arrow at $q(y)$, and r_s pulls back along a. Consequently $r_s k_s = T$, on objects and on morphisms. Since $r_s, T \in W$, two-out-of-three gives $k_s \in W$. This holds for every s, proving

$$X \times_S Y \longrightarrow X \times_S \Phi Y \quad \text{belongs to } W_S^{\mathrm{d}}.$$

For a general W-fibred X, its replacement ΦX is a split fibration with W-equivalent transports. The unit $X \to \Phi X$ is fine. After pullback to any Y, it is fine between W-fibred objects over Y, because this class of objects is stable under arbitrary base change. Fine and right-fine equivalences agree on that class, and forgetting Y preserves right-fine equivalences. Hence

$$X \times_S Y \longrightarrow \Phi X \times_S Y \quad \text{belongs to } W_S^{\mathrm{d}}.$$

Apply the split case to ΦX. Composing the two maps gives a right-fine equivalence from $X \times_S Y$ to $\Phi X \times_S \Phi Y$, whose image is exactly the canonical product comparison. This proves the assertion.□

The universal stability used in the last paragraph is part of the weak-fibration notion, not a hidden strengthening of it; see Grothendieck (1990–1991f, Chapter XII, Part III, Theorem 3, manuscript pp. 51–52). The construction also shows naturality in both X and Y, since each map was induced by the functorial comma replacement or by its Cartesian transport.

In particular, the proposed general formula $(*)$ on manuscript p. 201 is valid under its stated fibred hypothesis. The suspicion at the end of p. 202 that properness of X or smoothness of Y is necessary is not borne out. We checked the comma-category and base-change treatments in Maltsiniotis (2005, §§4–5) and the locally constant framework in Cisinski (2009); we did not locate this exact formulation there. The proof is included as a continuation of the manuscript's argument, without a claim that the result is new.

On n'a pas de foncteur $f_!^{\mathrm{lc}}$ au niveau des $\mathrm{HOT}_W^{\mathrm{lc}}$, sauf si on fait une hypothèse, telle W(4b), qui assure que $\mathrm{HOT}_W^{\mathrm{lc}!} \approx \mathrm{HOT}_W^{\mathrm{lc}}$. p. 126

Le théorème principal, que le foncteur $f_!$ est adjoint à gauche de f^*, est valable *sous la seule hypothèse* W(1, 2, 3) ([101]). Donc dualement pour $f_!^o$, f_o^*. Mais comme on n'a pas de foncteur $f_{\mathrm{lc}\,!}^*$, la question d'adjonction ne se pose pas pour f général, et sans hypothèse W(4b) sur W. Elle ne se pose, apparemment, que pour f un W-fibré trivial (cf. fin de ⑥, p. 198), et dans ce cas l'adjonction ne doit pas faire de difficultés. Mais tant que je n'ai pas de sentiment bien net au sujet de la signification des $\mathrm{HOT}_W^{\mathrm{lc}!}$, ce n'est pas là un résultat bien bandant [sic].

L'adjonction de $f_!$, f^* pour HOT_W permet déjà de montrer que le prédérivateur HOT_W satisfait les conditions Der 1, Der 4′, Der 5′ des dérivateurs. De plus, on a ce qu'on peut [page 204]

101. i.e. avec ces nouvelles notations Loc(1, 2, 3 bis) (cf. XVI).

appeler la propriété Der 3b pour HOT_W en tant que W-dérivateur, i.e.

> *Si $f \in W$, alors f est une* HOT_W*-équivalence* ([102]) (moyennant les seuls axiomes $\mathrm{W}(1,2,3)$ sur W). Plus précisément, f est une HOT_W-équivalence si et seulement si $\mathrm{hot}_W(f)$ est `[un]` isomorphisme, i.e. $f \in \overline{W}$, le saturé fort de W.

Si W *satisfait* W(4b), alors on a également un couple de foncteurs adjoints

$$\mathrm{HOT}^{\mathrm{lc}}_W(S') \underset{f^*_{\mathrm{lc}}}{\overset{f^{\mathrm{lc}}_!}{\rightleftarrows}} \mathrm{HOT}^{\mathrm{lc}}_W(S)$$

pout toute flèche $S' \longrightarrow S$ dans Cat. On voit aussi dans ce cas que

> si $f : S' \longrightarrow S$ est dans W, alors f^*_{lc} et $f^{\mathrm{lc}}_!$ entre $\mathrm{HOT}^{\mathrm{lc}}_W(S)$ et $\mathrm{HOT}^{\mathrm{lc}}_W(S')$ sont des équivalences quasi-inverses l'une de l'autre (moyennant W(4b)),

ce qui est l'axiome Der $3b_2$ 'version W-dérivateurs'. On ne peut s'attendre à mieux, du côté Der 3!

Oubli : Soit $f : S' \longrightarrow S$, on a alors $\boxed{f_! f^*} : \mathrm{HOT}_W(S) \longrightarrow \mathrm{HOT}_W(S)$ est égal à $\mathrm{mult}_{S'/S}$ (cf. p. 200). Il est donc égal à mult_ξ, où $\xi = \mathrm{hot}_{S,W}(S')$, si on suppose ou bien S' W-lisse sur S, ou bien S' W-fibré sur S (cf. (∗∗), p. 201).

⑨ Théorème de changement de base pour $f_!$ dans HOT_W.

Si on a p. 127

$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow{g} & S', \end{array}$$

Commentary · Later developments [ms. 204]

The final adjunction and the surviving base-change fragment

Grothendieck closes the revision by separating the constructions that need only the three standing axioms from the stronger locally constant comparison. Postcomposition $f_!$ respects the three relative equivalence classes, and the earlier unit and counit prove $f_! \dashv f^*$ for HOT_W without W(4b). The locally constant adjunction requires the additional comparison that identifies the fine theory with the coarse localization.

For $f \in W$ under W(4b), the locally constant unit and counit are isomorphisms; hence $f^{\mathrm{lc}}_!$ and f^*_{lc} are inverse equivalences. This assertion concerns locally constant coefficients. It does not say that restriction on all coherent diagrams is an equivalence whenever the indexing categories have the same homotopy type. For instance, the terminal category and the walking arrow have equivalent nerves, whereas the latter still indexes a genuine coherent morphism. The distinction is already built into the separate lateral and locally constant categories.

The constant-coefficient claim has an elementary calculation. If $p : S \to e$ and $T \in \mathrm{Cat}$, the constant coefficient represented by T is represented over S by $S \times T$. Its homotopy colimit is therefore represented by $S \times T$ as an absolute category. A functor $f : S' \to S$ acts by $f \times \mathrm{id}_T$. Product stability gives the implication $f \in W \Rightarrow f \times T \in W$. Conversely, testing $T = e$ detects whether $[f]$ is invertible in $\mathrm{Cat}[W^{-1}]$. This explains the appearance of the strong saturation $\overline{W}$ in the final statement, rather than an assertion that every chosen class W was strongly saturated from the outset.

The last paragraph of the source displays a square and the hypotheses "f smooth or g proper", then stops. Its missing continuation is a source lacuna, not an unproved conclusion which we may

102. On le prouve en interprétant la notion de HOT_W-équivalence par la HOT_W*-homologie.* Cela revient finalement à ceci : Si $f : S' \longrightarrow S$ est dans W, alors $\forall T$, $S' \times T \longrightarrow S \times T$ aussi!

attribute to Grothendieck. If the square is Cartesian, the expected statement can be read against the base-change result proved earlier in the chapter: the canonical mate

$$f'_! q^* \longrightarrow g^* f_!$$

is invertible for such a square. The surviving fragment does not itself repeat the Cartesian hypothesis; it is necessary in this reconstruction. In the smooth-f case, represent the coefficient by $Z \to X$ smooth over X. Its composite to S is smooth, so both sides are represented by the same category $Z \times_S S'$ over S'. In the proper-g case, ordinary pullback along g computes inverse image for every representative, and its pullback q is proper as well; the same equality of representatives proves the formula. The map is the standard mate built from the unit and counit, so the identification agrees with the canonical base-change comparison rather than merely producing some isomorphism between the functors.

This is the categorical form of the base-change mechanism isolated in Maltsiniotis (2005, Proposition 5.3, Theorem 5.4, and Remark 5.5), with the opposite-category convention adjusted to the present $s\backslash X$ model. The surviving text is left unchanged at its stopping point; the preceding calculation belongs to the commentary.

Overview · VI-c

Chapter VI, manuscript pages 138–204: operations, fibres, and the choice of equivalences.

These pages bring the construction of HOT_W to a point where it can support a calculus of operations (Grothendieck, 1990b). The principal achievement is an adjunction. For a functor $f : S' \to S$, composition of structural maps already gives a direct-image functor on categories over the base. After localization, this becomes the left adjoint $f_!$ of the inverse-image functor f^*. The work lies in making the inverse image homotopically meaningful, identifying the unit and counit, and proving that their two composites are identities. The ensuing discussion of products, base change, and locally constant objects repeatedly returns to the choice of a concrete representative and to the changes of representative that survive the intended operation.

The notation needs a fixed orientation. We follow the manuscript's presheaf convention. A split category fibred over S represents a functor $S^{\mathrm{op}} \to \mathrm{Cat}$. For $X \to S$, the comma replacement $\Phi_S(X)$ has fibre $s\backslash X$ at s; its unit $i_X : X \to \Phi_S(X)$ is a right-fine equivalence. Consequently

$$f^*\mathrm{hot}_{S,W}(X) \simeq \mathrm{hot}_{S',W}\big(\Phi_S(X) \times_S S'\big), \qquad f_!\mathrm{hot}_{S',W}(X') = \mathrm{hot}_{S,W}(X').$$

The second formula remembers the change of structural map. It does not assert that the representative remains fibred or smooth over the new base. This is the reason the first formula cannot generally be replaced by strict pullback of X.

The adjunction proof on pages 138–146 is unusually revealing. The unit is the S'-map induced by $i_{X'}$ and the structural map $X' \to S'$. For the counit one first tries to invert the pullback of i_X; the attempt fails because that pullback need not belong to the relevant class of equivalences. The correct formula is

$$\beta_X = (i_X)^{-1}\,\mathrm{pr}_1^{\Phi_S(X)}.$$

Its inverse is taken in the localization over S, where i_X is known to be invertible. One triangle identity is then the definition of the unit, and the other is naturality of i. Our commentary writes out this reduction, with the domains and codomains kept visible. The later passage to locally constant objects is a formal adjunction argument between reflective subcategories, once the reflection and the appropriate commutation squares are available.

Products and the operation attached to a representative.

The next issue is more subtle than the construction of a multiplication law might suggest. Two smooth representatives have a strict product over S that computes the product in $\mathrm{HOT}_W(S)$. With arbitrary representatives one must use

$$\mathrm{hot}_{S,W}(X) \times_S \mathrm{hot}_{S,W}(Y) \simeq \mathrm{hot}_{S,W}\big(\Phi_S(X) \times_S \Phi_S(Y)\big).$$

The first corollary on page 152 claims that one smooth factor suffices to omit both replacements. Grothendieck retracts it immediately. Over the walking arrow $0 \to 1$, the smooth inclusion of 0 and the terminal-point inclusion of 1 have empty strict intersection, whereas replacing the latter by its comma fibration changes the calculation. This small example determines the correct scope of every later product formula.

What remains for an arbitrary $X \to S$ is the endofunctor $\mathrm{multhot}_{X/S}$, obtained by multiplying smooth representatives by this particular X. It gives the unconditional identity

$$f_!f^* \simeq \mathrm{multhot}_{S'/S}\,.$$

An identification with multiplication by the localized object $\mathrm{hot}_{S,W}(S')$ requires a further argument. The distinction concerns functorial dependence on the first representative, rather

than a failure of associativity or of the usual coherence of products. We return to it at the end of the chapter, where a proof using the Grothendieck construction extends the calculation for weak W-fibrations. The proof and its precise assumptions are given in the development block, independently of an appeal to a general projection formula.

The formula for a left Kan extension at an object is obtained in the same concrete way. Its value at s is represented by $s\backslash X'$, rather than by the strict fibre X'_s. The comma square carries its canonical natural transformation; it is not in general a strictly commutative square. With that transformation and the presheaf variance made explicit, the base-change mate has the standard orientation, and the computation proves it invertible. This supplies the pointwise left-Kan-extension axiom. The smooth/proper base-change theorem then follows by choosing representatives on which strict pullback is legitimate. The initial detour through a general derivator theorem is incomplete because it invokes pointwise detection of isomorphisms. The direct argument on pages 168–169 removes that dependence.

Why four localizations appear.

The revision beginning on page 171 is structural. Grothendieck separates the basic localizer axioms from the additional principle that a total equivalence between weak fibrations is an equivalence on every fibre. For a map $u : X \to Y$ over S, the classes used in the discussion are

$$\begin{aligned} W_S &: u \in W \text{ on the total categories,} \\ W_S^{\mathrm{f}} &: u_s \in W \text{ for every strict fibre,} \\ W_S^{\mathrm{d}} &: s\backslash u \in W \text{ for every } s, \\ W_S^{\mathrm{g}} &: u/s \in W \text{ for every } s. \end{aligned}$$

On weak fibrations, the fine conditions agree; their implication to total equivalence is available under the basic axioms. The converse is W(4b). Without it, the fine localization of weak fibrations and their coarse localization cannot be identified merely because both admit useful replacements. This yields HOT_W, its opposite-variance counterpart, $\mathrm{HOT}_W^{\mathrm{lc}}$, and $\mathrm{HOT}_W^{\mathrm{lc!}}$, with a localization λ between the last two.

The path functor C exposes the difficulty. Its unit is a total equivalence and its values are perfect over the base. These properties give coarse equivalences of presentations. They do not, by themselves, prove that the unit is fine on a weak fibration. W(4b) supplies exactly that step, identifies the two locally constant theories, and allows the reflection formulas to be read as genuine adjunctions with fully faithful right adjoints. The audit keeps this hypothesis attached to each use of that conclusion. A calculation with action groupoids makes the distinction visible on morphisms: coarse localization can identify maps that remain distinct in the fine theory.

This is also the place to separate historical uncertainty from present knowledge. The minimality theorem for the usual homotopy localizer, in the modern basic-localizer framework, is due to Cisinski (2004). It answers the proposed search for a smaller basic localizer; it does not identify every generalized coefficient theory with ordinary homotopy theory. The manuscript's varying axioms and its changing use of "fibration" must still be translated before a later theorem is applied.

Alternating replacement and the questions it answers.

One application of Φ cannot produce all the desired geometry. The fork-shaped base with two incomparable terminal branches gives a particularly strong obstruction: for a nondegenerate localizer, the comma replacement of a nonempty category over that base cannot be proper. The commentary verifies the categorical retraction in the preceding example, repairs the central object of the printed diagram, and gives the missing last step in the emptiness argument. A separately marked extension treats a class of partially ordered bases by the same mechanism. These arguments concern properness of a particular replacement, not the nonexistence of any satisfactory presentation.

Grothendieck then alternates the two comma constructions and takes the colimit of the resulting sequence. The odd and even subsequences respectively provide smooth and proper presentations. The proof uses W(6 bis): closure of W under colimits of sequences of arrows. Its historical formulation does not assert arbitrary filtered closure. The limiting object is perfect, and its unit is fine when the original object is a weak fibration. This gives a fine equivalence between the weak-fibration and perfect-object presentations without using W(4b). It does not identify fine and coarse equivalences.

The later theorem of Cisinski (2006a, Corollary 4.2.22) makes W(6 bis) automatic for basic localizers. With the identification $W_\omega = W'_\omega = W''_\omega = W_\infty$ established in the commentary, the replacement therefore answers the perfect-presentation question affirmatively under the standing axioms. The same fine units transfer the original restricted W(4b′) test to all weak fibrations. These conclusions concern the relative localization axiom W(2); they do not silently extend a colimit theorem to every weaker axiom system considered in the manuscript.

The practical proposition on pages 196–197 combines this construction with restricted fibre detection. Its last adjunction verification is expressly postponed. We supply it by first transporting fibre detection along the functorial replacement and then comparing the resulting unit with the established C-reflection. The later Chapter XVI confirms the role of replacement in relating the fibration axioms; the brief status block locates its theorem and keeps its historical hypotheses visible. No priority claim is attached to the elementary arguments supplied here.

The reach of the construction.

For the ordinary homotopy theory of spaces, the contemporary description of locally constant diagrams uses homotopy Kan extensions and localization of diagram categories; Cisinski (2009) gives a precise treatment. The model-category construction of derivators supplies a standard framework (Cisinski, 2003; Groth, 2013). More generally, Der 2 holds for every basic localizer (Cisinski, 2006a, Propositions 3.1.30 and 4.2.7). The commentary after manuscript p. 159 explains the comparison which permits that conclusion. The unrestricted strict-bifibration presentation over an arbitrary base remains outside what we have established: a free bifibration alone does not provide a fine equivalence from the given weak fibration. Over groupoid bases we give the complete comparison directly.

The surviving final recap deliberately lists Der 1, Der 4′, Der 5′, and the appropriate W-relative form of Der 3b. Der 2 has been withdrawn from the earlier list pending a proof; its later resolution does not supply a missing argument to the historical text. The audit also preserves the missing manuscript page 170 and the incomplete final base-change paragraph. What can be proved from the surviving material is supplied in commentary; the missing text is not reconstructed.

G. Maltsiniotis

Comme le formalisme ‘simplifié’ des chemins que j’ai voulu dégager à la va-vite s’est révélé d’une lourdeur insupportable, de nature à le rendre quasiment inutilisable, je vais essayer de dégager un formalisme souple, collant à l’intuition, au prix seulement d’un effort conceptuel supplémentaire. p. 1 [page 1]

1 Intervalles et leur variantes

On appelle *catégorie intervalle standard* une catégorie définie par un ensemble ordonné, dont l’ensemble des élements est un intervalle d’entiers $[0, n]$ ($n \in \mathbf{N}$, on n’exclut pas le cas $n = 0$, i.e. de la catégorie ponctuelle $\{0\}$) :

$$\mathrm{Ob}\, I = [0, n] \subseteq \mathbf{N},$$

et satisfaisant l’hypothèse suivante :

a) pour toute paire de deux sommets consécutifs $i-1$, i de I ($1 \leq i \leq n$), il y a une flèche qui les relie, donc soit $i \longrightarrow i+1$, soit $i \longleftarrow i+1$ [plutôt $i-1 \longrightarrow i$, $i-1 \longleftarrow i$] (cette flèche est notée $\underline{u}_i$,

$$(i-1) \xrightarrow{\underline{u}_i} i \qquad \text{ou} \qquad (i-1) \xleftarrow{\underline{u}_i} i \ \ ).$$

b) La catégorie I est engendrée par l’ensemble de ses flèches $\underline{u}_i$ (appelées *flèches de transition*).

La flèche de transition est dite *directe* si elle va de $i-1$ à i, *rétrograde* dans le sens inverse. Si on affecte l’intervalle $[i-1, i]$ du signe + ou − suivant que $\underline{u}_i$ est directe ou rétrograde, on voit donc que les intervalles standard de longueur donnée n correspondent biunivoquement aux systèmes de signes + ou − sur les n intervalles de transition $[i-1, i]$ ($1 \leq i \leq n$), il y en a donc 2^n. Le sommet 0 est l’*origine* ou la *source* de l’intervalle, le sommet n l’*extrémité* ou le *but* de l’intervalle. [page 2]

Commentary · Exposition [ms. 1]

A combinatorial interval carries two orders

Grothendieck begins again because a path should be easy to concatenate and easy to change without losing its endpoints. The extra conceptual effort announced here consists in making its shape an object of study. Before forming a category of all paths, he isolates the finite categories which can serve as their domains. The commentary on Chapter VI, manuscript p. 69 (“Concatenation and the two iterated units”) discusses the preceding path construction; the present chapter reorganizes its combinatorics.

A standard interval is the free category on an oriented path graph. Write its transition signs as

$$\tau = (\varepsilon_1, \dots, \varepsilon_n), \qquad \varepsilon_i \in \{+, -\}.$$

There is one object at each integer from 0 to n. A positive sign supplies the generating arrow $i-1 \to i$ and a negative sign supplies $i \to i-1$. The free category is thin: between two fixed vertices there is at most one directed path, since the underlying undirected graph has no cycle. Thus the description as a category associated with a partially ordered set introduces no additional relations. Conversely, the two conditions in the text reconstruct precisely this free category.

For later use we record the complete hom-set calculation. If $i < j$, then

$$\begin{aligned} I_\tau(i, j) \neq \varnothing \quad &\Longleftrightarrow \quad \varepsilon_{i+1} = \cdots = \varepsilon_j = +, \\ I_\tau(j, i) \neq \varnothing \quad &\Longleftrightarrow \quad \varepsilon_{i+1} = \cdots = \varepsilon_j = -. \end{aligned}$$

Every nonempty hom-set contains exactly one arrow. These formulas prove both the classification by sign words and the count 2^n. They also explain why a functor out of an interval will be specified freely by its values on the transition arrows.

The numerical order and the categorical partial order have different jobs. The first tells us in which order the vertices are visited; the second tells us which composites exist. For the shape $0 \to 1 \leftarrow 2$, the designated source of the interval is 0 and its designated target is 2, although neither statement says that 0 is initial or 2 terminal. A path of this shape travels along the first arrow and against the second. Confusing these two orders would already make the later distinction between an opposite path and an opposite category disappear.

Length counts transitions. The interval of length zero has one vertex and no transition, and the interval of length n has $n+1$ vertices. We keep this convention throughout; it will identify the isolated equality $n = \operatorname{card} I$ on ms. 13 as a printed slip rather than a competing convention.

Un intervalle standard est *orienté,* du fait qu'on à la relation d'ordre *total* naturelle sur l'ensemble de ses sommets, savoir celle des entiers dans $[0, n]$. Quand on parlera de la relation d'ordre sur I, qu'un sommet i en *'précède'* ou *'suit'* un autre j ($i \leq j$ ou $i \geq j$ respectivement), c'est de cette relation d'ordre qu'on voudra parler. Celle associée à la structure de catégorie ne sera jamais regardée comme une relation d'ordre. Il y a également une relation d'ordre total naturelle sur l'ensemble des flèches de transition $\underline{u}_i$ ($1 \leq i \leq n$), donnée par la relation d'ordre des entiers i, $1 \leq i \leq n$, qui les indexent. On dira qu'une flèche i `[plutôt` $\underline{u}_i$`]` de transition *précède* ou *suit* une autre `[`$\underline{u}_j$`]`, ou qu'elle est *successeur immédiat* ou *prédécesseur immédiat* d'une autre (si $i = j+1$ ou $i = j-1$).

Si on a un ensemble d'entiers p. 2

$$E \subseteq \mathbf{Z},$$

on considérera dans E la relation d'équivalence engendrée par la relation entre deux éléments (i, j) de E : j est successeur immédiat de i *dans* $\mathbf{Z}$ (i.e. $j = i+1$). Deux éléments distinct i, j de E sont congrus pour cette relation si et seulement si l'intervalle d'entiers qu'ils déterminent est $\subseteq E$, donc

$$\text{si } i < j,\ i \text{ et } j \text{ sont } \textit{'connectés'} \text{ dans } E \text{ si et seulement si } [i, j] \subseteq E.$$

Quand on parlera des 'composantes connexes' de E, il s'agira toujours des classes suivant cette relation d'équivalence. [page 3]

Nous identifierons l'ensemble des flèches de transition $\operatorname{Fl}\operatorname{tr}(I)$ de I à l'intervalle d'entiers $[1, n]$, donc à une partie de $\mathbf{Z}$. Si on a une partie $E \subseteq \operatorname{Fl}\operatorname{tr}(I)$, on y a donc la notion de flèches de transition 'connectées' dans E, et la notion de connexité pour E. Si $i < j$, $\underline{u}_i$ et $\underline{u}_j$ sont connectées si et seulement si toutes les flèches de transition intermédiaires entre $\underline{u}_i$ et $\underline{u}_j$ sont dans E. Et E est connexe si et seulement s'il est soit vide, soit formée d'une suite de flèches de transition dont chacune est successeur immédiat de celle qui la précède,

$$E = \{\underline{u}_i, \underline{u}_{i+1} \ldots, \underline{u}_{i+l-1}\},$$

où l est le cardinal de E. Une telle E est appelée une *chaîne* de flèches de transition, et l est sa longueur. Une chaîne est dite *composable* si le composé $\underline{u}_{i+l-1} \circ \cdots \circ \underline{u}_{i+1} \circ \underline{u}_i$ `[ou` $\underline{u}_i \circ \underline{u}_{i+1} \circ \ldots \circ \underline{u}_{i+l-1}$`]` a un sens, i.e. si elles sont toutes de même sens, soit directe, soit rétrograde.

On désigne par $\operatorname{Fl}\operatorname{tr}^+(I)$, $\operatorname{Fl}\operatorname{tr}^-(I)$ l'ensemble des flèches de transition directes, ou rétrogrades, respectivement. Leurs composantes connexes ne sont autres que les chaînes composables maximales. Ainsi, les chaînes composables maximales forment une partition de l'ensemble des flèches de transition, en intervalles d'entiers mutuellement disjoints. Les chaînes forment elles-mêmes un ensemble totalement ordonné

$$C_1,\ C_2,\ \ldots\ C_r \qquad (1 \leq r \leq n).$$

L'entier r s'appelle la *'longueur utile'* de l'intervalle I, c'est donc le cardinal de l'ensemble de ses chaînes composables maximales. [page 4]

Deux chaînes composables maximales [consécutives] sont toujours de signe opposé, si l'une est directe l'autre est rétrograde, et inversement. La première chaîne composable maximale C_1 (disons simplement *'chaîne structurale'*) a le même signe que $\underline{u}_1$; [on] dit que la *direction initiale* de I est directe, resp. rétrograde, s'il en est ainsi de $\underline{u}_1$, ou ce qui revient au même, de C_1. De même on définit la *direction finale* de I comme celle de $\underline{u}_n$, ou encore celle de C_r. Direction initiale et finale sont égales si la longueur utile r est impaire, inégales si elle est paire. (**NB** Ce n'est que pour $n = 0$, i.e. quand $I = \{0\}$ est la catégorie ponctuelle, que direction initiale et direction finale ne sont pas définies.) p. 3

Les chaînes composables correspondent aux sous-catégories pleines de I qui sont isomorphes à une catégorie $\mathbf{\Delta}_i$ (où i est la longueur de la chaîne). Notons que $\mathbf{\Delta}_i$ n'a pas d'autre automorphisme que l'identité, donc les chaînes maximales de longueur donnée $i \geq 1$ correspondent exactement aux foncteurs

$$\mathbf{\Delta}_i \hookrightarrow I$$

qui sont injectifs sur les sommets. Un tel foncteur est pleinement fidèle, et un monomorphisme. Ce foncteur définit une application strictement croissante ou strictement décroissante sur les sommets, suivant que la chaîne est directe ou rétrograde. [page 5]

Commentary · Exposition [ms. 4]

Runs, simplices, and the meaning of maximality

Grothendieck next separates the places where a path can be composed from the places where its direction turns. A maximal constant-sign run of the word τ is his structural chain. If the run lengths are $l_1, \ldots, l_r$, then

$$n = l_1 + \cdots + l_r,$$

and the sign of the ath run is $(-1)^{a-1}\varepsilon_1$, when signs are written as ± 1. This proves the parity rule for initial and final directions. The useful length r records the number of changes of compositional regime, rather than the number of arrows which happen to have been written down.

The paragraph identifying chains with simplex subcategories needs a small but substantive separation. A chain was defined on ms. 3 to be a contiguous set of transitions. An object-injective functor $\Delta_k \to I$ may skip vertices. For example,

$$\Delta_1 \longrightarrow \Delta_2, \qquad 0 \longmapsto 0, \quad 1 \longmapsto 2,$$

is fully faithful, but its image is not the domain of one transition of Δ_2; nor does it describe its maximal structural chain, whose length is two. The words "chaînes maximales" and the unrestricted injectivity condition both occur in the edition. They therefore remain in the transcription, with their correction supplied here.

The exact statement is useful in its own right. For $k > 0$, an injective functor from Δ_k picks $k+1$ vertices in a single structural interval, in their categorical order. Indeed its first and last image vertices are connected by an arrow, so every vertex between them in the numerical order belongs to the same constant-sign run. All intermediate image vertices lie between these two in that run's categorical order. Conversely, any such selection determines an injective functor. It is fully faithful because the target is thin and its order on those vertices is exactly the simplex order. Its object function is strictly increasing in the external orientation for a positive run and strictly decreasing for a negative run.

To recover a chain in the earlier sense, impose numerical contiguity of the image. To recover a maximal structural chain, require the image to be the whole structural interval. These distinctions do not disturb the intended decomposition into runs. They identify which extra condition the printed correspondence omitted, while preserving its correct full-faithfulness assertion.

Notons que tout simplexe type $\mathbf{\Delta}_i$, $i \geq 0$, peut être vu comme un intervalle, de longueur i, de longueur utile 1 (si $i \geq 1$, 0 si $i = 0$). Son origine est 0, son extrémité est i. Mais appelons une catégorie quelconque une *catégorie intervalle* si elle est isomorphe à un intervalle standard. Notons ici

Proposition 1. *Soit I un intervalle standard de longueur $n \geq 1$.*

a) Soit $i \in I$. Pour que $i \in \{0, n\}$, i.e. pour que i soit un des deux 'bouts' *(ou* 'extrémités'*) (source ou but) de I, il faut et il suffit que l'une des deux catégories I/i ou $i\backslash I$ soit la catégorie ponctuelle et que l'autre soit isomorphe à un $\mathbf{\Delta}_j$ ([1]). (Caractérisation intrinsèque des bouts d'un intervalle.) Pour que i soit la source, il faut et il suffit que $i\backslash I$* `[phrase incomplète]`

b) Tout foncteur $I \longrightarrow I$ qui fixe les deux extrémités de I est l'identité.

Corollaire. *Le groupe des automorphismes de I a au plus deux éléments. S'il en a deux, l'automorphisme non trivial échange les deux extrémités. (On dit alors que l'intervalle est* symétrique.*)*

Commentary · Exposition [ms. 5]

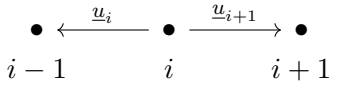
The endpoint determines an orientation, not an endofunctor

The purpose of Proposition 1 is to make orientation intrinsic enough to transport it through isomorphisms. Its first assertion is correct. At an endpoint, one of the two slices is a point and the other is the linearly ordered category running along the unique adjacent structural chain. An interior vertex at which the signs agree has both a nonidentity incoming and a nonidentity outgoing arrow, so neither slice is a point. At a turning vertex, one slice is a point, but the other has two nonempty branches meeting at their common source or common target. In the source case it has two incomparable maximal objects, and in the target case two incomparable minimal objects. It cannot be a simplex category. This gives the stated characterization of the two endpoints.

The second assertion is false with the word "foncteur" which the edition prints. On Δ_2 the monotone map

$$0 \longmapsto 0, \qquad 1 \longmapsto 0, \qquad 2 \longmapsto 2$$

defines a nonidentity endofunctor fixing both endpoints. The arrow $1 \to 2$ is sent to the composite $0 \to 2$; there is no requirement that a functor preserve a generating transition as a generating transition. This is exactly the flexibility which the later category of types is intended to accommodate.

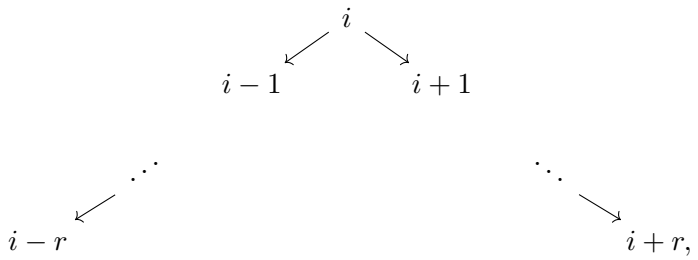


What the subsequent argument proves is that an *automorphism* fixing the endpoints is the identity. Here is a direct proof which also supplies the uniqueness statements used on ms. 7–9. A nonidentity arrow of an interval is indecomposable into two nonidentity arrows if and only if it is a transition: the displayed hom-set formula proves this, by factoring every longer directed segment at an intermediate vertex. Isomorphisms preserve indecomposability. The graph of indecomposable arrows, after forgetting directions, is the ordinary path with vertices $0, \ldots, n$. A graph automorphism fixing 0 fixes its unique neighbour, then that neighbour's still unvisited neighbour, and so on. It fixes every vertex and hence every arrow. Every graph automorphism is consequently the identity or vertex reversal. The categorical automorphism group is a subgroup of this two-element group.

This is also the intrinsic reconstruction of the external total order: choose one endpoint, call it s_0, and successively take the unique neighbour not already visited. Grothendieck's slice argument implements the same reconstruction in categorical terms. In its inductive paragraph the slices must be taken in the remaining full tail I' at s_i; the printed $i\backslash I$ and I/i have dropped that qualification. Neither reconstruction is preserved by arbitrary functors, which may collapse or lengthen transitions.

The unfinished sentence about characterizing the *source* of the interval should not be completed by guessing. The underlying category determines the pair of endpoints, but a symmetric interval has an automorphism interchanging them. Selecting one of them is precisely the additional orientation. After the definition of a reduced interval on ms. 12 we prove a sharp version of the stronger rigidity assertion: all endpoint-fixing endofunctors are identities exactly for reduced intervals.

[page 6]



NB Si i n'est pas un bout, et si néanmoins l'une des deux catégories $i\backslash I$, I/i est ponctuelle, disons I/i, alors au voisinage immédiat de i, I a la forme

1. où j est la longueur de l'unique chaîne structurale qui 'touche' i (i.e. telle que i soit dans la sous-catégorie pleine définie par ladite chaîne).

($\underline{u}_i$ rétrograde, $\underline{u}_{i+1}$ directe - si c'était $i\backslash I$ la ponctuelle, alors $\underline{u}_i$ serait directe, $\underline{u}_{i+1}$ rétrograde - en tous les cas ces deux flèches sont de sens opposé, i.e. non composables). On trouve donc que $i\backslash I$ est une catégorie de la forme

p. 4

où r est la longueur de la chaîne structurale contenant $\underline{u}_i$, s celle de la chaîne structurale contenant $\underline{u}_{i+1}$. Cette catégorie est une somme amalgamée $\mathbf{\Delta}_r \amalg \mathbf{\Delta}_s$ (recollées suivant leur origine), mais n'est pas isomorphe à une $\mathbf{\Delta}_j$, p. ex. faute d'avoir un objet final.

Cette observation prouve a). Pour prouver b), il suffit de prouver que l'ordre total sur I est déterminé de façon intrinsèque, par le choix de *l'origine* s_0 de I (parmi ces deux extrémités). Supposons que l'on ait déjà déterminé intrinsèquement les sommets s_0, s_1, …, s_i ($i \geq 0$). Comment déterminer s_{i+1}? (Quand $i < n$.) Soit I' la sous-catégorie pleine de I formée des [page 7]
$j \in I$ qui ne sont pas parmi les s_j `[plutôt` s_k`]` déjà construits, sauf le dernier s_i (donc $s_i \in I'$, $\operatorname{card} I' \geq 2$). Alors I' est isomorphe à un intervalle standard, avec s_i correspondant à l'origine. Une des catégories $i\backslash I$, I/i est ponctuelle, l'autre isomorphe à une catégorie $\mathbf{\Delta}_j$, et de plus, i est objet initial ou final de $\mathbf{\Delta}_j$. Si c'est l'objet initial 0, on prend pour s_{i+1} le successeur immédiat de i dans $\mathbf{\Delta}_j$. Si c'est l'objet final j, on prend pour s_{i+1} le prédécesseur immédiat $j - 1$.

Si on était parti du but n de I, au lieu de partir de la source, on aurait trouvé la relation d'ordre total opposée. Affectant l'élément but du numéro d'ordre 0, on trouve une renumération de I, i devenant $n - i$, et les flèches de transition qui étaient directes pour la relation d'ordre initiale, deviennent rétrogrades dans la relation d'ordre opposée, et inversement. On voit ainsi :

Proposition 2. *Si I est un intervalle standard, il existe un unique couple (I', θ), où I' est un intervalle standard, et θ un isomorphisme $I \xrightarrow{\sim} I'$ qui transforme le but de I dans la source de I' (et la source de I en le but de I').*

Cet intervalle I' est appelé l'intervalle *opposé* de I. Il faut le voir, intrinsèquement, comme la 'même' categorie I, mais avec une 'orientation' opposée.

Une façon plus claire de voir ceci est la suivante. Soit J une catégorie intervalle, i.e. [page 8]
isomorphe à un intervalle standard. Alors il y a exactement (si $I \not\simeq e$) *deux* couples (I, θ) d'un intervalle standard I et d'un isomorphisme $\theta : I \xrightarrow{\sim} J$. Ces deux isomorphismes induisent sur J deux ordres totaux, opposés l'un de l'autre. Chaque couple est déterminé de façon unique par ledit ordre total, qu'on appelera une *orientation* de l'intervalle J. Ainsi J a deux orientations, et chacune détermine un *isomorphisme orienté* (i.e. respectant les orientations) p. 5
de J avec un intervalle standard ([2]). Ces deux intervalles sont les mêmes si et seulement s'il existe un automorphisme de J (nécessairement unique) qui échange ses deux orientations, ou ce qui revient au même, qui échange entre elles les deux extrémités. (Ainsi les catégories opposées l'une de l'autre

2. **NB** On parlera de l'intervalle *orienté opposé* I^{opp} d'un intervalle *orienté* I, qu'il faut se garder de confondre avec la catégorie opposée I^o. Ici I^{opp} a même catégorie sous-jacente que I, mais avec une orientation opposée.

sont chacunes des intervalles symétriques.) Choisir une orientation revient aussi ‘a choisir l'origine parmi les deux extrémités.

Notons que la *catégorie opposée* à un intervalle est un intervalle, et la catégorie opposée à un intervalle standard est l'intervalle standard qui s'en déduit en changeant tous les signes sur les intervalles de transition $[i-1, i]$ $(1 \leq i \leq n)$. On se gardera de confondre la propriété $I \simeq I^o$, avec la propriété de symétrie.

Ainsi les deux catégories (Ψ_1 et Φ_1) ci-dessus sont symétriques, mais opposées l'une de l'autre sans être isomorphes. D'autre part, les $\mathbf{\Delta}_i$ ne sont pas symétriques, mais chacune isomorphe à la catégorie opposée. [page 9]

Si I est isomorphe à la catégorie opposée I^o, et si θ est un tel isomorphisme (nécessairement unique), alors il est immédiat que θ renverse l'orientation (sinon ce serait l'identité sur les sommets, et les flèches de transition seraient à la fois directes et indirectes), donc $\theta(0) = n$, $\theta(1) = n-1$, et on veut que $\underline{u}_1$ et $\underline{u}_n$ sont de même signe. Mais si I est symétrique, $\underline{u}_1$ et $\underline{u}_n$ sont de signe opposé. Donc I ne peut être à la fois symétrique et isomorphe à l'intervalle opposé `[plutôt à la catégorie opposée; exception :` $I = \{0\}$`]`.

Pour toute catégorie $\mathbf{\Delta}_i$, celle-ci étant un intervalle, il y a (si $i > 0$) *deux orientations.* En tant qu'intervalles orientés, il y a $\mathbf{\Delta}_i^+$ (avec l'orientation ordinaire, donné par l'ordre ordinaire sur $\mathrm{Ob}\,\mathbf{\Delta}_i = [0, i]$), et $\mathbf{\Delta}_i^-$ avec l'orientation opposée.

p. 6
[page 10]

Commentary · Examples [ms. 9]

Reversal and categorical duality in a sign word

Grothendieck's two uses of “opposite” describe operations which can be written down independently. This makes the examples of symmetry and self-duality entirely explicit. For a sign word $\tau = (\varepsilon_1, \ldots, \varepsilon_n)$, put

$$R\tau = (-\varepsilon_n, \ldots, -\varepsilon_1),$$
$$D\tau = (-\varepsilon_1, \ldots, -\varepsilon_n).$$

The first is the standard model of the same category with its external orientation reversed; the standardizing isomorphism sends i to $n-i$. The second is the categorical opposite with the original numerical orientation. The two involutions commute, and $RD\tau$ is the word read backwards without changing its signs.

For $n > 0$, the interval is symmetric precisely when

$$\varepsilon_i = -\varepsilon_{n+1-i} \qquad (1 \leq i \leq n).$$

Necessity follows because a nonidentity automorphism must be reversal, by the preceding proof; sufficiency follows by checking each transition. This condition forces n to be even. Likewise $I \cong I^o$ precisely when

$$\varepsilon_i = \varepsilon_{n+1-i} \qquad (1 \leq i \leq n).$$

The isomorphism must reverse the numerical order: an order-preserving bijection of the vertex line would be the identity and would have to reverse a nonidentity transition without changing its endpoints. These two sign conditions cannot hold together for a nonempty word.

For instance, $(+,-)$ and $(-,+)$ satisfy the first condition. They give the cospan and span, each symmetric, but the two categories are not isomorphic: one has a terminal object and two minimal objects, the other an initial object and two maximal objects. The constant word $(+,+,+)$ satisfies the second condition and gives the self-dual category Δ_3 with no nonidentity automorphism. A less uniform self-dual example is $(+,-,+)$; its middle sink and source are exchanged under the anti-isomorphism. For a reduced alternating word, symmetry holds at positive even length and self-duality at odd length.

The point is separate: it has a unique orientation and only the identity automorphism, and both operations leave it unchanged. Keeping this case explicit avoids construing its coincident endpoints as two different choices.

2 Sous-catégories pleines d'un intervalle

Soit I une catégorie intervalle orientée, de longueur $n \geq 1$. Nous identifierons $\mathrm{Ob}\, I$ à l'ensemble des entiers $[0, n]$. Pour une chaîne $\underline{u}_i$, $\underline{u}_{i+1}$, …, $\underline{u}_{i+l-1}$ de flèches de transition dans I, on appelle *domaine* de la chaîne, l'ensemble des sources et de buts de ces éléments. C'est donc un intervalle d'entiers $[i-1, i+l-1]$, de longueur l égale à celle de la chaîne, dont l'origine est déterminé par la première flèche $\underline{u}_i$ de la chaîne (c'est sa source, si $\underline{u}_i$ est directe, et son but si $\underline{u}_i$ est rétrograde), et dont l'extrémité est déterminée par la dernière $\underline{u}_{i+l-1}$. Les intervalles d'entiers (vus comme des sommets de I) correspondant aux chaînes structurales sont appelés les *intervalles structuraux* ou *intervalles critiques* de I. Contrairement aux chaînes structurales, ces intervalles ne forment pas une partition de I, puisque deux intervalles structuraux peuvent avoir une extrémité commune. Si les chaînes structurales sont

$$C_1,\ C_2,\ \ldots\ ,\ C_r \qquad (r = \text{ longueur utile de } I)$$

de longueurs

$$l_1,\ l_2,\ \ldots\ ,\ l_r,$$

alors les intervalles structuraux sont

$$\underbrace{[0, l_1]}_{I_1},\ \underbrace{[l_1, l_1+l_2]}_{I_2},\ \ldots\ ,\ \underbrace{[l_1+\cdots+l_{r-1}, l_1+\cdots+l_{r-1}+l_r]}_{I_r},$$

une suite d'intervalles d'entiers dont deux consécutifs ont une extrémité commune, et tels que si $i < j$, chaque élément de I soit $\leq$ chaque élément de I_j. On appelle *sommet critique* de I les extrémités des intervalles structuraux.

Proposition 3. *Soit $s \in I$, soit $I' = I/s$ (sous-catégorie pleine de I des s' tels qu'il existe $s' \longrightarrow s$), $I'' = I/s$* `[plutôt` *$I'' = s\backslash I$*`]`*, $I'_0 = (I/s)\backslash\{s\}$, $I''_0 = (s\backslash I)\backslash\{s\}$ ([3]). Pour que s soit critique, il faut et il suffit que $I\backslash\{s\}$ soit catégorie somme de I'_0 et I''_0.*

Commentary · Exposition [ms. 10] [page 11]

Critical vertices and the correct deletion test

Grothendieck wants to retain exactly the vertices which a path cannot bypass by composing arrows. These are the endpoints of the structural intervals. If their positions are

$$0 = c_0 < c_1 < \cdots < c_r = n,$$

then $[c_{a-1}, c_a]$ is one constant-sign run, and each interior c_a is a change of sign. In the categorical partial order, the critical vertices are exactly the minimal and maximal vertices. This observation explains the two slices in Proposition 3, but it also exposes an error in its global formulation.

Let

$$A = (I/s) \setminus \{s\}, \qquad B = (s\backslash I) \setminus \{s\}.$$

These are respectively the strict predecessors and strict successors of s in the categorical order. They do not in general exhaust the other vertices. In $0 \to 1 \leftarrow 2$, take $s = 0$. It is critical; A is empty and B consists of 1, whereas $I \setminus \{0\}$ still contains 2. Thus the printed equality with all of $I \setminus \{s\}$ cannot be right. The edition prints the same reading.

The footnote gives the valid local test: there is no arrow between A and B. If s is critical, it is minimal or maximal and one of these categories is empty. If s is not critical, its two adjacent transitions have the same sign. One adjacent vertex is a strict predecessor and the other a strict successor; their composite through s is an arrow between A and B. Equivalently, the full subcategory on the vertices comparable with s, after removing s, is the coproduct $A \amalg B$ exactly when s is critical.

For the application to subintervals on the next page, the appropriate *global* test uses the numerical order. Suppose $0 < s < n$, and let L and H be the full subcategories on $[0, s-1]$ and $[s+1, n]$. Then

$$I \setminus \{s\} = L \amalg H \quad \Longleftrightarrow \quad s \text{ is critical.}$$

3. i.e. qu'on ait : il n'y a pas de flèches entre un élément de I'_0 et un élément de I''_0.

If s is a turning vertex, an arrow from one side to the other would traverse two transitions of opposite signs, which is impossible. If it is not a turning vertex, the two neighbouring vertices are connected by their composite through s, an arrow still present in the full subcategory obtained by deleting s. This corrected statement proves the separation property used in Proposition 5. At a numerical endpoint, deleting it leaves a connected interval; its criticality is already accounted for by its being an endpoint.

Proposition 4. *Soient i, j dans I, avec $i < j$. Conditions équivalentes :*

a) Il existe une flèche entre i et j (soit $i \longrightarrow j$, soit $j \longrightarrow i$).

b) i et j appartiennent à un même intervalle structural (nécessairement unique).

c) La sous-catégorie pleine de I définie par l'ensemble d'objets $[i, j]$ est isomorphe à une $\mathbf{\Delta}_\alpha$ (on aura $\alpha = j - i$).

On dira alors que i et j sont *directement connectés* dans I. (Et on utilisera la même terminologie dans une catégorie quelconque : i et j sont directement connectés si et seulement si $\mathrm{Hom}_I(i, j)$ *ou* $\mathrm{Hom}_I(j, i)$ est non vide.) p. 7

Proposition 5. *Soit $J \subseteq I$ une partie de I, considérons la sous-catégorie pleine de I qu'elle définit. Alors :*

a) Les composantes connexes J_α de J sont des intervalles et l'ordre induit sur un J_α par celui de I est une orientation (dite orientation induite*) de J_α.*

b) Supposons $\operatorname{card} J > 1$. *Soit i le plus petit élément de J, j le plus grand élément, donc $i < j$. Pour que J lui-même soit un intervalle, il faut et il suffit que tout sommet critique dans $[i, j]$ soit élément de J.*

([4]).

NB Si $s \in [i, j]$ est un sommet critique de I qui n'est pas dans J, alors par la proposition 3 il disconnecterait J, i.e. J serait somme directe de deux sous-catégories J' et J'' non vides ($i \in J'$, $j \in J''$), donc J ne serait pas un intervalle.

[page 12]

Commentary · Examples [ms. 11]

Connected full subcategories and the vertices they must retain

Grothendieck is preparing a reduction which composes consecutive arrows without identifying a change of direction. The distinction between a full subcategory and an arbitrary subcategory matters here. A full subcategory retains every composite whose endpoints remain, even when an intermediate vertex has been removed. Thus numerical gaps do not necessarily disconnect it.

Let $J = \{j_0 < \cdots < j_m\}$ be a nonempty subset of the vertices of I, with its full induced category. Two successive chosen vertices j_a, j_{a+1} are joined by an arrow if and only if the signs between them are constant. By Proposition 4 this is equivalent to there being no critical vertex strictly between them. Whenever this condition fails, there can be no arrow from any chosen vertex at or before j_a to any chosen vertex at or after j_{a+1}, in either direction: such an arrow would cross the same change of sign. The connected components are therefore the maximal consecutive blocks of the list $(j_0, \ldots, j_m)$ in which successive entries are directly connected.

Within one such block, make a generating transition between each successive pair, in the direction of its arrow in I. The free category on this oriented line is exactly the induced category. To verify fullness, an arrow between nonconsecutive retained vertices exists in I precisely when the signs on the whole intervening segment agree. That is also precisely the condition that the successive arrows of the block compose. This proves Proposition 5(a), including the claim about the induced orientation. It proves (b) as well: the whole chosen list is connected exactly when every ambient critical vertex between its extreme vertices was retained.

For a concrete calculation take

$$I : \quad 0 \longrightarrow 1 \longrightarrow 2 \longleftarrow 3 \longleftarrow 4 \longrightarrow 5.$$

4. On appelle *sous-intervalle* de I une sous-categorie pleine connexe, i.e. qui est elle-même un intervalle. Notons d'ailleurs que *toute* sous-catégorie I' de I qui est un intervalle, est nécessairement pleine, cf. plus bas `[paragraphe]` des foncteurs entre intervalles.

Its critical vertices are $0, 2, 4, 5$. The full category on $\{0, 2, 4, 5\}$ is the reduced interval

$$0 \longrightarrow 2 \longleftarrow 4 \longrightarrow 5.$$

Deleting 1 or 3 has merely replaced a pair of arrows by its composite. The full category on $\{0, 1, 4, 5\}$ has two components, $\{0, 1\}$ and $\{4, 5\}$, because the omitted turning vertex 2 separates them. The least subinterval containing 1 and 5 is $\{1, 2, 4, 5\}$: the endpoints must remain, the two intervening turns must remain, and the preceding calculation shows that nothing else is required. This is the corollary on ms. 12.

The last sentence of footnote 4 asserts more than fullness permits: an interval subcategory need not be full. Inside Δ_2, keep all three objects and the arrows $0 \to 1$ and $0 \to 2$, but omit $1 \to 2$. This is a subcategory, because its two nonidentity arrows are not composable. Abstractly it is the span interval with vertex order $1, 0, 2$. It is not full in Δ_2. Thus fullness must remain part of the definition of a subinterval; it cannot be inferred solely from the abstract shape of the subcategory.

Finally, for a full subinterval with at least two vertices, an interior retained vertex is a turn in the induced shape exactly when it was an ambient critical vertex. This proves Proposition 6. The reduced interval is consequently the smallest full connected part of I which contains its endpoints, and its length is the useful length of I.

Corollaire. *L'ensemble des sommets critiques de I est aussi l'ensemble des sommets du plus petit sous-intervalle de I contenant les extrémités. Plus généralement, si $i < j$ sont deux sommets de I, le plus petit sous-intervalle de I contenant i, j est formé de i, j et des sommets critiques s tels que $i < s < j$.*

Définition. Un intervalle est dit *réduit* (ou *irrédondant*) si tous ses sommets sont critiques, ou ce qui revient au même, si ses chaînes structurales sont de longueur 1.

Un intervalle orienté *réduit* est connu, à isomorphisme près, quand on connaît

a) sa longueur n,

b) sa direction initiale + (directe) ou − (rétrograde).

NB Cette direction est la même que la direction finale si n est impair, elle est opposée si n est pair.

Ainsi, suivant les deux cas de direction initiale, on trouve

$$0 \longrightarrow 1 \longleftarrow 2 \longrightarrow \cdots \qquad \cdots\ n \qquad (\text{Avec} \quad \begin{array}{ll} n-1 \longrightarrow n & \text{si } n \text{ impair,} \\ n-1 \longleftarrow n & \text{si } n \text{ pair.)} \end{array}$$

$$0 \longleftarrow 1 \longrightarrow 2 \longleftarrow \cdots \qquad \cdots\ n \qquad (\text{Avec} \quad \begin{array}{ll} n-1 \longleftarrow n & \text{si } n \text{ impair,} \\ n-1 \longrightarrow n & \text{si } n \text{ pair.)} \end{array}$$

Proposition 6. *Un sous-intervalle J, ayant i et j $(i < j)$ comme plus petit et plus grand sommet, est réduit si et seulement si tout $s \in J$ distinct de i et de j est critique.* p. 8

Corollaire. *La sous-catégorie pleine de I formée des sommets critiques est un sous-intervalle. On l'appelle l'intervalle réduit associé à I, noté $I_{\text{réd}}$.*

p. 9

[page 13]

Commentary · Development (commentators') [ms. 12]

The critical-vertex inclusion has two adjoints

The reduced interval retains every turn, but Grothendieck has not yet described how to return to it from an arbitrary vertex. There are two particularly useful choices, one following the categorical source of a run and one following its categorical target. They relate reduction to the endpoint-preserving transformations which a path calculus needs.

Two canonical collapses. [ours] Let $j : R = I_{\text{red}} \hookrightarrow I$ be the full inclusion of the critical vertices of an oriented interval. There are retractions $r_s, r_t : I \to R$ with

$$r_t \dashv j \dashv r_s, \qquad r_s j = r_t j = \mathrm{id}_R.$$

Both retractions fix the endpoints. At a noncritical vertex x, $r_s(x)$ is the categorical source of its structural interval and $r_t(x)$ is that interval's categorical target. At a critical vertex both are the identity. For the point we set $R = I$ and take all three functors to be the identity.

Proof. A noncritical vertex lies strictly inside a unique structural interval. On a positive run $[a, b]$, the source-collapse sends every interior vertex to a, leaves b at b, and is a monotone map of its categorical chain. On a negative run the source is b and the same argument applies with the categorical order reversed. The target-collapse is obtained by exchanging source and target. The run-wise maps agree at shared critical vertices. Every arrow belongs to one run, so these formulas give functors on the whole interval.

To verify the adjunctions rather than merely exhibit homotopies, let q be a critical vertex. If x is itself critical, fullness of j gives the required hom-set bijections. If x is interior to a run, the only critical vertices comparable with x are its source a and target b, with $a \to x \to b$ in the categorical order. Indeed an arrow extending beyond either endpoint of that run would have to pass a change of sign. Consequently

$$I(jq, x) \neq \varnothing \iff q = a \iff R(q, r_s x) \neq \varnothing,$$
$$I(x, jq) \neq \varnothing \iff q = b \iff R(r_t x, q) \neq \varnothing.$$

For the middle equivalences we use that a source endpoint is a minimal vertex of I and a target endpoint a maximal vertex; hence the same holds in R. All these hom-sets are empty or singletons, so the bijections are unique and natural. They establish $j \dashv r_s$ and $r_t \dashv j$. The two retraction identities follow directly from the definition. The counit and unit are the unique arrows

$$j r_s(x) \longrightarrow x, \qquad x \longrightarrow j r_t(x),$$

which are identities whenever x is critical. This also verifies the triangle identities directly. □

These natural transformations are categorical deformations relative to all critical vertices, in particular relative to both endpoints. Applying the nerve, a natural transformation $F \Rightarrow G$ supplies a simplicial homotopy through the functor $I \times \Delta_1 \to I$ which it defines. Thus Nj has homotopy inverses Nr_s and Nr_t. Nothing in this argument asserts that the interval categories themselves are equivalent: a skeletal interval with an interior noncritical vertex has strictly more objects than its reduction.

The effect on diagrams gives a more informative comparison. For every category X, precomposition yields

$$r_s^* \dashv j^* \dashv r_t^*, \qquad j^* r_s^* = j^* r_t^* = \mathrm{id}_{\mathrm{Fun}(R,X)}.$$

This reversal of adjunctions under precomposition is the standard calculation of Riehl (n.d., Proposition 4.3.7); it can also be read directly from the two displayed natural transformations by applying each diagram $I \to X$. The source extension inserts identity arrows before the final arrow of each directed run, and the target extension inserts them after its first arrow. Restriction to R composes each run.

For $I = \Delta_2$, $R = \{0, 2\}$ and $X = \Delta_1$, consider the two diagrams with vertex values

$$F = (0, 0, 1), \qquad G = (0, 1, 1).$$

They have the same restriction $(0, 1)$ to R. There is no natural transformation $G \to F$, since its middle component would have to be $1 \to 0$ in Δ_1, whereas their restrictions have an identity map. Hence j^* is not full and is not an equivalence. If X is a groupoid, every component of both comparison transformations is invertible, and j^* is an equivalence, with either section as an inverse. Reduction therefore loses factorization data in general, but loses no such data when all arrows of the target are already invertible.

The general precomposition-adjunction statement is known and cited above. The critical-vertex reduction itself also appears in Arakawa and Cnossen (2026, Lemma 4.16). For the additional explicit adjoints and the sharp rigidity criterion below, we checked that construction, the local interval arguments here, and the adjunction calculus in Riehl (n.d., §4.3); targeted searches for critical-vertex reductions and their adjoints did not locate these particular formulations. We supply the extra deductions as elementary developments of the present definitions, without a priority claim.

Commentary · Development (commentators') [ms. 12]

The exact scope of endpoint rigidity

The false generality of Proposition 1(b) suggests asking precisely which part of an interval allows an endpoint-preserving functor to move a vertex. The preceding collapses give one implication, while a finite displacement argument gives the other.

Endpoint rigidity criterion. [ours] For a finite oriented interval I, the following are equivalent: I is reduced; every endofunctor of I fixing its two designated endpoints is the identity. We include the point as a reduced interval.

Proof. Suppose I is reduced, of length $n > 0$, and identify its vertices with $[0, n]$. A nonidentity arrow of I is then a single transition: two consecutive transitions have opposite signs and cannot compose. If $f : I \to I$ is any functor, the image of a transition is therefore either an identity or a transition. Its object function satisfies

$$-1 \le f(i) - f(i-1) \le 1 \qquad (1 \le i \le n).$$

If $f(0) = 0$ and $f(n) = n$, summation gives

$$n = f(n) - f(0) = \sum_{i=1}^{n} \big(f(i) - f(i-1)\big) \le n.$$

Equality forces every summand to be 1. Thus $f(i) = i$ for all i, and thinness forces f to be the identity on arrows as well. We have made no monotonicity assumption on f; it is a consequence of the equality. The point case is immediate.

Conversely, if I is not reduced, a structural interval has an interior vertex. The endofunctor jr_s of the preceding result fixes every critical vertex and hence both endpoints, but sends that interior vertex to the source of its run. It is not the identity. □

The obstruction is therefore exactly a nontrivial factorization inside a constant-sign run. Automorphisms cannot change such a factorization because they preserve the graph of indecomposable arrows. General functors can replace it by an identity followed by a longer composite. This is why the automorphism proof on ms. 6–7 is sound while its printed extension to all endofunctors fails.

3 Chemins. Catégorie de chemins d'un type donné τ.

Soient I un intervalle orienté, et X une catégorie. On appelle *chemin de type I dans X* tout foncteur $I \longrightarrow X$, et *catégorie de chemins de type I dans X* la catégorie

$$\underline{\mathrm{Ch}}_I(X) = \underline{\mathrm{Hom}}(I, X).$$

Comme I est *canoniquement* isomorphe à une catégorie intervalle standard I_0, on peut identifier les chemins de type I, au de type I_0. Le type τ d'un chemin le longueur n ($= \operatorname{card} I$) dans X peut donc être décrit par une suite de n signes + ou −

$$\tau_1,\ \tau_2,\ \ldots\ ,\ \tau_n \qquad (\tau_i \in \{-1, +1\} \text{ pour } 1 \le i \le n).$$

À cause du fait que I est engendré pas ses flèches de transition, un foncteur $c : I \longrightarrow X$ est déterminé quand on connaît

a) Les $c(i)$ ($i \in I$), i.e. une suite de $n+1$ objets de X :

$$a_0,\ a_1,\ \ldots\ ,\ a_n\ ([5]);$$

b) Les $c(\underline{u}_i)$ (où les $\underline{u}_i$ sont les flèches de transition dans I), i.e. pour tout $i \in [1, n]$ une flèche u_i dans X entre a_{i-1} et a_i, allant de a_{i-1} dans a_i si $\underline{u}_i$ est directe ($\tau_i = +1$), et de a_i dans a_{i-1} si $\underline{u}_i$ est rétrograde ($\tau_i = -1$),

5. a_0 est dit la *source* du chemin, a_n son but.

et à toute telle donnée a), b) correspond un foncteur. Ainsi on pourra identifier les chemins de type I dans X aux diagrammes du type précisé dans X. Et les morphismes entre chemins correspondent de même aux morphismes entre diagrammes a et a', une flèche $a \xrightarrow{\alpha} a'$ étant donc une suite de $n+1$ flèches [page 14]

$$\alpha_i : a_i \longrightarrow a'_i, \qquad i \in [0, n],$$

satisfaisant la condition de commutativité pour les n carrés

$$\begin{array}{ccc} a_{i-1} & \xrightarrow{u_i} & a_i \\ {\scriptstyle \alpha_{i-1}}\downarrow & & \downarrow{\scriptstyle \alpha_i} \\ a'_{i-1} & \xrightarrow{u'_i} & a'_i \end{array} \qquad \text{(cas } \underline{u}_i \text{ directe)}$$

ou

$$\begin{array}{ccc} a_{i-1} & \xleftarrow{u_i} & a_i \\ {\scriptstyle \alpha_{i-1}}\downarrow & & \downarrow{\scriptstyle \alpha_i} \\ a'_{i-1} & \xleftarrow{u'_i} & a'_i. \end{array} \qquad \text{(cas } \underline{u}_i \text{ rétrograde)}$$

p. 10

Si on a une flèche entre deux sommets quelconque i, j dans I, avec $i < j$ et j non successeur immédiat de i, alors i, j appartiennent à un même intervalle critique, et dans I on aura

$$i \xrightarrow{\underline{u}_{i+1}} i+1 \xrightarrow{\underline{u}_{i+2}} \cdots\ j-1 \xrightarrow{\underline{u}_j} j \qquad \text{une chaîne de longueur } j-i \geq 2$$

ou

$$i \longleftarrow i+1 \longleftarrow \quad \cdots\ j-1 \longleftarrow j,$$

et la flèche correspondante entre a_i et a_j s'obtient en composant les flèches u_i correspondantes.

[page 15]

Commentary · Exposition [ms. 14]

A fixed path type is a freely generated diagram

Grothendieck now uses the work on intervals to make path data and path morphisms completely explicit. Fixing the type does not impose any compatibility among the arrows of the path beyond their sources and targets. This is the benefit of having chosen a free path category as the domain.

For example, let the type be $(+,+,-)$. A diagram consists of

$$a_0 \xrightarrow{u_1} a_1 \xrightarrow{u_2} a_2 \xleftarrow{u_3} a_3.$$

The only nonidentity arrow of the domain which is not a transition is $0 \to 2$, and its image must be u_2u_1. Given a second diagram $a'_0 \to a'_1 \to a'_2 \leftarrow a'_3$, a map between them consists of four arrows $\alpha_i : a_i \to a'_i$ satisfying

$$\alpha_1 u_1 = u'_1 \alpha_0, \qquad \alpha_2 u_2 = u'_2 \alpha_1, \qquad \alpha_2 u_3 = u'_3 \alpha_3.$$

Naturality for the longer arrow follows by calculation:

$$\alpha_2(u_2u_1) = (u'_2\alpha_1)u_1 = u'_2(u'_1\alpha_0) = (u'_2u'_1)\alpha_0.$$

Every longer constant-sign run is handled by the same induction, with the index order reversed when its arrows are retrograde. Thus the displayed transition squares are both necessary and sufficient for a natural transformation. Identities and composition are taken vertex by vertex; composing commutative squares verifies that the result is again a morphism of paths.

This also gives a useful exact model of the fixed-type category. Let $\mathrm{Arr}(X) = \mathrm{Fun}(\Delta_1, X)$, with ordinary domain and codomain functors d, c. For a positive transition its ordered endpoint pair is (d, c); for a negative one it is (c, d). Then $\mathrm{Fun}(I_\tau, X)$ is the iterated strict fibre product of n copies of $\mathrm{Arr}(X)$, matching the second ordered endpoint of one to the first ordered endpoint of the next. On objects this identifies the shared vertices. On arrows it identifies the corresponding vertical

components of the naturality squares. The two descriptions are therefore isomorphic as categories, not merely bijective on objects. At length zero the category is X itself.

The construction retains all factorizations and all commuting ladders between them. It has not inverted the retrograde arrows in X and has not identified paths related by a ladder. Those operations would require additional choices or a localization. Here a retrograde transition simply says that the arrow of X points against the chosen order of traversal. Keeping this distinction explicit will matter when the category of types starts to vary.

Exemples.

1. $I = \mathbf{\Delta}_0 = e$, $\underline{\mathrm{Ch}}_I(X) \simeq X$. Les chemins de longueur 0 s'identifient aux objets a de X. L'unique élément id_e de $\mathrm{Fl}(I)$ donne id_a dans X.
2. $I = \mathbf{\Delta}_1^+$, $\underline{\mathrm{Ch}}_I(X) \simeq \underline{\mathrm{Fl}}(X)$. Les chemins de type $\mathbf{\Delta}_1^+$ sont ceux de longueur 1 et *directs,* i.e. donnés par une flèche
$$a_0 \longrightarrow a_1$$
dont la source est aussi la source a_0 du chemin. Par contre, les chemins de type $\mathbf{\Delta}_1^-$ sont donnés par des diagrammes
$$a_0 \longleftarrow a_1,$$
i.e. par des flèches dont le but est considéré comme source du chemin. Bien sûr, les catégories $\underline{\mathrm{Ch}}_{\mathbf{\Delta}_1^+}(X)$ et $\underline{\mathrm{Ch}}_{\mathbf{\Delta}_1^-}(X)$ sont canoniquement isomorphes, mais par un isomorphisme qui *échange source et but du chemin.* Nous nous garderons donc bien de confondre les deux chemins précédents.
3. $\mathbf{\Delta}_2^+$, $\mathbf{\Delta}_2^-$, correspondant aux diagrammes [page 16]
$$a_0 \longrightarrow a_1 \longrightarrow a_2$$
resp.
$$a_0 \longleftarrow a_1 \longleftarrow a_2,$$
on peut faire une remarque similaire que pour $\mathbf{\Delta}_1^+$, $\mathbf{\Delta}_1^-$.
4. Φ_1, Ψ_1, ce sont respectivement les intervalles p. 11
$$\Phi_1 :\ 0 \xleftarrow{u_0} 1 \xrightarrow{u_1} 2 \qquad \text{ou} \qquad \begin{array}{ccc} & & 0 \\ & \nearrow & \\ 1 & & \\ & \searrow & \\ & & 2 \end{array},$$
et
$$\Psi_1 :\ 0 \xrightarrow{u_0} 1 \xleftarrow{u_1} 2 \qquad \text{ou} \qquad \begin{array}{ccc} & & 0 \\ & \swarrow & \\ 1 & & \\ & \nwarrow & \\ & & 2 \end{array}.$$
Ils correspondent respectivement aux diagrammes
$$a_0 \xleftarrow{u_0} a_1 \xrightarrow{u_1} a_2$$
et
$$a_0 \longrightarrow a_1 \longleftarrow a_2.$$
Les catégories Φ_1, Ψ_1 sont opposées l'une de l'autre, et ne sont pas isomorphes. Aussi n'y a-t-il en général aucun isomorphisme entre $\underline{\mathrm{Ch}}_{\Phi_1}(X)$ et $\underline{\mathrm{Ch}}_{\Psi_1}(X)$.

Commentary · Context [ms. 16]

Zigzags before taking a localization

Grothendieck's paths belong to the same categorical language as fractions, while retaining information which a category of fractions has already identified. In Gabriel and Zisman (1967, Chapter I, §1.1), localization adjoins inverses to a specified collection of arrows and imposes the relations needed for functoriality and inversion. A span $x \leftarrow z \rightarrow y$ can consequently represent a morphism from x to y when its left arrow is among those to be inverted. The fixed-type path category written here makes no such selection: the objects and every component of a natural transformation are ordinary categorical data.

The two-dimensional comparison is equally concrete. The reduced hammocks of Dwyer and Kan (1980a, Definition 2.1) consist of commutative ladders of zigzags, but their vertical arrows and their left-pointing arrows are required to lie in a specified subcategory of weak equivalences; identity columns are removed and neighbouring columns of the same direction are composed. Their Proposition 3.1 identifies connected components of the resulting mapping spaces with ordinary localized morphisms. Grothendieck's full functor category of one fixed interval is therefore an ingredient of a comparable calculus, not by itself a hammock mapping space. The later commentary on the varying category of types explains the precise relation; here the historical comparison tells us why it is useful to retain ladders rather than only strings of arrows.

Soit I un intervalle orienté, et considérons l'*intervalle opposé* I^{opp}, ayant même catégorie sous-jacente mais l'orientation opposé. Comme la définition de la catégorie des chemins du type I ne fait pas intervenir l'orientation de I, on a donc un isomorphisme canonique

$$\underline{\mathrm{Ch}}_I(X) \xrightarrow{\sim} \underline{\mathrm{Ch}}_{I^{\mathrm{opp}}}(X).$$

[page 17]

Commentary · Examples [ms. 16]

A span and a cospan give different diagram categories

Grothendieck emphasizes that the direction of a turn changes the fixed-type category. The difference can be seen without any localization or homological algebra. We give a finite example which also distinguishes equivalence of categories, not only strict isomorphism.

Let X be the three-object poset

$$a \longleftarrow b \longrightarrow c.$$

A span diagram in X is a triple (x_0, x_1, x_2) with $x_1 \leq_X x_0$ and $x_1 \leq_X x_2$. If its middle value is b, each endpoint can independently be a, b, or c, giving nine diagrams. If the middle value is a, both endpoints must be a; if it is c, both must be c. Thus

$$\left|\mathrm{Ob}\,\mathrm{Fun}(\Phi_1, X)\right| = 3^2 + 1^2 + 1^2 = 11.$$

A cospan diagram has $x_0 \leq_X x_1$ and $x_2 \leq_X x_1$. For middle value b there is one possibility. For middle value a, both endpoints independently lie in $\{b, a\}$, giving four; for middle value c, both independently lie in $\{b, c\}$, again giving four. Hence

$$\left|\mathrm{Ob}\,\mathrm{Fun}(\Psi_1, X)\right| = 1^2 + 2^2 + 2^2 = 9.$$

Morphisms in both functor categories are completely determined: there is one from (x_0, x_1, x_2) to (y_0, y_1, y_2) exactly when $x_i \leq_X y_i$ for each i. The naturality squares then commute automatically because X is thin. These categories are posets and have no distinct isomorphic objects. An equivalence between posets is an isomorphism, since essential surjectivity is actual surjectivity and full faithfulness reflects their order. Their different object counts therefore rule out an equivalence.

Orientation reversal is a separate operation. For the span, interchanging x_0 and x_2 gives another span and an automorphism of its diagram category. It leaves the middle vertex and both arrow directions of the underlying span shape intact, while exchanging the two endpoint evaluations. Passing from the span to the cospan reverses the categorical arrows at the turn. The preceding count detects exactly that change.

Commentary · Later developments [ms. 16]

When a change of orientation becomes a stable equivalence

The span–cospan distinction remains real for the ordinary functor categories which Grothendieck has just defined. A later theorem explains why analogous diagram categories can nevertheless become equivalent after one passes to a stable homotopy theory. For a finite oriented tree Q, Groth and Šťovíček (2016, Theorem 9.19 and Corollary 9.23, arXiv v3) construct reflection equivalences and deduce strong stable equivalence between any two orientations of the same underlying tree. In particular, for a stable derivator $\mathbb{D}$,

$$\mathbb{D}^{\Phi_1} \simeq \mathbb{D}^{\Psi_1}.$$

These are equivalences of shifted derivators, natural with respect to exact morphisms. They are constructed using stable operations such as fibres, cofibres, and biproducts; they are not induced by an isomorphism of the span and cospan categories. The finite example above therefore presents no obstruction. It concerns arbitrary ordinary targets, whereas the reflection theorem uses stability to transform the values and arrows of the diagram. This gives a precise later setting in which changing the signs of an interval preserves a diagram theory even though it does not preserve its indexing category.

Néanmoins on se gardera de confondre un chemin de type I avec le chemin opposé de type I^{opp}, la source de l'un étant le but de l'autre et inversement. C'est dire qu'un chemin doit être vu comme *plus* qu'un simple foncteur

$$I \longrightarrow X,$$

il faut de plus se donner l'*orientation de I* comme faisant partie de la structure de chemin. Donc la définition formelle raisonnable, qui colle à l'intuition du chemin comme allant d'une *source* bien définie vers un *but* également bien défini, c'est qu'un chemin (défini en termes d'une catégorie intervalle I) est la donné d'un couple (ω, c), où ω est une orientation de I, et c un foncteur $c : I \longrightarrow X$. Quand on regarde la catégorie des chemins d'un 'type' déterminé, ce *type* est (I, ω), et non I. C'est quand ω est fixé une bonne fois que cette catégorie s'identifie impunément à $\underline{\mathrm{Hom}}(I, X)$ sans plus.

Il faut voir cette catégorie de chemins comme munie de la structure essentielle

$$\begin{array}{c} \underline{\mathrm{Ch}}_{(I,\omega)}(X) \\ \big\downarrow{\scriptstyle (\sigma,\beta)} \\ X \times X \end{array} \qquad \begin{array}{l} c \longmapsto (\sigma(c), \beta(c)) \\ \text{ou } \sigma(c) \text{ est la } \textit{source}, \\ \qquad \beta(c) \text{ le } \textit{but} \text{ de } c. \end{array}$$

p. 12
[page 18]

Commentary · Exposition [ms. 17]

The endpoints are part of the fixed-type object

Grothendieck's insistence on orientation is most transparent over the category of endpoint pairs. The category attached to an oriented type (I, ω) is not merely $\mathrm{Fun}(I, X)$; it comes with the functor

$$(\sigma, \beta) : \mathrm{Fun}(I, X) \longrightarrow X \times X.$$

On a natural transformation $\alpha : c \Rightarrow d$, its value is (α_0, α_n). Thus a morphism of paths may move the endpoints, and the displayed functor records exactly how. Its strict fibre over (x, y) consists of paths with endpoints x, y and natural transformations which are the identity at both endpoints. This fibre is a concrete category of fixed-endpoint ladders.

Let ω' be the reverse orientation on the same underlying interval category. The identity on that underlying category identifies the two ordinary functor categories; under this identification the endpoint pair changes from $(c(0), c(n))$ to $(c(n), c(0))$. Consequently the comparison is a functor over the transposition $s(x, y) = (y, x)$. If $x \neq y$, it carries the fibre over (x, y) to the fibre over (y, x), not to itself. This explains why equality of the underlying functor categories does not erase the distinction between a path and its reverse.

The endpoint map $\alpha : \{0,1\}_{\mathrm{disc}} \to I$ packages the same structure as restriction. For positive length its two images are distinct. For length zero it is the fold onto the sole vertex, so the word "inclusion" on the next page needs that qualification; restriction is then the diagonal $X \to X \times X$. All the formulas still hold. The subsequent discussion of symmetric types compares this identity-on-underlying-diagram reversal with the additional comparison induced by a reflection of the shape. Their difference belongs to the structure over $X \times X$, which is why the base category has been kept visible.

Ce foncteur s'identifie au foncteur de composition

$$c \longmapsto c \circ \alpha$$

où α est le foncteur d'inclusion

$$\begin{cases} \varepsilon \xrightarrow{\alpha} I \\ \varepsilon = \{0,1\}, & \text{catégorie discrète à deux éléments,} \\ \alpha \text{ donné par} & \alpha(0) = \text{ source de } I \\ & \alpha(1) = \text{ but de } I. \end{cases}$$

Si ω' est l'orientation opposée de I, on a un diagramme commutatif

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{(I,\omega)}(X) & \xrightarrow[\sim]{\varphi} & \underline{\mathrm{Ch}}_{(I,\omega')}(X) \\ \downarrow{\scriptstyle (\sigma,\beta)} & & \downarrow{\scriptstyle (\sigma',\beta')} \\ X \times X & \xrightarrow{\ s\ } & X \times X, \end{array}$$

où s est le foncteur de symétrie

$$s(x,y) = (y,x)$$

([6]). Donc l'isomorphisme φ ne respecte pas les flèches structurales 'source-but' (σ, β).

Il y a cependant un embarras quand il existe un isomorphisme d'intervalles *orientés*

$$\theta : (I,\omega) \xrightarrow{\sim} (I,\omega'),$$

i.e. quand I est symétrique. Ce n'est pas le cas pour les $\mathbf{\Delta}_i$ $(i \geq 1)$ (ces catégories n'ont pas d'autres automorphismes que l'identité), mais c'est le cas pour les catégories Φ_1, Ψ_1 de l'exemple 4°, plus généralement pour les catégories réduites de longueur *paire.* Comme [page 19]
chaque fois qu'on a un isomorphisme θ d'intervalles *orientés,* on trouve un isomorphisme entre les catégories de chemins de type (I,ω) et $(I,\omega)^{\mathrm{opp}} = (I,\omega')$, *compatible* cette fois avec les foncteurs (σ,β) :

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{(I,\omega)}(X) & \xrightarrow[\sim]{\Psi_\theta} & \underline{\mathrm{Ch}}_{(I,\omega')}(X) \\ & {\scriptstyle (\sigma,\beta)} \searrow \quad \swarrow {\scriptstyle (\sigma',\beta')} & \\ & X \times X. & \end{array}$$

Il est bon de regarder un *type* de chemins comme une donné non catégorique, mais p. 13
combinatoire, une simple suite τ de n signes τ_i $(1 \leq i \leq n)$ + ou − (n = longueur des chemins [page 20]
envisagés). Cette donné combinatoire définit un intervalle orienté standard, I_τ. Quand on a un intervalle orienté quelconque (I,ω), il définit un type τ, et on l'identifie canoniquement au type I_τ. Il vaut mieux écrire $\underline{\mathrm{Ch}}_\tau(X)$, plutôt que $\underline{\mathrm{Ch}}_{(I,\omega)}(X)$, pour bien indiquer que pour

6. Le foncteur φ est celui qui associe à tout chemin c, de type τ, le *chemin opposé* c^{opp} ou c^{-1}, de type τ^{opp}. Si $\tau = \tau^{\mathrm{opp}}$, c'est donc un chemin *de même type,* et φ est un *automorphisme* de $\underline{\mathrm{Ch}}_\tau(X)$. Cet automorphisme (fonctoriel en X) est déduit d'un automorphisme θ de I, cf. ci-dessous.

X donné, c'est là une catégorie totalement 'épinglée', sans automorphismes liés à la nature particulière de τ (à des automorphismes de τ!).

On peut préciser ce point ainsi. Soit τ' un autre type d'intervalles, et proposons-nous de déterminer des 'lois' qui permettent à tout chemin de type τ dans une catégorie arbitraire X, d'associer un chemin de type τ' de cette même catégorie, et ceci de façon 'fonctorielle', i.e. compatible avec les applications horizontales

$$\begin{array}{ccc} \mathrm{Ch}_\tau(X) & \xrightarrow{\mathrm{Ch}_\tau(f)} & \mathrm{Ch}_\tau(X') \\ {\scriptstyle L_X}\downarrow & & \downarrow{\scriptstyle L_{X'}} \\ \mathrm{Ch}_{\tau'}(X) & \xrightarrow{\mathrm{Ch}_{\tau'}(f)} & \mathrm{Ch}_{\tau'}(X') \end{array}$$

associées à un foncteur $f : X \longrightarrow X'$.

[page 21]

Commentary · Exposition [ms. 20]

Operations on paths are maps of their shapes

Grothendieck wants to do the combinatorics once, in a category small enough that every operation can be seen. A path in an arbitrary category carries many labels, but an operation valid for every category cannot depend on accidental properties of those labels. Its entire content is already present in the universal path. The passage from an oriented interval to its sign word makes this universal object unambiguous. It does not assert that a particular category of paths has no automorphisms; it removes the ambiguity coming from presenting the same unoriented interval in two different ways.

Write $P_I(X) = \mathrm{Hom}_{\mathrm{Cat}}(I, X)$ for the *set* of paths of shape I, keeping $X^I = \underline{\mathrm{Hom}}(I, X)$ for their category. The distinction between these two expressions matters in the displayed Yoneda argument. If

$$L_X : P_I(X) \longrightarrow P_J(X)$$

is natural in all functors $X \to Y$, put $\varphi = L_I(\mathrm{id}_I) : J \to I$. Applying naturality to the functor $c : I \to X$ gives

$$L_X(c) = c \circ L_I(\mathrm{id}_I) = c\varphi.$$

Thus every such operation is precomposition with exactly one φ, and every φ defines such an operation. This is the covariant Yoneda lemma, with the representing objects appearing in the reverse order; see Riehl (n.d., Theorem 2.2.4 and Corollary 2.2.8). No hypothesis about interval categories is needed for this argument.

There is then a canonical operation on morphisms of paths. If $v : c \Rightarrow d$, set $(L_X v)_j = v_{\varphi(j)}$. For an arrow $a : j \to k$ of J, its naturality square is the naturality square of v at $\varphi(a)$. Identities and composites are preserved component by component. Consequently the operation lifts to the functor

$$\varphi^* : X^I \longrightarrow X^J.$$

This proves the extension asserted on manuscript page 23, without assuming a separate coherence theorem. Natural transformations between changes of shape have an equally concrete meaning: $\alpha : \varphi \Rightarrow \psi$ gives $c\alpha : c\varphi \Rightarrow c\psi$, naturally in c and X.

The special advantage of intervals now enters. They are posets, so a functor into an interval is determined by its object function, and a natural transformation between two such functors exists precisely when the corresponding pointwise arrows exist. If it exists, it is unique. This uniqueness makes every required diagram of *shape transformations* commute. It does not make the categories X^I thin when X is an arbitrary category: those categories still remember all morphisms of X.

For fixed endpoints the same universal-path argument is even more economical. Suppose I and J have specified sources and targets. The operation $c \mapsto c\varphi$ preserves both endpoints for every X and c exactly when $\varphi(0_J) = 0_I$ and $\varphi(1_J) = 1_I$. Necessity follows by taking $X = I$ and $c = \mathrm{id}_I$; sufficiency is direct evaluation. This is the reason the first category of all changes of shape will soon have to be restricted.

Par exemple, prenant le type $\mathbf{\Delta}_2^+$ (i.e. $+1, +1$), correspondant aux chemins

$$a_0 \xrightarrow{u_1} a_1 \xrightarrow{u_2} a_2,$$

on peut associer à un tel chemin le chemin de type $[\mathbf{\Delta}_1^+]$

$$a_0 \xrightarrow{u_2u_1} a_2,$$

ou aussi le chemin de type $\mathbf{\Delta}_2^+$

$$a_0 \xrightarrow{u_2u_1} a_2 \xrightarrow{\mathrm{id}} a_2,$$

etc. Comme le foncteur

$$\begin{cases} X & \longmapsto & \mathrm{Ch}_\tau(X) & (= \mathrm{Ob}\,\underline{\mathrm{Ch}}_\tau(X)) \\ \mathrm{Cat} & \longrightarrow & (\mathrm{Ens}) \end{cases}$$

est *représenté* par l'objet I_τ de X [plutôt de Cat], le sorite des foncteurs représentables nous dit que de telles lois de formation de chemins de type τ à partir des chemins de type τ' [plutôt τ' à partir des chemins de type τ] correspondent biunivoquement aux flèches dans Cat

$$I_{\tau'} \xrightarrow{\varphi} I_\tau\ ,$$

en prenant simplement la 'loi' correspondante à φ p. 14

$$c \longmapsto c \circ \varphi \qquad \text{pour } c : I_\tau \longrightarrow X.$$

De façon plus précise, l'application naturelle

$$\underbrace{\mathrm{Hom}_{\mathrm{Cat}}(I_{\tau'}, I_\tau)}_{=\mathrm{Ob}\,\underline{\mathrm{Hom}}(I_{\tau'}, I_\tau)} \longrightarrow \mathrm{Hom}(\mathrm{Ch}_\tau, \mathrm{Ch}_{\tau'}),$$

où le deuxième Hom est considéré comme un Hom d'objets dans $\mathrm{Cat}^\vee = \underline{\mathrm{Hom}}(\mathrm{Cat}, \mathrm{Ens})$. Ainsi, dans les deux exemples plus haut, où $\tau = \mathbf{\Delta}_2^+$ et $\tau' = \mathbf{\Delta}_1^+$ ou $\mathbf{\Delta}_2^+$, les foncteurs en sens inverse sont [page 22]

$$\begin{array}{lll} \mathbf{\Delta}_2^+ & \{ & 0 \longrightarrow 1 \longrightarrow 2 \\ & & \uparrow \qquad\quad \uparrow \\ \mathbf{\Delta}_1^+ & \{ & 0 \longrightarrow\quad 1 \end{array}$$

et

$$\begin{array}{lll} \mathbf{\Delta}_2^+ & \{ & 0 \longrightarrow 1 \longrightarrow 2 \\ & & \uparrow \quad \nearrow \quad \uparrow \\ \mathbf{\Delta}_2^+ & \{ & 0 \longrightarrow 1 \longrightarrow 2\,. \end{array}$$

C'est là un principe général pour ramener toutes les 'opérations' $\pm$ canoniques sur des chemins dans des catégories arbitraires, et des énoncés les concernant, à des questions où X disparaît et où on travaille dans les catégories intervalles elles-mêmes. Un des avantages techniques, c'est que ce sont des catégories fort petites, donnant lieu de plus à une intuition topologique sûre (qui risque de se volatiliser par moments en travaillant dans des catégories de chemins), et aussi que dans de telles catégories, donc aussi dans les catégories de foncteurs entre elles, il y a toujours au plus *une seule flèche* allant d'un objet donné vers un autre. En d'autres termes, dans de telles catégories tous les diagrammes sont commutatifs. [page 23]

Bien sûr, on voit aussi que si on a une loi de formation L de chemins de type τ' à partir de chemins de type τ (avec la condition de fonctorialité par rapport à la catégorie X où on prend les chemins), cette loi est nécessairement *fonctorielle par rapport aux chemins :* si on a un homomorphisme

$$c \xrightarrow{v} c' \qquad \text{dans } \underline{\mathrm{Ch}}_\tau(X), \qquad \text{p. 15}$$

alors la loi L 'se prolonge' à de tels v pour donner

$$L(c) \xrightarrow{L(v)} L(c'),$$

avec les relations habituelles

$$L(\mathrm{id}_C) = \mathrm{id}_{L(c)}, \qquad L(v'v) = L(v')L(v).$$

Cela résulte de la description de L comme une opération L_φ en termes d'un foncteur bien déterminé

$$I_{\tau'} \xrightarrow{\varphi} I_\tau,$$

lequel à son tour donne pour toute X un *foncteur*

$$\begin{cases} \underline{\mathrm{Ch}}_\tau(X) & \longrightarrow & \underline{\mathrm{Ch}}_{\tau'}(X) \\ c & \longmapsto & c \circ \varphi \end{cases}$$

plus précis que simplement un *application* $\mathrm{Ch}_\tau(X) \longrightarrow \mathrm{Ch}_{\tau'}(X)$ entre les ensembles d'objets correspondants.

Commentary · Examples [ms. 23]

Composition and insertion of an identity

The two examples on manuscript pages 21–22 illustrate how a familiar operation becomes a finite calculation before any coefficient category is chosen. Take $I = [2] = (0 \to 1 \to 2)$ and $J = [1]$. The unique endpoint-preserving functor $\varphi : J \to I$ sends 0 to 0 and 1 to 2. A path $c = (a_0 \xrightarrow{u} a_1 \xrightarrow{v} a_2)$ therefore becomes the arrow $vu : a_0 \to a_2$.

A morphism from c to $d = (b_0 \xrightarrow{u'} b_1 \xrightarrow{v'} b_2)$ is a triple (h_0, h_1, h_2) satisfying $h_1 u = u' h_0$ and $h_2 v = v' h_1$. The induced morphism between the composite arrows is the square with sides h_0, h_2. Its commutativity follows from the explicit computation

$$h_2 vu = v' h_1 u = v' u' h_0.$$

The middle component has done its work and can be forgotten. The reversed variance is essential: an operation which reduces the length of a path is represented here by a functor from the shorter interval to the longer one.

For the second operation let $J = I = [2]$ and take the nondecreasing object function $\psi = (0, 2, 2)$. Then $\psi^* c = (a_0 \xrightarrow{vu} a_2 \xrightarrow{1} a_2)$, and $\psi^* h = (h_0, h_2, h_2)$. The first naturality square is the square just computed; the second is $h_2\, 1 = 1\, h_2$. Since $\psi\psi = \psi$, the resulting operation on paths is strictly idempotent. This equality is checked on the three objects of $[2]$, rather than on all categories and all pairs of composable arrows.

Endpoint preservation alone has not made such maps rigid. On $[2]$ the three nondecreasing endpoint-preserving endofunctors have object functions $(0, 0, 2)$, $(0, 1, 2)$, and $(0, 2, 2)$. They respectively place the composite in the second edge, leave the path unchanged, and place the composite in the first edge. This also supplies a concrete reminder of the correction to Proposition 1(b): fixing the endpoints does not force an arbitrary endofunctor of a nonreduced interval to be the identity. The rigidity there belongs to isomorphisms, while the present theory deliberately needs the noninvertible maps.

On a le choix maintenant entre

a) Une étude plus ou moins systématique des foncteurs entre intervalles. Je préfère attendre pour cela d'avoir besoin de ceci et de cela, et de ne faire que le strict minimum pour les constructions que j'ai en vue. [page 24]

b) Une description de la compositions des chemins.

c) Un formalisme des catégories de chemins *de type non précisé.*

Comme mon objectif est surtout de décrire de telles catégories $\underline{\mathrm{Ch}}(X)$ (sans indice τ!), avec des bonnes propriétés, je commencerai par c), regarderai ensuite b) comme un test crucial pour l'utilisabilité des notions obtenues, et enfin m'occuperai de a) quand je saurai de quoi j'aurai en besoin. p. 16

4 Catégorie de chemins $\underline{\mathrm{Ch}}(X)$

Je veux 'inclure' toutes les catégories $\underline{\mathrm{Ch}}_\tau(X)$ de chemins de tous les types qu'on veut, dans une même catégorie $\underline{\mathrm{Ch}}(X)$. Rappelons

$$\underline{\mathrm{Ch}}_\tau(X) = \underline{\mathrm{Hom}}(I_\tau, X),$$

où I_τ est l'intervalle (orienté) standard de type τ.

L'ensemble de tous les types d'intervalles peut être identifié au monoïde libre Ty à deux [page 25] générateurs Δ^+ et Δ^-, dont les éléments sont les suites finies quelconques (eventuellement vides) d'objets alternativement égales à Δ^+ et à Δ^-. Si le premier élément est Δ^+, on a un type de chemin à direction initiale directe, rétrograde dans le cas contraire. La décomposition de I_τ, ou de $\mathrm{Fl}\,(I_\tau)$, en intervalles critiques correspond à l'écriture réduite d'un mot comme

$$(\Delta^+)^{l_1}(\Delta^-)^{l_2}\ \cdots\ (\Delta^?)^{l_r} \qquad (\Delta^? = \Delta^+ \text{ si } r \text{ impair}, \Delta^? = \Delta^- \text{ si } r \text{ pair}),$$

ou comme

$$(\Delta^-)^{l_1}(\Delta^+)^{l_2}\ \cdots\ (\Delta^?)^{l_r} \qquad (\Delta^? = \Delta^- \text{ si } r \text{ impair}, \Delta^? = \Delta^+ \text{ si } r \text{ pair}).$$

Les l_i sont les longueurs des intervalles critiques successifs (ou des chaines structurales successives), leur nombre est la longueur réduite de l'intervalle.

On va considérer Ty comme l'ensemble des objets d'une catégorie $\underline{\mathrm{Ty}}$:

$$\begin{cases} \mathrm{Ob}\,\underline{\mathrm{Ty}} = \mathrm{Ty} = \text{ monoïde libre à deux générateurs } \Delta^+,\ \Delta^- \text{ précédents.} \\ \text{Si } \tau, \tau' \in \mathrm{Ty},\ \mathrm{Hom}(\tau, \tau') = \mathrm{Hom}_{\mathrm{Cat}}(I_\tau, I_{\tau'}). \end{cases}$$

([7]). On notera qu'on a non seulement un ensemble $\mathrm{Hom}_{\mathrm{Cat}}(I_\tau, I_{\tau'})$, mais même une catégorie $\underline{\mathrm{Hom}}(I_\tau, I_{\tau'})$, ce qui revient ici à dire que $\mathrm{Hom}(I_\tau, I_{\tau'})$ (i.e. $\mathrm{Hom}(\tau, \tau')$) peut être vu comme un ensemble *ordonné*. Mais pour l'instant nous allons ignorer cette relation d'ordre.

La composition des morphismes est la composition des foncteurs entre catégories I_τ. Ainsi [page 26] on a un foncteur *pleinement fidèle* ([8]) canonique

$$\tau \longmapsto I_\tau : \underline{\mathrm{Ty}} \xrightarrow{\rho} (\mathrm{Cat}) \qquad ([9]),$$

par quoi la catégorie I_τ `[plutôt` $\underline{\mathrm{Ty}}$`]` pourrait s'identifier à une sous-catégorie pleine de (Cat) (celle des I_τ). Mais je préfère ne pas identifier $\tau \in \mathrm{Ty}$ (donnée combinatoire) avec I_τ (donnée catégorique). p. 17

Commentary · Exposition [ms. 25]

Three successive categories of types

Grothendieck is testing which changes of parameter should count as morphisms of paths. The changes of definition in these pages are purposeful, but a notation retained through all three stages can obscure which fullness assertion remains true. We distinguish the stages here, without altering the source's notation. All three categories have the finite sign words as objects, including the empty word e.

Let T_{all} have every functor $I_\tau \to I_\upsilon$ as a morphism; let T_∂ retain just the functors preserving the two chosen endpoints; and let $T_\uparrow$ retain those which also preserve the external, linear order of vertices. Thus

$$T_\uparrow \subseteq T_\partial \subseteq T_{\mathrm{all}}.$$

7. Définition un peu canulée, il faut se borner aux homomorphismes de I_τ dans $I_{\tau'}$ compatibles avec source et but - cf. p. 29.

8. faux, cf. annotation marginale page précédente - on ne prend pas *tous* les foncteurs dans Cat entre I_τ et $I_{\tau'}$.

9. foncteur *réalisation* d'un type (combinatoire) d'intervalles.

The category eventually denoted by $\underline{\mathrm{Ty}}$ in these pages is $T_{\uparrow}$. On page 25 it is initially T_{all}, while pages 29–31 pass through T_{∂}. For T_{all}, realization in Cat is fully faithful by definition. For T_{∂}, realization is fully faithful into $\varepsilon\backslash\mathrm{Cat}$, where ε is the discrete category on two objects; forgetting ε loses fullness. For $T_{\uparrow}$ even the embedding into $\varepsilon\backslash\mathrm{Cat}$ is generally not full. The footnotes retracting fullness on page 26 and the assertion of fullness on page 31 are therefore compatible when read at their respective stages.

Here is a small witness to the last distinction. From the alternating interval I_{+-+} to I_+ there is a functor with object function

$$(0,1,2,3) \longmapsto (0,1,0,1).$$

Every forward transition goes to $0 \to 1$ and the backward transition, whose categorical direction is from its right vertex to its left vertex, also goes to $0 \to 1$. Both endpoints are preserved, but the vertex function is not nondecreasing. Thus it belongs to T_{∂} and not to $T_{\uparrow}$. The monotonicity condition excludes this backtracking.

The sign words themselves form a free monoid on $+$ and $-$. Arbitrary adjacent repetitions are allowed; the alternating feature is the alternation of signs between *maximal constant runs*. A nonempty word has a unique expression $\varepsilon_1^{l_1} \cdots \varepsilon_r^{l_r}$ with $l_i > 0$ and $\varepsilon_{i+1} = -\varepsilon_i$. Its length is $\sum l_i$, its useful length is r, and its critical intervals are these runs with their endpoint vertices restored. The empty word has length and useful length zero and no initial sign. This last exception should remain in force whenever the text speaks of the first generator.

In the undercategory description, $\varepsilon \to I_e$ identifies the two objects of ε. It is a structure map, not an embedding; the hooked arrows drawn on page 29 should not be read as asserting injectivity in this degenerate case. Keeping e is indispensable: it will be the unit for concatenation.

Soit X une (petite?) catégorie. On a un contrafoncteur

$$\begin{cases} S & \longmapsto & \underline{\mathrm{Hom}}(S, X) \\ (\mathrm{Cat})^o & \longrightarrow & (\mathrm{Cat}) \end{cases}$$

défini par X, d'où en composant avec ρ un contrafoncteur

$$\underline{\mathrm{Ty}}^o \xrightarrow{\mathrm{CH}_X} \mathrm{Cat}.$$

C'est le contrafoncteur

$$\begin{cases} \tau \longmapsto \underline{\mathrm{Hom}}(I_\tau, X) \overset{\text{déf}}{=} \underline{\mathrm{Ch}}_\tau(X), \\ \text{i.e. } \mathrm{CH}_X(\tau) = \underline{\mathrm{Ch}}_\tau(X). \end{cases}$$

Mais un contrafoncteur sur une petite catégorie $\underline{\mathrm{Ty}}$ donne lieu à une *catégorie fibrée* (et même scindée) sur celle-ci.

Je vais désigner cette catégorie fibrée par $\underline{\mathrm{Ch}}(X)$. (Provisoirement - si elle s'avère trop grosse, je la restreindrai …) Ainsi on a [page 27]

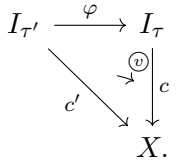
$$\begin{array}{c} \underline{\mathrm{Ch}}(X) \\ \big\downarrow{\scriptstyle \pi_X} \\ \underline{\mathrm{Ty}}\ . \end{array}$$

La fibre de $\underline{\mathrm{Ch}}(X)$ en $\tau \in \mathrm{Ob}\,\underline{\mathrm{Ty}}$ est la catégorie $\underline{\mathrm{Ch}}_\tau(X)$ des chemins de type τ dans X. Cela nous dit donc quelles sont les flèches dans $\underline{\mathrm{Ch}}(X)$ au dessus des flèches identiques dans $\underline{\mathrm{Ty}}$. Mais que sont les flèches plus générales? On se donne une flèche dans $\underline{\mathrm{Ty}}$

$$\varphi : \tau' \longrightarrow \tau, \qquad \text{i.e. } I_{\tau'} \xrightarrow{\varphi} I_\tau,$$

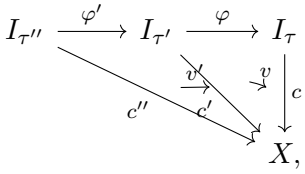
quelles sont les flèches de $\underline{\mathrm{Ch}}(X)$ au dessus de φ? Par le sorite général des catégories fibrées, si

$$\begin{aligned} c \in \underline{\mathrm{Ch}}(X)_\tau &= \underline{\mathrm{Ch}}_\tau(X) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(I_\tau, X) \\ c' \in \underline{\mathrm{Ch}}(X)_{\tau'} &= \underline{\mathrm{Ch}}_{\tau'}(X) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(I_{\tau'}, X) \end{aligned}$$



on a

$$\boxed{\mathrm{Hom}_{\varphi}(c', c) \simeq \mathrm{Hom}(c', \underbrace{\varphi^*(c)}_{=c\circ\varphi}).}$$



Donc : les homomorphismes du chemin c' de type τ' dans X, dans le chemin c de type τ, 'au dessus' du morphisme φ de τ' dans τ, i.e. du foncteur p. 18 [page 28]

$$\varphi : I_{\tau'} \longrightarrow I_{\tau},$$

est un homomorphisme v de c' dans $c \circ \varphi$, i.e.

La composition des flèches est évidente :

on a

$$v : \quad c' \quad \longrightarrow \quad c \circ \varphi, \quad \text{d'où } c' \circ \varphi' \xrightarrow{v*\varphi'} \underbrace{(c \circ \varphi) \circ \varphi'}_{=c\circ(\varphi\varphi')}$$

$$v' : \quad c'' \quad \longrightarrow \quad c' \circ \varphi'$$

et

$$v'' = (v * \varphi') \circ v', \qquad \text{donc} \qquad c'' \xrightarrow{v'} c' \circ \varphi' \xrightarrow{v*\varphi'} c \circ (\varphi\varphi'). \quad (c'')$$

Mais a-t-on des foncteurs source et but

$$\underline{\mathrm{Ch}}(X) \underset{\beta}{\overset{\sigma}{\rightrightarrows}} X \qquad \begin{array}{rcl} c & \longmapsto & \mathrm{source}(c) \\ c & \longmapsto & \mathrm{but}(c) \end{array} \qquad ?$$

Il faudrait donc qu'un homomorphisme v comme dessus

$$v : c' \longrightarrow c \circ \varphi$$

définisse

$$\begin{array}{rrcl} \sigma(c) : & \mathrm{source}(c') & \longrightarrow & \mathrm{source}(c) \\ \beta(c) : & \mathrm{but}(c') & \longrightarrow & \mathrm{but}(c). \end{array}$$

Commentary · Context [ms. 27]

The split fibration of all paths

Grothendieck now uses the machinery of descent to assemble paths of different shapes. The construction is the one in Grothendieck (1971a, Exposé VI, §§8–9): a strict contravariant functor to categories supplies a category with a chosen, strictly composable family of Cartesian lifts. The commentary on Chapter VI, manuscript pages 26 and 53–56, discussed splittings and their universal constructions. Here the splitting needs no choices, because it is given by literal precomposition.

For any of the three shape categories T, put $F_X(\tau) = X^{I_\tau}$. An object of its Grothendieck construction is (τ, c), and a morphism

$$(\tau', c') \longrightarrow (\tau, c)$$

is a pair (φ, v) with $\varphi : \tau' \to \tau$ and $v : c' \Rightarrow c\varphi$. If $(\varphi', v') : (\tau'', c'') \to (\tau', c')$, their composite is

$$(\varphi, v)(\varphi', v') = \big(\varphi\varphi', (v\varphi') \circ v'\big).$$

At $i \in I_{\tau''}$ the second component is $v_{\varphi'(i)} v'_i$. Threefold composition is associative because both parenthesizations have component $v_{\varphi'\varphi''(i)} v'_{\varphi''(i)} v''_i$ and the same shape map. The identity is $(1_\tau, 1_c)$. These checks explain the word "*évidente*" in the source without suppressing the variance.

The chosen lift of $\varphi : \tau' \to \tau$ at (τ, c) is

$$(\varphi, 1_{c\varphi}) : (\tau', c\varphi) \longrightarrow (\tau, c).$$

To verify its Cartesian property, let a map from (ω, d) to (τ, c) have shape $\varphi\theta$ and transformation $w : d \Rightarrow c\varphi\theta$. There is exactly one factor over θ through the displayed lift, namely (θ, w). The chosen lifts compose on the nose, since $(c\varphi)\theta = c(\varphi\theta)$. More generally (φ, v) is Cartesian exactly when v is invertible: it factors as the vertical arrow $(1, v)$ followed by this chosen lift, and a vertical Cartesian arrow is an isomorphism.

For $T = T_\partial$ or $T_\uparrow$ the endpoint functors send (φ, v) to $v_{0_{\tau'}}$ and $v_{1_{\tau'}}$. Their targets are $c(0_\tau)$ and $c(1_\tau)$ because φ preserves endpoints. The formula for composition immediately gives functoriality. Likewise a functor $H : X \to Y$ acts by $(\tau, c) \mapsto (\tau, Hc)$ and $(\varphi, v) \mapsto (\varphi, Hv)$, preserving the chosen Cartesian lifts. Restricting the permitted shape maps is literally base change of this split fibration, which proves the fiber-product assertion on page 30.

Size causes no mathematical obstruction here. Fix universes $\mathcal{U} \in \mathcal{V}$. The set of finite words and their finite interval functors is $\mathcal{U}$-small. If X is a $\mathcal{V}$-small category, each X^{I_τ} and the total construction are $\mathcal{V}$-small. One may therefore take $X = \mathrm{Cat}_{\mathcal{U}}$ after working in a sufficiently larger universe. This supplies the convention which the source deliberately leaves implicit.

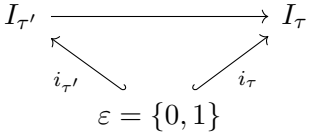
p. 19
[page 29]

Mais comme

$$\begin{cases} \sigma(c) = c(0_\tau),\ \beta(c) = c(1_\tau) \\ \text{où } 0_\tau,\ 1_\tau \text{ sont les objets source et but de l'intervalle orienté standard } I_\tau\ , \end{cases}$$

et de même pour τ', v n'induira bien

$$\underbrace{\sigma(c')}_{=c'(0_{\tau'})} \longrightarrow c(\varphi(0_{\tau'})) \stackrel{?}{=} \underbrace{\sigma(c)}_{c(0_\tau)},$$



et itou pour $\beta(c')$ et $\beta(c)$, que si on impose

$$\boxed{\begin{cases} \varphi(0_{\tau'}) &= 0_\tau \\ \varphi(1_{\tau'}) &= 1_\tau, \end{cases}}$$

i.e. que le foncteur envisagé φ soit *compatible avec la source et le but.* C'est ce visiblement qu'il fallait imposer dans la définition de

$$\mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau', \tau) = \underline{\mathrm{Hom}}^{\textcircled{m}t}(I_{\tau'}, I_\tau) \quad \text{-}$$

il faut prendre les foncteurs φ respectant les structures d'intervalle, i.e. rendant commutatif le diagramme

définissant l'orientation de $I_{\tau'}$ et de I_τ ([10]). Cette rectification faite, j'ai bon espoir que la catégorie $\underline{\mathrm{Ch}}(X)$ qu'on vient de construire est 'la bonne'. On pourrait désigner par $\underline{\mathrm{CH}}(X)$ la catégorie plus grande, sur la catégorie $\underline{\mathrm{Typ}}$ ayant mêmes objets que $\underline{\mathrm{Ty}}$, mais plus de morphismes : à savoir [page 30]

$$\begin{aligned} \mathrm{Hom}_{\underline{\mathrm{Typ}}}(\tau,\tau') &= \mathrm{Hom}_{\mathrm{Cat}}(I_\tau, I_{\tau'}) \\ \mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau,\tau') &= \mathrm{Hom}^{\mathrm{int}}_{\mathrm{Cat}}(I_\tau, I_{\tau'}) \\ &\quad \text{(homomorphismes respectant la structure d'intervalle).} \end{aligned}$$

On aura

$$\underline{\mathrm{Ch}}(X) \simeq \underline{\mathrm{CH}}(X) \times_{\underline{\mathrm{Typ}}} \underline{\mathrm{Ty}},$$

i.e. $\underline{\mathrm{Ch}}(X)$ est la *restriction* de la catégorie fibrée $\underline{\mathrm{CH}}(X)$ sur $\underline{\mathrm{Typ}}$, à la sous-catégorie (non-pleine) $\underline{\mathrm{Ty}}$ de $\underline{\mathrm{Typ}}$. p. 20

Commentary · Examples [ms. 28]

Changing shape need not have a direct image

The projection to the category of types is a fibration because paths can always be restricted. Extending a path to a new shape asks a different question, and generally requires colimits in its coefficient category. This is the usual distinction between a fibration and a bifibration; compare Grothendieck (1971a, Exposé VI, §10 and §11(f)).

Consider the interval $J = I_{-+} = (0 \leftarrow 1 \rightarrow 2)$ and its unique collapse $q : J \to e$. This collapse belongs even to $T_\uparrow$. Its inverse-image functor is the diagonal

$$q^* : X \longrightarrow X^J,$$

sending an object to its constant span. If an opCartesian lift over q existed at every span c, its target $q_!c$ would represent the functor

$$x \longmapsto \mathrm{Nat}(c, \mathrm{const}_x).$$

Indeed every map from c over q to a constant path would factor uniquely through the opCartesian lift. This is precisely the universal property of the pushout of the span $c(0) \leftarrow c(1) \rightarrow c(2)$.

Take $X = J$ itself and $c = 1_J$. There is no cocone on this diagram: neither 0 nor 2 maps to the other, and neither maps to 1. Thus $q_!c$ does not exist, and the path projection is not an opfibration in this example. This does not reveal a gap in Grothendieck's assertion, which is only that the construction is split fibrational. It identifies precisely what would be added by a stronger assertion.

For $X = \mathrm{Set}$ the same calculation has a complete answer. Let $A \leftarrow C \rightarrow B$ be a span. Then $q_!c$ is the quotient of $A \amalg B$ by the equivalence relation generated by identifying the two images of each $z \in C$. A map from this quotient to S is exactly a pair $A \to S$, $B \to S$ which agrees on C, so it is exactly a natural transformation $c \Rightarrow \mathrm{const}_S$. For a general change of shape φ and a cocomplete X, left Kan extension supplies the corresponding left adjoint to φ^*. Such extra adjoints come from X; the split fibration itself is available without them.

Commentary · Development (commentators') [ms. 29]

How much endpoint preservation is forced

The correction on page 29 gives exactly what is needed for endpoint maps obtained by taking components of a natural transformation. There is a slightly larger possibility if one allows those components to be followed by canonical arrows inside the target interval. Describing it clarifies why endpoint preservation is a structural choice, and why concatenation will justify the stricter choice.

Endpoint evaluation criterion. [ours] Let T be a subcategory of T_{all} with all sign words as objects. Its path construction admits functors $\sigma_X, \beta_X : \int F_X \to X$, natural in X, restricting in each

10. En fait, il faut sans doute restreindre encore plus les morphismes en exigeant qu'il soient *croissants* sur les objets - cf. page 31.

fiber to evaluation at the specified source and target, if and only if every $\varphi : \tau' \to \tau$ in T admits arrows

$$a_\varphi : \varphi(0_{\tau'}) \longrightarrow 0_\tau, \qquad b_\varphi : \varphi(1_{\tau'}) \longrightarrow 1_\tau \quad \text{in } I_\tau.$$

When they exist, these endpoint functors are unique. The permitted functors form a category T_{ev} containing T_∂, and it is the largest such subcategory of T_{all}.

Proof. For necessity take $X = I_\tau$ and the universal path $c = 1_{I_\tau}$. The Cartesian arrow

$$(\varphi, 1_\varphi) : (\tau', \varphi) \longrightarrow (\tau, 1_{I_\tau})$$

must be sent by σ_X to an arrow $\varphi(0_{\tau'}) \to 0_\tau$, and by β_X to an arrow $\varphi(1_{\tau'}) \to 1_\tau$. Each is unique when it exists, because an interval is thin. For composable maps $\tau'' \xrightarrow{\psi} \tau' \xrightarrow{\varphi} \tau$, the arrows

$$a_\varphi \circ \varphi(a_\psi), \qquad b_\varphi \circ \varphi(b_\psi)$$

have precisely the endpoints required for $\varphi\psi$. Identities satisfy the requirement as well. Hence the permitted functors form a category.

To construct the endpoint maps, define on $(\varphi, v) : c' \to c$

$$\sigma_X(\varphi, v) = c(a_\varphi) \circ v_{0_{\tau'}}, \qquad \beta_X(\varphi, v) = c(b_\varphi) \circ v_{1_{\tau'}}.$$

For a second morphism $(\psi, w) : c'' \to c'$, naturality of v at a_ψ gives

$$v_{0_{\tau'}} c'(a_\psi) = c\varphi(a_\psi) v_{\psi(0_{\tau''})}.$$

After composing with $c(a_\varphi)$ and $w_{0_{\tau''}}$, this says that the product of the two source arrows is

$$c(a_{\varphi\psi}) v_{\psi(0_{\tau''})} w_{0_{\tau''}},$$

which is the source arrow assigned to the composite. The same argument with b_ψ proves the target identity. Identity morphisms and naturality in X follow directly from the formulas.

Finally, every (φ, v) factors as a vertical morphism $(1, v)$ followed by a chosen Cartesian arrow. The endpoint functors are prescribed on vertical arrows. Naturality in X applies to $c : I_\tau \to X$ and forces their values on the Cartesian arrow to be $c(a_\varphi)$ and $c(b_\varphi)$. Thus the formulas are forced, proving uniqueness and maximality. □

For example, the functor $e \to I_+$ selecting 0 belongs to T_{ev}: its source comparison is an identity and its target comparison is $0 \to 1$. It does not preserve both endpoints. The functor selecting 1 does not belong to T_{ev}, since there is no arrow $1 \to 0$. This already prevents endpoint evaluation on T_{all}.

The enlargement does not solve the concatenation problem. Concatenate two copies of the admissible map $e \to I_+$ selecting 0. The common vertex of $e * e = e$ would have to map both to vertex 0 of the first target interval and to vertex 1, the starting vertex of the second interval in I_{++}. The two prescribed maps therefore do not glue. Strict endpoint preservation makes precisely these images agree. The theorem is an elementary specialization of the general description of functors out of a split fibration in Grothendieck (1971a, Exposé VI, Proposition 12.1). We checked that description and the Yoneda treatment cited above; we did not find this particular maximal class of interval maps stated there. The marker records this explicit deduction and proof, without a claim of priority.

NB Les catégories fibrées $\underline{\mathrm{CH}}(X)$, $\underline{\mathrm{Ch}}(X)$ sur $\underline{\mathrm{Typ}}$, $\underline{\mathrm{Ty}}$ dépendent fonctoriellement de X, variant dans (Cat), comme il se doit. Comme de juste, on s'y intéresse surtout quand X *n'est pas* dans (Cat), i.e. quand X est une 'grosse' catégorie (telle que (Cat) elle-même). Je me dispense d'expliciter ici les questions pertinentes d'Univers.

Deux tests essentiels, pour s'assurer si la notion est bonne

a) La théorie des $\mathcal{M}\Sigma^{-1}$.

b) La composition des chemins doit bien marcher.

On a le diagramme de foncteurs canoniques

$$\begin{array}{ccc} \underline{\mathrm{Ty}} & \hookrightarrow & \varepsilon\backslash\mathrm{Cat} \\ \downarrow & & \downarrow \\ \underline{\mathrm{Typ}} & \hookrightarrow & \mathrm{Cat}, \end{array}$$

où les flèches horizontales sont pleinement fidèles.

Commentary · Present state [ms. 30]

The fraction test and hammock localization

Grothendieck's two tests concern different levels of the construction. Concatenation should be an operation on actual paths and their morphisms; localization should arise after paths are subjected to specified identifications or homotopical comparisons. The category $\underline{\mathrm{Ch}}(X)$ constructed here has not yet been asserted to satisfy the universal property of a localization.

For a category $\mathcal{M}$ and a specified class Σ of arrows, ordinary localization is already constructed by Gabriel and Zisman (1967, Chapter I, §1.1 and Lemma 1.2). Its arrows are composable words of forward arrows and formal inverses of arrows in Σ, modulo the category relations and inverse relations. A functor out of the quotient is consequently equivalent to a functor from $\mathcal{M}$ sending Σ to isomorphisms. This existence statement does not require the Ore hypotheses needed for a calculus with uniformly short fractions.

The homotopical comparison already available before these notes is quite specific. In Dwyer and Kan (1980a, Definition 2.1 and Propositions 2.2 and 3.1), a hammock is a finite grid of zigzags, with backward horizontal arrows and vertical arrows required to be weak equivalences. Identity columns are removed and adjacent columns pointing in the same direction are composed. Their mapping simplicial sets are equivalent to the standard simplicial localization, and their sets of components recover ordinary localization:

$$\pi_0 L^H(\mathcal{M}, \Sigma)(x, y) \cong \mathrm{Hom}_{\mathcal{M}[\Sigma^{-1}]}(x, y).$$

Thus there is a proven construction in which changing the length and subdivision of zigzags is accompanied by the higher comparison data needed for mapping spaces.

This is a comparison of mathematical mechanisms, not an identification of the constructions. The present $\underline{\mathrm{Ch}}(X)$ allows arbitrary vertical natural transformations, has not specified which backward arrows may be inverted, and uses a single ordinary category of types. The hammock conditions, the fixed endpoints, and the higher simplices must all be supplied before a localization theorem can be invoked. The source's demand that the fraction theory "work" is a design requirement at this point, not a research conjecture left open in these pages. Its exact implementation in Grothendieck's subsequent text should be checked on its own definitions.

p. 21

5 Propriétés des morphismes d'intervalles

Je me suis plus ou moins convaincu que pour se prêter à des calculs et à des raisonnements simples, il faut encore plus restreindre les morphismes dans la définition de la catégorie $\underline{\mathrm{Ty}}$. Je vais exiger que les morphismes $\tau \longrightarrow \tau'$ soient des foncteurs

$$w : I_\tau \longrightarrow I_{\tau'}$$

qui sont compatibles avec la structure d'*intervalles orientés* de I_τ, $I_{\tau'}$, i.e. qu'ils transforment source en source, but en but, mais de plus qu'ils soient *croissants* sur les objets (pour la relation d'ordre de progression des chemins). C'est une restriction qui géométriquement me paraît assez naturelle. (Elle est similaire à la restriction analogue, dans la définition pré-catégorique des morphismes entre $\boldsymbol{\Delta}_i$ …) C'est cette hypothèse qui permet de faire une théorie de structure assez simple des morphismes d'intervalles. Mais pour l'instant je vais distinguer 'morphismes' et 'morphismes croissants'.

Commentary · Later developments [ms. 31]

The same type category in later zigzag constructions

Grothendieck's final restriction on changes of shape has a precise counterpart in the later literature on localization. The correspondence can be checked directly, before making any assertion about homotopy theory. Given a word τ, mark the backward transitions of I_τ and their composites, together with the identities. This makes I_τ a relative category. An increasing endpoint-preserving functor automatically respects this marking: a nonconstant image of a backward transition is a composite of backward transitions. Conversely, forgetting the marking of an increasing endpoint-preserving relative functor gives exactly a morphism of $\underline{\mathrm{Ty}}$. The objects, morphisms, and concatenation are therefore unchanged by this decoration.

Under $+ \leftrightarrow A$ and $- \leftrightarrow W^{-1}$, this identifies $\underline{\mathrm{Ty}}$ with the category Z of Mazel-Gee (2018, Definition 3.5, Remark 3.6, and footnotes 8–10, pp. 341–342). Their weak-equivalence labels restrict which diagrams in a coefficient category are allowed; they do not impose an additional restriction on these monotone shape maps. The empty word remains the monoidal unit. This is an identification of the finite indexing categories, rather than an inference from a resemblance between pictures.

The image factorization implicit in the manuscript also explains a useful structure. If $f : I_\tau \to I_\upsilon$ is increasing, the full subcategory on its image is an interval. Factor f through its standard oriented model:

$$I_\tau \xrightarrow{q} I_\omega \xhookrightarrow{j} I_\upsilon.$$

The first map is surjective on vertices and the second injective. Their uniqueness follows from the unique increasing enumeration of the image. Nonidentity surjections lower the length, and nonidentity injections raise it. Thus length is a Reedy degree. The reduced interval gives the smallest image of an endpoint-preserving injection: Proposition 5 says that every such image contains all critical vertices. If the interval is not reduced, its reduced inclusion is consequently initial among the proper injections into it; for a reduced interval there are none. These statements follow from the full-subcategory argument already given, without a new hypothesis on coefficients.

This Reedy structure and this exact use of critical vertices occur in Arakawa and Cnossen (2026, Example 4.12 and Lemma 4.16), where the category is denoted Zig_∂. Their work is an August 2026 preprint. We cite these known applications, rather than present the Reedy interpretation as an original result. What remains to be added to the present manuscript is the relative and homotopical diagram theory over this category of shapes.

Soit [page 32]

$$f : I_\tau \longrightarrow I_{\tau'}$$

un morphisme d'intervalles orientés. Considérons les sous-catégories pleines, isomorphes à des Δ_i^+ ou Δ_i^- comme intervalles orientés, définis par les intervalles critiques de I_τ. Ils forment une suite Σ_τ de sous-catégories de I_τ

$$\Sigma_\tau = (\mathbf{\Delta}_{l_1}^{\varepsilon_1}(\tau), \mathbf{\Delta}_{l_2}^{\varepsilon_2}(\tau), \ldots, \mathbf{\Delta}_{l_r}^{\varepsilon_r}(\tau))$$

dont I_τ est la somme amalgamée (on reviendra sur ce point plus `[bas]`), r étant la longueur utile de τ. On les appelle les *sous-intervalles critiques* de I_τ. Ainsi f se décompose en une suite de morphismes

$$f_i : \mathbf{\Delta}_{l_i}^{\varepsilon_i} \longrightarrow I_{\tau'}, \qquad i \in [1, r],$$

tels que

a) pour $i \in [1, r-1]$, le but de f_i soit égal à la source de f_{i+1}.
De plus,

b) f_1 transforme source en source, et f_r transforme but en but.

Inversement, quand on se donne des f_i satisfaisant ces deux conditions, ils définissent un morphisme d'intervalles f unique. (Et si la condition b) n'est pas exigée, on trouve une description des morphismes de catégories $I_\tau \longrightarrow I_{\tau'}$.)

On va d'abord regarder un foncteur quelconque [page 33]

$$f : \mathbf{\Delta}_i^\varepsilon \longrightarrow I_{\tau'} \qquad (\varepsilon \in \{\pm 1\}) \quad .$$

Commentary · Exposition [ms. 32]

A functor cannot cross a turn in one run

Grothendieck begins the structure theorem by cutting an interval where its direction changes. Each piece is a chain, and the image of a chain remains comparable even when its length changes. This elementary observation is what allows a map of long zigzags to be described by a finite amount of ordered data.

For a nonempty word τ let

$$0 = s_0 < s_1 < \cdots < s_r = n$$

be its critical vertices, and let $K_i = [s_{i-1}, s_i]$ be its maximal constant-sign runs, regarded as full subcategories. The category I_τ is obtained by gluing the K_i at their common endpoint vertices. To see the universal property directly, choose functors $f_i : K_i \to Y$ agreeing at shared endpoints. They determine the image of every generating transition of I_τ. Each nonidentity arrow of I_τ is the unique composite of the transitions along a single run, so its image is forced to be the corresponding composite in Y. The only composition equations are associativity along those runs, and these hold in Y. Thus the f_i extend uniquely to a functor. For $Y = I_\upsilon$, imposing the values of $f_1(s_0)$ and $f_r(s_r)$ additionally imposes endpoint preservation, exactly as on page 32.

Now let K be a critical run of the source and suppose $f|K$ is nonconstant. The image vertices are pairwise comparable in I_υ: any two source vertices are joined by an arrow in one direction, whose image joins their images. Let $a < b$ be the smallest and largest distinct image vertices in the external order. Their comparability means that all target transitions between a and b have one sign. They therefore lie in a unique maximal run J', and so do all the image vertices between them. This proves both the existence and uniqueness in Proposition 7.

If the source run has sign ε and J' has sign η, the object function of $f|K$ is nondecreasing when $\varepsilon = \eta$ and nonincreasing when $\varepsilon = -\eta$. A nonconstant function which is nondecreasing in the external order cannot be of both sorts. Hence an increasing functor sends every nonconstant source run into a target run of the same sign. This proves the sign assertion as well; no endpoint hypothesis has been used.

The preceding paragraph of the source overstates the constant case. A vertex strictly inside a long target run belongs to one critical interval; an interior *critical* vertex belongs to two; an endpoint of a positive-length interval belongs to one. For instance, the constant map with value 1 in $I_{++} = [2]$ factors through its sole critical interval, although 1 is not an endpoint. This is a printed slip, retained in the text, and it does not affect Proposition 7 because that proposition assumes nonconstancy. There is also a harmless zero-length exception to the footnote's comparable-subset lemma: I_e has one vertex and no critical runs. A nonconstant map cannot have this target, so the proposition itself remains valid without an added exception.

p. 22

Supposons pour fixer les idées que $\varepsilon = +1$, i.e. que le premier membre soit un intervalle critique direct … On trouve que f se factorise par un sous-intervalle critique de $I_{\tau'}$, soit $\mathbf{\Delta}_j^{\varepsilon'}$. Il est donc défini par une application croissante de $\mathbf{\Delta}_i^{\varepsilon}$ dans $\mathbf{\Delta}_j^{\varepsilon'}$ (si ε, ε' `[sont]` de même signe), une application décroissante dans le sens inverse ([11]). Mais si on exige que f soit croissant, alors il faut que *ou bien* f soit constant (auquel cas, si sa valeur n'est pas une extrémité de $I_{\tau'}$, il y a exactement *deux* intervalles critiques de $I_{\tau'}$ par lesquels se factorise f) *ou bien* f non constant et $\varepsilon = \varepsilon'$ (et en tous cas, si f non constant, alors l'intervalle critique par lequel se factorise f est unique). Pour résumer :

Proposition 7. *Soient I_τ, $I_{\tau'}$ deux intervalles orientés,*

$$f : I_\tau \longrightarrow I_{\tau'}$$

un foncteur. Alors pour tout intervalle critique $J \subseteq I_\tau$ tel que $f|J$ soit non constant, il existe un unique intervalle critique $J' \subseteq I_{\tau'}$ tel que $f|J$ se factorise par J', i.e. tel que $f(J) \subseteq J'$. Si f est croissant, alors J et J' sont de même signe, i.e. tous deux directs, ou tous deux rétrogrades. [page 34]

11. **Lemme.** *Si $I_{\tau'}$ est un intervalle, toute partie J de $I_{\tau'}$ telle que pour deux éléments de J, il existe toujours une flèche de l'un dans l'autre, est contenue dans un intervalle critique (unique si* $\operatorname{card} J \geq 2$*).*

Ainsi, si on regarde la suite $s_0, s_1, \ldots, s_n$ des sommets critiques de τ, alors

$$t_0 = f(s_0),\ t_1 = f(s_1),\ \ldots\ ,\ t_n = f(s_n)$$

forment une suite de sommets de $I_{\tau'}$, telle que deux consécutifs soient reliés par une flèche de $I_{\tau'}$. Donc la sous-catégorie pleine de $I_{\tau'}$ définie par ces t_i est connexe, c'est donc un sous-intervalle. Si f est croissant, ce sous-intervalle est $[t_0, t_n]$. Si f est un morphisme d'intervalles, il contient tous les sommets critiques de $I_{\tau'}$. Dans tous les cas, prenant t_i, t_j $(i < j)$ et appliquant ce qui précède à $f|J$, où J est le sous-intervalle de I d'origine s_i, d'extrémité s_j, on voit que tout sommet critique de $I_{\tau'}$ compris entre t_i et t_j est parmi les t_k $(i \leq k \leq j)$. Pour résumer :

Corollaire. *Soient $s_i \leq s_j$ deux sommets critiques de $I_{\tau'}$. Alors tout sommet critique de $I_{\tau'}$ compris entre $f(s_i) = t_i$ et $f(s_j) = t_j$, est l'image d'un sommet critique s_k compris entre s_i et s_j (i.e. $i \leq k \leq j$). En particulier, si f est un morphisme d'intervalles,*

$$f(I_{\tau\,\text{réd}}) \supseteq I_{\tau'\,\text{réd}}$$

(où $I_{\tau\,\text{réd}}$ désigne l'ensemble des sommets critiques de I_τ ou aussi le sous-intervalle réduit qu'il définit).

Commentary · Exposition [ms. 34]

Critical vertices are crossed, not necessarily preserved

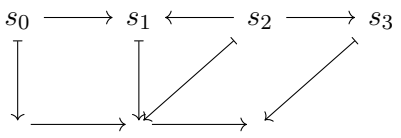
The next step records which turns in the target must be encountered by a map. This is weaker than preservation of all critical vertices, and the distinction is needed when the target is not reduced. It also prevents an ordinary interval of integers from being confused with a connected full subcategory of an interval category.

Let $s_0, \ldots, s_r$ be the critical vertices of the source and put $t_i = f(s_i)$. Consecutive t_i are comparable, since they are images of the endpoints of a source run. Thus the full subcategory on the *set* $\{t_0, \ldots, t_r\}$ is connected. Suppose t_i and t_j lie on opposite sides of an interior critical vertex z of the target. If no t_k, $i \leq k \leq j$, were equal to z, some consecutive pair in this finite sequence would lie strictly on opposite sides of z. Such a pair cannot be comparable: the two transitions adjoining an interior critical vertex have opposite signs. This contradiction proves that $z = t_k$ for some k in the indicated range. The argument permits backtracking and repetitions; it does not require monotonicity.

If f preserves the two endpoints, take $i = 0$ and $j = r$. Every target critical vertex is consequently the image of a source critical vertex. This is the content of the corollary, whose first occurrence of $I_{\tau'}$ should be read as I_τ when it describes the s_i. The stronger inclusion in the other direction is false. In the displayed example $I_{+-+} \to I_{++}$, the object function is

$$(0, 1, 2, 3) \longmapsto (0, 1, 1, 2).$$

All four source vertices are critical. Their image contains the two target endpoints and also its noncritical vertex 1; the middle source transition collapses. The example therefore gives exactly the one-sided containment asserted in the text.



There is a second printed overstatement just before the corollary. Even for increasing f, the full subcategory on the t_i need not have *every* integer vertex between t_0 and t_r. Take the identity of I_{++}. Its source critical vertices are $0, 2$, so their image is $\{0, 2\}$, a full subcategory isomorphic to $[1]$, whereas the ambient interval $[0, 2]$ has three vertices. The correct statement is that the image subcategory has least and greatest vertices t_0, t_r, its order-convex hull is $[t_0, t_r]$, and it contains every ambient critical vertex in that hull. This is all that the argument uses.

One can now see why the image of $\mathrm{Cr}(\tau, f) \to \mathrm{Cr}(\upsilon)$ is an interval in the ordered set of target runs. Join successive numbers t_i by real line segments, obtaining a continuous walk in $[0, m]$. Each nonconstant segment is contained in the unique target run attached to K_i. If the walk reaches two distinct target runs, it must traverse every intervening run, and each such traversal occurs on at least one nonconstant segment. Conversely, a target run not encountered by the walk cannot be attached to any K_i. The same argument shows that every target run meeting the segment between $f(0)$ and $f(n)$ in a positive-length segment is encountered. In particular, endpoint preservation makes the run map surjective. This completes the proofs of Corollary 2(a)–(c), including the parts for maps which backtrack.

On fera attention que même si f est croissant, on *n'a pas* en général $f(I_{\tau\,\text{réd}}) \subseteq I_{\tau'\,\text{réd}}$, i.e. [page 35]
f ne transforme pas forcément sommets critiques en sommets critiques, Exemple minimal : p. 23

Φ_3^+ :

$\mathbf{\Delta}_2^+$:

Φ_3^+ est réduite, les deux sommets critiques transformés en le sommet non critique 1.

Désignons par $\mathrm{Cr}(\tau)$ l'ensembles des intervalles critiques de I_τ, en correspondance biunivoque (respectant l'ordre total) avec l'ensemble des flèches de transition de $I_{\tau\,\text{réd}}$,

$$\mathrm{Cr}(\tau) \simeq \mathrm{Fl\,tr}\,(I_{\tau\,\text{réd}}).$$

Soit, pour un foncteur

$$f : I_\tau \longrightarrow I_{\tau'},$$

$\mathrm{Cr}(\tau, f)$ l'ensemble des intervalles critiques de I_τ sur lesquels f ne soit pas constant. On a alors une application

$$(*) \qquad \mathrm{Cr}(\tau, f) \longrightarrow \mathrm{Cr}(\tau')$$

induite par f via la proposition 7, associant à tout $J \in \mathrm{Cr}(\tau, f)$ l'unique $J' \in \mathrm{Cr}(\tau')$ tel que $f(J) \subseteq J'$. On a de plus

Corollaire 2.

a) L'image de $(*)$ *est un segment de l'ensemble totalement ordonné* $\mathrm{Cr}(\tau')$*, i.e. si deux intervalles critiques* J'*,* J'' *dans* $I'_{\tau'}$ *sont dans l'image, il en est de même de tous ceux qui sont compris entre eux.* [page 36]

b) Cette image contient aussi l'intervalle critique de $I_{\tau'}$ *(il y en a au plus un) qui contient* $f(0_\tau)$ *(resp.* $f(1_\tau)$*) et dont l'intersection avec le segment* $[f(0_\tau), f(1_\tau)]$ *est de cardinal* ≥ 2*, ainsi que tous les intervalles critiques contenus dans ledit segment.*

c) Si f *est un morphisme d'intervalles orientés, alors l'application induite*

$$\mathrm{Cr}(f) : \mathrm{Cr}(\tau, f) \longrightarrow \mathrm{Cr}(\tau')$$

est surjective. De façon plus précise, soit $J' \subseteq \mathrm{Cr}(\tau')$*, et soit* $J = f^{-1}(J')$*. Alors* $\mathrm{Cr}(f)^{-1}(\{J'\})$ *est formé des intervalles critiques dans* $\mathrm{Cr}(\tau, f)$ contenus dans J*. On a de plus,* si f est croissant,

$$\mathrm{long}(J') = \sum_{K \in \mathrm{Cr}(f)^{-1}(\{J'\})} \pi_{\mathrm{n}}(K, f),$$

où $\pi_{\mathrm{n}}(K, f)$ *est la 'partie' (numérique) de* $f|K$*, i.e. la longueur de l'intervalle* $[f(0_K), f(1_K)]$*. (***NB** *Si* K *est un intervalle critique de* I *tel que* $K \notin Cr(\tau, f)$*, i.e.* $f|K$ *est constant, on posera* $\pi_{\mathrm{n}}(K, f) = 0$*. Donc la formule précédente se lit aussi*

$$\mathrm{long}(J') = \sum_{\underbrace{K \in \mathrm{Cr}(I_\tau),\ K \subseteq J}_{\text{(i.e. } K \in \mathrm{Cr}(f^{-1}(J')))}} \pi_{\mathrm{n}}(K, f).\ )$$

Corollaire 3. *Si* f *est un morphisme* croissant *d'intervalles orientés, alors pour tout* $J' \in \mathrm{Cr}(\tau')$*, on a*

$$(0 \leq)\ \ \mathrm{card}\,\mathrm{Cr}(f)^{-1}(\{J\}) \longrightarrow \mathrm{long}(J'), \qquad \text{p. 24}$$

l'égalité n'étant obtenue que si les parties de f *sur les intervalles critiques de* I_τ *qui sont au dessus de* J' *sont toutes égales à* 0 *ou* 1 *(donc si et seulement si sur les* $J \in \mathrm{Cr}(f)^{-1}(\{J'\})$*, elles sont égales à* 1*).* [page 37]

Commentary · Exposition [ms. 36]

The length budget over a target run

Monotonicity turns the preceding coverage statement into an additive formula. A map may pause, but it cannot spend the same portion of the target twice. This is the numerical mechanism behind Corollaries 3–5.

Let $f : I_\tau \to I_\upsilon$ be increasing and preserve endpoints. For a source critical run $K_i = [s_{i-1}, s_i]$, write

$$d_i = f(s_i) - f(s_{i-1}) \geq 0.$$

When $d_i > 0$, Proposition 7 associates to K_i the unique target run containing its image; this is $\mathrm{Cr}(f)(K_i)$. Fix a target run $J' = [a, b]$. The nonconstant segments $[f(s_{i-1}), f(s_i)]$ attached to J' cover $[a, b]$, meet only at consecutive endpoints, and are encountered in their natural order. Coverage follows because $f(0) = 0$, $f(n) = m$ and every intervening critical vertex is attained; disjointness of interiors follows from the monotonicity of the sequence $f(s_i)$. Their lengths therefore add to $b - a$:

$$b - a = \sum_{\substack{K_i \in \mathrm{Cr}(\tau, f) \\ \mathrm{Cr}(f)(K_i) = J'}} d_i.$$

This is the formula for $\pi_{\mathrm{n}}(K_i, f)$ in the source. It is valid even if f skips noncritical target vertices, because length measures the whole segment spanned by the image, not the number of image vertices.

Every summand displayed is a positive integer. Consequently, if $k_{J'} = |\mathrm{Cr}(f)^{-1}(J')|$, then

$$1 \leq k_{J'} \leq b - a,$$

and equality on the right holds precisely when every positive d_i in the sum is 1. The printed arrow in Corollary 3 is a typesetting slip for $\leq$, and its unprimed J in the singleton should be J'. The subsequent discussion of equality gives the intended reading independently of our proof.

For a first calculation take $I_{+-+} \to I_{++}$ with vertex function $(0, 1, 1, 2)$. Its three source runs have lengths of image $1, 0, 1$; the single target run has length 2. Thus $k_{J'} = 2$ and the upper bound is attained. For the identity $I_{++} \to I_{++}$, the sole source run has image length 2, so $k_{J'} = 1 < 2$. Both maps are increasing and preserve endpoints. What is counted is the number of nonconstant *runs*, not the number of nonidentity generating arrows.

The alternative summation on page 36 may harmlessly include every global source run contained in $f^{-1}(J')$: the added terms have zero length. Its parenthetical identification of these runs with all critical runs of the preimage is, however, too literal. A preimage can contain a truncated piece of a neighboring global run on which f is constant. For example, take

$$f : I_{++--} \longrightarrow I_{+-}, \qquad (0, 1, 2, 3, 4) \longmapsto (0, 1, 1, 1, 2).$$

For $J' = [0, 1]$, its preimage has vertices $0, 1, 2, 3$ and critical runs $[0, 2]$ and $[2, 3]$. Only $[0, 2]$ is a full global source run contained in the preimage; $[2, 3]$ is a proper part of the global run $[2, 4]$. The extra piece is constant with value 1, hence contributes zero. The equality of sums survives, but equality of the indexing sets does not. One should either keep the global-run indexing or explicitly allow such zero-contribution boundary pieces.

Corollaire 4. *Supposons de plus* I' $[= I_{\tau'}]$ *réduit. Alors*

$$Cr(f) : Cr(\tau, f) \longrightarrow Cr(\tau') \ (\simeq \mathrm{Fl}\,\mathrm{tr}(\tau'))$$

est bijective.

Donc dans ce cas, τ' réduit, on obtient une application en sens inverse

$$\begin{array}{ccc} \mathrm{Tr}(\tau') \simeq \mathrm{Cr}(\tau') & \xrightarrow{\quad \mathrm{Cr}^*(f) \quad} & \mathrm{Cr}(\tau) \\ & {\scriptstyle \mathrm{Cr}(f)^{-1}} \searrow \quad \nearrow {\scriptstyle \text{inclusion}} & \\ & \mathrm{Cr}(\tau, f), & \end{array}$$

application qui transforme l'intervalle critique J' $(= \{i-1, i\})$ en l'*unique* intervalle critique J de I_τ tel que

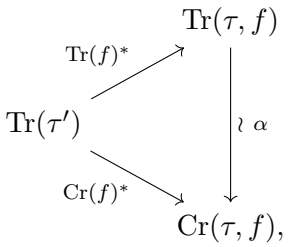
$$f(J) = J'.$$

Mais $J \simeq \mathbf{\Delta}_i^\varepsilon$, et on a donc un morphisme *surjectif* [page 38]

$$f_0 : \mathbf{\Delta}_i^\varepsilon \longrightarrow J' \simeq \mathbf{\Delta}_1^\varepsilon.$$

On voit tout de suite qu'il existe alors une *unique* flèche de transition u de $\mathbf{\Delta}_i^\varepsilon$, telle que $f(u) \neq \mathrm{id}$. Donc on trouve le corollaire suivant, plus précis que le corollaire 4 :

Corollaire 5. *Soit $f : I_\tau \longrightarrow I_{\tau'}$ un morphisme croissant d'intervalles orientés, avec $I_{\tau'}$ réduit, et soit $\mathrm{Tr}(\tau, f)$ l'ensemble des flèches de transition $\underline{u}_i$ de I_τ telle que $f(\underline{u}_i) \neq \mathrm{id}$, i.e. telles que $\pi(u_i, f) = 1$. Alors f induit une application*



$$\mathrm{Tr}(\tau, f) \longrightarrow \mathrm{Tr}(\tau')$$

qui est bijective, et (bien sûr) croissante, donc un isomorphisme d'ensembles ordonnés.

Ainsi l'application $\mathrm{Tr}(\tau') \longrightarrow \mathrm{Cr}(\tau, f)$ de tantôt se précise par une application bijective

$$\mathrm{Tr}(f)^* : \mathrm{Tr}(\tau') \longrightarrow \mathrm{Tr}(\tau, f),$$

reliée à $\mathrm{Cr}(f)^*$ plus haut par le triangle commutatif

l'application α associant à toute $u_i \in \mathrm{Tr}(\tau, f)$ l'unique intervalle critique qui 'contienne' u_i p. 25
(i.e. tel que u_i soit une flèche dudit intervalle, ou encore, fasse partie de la 'chaîne critique' [page 39]
associée …).

Commentary · Examples [ms. 38]

A reduced target remembers the surviving transitions

Grothendieck next specializes the length formula to a target with no redundant vertices. Every target run then has length one. There is exactly one nonconstant source critical run over it, and that source run can cross its two target vertices only once. This converts a numerical constraint into the combinatorial invariant used in Proposition 8.

More explicitly, on a source run $K = [s, t]$ mapping onto the two vertices $a, a+1$, the nondecreasing vertex function has the form

$$f(s) = \cdots = f(i-1) = a, \qquad f(i) = \cdots = f(t) = a+1$$

for exactly one i with $s < i \leq t$. Hence exactly one transition in K has nonidentity image. The run and its target have the same sign, so this transition maps to the target's unique transition in its categorical direction, including when that direction is backward. Performing this construction for all target runs gives the bijection of Corollary 5. It is increasing because the source runs and their crossings occur in the same external order as the target runs. The triangle with α commutes because α forgets which transition was selected and remembers its containing source run.

Take $\tau = ++--++$ and $\upsilon = +-+$. Choose transitions $2, 4, 6$ in the source. The associated vertex map is

$$(0, 1, 2, 3, 4, 5, 6) \longmapsto (0, 0, 1, 1, 2, 2, 3).$$

The first source run maps across the first forward target edge at transition 2; the second maps across the backward target edge at transition 4; the third crosses the final forward edge at transition 6. The other three transitions become identities. If a path of type υ in X is

$$x_0 \xrightarrow{a} x_1 \xleftarrow{b} x_2 \xrightarrow{c} x_3,$$

restriction along this map is the path

$$x_0 \xrightarrow{1} x_0 \xrightarrow{a} x_1 \xleftarrow{1} x_1 \xleftarrow{b} x_2 \xrightarrow{1} x_2 \xrightarrow{c} x_3.$$

In each of the three source runs either of its two transitions could instead be the surviving one. These choices give $2^3 = 8$ different maps to this reduced target, all explicitly determined by their three crossing positions. The general theorem on the next pages will allow arbitrary sign words and express this determination as a signed-subsequence bijection.

When the target is e, there are no target runs and no nondegenerate transitions. The unique endpoint-preserving map $I_\tau \to I_e$ collapses every transition. Both sides of the bijection in Corollary 5 are empty, so the assertion includes this case. When the source is e and the target has positive length, no endpoint-preserving map exists. These two degenerate cases explain why the later subset description needs the empty word as well as the alternating nonempty words.

On a mieux encore :

Proposition 8. *Soient $\tau, \tau' \in \mathrm{Ty}$, τ'* réduit. *Pour tout morphisme croissant d'intervalles orientés*

$$f : I_\tau \longrightarrow I_{\tau'}$$

(on va dire simplement que f est une flèche dans $\underline{\mathrm{Ty}}$, et écrire $f \in \mathrm{Hom}_{\underline{\mathrm{Ty}}}(I_\tau, I'_\tau)$), associons lui la partie $\mathrm{Tr}(\tau, f)$ des flèches de transition de I_τ non dégénérées pour f. Ces flèches forment un ensemble totalement ordonné affecté de signes + ou − (caractère direct ou rétrograde des flèches), et f induit une bijection d'ensembles totalement ordonnés

$$\underbrace{E_f}_{\subseteq \mathrm{Tr}(\tau)} = \mathrm{Tr}(\tau, f) \simeq \mathrm{Tr}(\tau'),$$

et même un isomorphisme d'ensembles totalement ordonnés 'affectés de signes'. Ainsi, à toute f on associe une partie E_f de $\mathrm{Tr}(\tau)$, et telle que son 'type' soit égal à τ'. Désignons par

$$\mathfrak{P}_{\tau'}(\mathrm{Tr}(\tau)) \subseteq \mathfrak{P}(\mathrm{Tr}(\tau))$$

l'ensemble des parties E de $\mathrm{Tr}(\tau)$ dont le type soit τ'.

Alors l'application [page 40]

$$f \longmapsto \mathrm{Tr}(\tau, f) : \mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau, \tau') \longrightarrow \mathfrak{P}_{\tau'}(\mathrm{Tr}(\tau))$$

est bijective *: se donner un morphisme $f : \tau \longrightarrow \tau'$ dans $\underline{\mathrm{Ty}}$,* revient au même *que de se donner une suite strictement croissante de flèches de transition*

$$\underline{u}_{i_1},\ \underline{u}_{i_2},\ \ldots\ ,\underline{u}_{i_{n'}} \qquad (n' = \log \tau')$$

dans I_τ ($i_1 < i_2 < \cdots < i_{n'}$), telle que la suite des signatures correspondante

$$(\varepsilon_{i_1}, \varepsilon_{i_2}, \ldots, \varepsilon_{i_{n'}}) = \tau'$$

soit égale à τ'.

Commentary · Exposition [ms. 40]

Choosing the transitions that survive

The reduced target allows Grothendieck to replace a functor by a selection of edges. This is the first form of the normal form that will make concatenation manageable: each edge of the target has one identifiable ancestor in the source. The hypothesis that the target is reduced is doing exactly the work needed here.

Write the source signature as $\tau = (\varepsilon_1, \dots, \varepsilon_n)$ and the reduced target as $\tau' = (\varepsilon'_1, \dots, \varepsilon'_m)$. An increasing endpoint-preserving functor has a nondecreasing object map

$$f : [0, n] \longrightarrow [0, m], \qquad f(0) = 0, \quad f(n) = m.$$

The image of the ith transition is either an identity or a nonidentity arrow joining $f(i-1)$ to $f(i)$. In a reduced interval every nonidentity arrow is a transition: two successive transitions have opposite signs and cannot compose. Consequently

$$f(i) - f(i-1) \in \{0, 1\}.$$

Exactly m differences are 1. If their indices are $i_1 < \cdots < i_m$, preservation of arrow direction gives $\varepsilon_{i_j} = \varepsilon'_j$. Conversely such a signed subsequence defines

$$f(k) = \#\{j \mid i_j \le k\}.$$

On a selected transition this map uses the corresponding target transition; on every other transition it uses an identity. These choices extend uniquely to a functor because the source is the free category on its oriented linear graph. They preserve the two endpoints and recover the selected subsequence. This proves Proposition 8, including its empty-target case: the empty subsequence gives the unique functor to the point.

For example, from the word $++-+$ to the reduced word $+-+$ there are exactly two morphisms. The negative transition must be the third source edge, the last positive transition must be the fourth, and the first positive transition may be either the first or the second. Their object maps are respectively

$$(0, 1, 1, 2, 3), \qquad (0, 0, 1, 2, 3).$$

The two paths retain different occurrences of the first positive step. Thus the type records positions, not merely the numbers of positive and negative transitions.

For a single-edge target the same argument gives the stated representability of positive and negative transitions. A positive edge at position i determines the map to Δ_+ which is 0 before that edge and 1 after it; a negative edge determines the analogous map to Δ_-. Naturality remains to be explained because an edge can be stretched over several target edges. The next construction supplies exactly that explanation. When the target is not reduced, the selection alone is insufficient: the unique morphism $\Delta_+ \to \Delta_+^2$ stretches one edge across two, so the size of each surviving image must also be retained.

Corollaire 1. *Pour tout τ, on a des bijections canoniques*

$$\begin{cases} \mathrm{Tr}^+(\tau) & \simeq & \mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau, \Delta^+) \\ \mathrm{Tr}^-(\tau) & \simeq & \mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau, \Delta^-), \end{cases}$$

fonctorielles en τ *(variant dans* $\underline{\mathrm{Ty}}$*).*

Pour donner un sens au corollaire, il faut définir p. 26

$$\tau \longmapsto \mathrm{Tr}^+(\tau), \qquad \tau \longmapsto \mathrm{Tr}^-(\tau)$$

comme *foncteurs* contravariant en τ, donc pour un morphisme

$$f : I_{\tau_2} \longrightarrow I_{\tau_1}$$

dans $\underline{\mathrm{Ty}}$, définir des applications [page 41]

$$\begin{array}{rcl} \mathrm{Tr}^+(f)^* : \mathrm{Tr}^+(\tau_1) & \longrightarrow & \mathrm{Tr}^+(\tau_2) \\ \mathrm{Tr}^-(f)^* : \mathrm{Tr}^-(\tau_1) & \longrightarrow & \mathrm{Tr}^-(\tau_2), \end{array}$$

en d'autres termes, une application

$$\mathrm{Tr}(f)^* : \mathrm{Tr}(\tau_1) \quad \longrightarrow \quad \mathrm{Tr}(\tau_2)$$

'compatible avec les signatures'. Dans le corollaire 5 plus haut, on a défini une telle application seulement pour τ' réduit $[\tau_1 = \tau',\ \tau_2 = \tau]$ ([12]). Pour une flèche u de I_τ, appelons *partie ensembliste* de f sur u, où de u pour f, la partie ensembliste de la flèche $f(u)$ dans $I_{\tau'}$, i.e. le segment $[f(i-1), f(i)] \subseteq I_{\tau'}$ (ici $u = \underline{u}_i$). Soit

$$\underline{u}_{i_1},\ \ldots\ ,\underline{u}_{i_N} \qquad \text{ou } (v_1, v_2, \ldots, v_n)$$

la suite croissante des éléments de $\mathrm{Tr}(\tau, f)$, on voit alors par récurrence sur i que pour $i \in [1, N-1]$, on a

$$\begin{array}{rcl} f(\mathrm{but}(v_i)) & = & f(\mathrm{source}(v_{i+1}))\ \ (= t_i), \\ f(\mathrm{source}(v_1)) & = & 0_{\tau'}, \\ f(\mathrm{but}(v_N)) & = & 1_{\tau'}. \end{array}$$

Considérons la suite

$$\{\overbrace{0_{\tau'}}^{=t_0}, t_1, t_2, \ldots, t_{N-1}, \overbrace{1_{\tau'}}^{=t_N}\},$$

elle est définie par le sous-ensemble correspondant de $I_{\tau'}$, qu'on appelera l'ensemble des *sommets critiques de $I_{\tau'}$ pour f*. C'est une suite contenant $0_{\tau'}$, $1_{\tau'}$, et telle que deux éléments consécutifs sont reliés dans $I_{\tau'}$ par une flèche, ce qui équivaut à dire qu'elle contient les sommets critiques (intrinsèques) de $I_{\tau'}$. D'autre part, pour tout intervalle de transition $[i-1, i]$ de $I_{\tau'}$ ($i \in [1, n']$), il existe un et un seul intervalle de transition $[t_{j-1}, t_j]$ pour cette suite ($j \in [1, N]$), telle qu'on ait $[i-1, i] = [t_{j-1}, t_j]$. C'est dire qu'il existe une et une seule $v_j \in \mathrm{Tr}(\tau, f)$ telle que la partie de f sur v_j (savoir justement $[j-1, j]$) contienne (celle de) $\underline{u}_i$. Pour résumer : p. 27 [page 42]

Corollaire 2. *Soit $f : \tau \longrightarrow \tau'$ dans* Ty. *Alors pour toute $u \in \mathrm{Tr}(\tau') = \mathrm{Tr}(I_{\tau'})$, il existe une et une seule $v \in \mathrm{Tr}(\tau)$ telle que la partie de f sur v contienne u. De plus, les signatures de u et de v sont égales.*

C'est ainsi qu'on obtient donc une application

$$\mathrm{Tr}(f)^* : \mathrm{Tr}(\tau') \quad \longrightarrow \quad \mathrm{Tr}(\tau) \qquad (\text{se factorisant par } \mathrm{Tr}(\tau, f))$$

induisant

$$\begin{array}{rcl} \mathrm{Tr}^+(f)^* : \mathrm{Tr}^+(\tau') & \longrightarrow & \mathrm{Tr}^+(\tau) \\ \mathrm{Tr}^-(f)^* : \mathrm{Tr}^-(\tau') & \longrightarrow & \mathrm{Tr}^-(\tau). \end{array}$$

La transitivité pour un composé

$$\tau \xrightarrow{f} \tau' \xrightarrow{g} \tau''$$

ou

$$I_\tau \xrightarrow{f} I_{\tau'} \xrightarrow{g} I_{\tau''}$$

est immédiate. Si u, u', u'' sont des flèches de transition dans I_τ, $I_{\tau'}$, $I_{\tau''}$ respectivement, telles que

$$\begin{array}{rcll} \pi(g, u') & \supseteq & \pi(u''), & \text{i.e. } u' = \mathrm{Tr}(g)^*(u'') \\ \pi(f, u) & \supseteq & \pi(u'), & \text{i.e. } u = \mathrm{Tr}(f)^*(u'), \end{array}$$

alors on a

$$\pi(gf, u) \ \supseteq\ \pi(u''), \qquad \text{i.e. } u = \mathrm{Tr}(gf)^*(u'').$$

12. Ce qui suit ne fait pas intervenir les signatures - c'est un sorite sur les applications croissantes entre ensembles finis totalement ordonnés. [page 43]

Si les flèches en question ont comme partie intrinsèque $[i-1,i]$, $[i'-1,i']$, $[i''-1,i'']$ respectivement, l'hypothèse est

$$\begin{array}{rcl} g(i'-1) & \leq & i''-1, \quad g(i') \geq i'' \\ f(i-1) & \leq & i'-1, \quad f(i) \geq i' \end{array}$$

et comme g est croissant, on a déduit

$$\begin{array}{rcll} gf(i-1) & \leq & g(i'-1) & (\leq i''-1) \\ gf(i) & \geq & g(i') & (\geq i''), \end{array}$$

c.q.f.d.

Commentary · Examples [ms. 42]

A stretched edge and the containment convention

Grothendieck is assigning every target transition to the unique source transition whose image crosses it. One small example fixes both the meaning of this assignment and two printed slips immediately before Corollary 2.

Let $f : \Delta_+ \to \Delta_+^2$ have object map $f(0) = 0$, $f(1) = 2$. There is one surviving source transition, so $N = 1$, $t_0 = 0$ and $t_1 = 2$. The two target transitions have underlying vertex segments $[0,1]$ and $[1,2]$. Both are contained in $[t_0, t_1] = [0,2]$, and neither equals it. Thus the printed relation

$$[i-1,i] = [t_{j-1}, t_j]$$

must be read mathematically as $[i-1,i] \subseteq [t_{j-1}, t_j]$. The parenthesis identifying the part of f on v_j as $[j-1,j]$ has the same problem: that part is $[t_{j-1}, t_j]$. Both readings occur in the edition; they are retained in the source and repaired here. Corollary 2 itself uses containment and is correct.

The intervals $[t_{j-1}, t_j]$ may meet at a vertex, but their sets of transitions are disjoint. Since $t_0 = 0$, $t_N = m$ and the t_j are strictly increasing, these transition sets partition $\{1, \ldots, m\}$. A transition cannot lie in two of them: its two endpoints would then have to belong to their intersection, which contains at most one vertex. This proves uniqueness without assuming that the target is reduced. Functoriality forces every edge in the block assigned to v_j to have the sign of v_j.

The words "source" and "but" in the preceding display concerning the v_j must here be read as the first and last vertices in the traversal order. On a retrograde transition they are the reverse of its categorical domain and codomain. Writing $f(i_j - 1)$ and $f(i_j)$ avoids this ambiguity. If the target is the point there are no target transitions and the pullback map of transition sets is the unique map from the empty set; no first or last surviving transition should be invoked.

p. 28

Ainsi, le corollaire 1 plus haut obtient un sens précis et il est démontré du même coup, vu que les correspondances du corollaire 1 sont données par

$$\underbrace{f}_{\in \mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau, \Delta^\varepsilon)} \longmapsto \mathrm{Tr}(f)^*(\underline{u}),$$

où $\underline{u}$ est l'unique flèche de transition de Δ^ε.

Commentary · Exposition [ms. 43]

Edges reverse the direction of a map

The contravariant transition map contains more information than its notation initially suggests. It determines the whole functor, and gives a particularly economical modern description of the final category of types. This observation explains why the later calculations require only ordered lists and nonnegative integers.

Let $\mathcal{O}_\pm$ have as objects finite linearly ordered sets equipped with a sign at each element, including the empty set, and as arrows the nondecreasing maps which preserve signs. We use the skeletal

version with underlying sets $[1,n]$. For $f:\tau\to\tau'$ in $\underline{\mathrm{Ty}}$, where τ and τ' have lengths n and m, define

$$q_f:[1,m]\longrightarrow[1,n],\qquad q_f(j)=\min\{i\mid j\le f(i)\}.$$

The endpoint conditions ensure that this minimum exists when $m>0$; its defining inequalities are

$$f(q_f(j)-1)<j\le f(q_f(j)).$$

This is Grothendieck's $\mathrm{Tr}(f)^*$. It is nondecreasing, and it preserves signs because the image of a source transition is a monochromatic string of target transitions of that same sign.

Conversely, suppose $q:[1,m]\to[1,n]$ is nondecreasing and sign-preserving. Put

$$F_q(i)=\#q^{-1}([1,i]),\qquad 0\le i\le n.$$

The fibre $q^{-1}(i)$ is a consecutive block, possibly empty, whose target signs are all ε_i. Hence the consecutive vertices $F_q(i-1)$ and $F_q(i)$ are joined in the target by an arrow of the required direction, or coincide when the fibre is empty. Sending the ith source transition to this arrow defines a unique functor. Its object map is nondecreasing, begins at 0, and ends at m. The inequalities above show $q_{F_q}=q$, while counting the target edges crossed by the first i source edges gives $F_{q_f}(i)=f(i)$. These constructions are inverse, including the empty cases. There is no map from the point to a nonpoint interval in $\underline{\mathrm{Ty}}$, just as there is no function from a nonempty edge set to the empty one.

If $g:\tau'\to\tau''$, a target edge of τ'' has a unique ancestor in τ' and then a unique ancestor in τ. Equivalently, applying the displayed inequalities twice gives

$$q_{gf}=q_fq_g.$$

Identities induce identities. We therefore have an isomorphism of skeletal categories

$$\underline{\mathrm{Ty}}\ \cong\ \mathcal{O}_{\pm}^{\mathrm{op}}.$$

The reversal of variance is essential: a functor stretches a source edge into a target block, whereas q_f sends each member of that block back to its source edge. The signs can be forgotten for the construction on ordered sets, as Grothendieck observes, but must be restored to say when the resulting vertex map is a functor between the oriented interval categories.

This identification also establishes the naturality promised in Corollary 1. If an edge of sign ε represents $h:\tau'\to\Delta_\varepsilon$, the edge representing hf is q_f of the edge representing h. It is precisely ordinary precomposition in the representable presheaf $\mathrm{Hom}_{\underline{\mathrm{Ty}}}(-,\Delta_\varepsilon)$. The underlying single-sign calculation is the familiar ordinal description of the simplicial category; see Aguiar and Mahajan (2010, Appendix D.1, pp. 713–715). The signed formulation follows by retaining the labels throughout the inverse constructions above.

On va utiliser ces sorites pour donner, pour tout $\tau\in\underline{\mathrm{Ty}}$, une description combinatoire simple des catégories $\underline{\mathrm{Ty}}/\tau$ et $\tau\backslash\underline{\mathrm{Ty}}$, ou du moins de leurs ensembles d'objets.

1° Description de $\mathrm{Ob}\,(\tau\backslash\underline{\mathrm{Ty}})$**.**

À $f\in\mathrm{Ob}(\tau\backslash\underline{\mathrm{Ty}})$, i.e.

$$f:\tau\longrightarrow\tau'\qquad\text{i.e. } f:I_\tau\longrightarrow I_{\tau'}$$

dans $\underline{\mathrm{Ty}}$, est associé $E=E_f=\mathrm{Tr}(\tau,f)\subseteq\mathrm{Tr}(\tau)$, l'ensemble des flèches de transition critiques (i.e. non dégénérées) pour f. À chaque $u\in E$, associons l'entier $\mathrm{long}(\pi(f,u))$, la *partie* de f sur u. Alors (τ',f) est déterminé de façon unique par le couple [page 44]

$$(E,\pi),\qquad E\in\mathfrak{P}(\mathrm{Tr}(\tau)),\qquad \underbrace{\pi}_{\text{pondération}}:E\longrightarrow\underbrace{\mathbf{N}^*}_{\substack{=\text{ensemble des}\\ \text{entiers}\ge 1}}.$$

Ou si on préfère, par l'application $\pi=\pi_f$

$$\mathrm{Tr}(\tau)\xrightarrow{\pi}\mathbf{N},\qquad u\longmapsto\pi(u)=\pi(u,f)=\mathrm{long}(\pi_{\tau'}(f(u)))$$

(qui redonne E comme

$$E=\pi^{-1}(\mathbf{N}^*)\qquad).$$

Cette application n'est soumise à aucune restriction,

$$\mathrm{Ob}\,(\tau\backslash\underline{\mathrm{Ty}}) \xrightarrow[\sim]{\text{bij.}} \mathrm{Hom}_{\mathrm{Ens}}(\mathrm{Tr}(\tau), \mathbf{N}).$$

On récupère τ' à partir de π ainsi. On prend $E = \pi^{-1}(\mathbf{N}^*)$ (flèches de transition non dégénérées pour π), E est totalement ordonné par l'ordre induit par celui de $\mathrm{Tr}(\tau)$, il est de plus signaturé [sic] par la signaturation [sic] de $\mathrm{Tr}(\tau)$, soit

$$(\varepsilon_1, n_1),\ \ldots\ ,\ (\varepsilon_r, n_r)$$

la suite des signatures et pondérations, de la suite des éléments de E ($\varepsilon_i \in \{\pm 1\}$, $n_i \in \mathbf{N}^*$ pour $i \in [1, r]$). Alors,

$$\tau' = \Delta_{\varepsilon_1}^{n_1} \Delta_{\varepsilon_2}^{n_2} \cdots \Delta_{\varepsilon_r}^{n_r}, \qquad r = \mathrm{card}\, E,$$

dans le monoïde libre Ty, où on a désigné par Δ_+, Δ_- (au lieu de Δ^+, Δ^-) les deux générateurs. L'application

$$I_\tau \longrightarrow I_{\tau'}$$

est décrite de façon unique en disant qu'elle est *constante* sur chacune des 'composantes connexes' (au sens de la numérotation des sommets de I_τ) de l'ensemble $E' = E'(f) \subseteq I_\tau = [0, n]$ des sommets qui sont sources ou buts de flèches de transition dégénérées pour f, i.e. dans $\mathrm{Tr}(\tau)\backslash E$. Et sur le α-ème élément de E ($\alpha \in [1, r = \mathrm{card}\, E]$), d'indice i_α dans $\mathrm{Tr}(\tau)$, f induit le foncteur

p. 29 [page 45]

$$\mathbf{\Delta}_{\varepsilon_\alpha} \simeq \underbrace{J_{i_\alpha}}_{\substack{\text{intervalle de transition d'indice } i_\alpha \\ \text{dans } I_\tau}} \longrightarrow I_{\tau'}$$

donné par *l'unique* Ty-*flèche* dans I_τ de J_{i_α} dans le α-ème facteur, de type $\Delta_{\varepsilon_\alpha}^{n_\alpha}$, de τ', donné par $(*)$

$$\Delta_{\varepsilon_\alpha}^{n_\alpha} \simeq \text{type de } \mathbf{\Delta}_{n_\alpha}^{\varepsilon_\alpha} \quad \ldots$$

Commentary · Examples [ms. 44]

Weight vectors and composition by block sums

The outgoing classification now has coordinates which are useful for actual calculations. For a fixed source $\tau = (\varepsilon_1, \ldots, \varepsilon_n)$, put

$$a_i = f(i) - f(i-1) = \#q_f^{-1}(i), \qquad A_i = \sum_{h=1}^{i} a_h, \quad A_0 = 0.$$

Every a_i is a nonnegative integer. The target is the word

$$\tau' = \varepsilon_1^{a_1} \varepsilon_2^{a_2} \cdots \varepsilon_n^{a_n}, \qquad f(i) = A_i,$$

where exponent zero means omission. These equations prove the claimed unrestricted parametrization of $\mathrm{Ob}(\tau\backslash\underline{\mathrm{Ty}})$: they construct an outgoing morphism from every weight vector and recover the vector from every outgoing morphism. When adjacent source signs agree, their target blocks may merge into one critical interval, but their individual lengths remain part of the morphism.

Take the source $+ - + + -$ and the weights $(2, 0, 1, 3, 0)$. Its target is $+ + + + + +$, and its vertex map is

$$(0, 2, 2, 3, 6, 6).$$

The pullback on target transitions is $(1, 1, 3, 4, 4, 4)$. Both negative source edges have been collapsed. The two consecutive positive source edges at positions 3 and 4 survive separately, even though their target images lie in the same positive run.

To see composition, give the six target edges the further weights

$$(b_1, \ldots, b_6) = (1, 0, 2, 1, 0, 3).$$

The second map has vertex values $(0,1,1,3,4,4,7)$ and target $+^7$. The composite has weights $(1,0,2,4,0)$, since its ith weight is

$$c_i = \sum_{j=A_{i-1}+1}^{A_i} b_j.$$

Thus its vertex map is $(0,1,1,3,7,7)$, which is also obtained by direct substitution into the two displayed object maps. An empty block contributes zero; a block of length greater than one contributes a sum. This is the numerical content of composition in Section 6.

The formula gives a useful direct verification of associativity. Given a third weight vector, first replacing every b_j by the sum over its descendants and then summing over the a_i-block is the same finite sum as first merging the b_j-blocks and then summing over the merged block. The order and boundaries of the summands are unchanged. No cancellation, choice of representative, or equivalence relation enters this calculation.

2° Détermination de $\mathrm{Ob}\,(\underline{\mathrm{Ty}}/\tau')$.

Si $(\tau, f) \in \mathrm{Ob}\,(\underline{\mathrm{Ty}}/\tau')$, donc

$$f : I_\tau \longrightarrow I_{\tau'},$$

on lui associe tout d'abord la partie

$$\mathrm{Cr}(\tau', f) = E'_f = E' \subseteq I_{\tau'}$$

formée des sommets (dits 'critiques pour f', cf. page 41) de $I_{\tau'}$ qui sont source ou but d'une flèche $f(u)$, où $u \in \mathrm{Tr}(\tau, f)$, i.e. $f(u)$ n'est pas dégénérée ([13]). E' contient $f(I_{\tau\,\mathrm{réd}})$ (i.e. les images par f des sommets critiques de I_τ), mais peut être plus grand. (P.ex. si $\tau = \tau'$, $f = \mathrm{id}$, [page 46]
$E' = I_{\tau'}$, qui est donc strictement plus grand que $I_{\tau'\,\mathrm{réd}}$ si τ' n'est pas réduit.) Pour tout $i \in E'$, considérons $f^{-1}(\{i\}) \subseteq I_\tau$. Comme f `[est]` croissant, c'est un intervalle de l'ensemble totalement ordonné I_τ, donc c'est un sous-intervalle de la catégorie intervalle I_τ. Comme tel, il a une signature $\tau_i \in \mathrm{Ty}$. On a donc une application

$$\eta_f \text{ ou } \eta : E' \longrightarrow \mathrm{Ty}.$$

Je dis que $(\tau, f) \in \mathrm{Ob}\,(\underline{\mathrm{Ty}}/\tau')$ est déterminé de façon unique par ce couple

$$(E', \eta) \begin{cases} E' \in \mathfrak{P}(I_{\tau'}) = \mathfrak{P}([0, n']) \\ \eta : E' \longrightarrow \mathrm{Ty}\ . \end{cases}$$

De plus, celui-ci est soumis à la seule restriction que

$$E' \supseteq \mathrm{Cr}(\tau') = \text{ensemble des sommets critiques de } I_{\tau'}$$

(où ce qui revient au même, que E' contient $0_{\tau'}$, $1_{\tau'}$ et que deux éléments consécutifs de E' p. 30
sont reliés par une flèche de $I_{\tau'}$) :

$$\begin{cases} \mathrm{Ob}\,(\mathrm{Ty}/\tau') \simeq \text{ensemble des couples } (E', \eta), \text{ avec} \\ \qquad\qquad E' \subseteq [0, \underbrace{n'}_{=\log \tau'}], \quad E' \supseteq \mathrm{Cr}(\tau'), \\ \qquad\qquad \eta : E' \longrightarrow \mathrm{Ty}\ . \end{cases}$$

Soit

$$0 = t_0 < t_1 < \cdots < t_r = n'$$

13. dégager un lemme f croissante inutile.

la suite des éléments de E', soit pour $\boxed{i \in [1, N]}$

$$\left\| \begin{array}{l} l_i = t_i - t_{i-1} \\ \varepsilon_i \quad \text{signature de } [t_{i-1}, t_i] \text{ dans } I_{\tau'} \ , \end{array} \right.$$

et pour $\boxed{i \in [0, N]}$, soit

$$\| \quad \tau_i = \eta(t_i).$$

[page 47]

Alors le type τ est donné par

$$(*) \qquad \tau = \tau_0 \Delta_{\varepsilon_1} \tau_1 \Delta_{\varepsilon_2} \cdots \Delta_{\varepsilon_N} \tau_N,$$

[de] longueur $N + \sum_{i=0}^{N} \underbrace{\operatorname{long}(\tau_i)}_{\lambda_i \geq 0}$.

Commentary · Exposition [ms. 45]

Fibres are components of the collapsed-edge graph

Grothendieck wants a geometric reconstruction of the same weight vector. The intended reconstruction is correct once the graph of collapsed transitions is kept, but the printed description in terms of a set of vertices loses information that is needed to find its components.

Consider $\tau = +++$ with weights $(0, 1, 0)$. The corresponding map to $+$ is

$$f(0) = f(1) = 0, \qquad f(2) = f(3) = 1.$$

The vertices incident to a collapsed transition form the whole set $\{0, 1, 2, 3\}$. As a subset of the integers this set is connected. Consequently the assertion that f is constant on its integer-connected components would make f constant everywhere, contrary to the displayed functor. This is a printed mathematical slip, not a defective proof of the weight classification.

Instead, take the graph with all source vertices and only those edges $[i-1, i]$ for which $a_i = 0$. Its components are consecutive strings of zero-weight edges, together with any isolated vertices. In the example they are $\{0, 1\}$ and $\{2, 3\}$. Since

$$f(j) - f(i) = \sum_{h=i+1}^{j} a_h \qquad (i \leq j),$$

nonnegativity shows that two vertices have the same image if and only if every intervening edge has weight zero. The graph components are therefore exactly the nonempty vertex fibres of f. On each surviving transition the endpoint values are determined by the cumulative sum of the earlier weights. This proves both existence and uniqueness of the proposed geometric reconstruction after the correction.

The same observation produces a canonical factorization. First collapse the zero-weight edges, leaving the signed subword consisting of the active source edges; then stretch its successive edges by their positive weights. The first vertex map is surjective, the second strictly increasing, and both preserve the endpoints. Uniqueness follows either from the fibre components or from the unique image factorization of q_f in the category of signed ordered sets. This factorization will let us distinguish a combinatorial contraction from a contraction which has an inverse on one side.

3° Description de $\underline{\mathrm{Fl}(\mathrm{Ty})}$.

Si

$$f : \tau \longrightarrow \tau' \qquad \texttt{[est]} \text{ dans } \underline{\mathrm{Ty}} \ ,$$

on lui associe comme tantôt un entier $\underline{N \geq 0}$ ($N = \operatorname{card} \mathrm{Cr}(\tau', f) - 1$, $N = 0$ si et seulement si $\tau' = 1$, type de l'intervalle ponctuel), des applications

$$\left\{ \begin{array}{lcll} [1, N] & \longrightarrow & [+1, -1] \times \mathbf{N}^*, & i \longmapsto (\varepsilon_i, l_i) \\ [0, N] & \longrightarrow & \mathrm{Ty} & i \longmapsto \tau_i \end{array} \right.$$

([14]). La flèche f dans $\underline{\mathrm{Ty}}$ est determinée par ces données. Le type τ est donné par la formule $(*)$ ci-dessus, le type τ' par

$$(*') \qquad \tau' = \Delta_{\varepsilon_1}^{l_1}\Delta_{\varepsilon_2}^{l_2}\ \cdots\ \Delta_{\varepsilon_N}^{l_N}, \qquad \text{longueur } n' = \textstyle\sum l_i,$$

et l'application croissante de $I_\tau = [0, N + \sum \mathrm{long}(\tau_i)]$ dans $I_{\tau'} = [0, \sum l_i]$ est donnée ainsi : p. 31

constante sur $[0, 0+\lambda_0]$	$\longmapsto$	0
constante sur $[\lambda_0+1, \lambda_0+1+\lambda_1]$	$\longmapsto$	l_1
constante sur $[\lambda_0+\lambda_1+2, \lambda_0+\lambda_1+2+\lambda_2]$	$\longmapsto$	l_2
$\dots$		
constante sur $[\lambda_0+\lambda_1+\cdots+\lambda_i+(i+1), \lambda_0+\cdots+\lambda_i+\lambda_{i+1}+(i+1)]$	$\longmapsto$	l_i.

p. 32

Commentary · Exposition [ms. 47] [page 48]

Reading the morphism from its target

The incoming classification organizes a morphism by the places where its nonconstant pieces meet. It is the same normal form viewed from the target: choose the visited vertices, and at each visited vertex record the entire interval that has been collapsed there. This description is useful because the intervening noncollapsed transitions are then forced.

Let $f : I_\tau \to I_{\tau'}$ be increasing and endpoint-preserving, with target length m. The uniform definition is

$$E' = \mathrm{im}(f) \subseteq [0, m].$$

When $m > 0$, it agrees with the printed definition by endpoints of nondegenerate images. Indeed, take a vertex value t assumed by f. If not every source vertex has value t, connectedness of the underlying source path supplies an edge from the nonempty set $f^{-1}(t)$ to its complement. That edge is nondegenerate and one of its image endpoints is t. Conversely every such endpoint is a value of f. This argument does not require monotonicity, and supplies the elementary lemma requested in footnote 13, provided the functor is nonconstant.

For $m = 0$ all transition images are identities, so the printed endpoint definition would instead give $E' = \varnothing$. The later claim that E' contains the endpoint, and the definition $N = \#E' - 1$, then fail. Taking $E' = \mathrm{im}(f) = \{0\}$ repairs the nullary case and agrees with the explicit description of $N = 0$ on manuscript page 47. This is an omitted boundary convention; it does not change the nonconstant construction.

Write the distinct elements of E' as

$$0 = t_0 < t_1 < \cdots < t_N = m.$$

Every two consecutive values are joined by a target arrow: the source transition between their two adjacent nonempty fibres has exactly these image endpoints. Hence the segment from t_{j-1} to t_j is monochromatic, with sign ε_j. Equivalently, E' contains the intrinsic critical vertices of the target, namely its endpoints and every place where the signs change. The notation $\mathrm{Cr}(\tau')$ has changed meaning at this point in the manuscript: here it denotes these vertices, whereas earlier it denoted critical intervals. Keeping these two sets distinct removes a potential confusion in the formula.

The fibre over t_j is a nonempty consecutive interval of vertices; let its signature be τ_j and its length λ_j. Reading the source from left to right gives exactly

$$\tau = \tau_0\Delta_{\varepsilon_1}\tau_1\Delta_{\varepsilon_2}\cdots\Delta_{\varepsilon_N}\tau_N.$$

Conversely, choose any subset E' containing the critical vertices and any words $\tau_0, \dots, \tau_N$. Form this source word. Collapse the τ_j-block to t_j, and map the transition between consecutive blocks to the target arrow joining t_{j-1} and t_j, in the direction prescribed by ε_j. This defines an increasing endpoint-preserving functor; its image is exactly E', and its fibres have the prescribed words. Each

14. **NB** Si $N = 0$, $[1, N] = \emptyset$, et il n'y a pas de ε_i, l_i; l'application $\underbrace{[0, N]}_{=\{0\}} \longrightarrow$ Ty se réduit à la donnée de $\tau_0 \in$ Ty.

arrow is uniquely determined by its endpoints in an interval category, so there is no additional gluing datum. The two constructions are inverse. For a point target they reduce to the arbitrary word τ_0 and its unique map to the point.

For use in computations, set

$$l_j = t_j - t_{j-1}, \qquad B_j = j + \sum_{h<j} \lambda_h.$$

The correct full formula is

$$f(k) = t_j = \sum_{h=1}^{j} l_h \quad \text{for } B_j \le k \le B_j + \lambda_j, \qquad 0 \le j \le N.$$

The source's explicit table gives l_2 on the third fibre, where the value must be $l_1 + l_2$; its final row similarly needs the corresponding cumulative sum. The formula above repairs all rows at once. For example, take target $++-$, visited vertices $E' = \{0, 2, 3\}$, and fibre words $\tau_0 = -$, $\tau_1 = +$, τ_2 empty. Then the source is $-++-$ and the object map is $(0, 0, 2, 2, 3)$. The first positive transition crosses the two target positive edges, the next is collapsed, and the final negative transition crosses the final target edge. The two jumps have sizes 2 and 1, while the final vertex value is their sum 3.

Commentary · Development (commentators') [ms. 47]

Which contractions admit a section

The normal form makes it possible to ask precisely when a deleted collection of transitions can be restored functorially. This is useful for the later path formalism: a surjection of underlying vertex sets need not be a split epimorphism in the category of signed types. The signs can obstruct every possible section.

Section criterion for a contraction. [ours] Let $\tau = (\varepsilon_1, \dots, \varepsilon_n)$ and let $E = \{e_1 < \cdots < e_k\}$ be a subset of its transition positions. Let

$$p_E : \tau \longrightarrow \tau|_E$$

be the contraction with weights 1 at the positions in E and 0 elsewhere. If $k = 0$, it has a section exactly when $n = 0$. If $k > 0$, it has a section exactly under the following conditions. Every sign before e_1 equals ε_{e_1}, and every sign after e_k equals ε_{e_k}. In each open gap (e_j, e_{j+1}), the sequence of signs is a possibly empty string of ε_{e_j} followed by a possibly empty string of $\varepsilon_{e_{j+1}}$. When these conditions hold, the number of sections is

$$\prod_{\substack{1 \le j < k \\ \varepsilon_{e_j} = \varepsilon_{e_{j+1}}}} (e_{j+1} - e_j).$$

An empty product is 1.

Proof. Under the signed-edge anti-isomorphism, p_E corresponds to the inclusion $E \hookrightarrow [1, n]$. A section of p_E therefore corresponds exactly to a nondecreasing sign-preserving retraction

$$r : [1, n] \longrightarrow E, \qquad r(e_j) = e_j.$$

If E is empty such a map exists exactly when its domain is empty. Assume henceforth $k > 0$. Monotonicity forces every index before e_1 to map to e_1, and every index after e_k to map to e_k. This proves the two exterior conditions, and these parts of r are unique.

For $e_j < i < e_{j+1}$, monotonicity forces $e_j \le r(i) \le e_{j+1}$. Since there is no element of E strictly between them, $r(i)$ is one of these two endpoints. Moreover the indices mapped left must all precede the indices mapped right. There is therefore a single cut in the gap. Sign preservation is equivalent to the signs before the cut being ε_{e_j} and those after it being $\varepsilon_{e_{j+1}}$. This proves necessity of the gap condition. If the endpoint signs differ, an admissible cut is unique. If they agree, every sign in the gap must have that common value and all $d + 1$ cuts are admissible, where $d = e_{j+1} - e_j - 1$.

Conversely, choose an admissible cut independently in every gap, use the forced exterior values, and fix every e_j. The resulting map is nondecreasing across each gap and its boundary, hence globally

nondecreasing; it preserves signs by construction and retracts onto E. These choices describe every retraction exactly once. Multiplying their independent numbers gives the displayed product. The signed-edge correspondence turns each retraction back into a unique section of p_E, completing the proof.

For $\tau = +-$ and $E = \{1\}$ the trailing negative sign violates the exterior condition. Thus the surjective vertex map $+- \to +$ has no section. For $\tau = +++$ and $E = \{1, 3\}$ the gap has one omitted positive edge, and there are exactly two sections; their vertex maps $[0, 2] \to [0, 3]$ are $(0, 1, 3)$ and $(0, 2, 3)$. This distinguishes the collapse of an edge from a simplicial degeneracy with an available section.

We checked the ordinal description and comonoid interpretation in Aguiar and Mahajan (2010, Appendix D), the zig-zag and Reedy structures of Arakawa and Cnossen (2026, Definition 1.1 and Example 4.12), and searched for signed or coloured ordinal retractions and sections of Grothendieck's interval maps. We could not find this exact interval-form criterion and count in those sources. The result is an elementary consequence of the normal form, recorded here as a proved continuation of the calculation, without a claim of priority.

6 Composition dans $\underline{\mathrm{Ty}}$

On a une loi de composition (partout définie) dans $\mathrm{Ob}\,(\underline{\mathrm{Ty}}) = \mathrm{Ty}$, c'est celle du monoïde libre à deux générateurs Δ_+, Δ_-. Cette loi de composition s'interprète, au niveau catégorique (et non plus seulement combinatoire) comme une somme amalgamée

$$I_{\tau\tau'} = I_\tau \amalg_{(e, \underline{1}_\tau, \underline{0}_{\tau'})} I_{\tau'},$$

où e est la catégorie unité, et où $\underline{1}_\tau$, $\underline{0}_{\tau'}$ représentent maintenant les morphismes $e \longrightarrow I_\tau$, $e \longrightarrow I_{\tau'}$, ayant comme image l'élément but et l'élément source respectivement de l'intervalle orienté envisagé. On a donc un carré cocartésien dans (Cat)

$$\begin{array}{ccc} & e & \\ {\scriptstyle \underline{1}_\tau}\swarrow & & \searrow{\scriptstyle \underline{0}_{\tau'}} \\ I_\tau & \text{cocart.} & I_{\tau'} \\ {\scriptstyle i_{\tau,\tau'}}\searrow & & \swarrow{\scriptstyle j_{\tau,\tau'}} \\ & I_{\tau\tau'}, & \end{array}$$

où toutes les flèches sont des foncteurs mono et pleinement fidèles. Que ce diagramme (évidemment commutatif) soit bien cocartésien dans (Cat) revient, par définition, à dire que pour toute X dans Cat, le diagramme transposé

$$\begin{array}{ccccc} & & X & & \\ & {\scriptstyle \text{(but)}\ \beta_\tau}\nearrow & & \nwarrow{\scriptstyle \sigma_{\tau'}\ \text{(source)}} & \\ \underline{\mathrm{Ch}}_\tau(X) & & & & \underline{\mathrm{Ch}}_{\tau'}(X) \\ & \nwarrow & & \nearrow & \\ & & \underline{\mathrm{Ch}}_{\tau\tau'}(X), & & \end{array}$$

`[est cartésien]`

ce qui revient à la tautologie suivante qu'un chemin C dans X de type $\tau\tau'$ 'n'est autre chose' qu'un couple (c, c') d'un chemin c de type τ et d'un chemin c' de type τ' 'mis bout à bout' (dans cet ordre), i.e. tels que [page 49]

$$\mathrm{but}(c) = \mathrm{source}(c')$$

(et on a alors

$$\begin{aligned} \mathrm{source}(C) &= \mathrm{source}(c) \\ \mathrm{but}(C) &= \mathrm{but}(c') \end{aligned}$$

). p. 33

Il se pose ici le sempiternel problème si on va noter ce chemin $c{\cdot}c'$, ce qui semble à première vue s'imposer, ou plutôt $c' \circ c$, regardant le chemin c de $x = \text{source}(c)$ vers $y = \text{but}(c)$ comme une sorte de morphisme de x dans y (cf. plus bas le formalisme des catégories de fractions), c' comme un morphisme de $y = \text{source}(c')$ vers $z = \text{but}(c')$, et en interprétant le composé C comme le composé de ces deux morphismes c, c' (dans cet ordre du point de vue des opérations à effectuer), qu'on note traditionellement $c' \circ c$ ou $c' \cdot c$, et non $c \circ c'$ ou $c \cdot c'$, hélas! C'est cette notation que nous allons suivre plus bas.

Mais pour l'instant on ne va pas se soucier des chemins dans des catégories quelconques X, mais revenir au formalisme des τ et des I_τ eux-mêmes. L'interprétation catégorique de $\tau\tau'$ comme une somme amalgamée nous assure que cette opération de composition est fonctorielle : [page 50]

$$\tau_1 \xrightarrow{f} \tau_2, \quad \tau_1' \xrightarrow{f'} \tau_2' \qquad \text{donne } \tau_1\tau_1' \xrightarrow{f*f'} \tau_2\tau_2'$$

(on n'écrira pas $f \cdot f'$ pour la flèche notée $f * f'$, à cause de la confusion possible avec la composition des flèches dans $\underline{\text{Ty}}$). On a transitivité de façon évidente : si de plus $\tau_2 \xrightarrow{g} \tau_3$, $\tau_2' \xrightarrow{g'} \tau_3'$, `[on a]`

$$(gf) * (g'f') = (g * g') \circ (f * f').$$

Donc on a un bifoncteur de composition

$$\underline{\text{Ty}} \times \underline{\text{Ty}} \longrightarrow \underline{\text{Ty}} \qquad (c, c') \longmapsto c \cdot c' \text{ ou } c * c'.$$

(En fait, on a aussi un bifoncteur

$$\underline{\text{Typ}} \times \underline{\text{Typ}} \longrightarrow \underline{\text{Typ}},$$

mais on préfère oublier maintenant la catégorie $\underline{\text{Typ}}$, qui donne un formalisme nettement moins simple.)

Commentary · Context [ms. 49]

Concatenation is a pushout with chosen endpoints

Grothendieck's reason for introducing types now becomes visible: the concatenation of words should encode the actual gluing of paths, including their transformations. An interval is a free category on an oriented linear graph. Gluing the last vertex of the first graph to the first vertex of the second produces the graph of the concatenated word, and the free-category construction preserves this pushout. Therefore

$$I_{\tau\tau'} = I_\tau \amalg_e I_{\tau'}$$

is a pushout in Cat with the specified endpoint maps. Any directed path between two vertices of one summand stays in that summand: entering the other would require crossing the gluing vertex twice in an underlying linear graph. Thus the inclusions are fully faithful as well as injective on objects.

The corresponding assertion about path categories is also literal. Restriction gives an isomorphism

$$\text{Fun}(I_{\tau\tau'}, X) \cong \text{Fun}(I_\tau, X) \times_X \text{Fun}(I_{\tau'}, X),$$

where the fibre product uses evaluation at the two endpoints being identified. On objects, two functors agree at the common vertex exactly when their two paths concatenate. On morphisms, two natural transformations glue exactly when their components at that vertex are equal. Naturality along each generating edge then gives naturality on every composite. This verifies the categorical pullback, rather than only the corresponding assertion about sets of paths.

The convention on the order of composition now has a concrete meaning. The word $\tau\tau'$ is read first through τ and then through τ', whereas the corresponding categorical composition is written $c' \circ c$. This harmless reversal of written order should be fixed before discussing fractions. It is not an opposite-category operation and does not reverse any transition.

The endpoint data are indispensable. The parenthetical assertion on manuscript page 50 that concatenation also gives a bifunctor on $\underline{\text{Typ}}$, as defined on page 30 using *all* functors, is false. The one-arrow categories I_+ and I_- are isomorphic in $\underline{\text{Typ}}$. A bifunctor whose object operation is word

concatenation would carry this isomorphism, together with id_{I_+}, to an isomorphism between I_{++} and I_{-+}. The former is a three-object chain; the latter has one initial object and two incomparable maximal objects. They are not isomorphic. Thus the claimed bifunctor cannot exist on that larger category. It does exist on endpoint-preserving functors, even without monotonicity, because their restrictions agree at the glued vertex. The final category $\underline{\mathrm{Ty}}$ satisfies this requirement and remains closed under concatenation. This correction isolates precisely the structure that the path formalism needs.

Cette composition est *strictement* associative et *strictement unitaire* (l'unité étant bien sûr l'élément unité 1 du monoïde libre Ty, correspondant à la catégorie ponctuelle $\{0\}$), et pas seulement 'à isomorphisme près'. Et pour cause, puisque dans $\underline{\mathrm{Ty}}$ les isomorphismes sont des identités. *Donc* $\underline{\mathrm{Ty}}$ *est un monoïde dans la catégorie* (Cat) des petites catégories!

Cela implique que non seulement $\mathrm{Ob}\,\underline{\mathrm{Ty}} = \mathrm{Ty}$, mais aussi $\mathrm{Fl}(\underline{\mathrm{Ty}})$, et plus généralement tous les ensembles de la forme $\mathrm{Hom}_{\mathrm{Cat}}(X, \underline{\mathrm{Ty}})$ sont des monoïdes, et ceci fonctoriellement en X, par exemple les composantes $\mathrm{Hom}_{\mathrm{Cat}}(\mathbf{\Delta}_i, \underline{\mathrm{Ty}})$ de l'ensemble semi-simplicial 'nerf' de $\underline{\mathrm{Ty}}$, [page 49′ (il y a un décalage dans la numérotation)]

$$\mathrm{Nerf}_i(\underline{\mathrm{Ty}}) = \mathrm{Hom}_{\mathrm{Cat}}(\mathbf{\Delta}_i, \underline{\mathrm{Ty}}),$$

sont des monoïdes, et les applications semi-simpliciales entre elles sont des homomorphismes de monoïdes : le nerf de $\underline{\mathrm{Ty}}$ est un *monoïde semi-simplicial.*

On va décrire ces monoïdes $\mathrm{Nerf}_i(\underline{\mathrm{Ty}})$, et constater que ce sont tous des monoïdes *libres,* tout comme $\mathrm{Nerf}_0(\underline{\mathrm{Ty}}) = \mathrm{Ob}\,\underline{\mathrm{Ty}} = \mathrm{Ty}$. Les applications semi-simpliciales entre ces monoïdes sont donc connus quand on les connaît sur les *générateurs* de ces monoïdes libres (lesquels générateurs sont aussi les éléments indécomposables, donc définis intrinsèquement en termes de la structure multiplicative). p. 34

Pour $\mathrm{Nerf}_0(\underline{\mathrm{Ty}}) = \mathrm{Ty}$, c'est une chose vue, les générateurs sont

$$\Delta_+, \Delta_-,$$

correspondant respectivement aux intervalles orientés

$$\begin{aligned} \mathbf{\Delta}_+ &: \quad 0 \quad \longrightarrow \quad 1 \\ \mathbf{\Delta}_- &: \quad 0 \quad \longleftarrow \quad 1. \end{aligned}$$

Pour $\mathrm{Nerf}_1(\underline{\mathrm{Ty}}) = \mathrm{Fl}(\underline{\mathrm{Ty}})$, i.e. pour les flèches, le résultat $3^o)$ du paragraphe précédent (détermination de $\mathrm{Fl}(\underline{\mathrm{Ty}})$) s'interprète aussi en disant que $\mathrm{Fl}(\underline{\mathrm{Ty}})$ est le monoïde libre engendré par un système de générateurs infini [page 50′]

$$\mathfrak{f}_{\varepsilon,n}\ , \qquad (\varepsilon, n) \in \{+1, -1\} \times \mathbf{N},$$

indexé par l'ensemble produit $\{+1, -1\} \times \mathbf{N}$. Ici $\mathfrak{f}_{\varepsilon,n}$ désigne l'unique flèche dans $\underline{\mathrm{Ty}}$

$$\mathfrak{f}_{\varepsilon,l} : \Delta_\varepsilon \longrightarrow \Delta_\varepsilon^l$$

(où bien sûr l'exposant l désigne une exponentation pour la loi de composition dans $\underline{\mathrm{Ty}}$

$$\Delta_\varepsilon^l = \underbrace{\Delta_\varepsilon \circ \Delta_\varepsilon \circ \ \cdots \ \circ \Delta_\varepsilon}_{l \text{ copies}},$$

et non la puissance cartésienne dans Cat, où dans $\underline{\mathrm{Ty}}$ (où elle n'existe que si $l \in \{0, 1\}$)). Dans la description de $\mathrm{Fl}(\underline{\mathrm{Ty}})$ dans le paragraphe précédent, on a écrit le 'terme général' du monoïde libre en groupant ensemble les groupes de foncteurs successifs de la forme $f_{+,0}$, $f_{-,0}$, i.e. corréspondant aux deux flèches de dégénérescence indécomposables (pour $*$)

$$\begin{cases} f_{+,0} : \quad \Delta_+ \quad \longrightarrow \quad e \\ f_{-,0} : \quad \Delta_- \quad \longrightarrow \quad e \end{cases}$$

([15]). Le sous-monoïde libre de Fl(Ty) engendré par ces deux éléments est le monoïde des flèches de dégénérescence (pure) quelconques dans Ty : p. 35 [page 51]

$$f_\tau : I_\tau \longrightarrow e \qquad (\tau \in \mathrm{Ty}),$$

et on a

$$f_\tau * f_{\tau'} = f_{\tau\tau'},$$

i.e. l'application

$$\tau \longmapsto f_\tau : \quad \underbrace{\mathrm{Ob}\,(\underline{\mathrm{Ty}})}_{=\mathrm{Ty}=\mathrm{Nerf}_0(\underline{\mathrm{Ty}})} \longrightarrow \underbrace{\mathrm{Fl}(\underline{\mathrm{Ty}})}_{\mathrm{Nerf}_1(\underline{\mathrm{Ty}})}$$

est un homomorphisme de monoïdes, transformant Δ_ε ($\varepsilon \in \{+1,-1\}$) dans $\mathfrak{f}_{\varepsilon,0}$. Ce n'est pas l'application de dégénérenscence de Nerf_0 dans Nerf_1, i.e. l'application $\tau \longmapsto \mathrm{id}_\tau$. Celle-ci est donnée par

$$\begin{array}{ccc} \mathrm{Ob}\,(\underline{\mathrm{Ty}}) & \longrightarrow & \mathrm{Fl}(\underline{\mathrm{Ty}}) \\ \tau & \longmapsto & \mathrm{id}_\tau \end{array} \quad : \quad \left| \begin{array}{lcll} & \Delta_\varepsilon & \longmapsto & \mathfrak{f}_{\varepsilon,1} \qquad (\varepsilon \in \{+1,-1\}) \\ \text{i.e.} & \Delta_+ & \longmapsto & \mathfrak{f}_{+,1} \\ & \Delta_- & \longmapsto & \mathfrak{f}_{-,1}\ . \end{array} \right.$$

Quant aux homomorphismes source et but

$$\mathrm{Fl}(\underline{\mathrm{Ty}}) \underset{\beta\ (\mathrm{but})}{\overset{\sigma\ (\mathrm{source})}{\rightrightarrows}} \mathrm{Ob}\,(\underline{\mathrm{Ty}}),$$

ils sont évidents sur les générateurs

$$\left\{ \begin{array}{rcl} \sigma(\mathfrak{f}_{\varepsilon,l}) & = & \Delta_\varepsilon \\ \beta(\mathfrak{f}_{\varepsilon,l}) & = & \Delta_\varepsilon^l. \end{array} \right.$$

Commentary · Later developments [ms. 50']

The type category is generated by two comonoids

The strict monoidal structure places Grothendieck's calculation beside a classical universal property of the simplicial category. In the single-sign case, endpoint-preserving maps of finite intervals are opposite to monotone maps of finite ordered edge sets. The latter category, with ordinal sum, contains the universal monoid; its opposite contains the universal counital coassociative comonoid. An explicit account, with the weak-composition coordinates used here, is Aguiar and Mahajan (2010, Appendix D.1–D.2, especially Proposition D.2, pp. 713–716), which traces the universal property to Mac Lane's Proposition VII.5.1. The two signs simply keep two independent copies of this structure in the same ordered word.

In Ty put

$$\delta_\varepsilon = \mathfrak{f}_{\varepsilon,2} : \Delta_\varepsilon \longrightarrow \Delta_\varepsilon^2, \qquad e_\varepsilon = \mathfrak{f}_{\varepsilon,0} : \Delta_\varepsilon \longrightarrow 1, \qquad \varepsilon \in \{+,-\}.$$

Both ways of applying δ_ε twice give the unique endpoint-preserving map from Δ_ε to Δ_ε^3. Applying e_ε to either output of δ_ε gives the identity, since its surviving weight is 1. Thus each Δ_ε is a counital coassociative comonoid. There is no specified relation between the positive and negative comonoids.

More precisely, a strict monoidal functor from Ty to a strict monoidal category $(\mathcal{C}, \otimes, \mathbf{1})$ is uniquely specified by a pair of counital coassociative comonoids C_+ and C_- in $\mathcal{C}$. Here is the construction, which also proves the assertion. For either comonoid, let $\delta^{(a)} : C \to C^{\otimes a}$ denote the iterated comultiplication, with $\delta^{(0)}$ its counit and $\delta^{(1)} = \mathrm{id}$. Coassociativity and the counit laws give, for every list $b_1, \ldots, b_a$ of nonnegative integers,

$$\big(\delta^{(b_1)} \otimes \cdots \otimes \delta^{(b_a)}\big)\delta^{(a)} = \delta^{(b_1+\cdots+b_a)}.$$

15. **NB** Le 'mot' vide de Fl(Ty) correspond à la flèche id_1, où 1 est l'élément unité de Ty, réalisant l''intervalle' ponctuel.

For completeness, the binary identity $(\delta^{(p)} \otimes \delta^{(q)})\delta^{(2)} = \delta^{(p+q)}$ follows by induction on positive p, q using coassociativity; the cases $p = 0$ or $q = 0$ are the counit identities, including $p = q = 0$. Applying this binary identity successively to the first $a - 1$ factors and the last factor proves the displayed formula by induction on a. The case $a = 0$ says that the identity of the unit composed with the counit is the counit.

Send the word $\varepsilon_1 \cdots \varepsilon_n$ to $C_{\varepsilon_1} \otimes \cdots \otimes C_{\varepsilon_n}$ and send its outgoing morphism of weights $(a_1, \ldots, a_n)$ to

$$\delta_{\varepsilon_1}^{(a_1)} \otimes \cdots \otimes \delta_{\varepsilon_n}^{(a_n)}.$$

The block-sum formula for composition and the preceding identity prove that this assignment is a functor. The all-one vector gives identities; the empty word gives the unit; concatenation of vectors gives the tensor product of maps. It is therefore strict monoidal. Conversely every outgoing morphism is the tensor product of its one-edge factors, and each such factor is an iterated comultiplication or counit. A strict monoidal functor must have the displayed values, establishing uniqueness.

This is a reinterpretation of the known ordinal/comonoid universal property, not a new homotopy theorem. It explains the two apparently different generators in the manuscript: $\mathfrak{f}_{\varepsilon,0}$ erases a transition, whereas $\mathfrak{f}_{\varepsilon,2}$ subdivides one. Their iterates produce every allowed reparametrization. No braiding is present: the order of the source transitions is part of the structure and cannot be permuted.

Je vais décrire maintenant $\mathrm{Nerf}_2(\underline{\mathrm{Ty}})$, i.e. les systèmes

$$\tau \xrightarrow{f} \tau' \xrightarrow{g} \tau''.$$

Se donner $f \in \mathrm{Fl}(\underline{\mathrm{Ty}})$ revient à se donner une suite ordonnée de générateurs $f_{\varepsilon,l}$, donc une suite [page 52]

$$\mathfrak{f}_{\varepsilon_1,l_1},\ \mathfrak{f}_{\varepsilon_2,l_2},\ \ \cdots\ \ ,\mathfrak{f}_{\varepsilon_n,l_n}$$
$$((\varepsilon_i, l_i))_{1\leq i\leq n} \in [\{\pm 1\} \times \mathbf{N}]^n.$$

On a alors

$$x = \Delta_{\varepsilon_1}\Delta_{\varepsilon_2}\cdots\Delta_{\varepsilon_n} \qquad \log x = n$$
$$y = \Delta_{\varepsilon_1}^{l_1}\Delta_{\varepsilon_2}^{l_2}\cdots\Delta_{\varepsilon_n}^{l_n} \qquad \log y = \textstyle\sum_{i\in[1,n]} l_i.$$

Se donner $q : y \longrightarrow z$, i.e. un objet de $y\backslash\underline{\mathrm{Ty}}$, revient à se donner une application de l'ensemble des $m = \sum l_i$ flèches de transition de y dans $\mathbf{N}$. En fait, on a p. 36

$$\mathrm{Tr}(y) = \mathrm{Tr}(\Delta_{\varepsilon_1}^{l_1}) \amalg \mathrm{Tr}(\Delta_{\varepsilon_2}^{l_2}) \amalg \cdots \amalg \mathrm{Tr}(\Delta_{\varepsilon_n}^{l_n})$$

('ensemble somme', i.e. réunion disjointe), donc

$$\mathrm{Hom}_{\mathrm{Ens}}(\mathrm{Tr}(y)) \simeq \prod_{i\in[1,n]} \mathrm{Hom}_{\mathrm{Ens}}(\underbrace{\mathrm{Tr}(\Delta_{\varepsilon_i}^{l_i})}_{[1,l_i]}, \mathbf{N}),$$

donc la donnée de g équivaut à la donnée d'un système de n applications

$$\begin{cases} \pi_i : [1, l_i] \longrightarrow \mathbf{N} & \text{(pondération de } \Delta_{\varepsilon_i}^{l_i}) \\ \text{pour } i \in [1, n]. \end{cases}$$

Mais pour $i \in [1, n]$, considérons l'élément de Nerf_2

$$\Delta_{\varepsilon_1} \xrightarrow{\mathfrak{f}_{\varepsilon_i,l_i}} \Delta_{\varepsilon_i}^{l_i} \xrightarrow{g_{\varepsilon,\pi_i}} \underbrace{\Delta_{\varepsilon_i}^{\pi_i(1)}\Delta_{\varepsilon_i}^{\pi_i(2)}\cdots\Delta_{\varepsilon_i}^{\pi_i(l_i)}}_{\Delta_{\varepsilon_i}^{\sum_j \pi_i(j) \overset{\text{déf}}{=} \log(\pi_i)}}, \tag{1}$$

où g_{ε_i,π_i} est la flèche définie en termes de π_i au paragraphe précédent. Mais ce n'est autre aussi que [page 53]

$$g_{\varepsilon_i,\pi_i} = \mathfrak{f}_{\varepsilon_i,\pi_i(1)} * \mathfrak{f}_{\varepsilon_i,\pi_i(2)} * \cdots * \mathfrak{f}_{\varepsilon_i,\pi_i(l_i)}. \tag{2}$$

L'élément de Nerf_2 envisagé ne dépend que de

$$(\varepsilon_i, l_i, \pi_i), \qquad \text{où } (\varepsilon_i, l_i) \in \{\pm 1\} \times \mathbf{N},\ \pi_i : [1, l_i] \longrightarrow \mathbf{N}.$$

(**NB** Si $l_i = 0$, $[1, l_i] = [1, 0] = \emptyset$ par convention, et π_i est l'unique application $\emptyset \longrightarrow \mathbf{N}$, donc la donnée $(\varepsilon_i, l_i, \pi_i)$ revient alors à (ε_i, l_i).)

Si

$$(\varepsilon, l, \pi) \ \text{ comme dessus}, \qquad (\varepsilon, l) \in \{\pm 1\} \times \mathbf{N},\ \pi : [1, l] \longrightarrow \mathbf{N},$$

désignons par

$$\mathfrak{f}_{\varepsilon,l,\pi}$$

l'élément de Nerf_2 donné par

$$\Delta_\varepsilon \xrightarrow{\mathfrak{f}_{\varepsilon,l}} \Delta_\varepsilon^l \xrightarrow{\mathfrak{f}_{\varepsilon,\pi(1)} \ * \cdots * \ \mathfrak{f}_{\varepsilon,\pi(l)}} \Delta_\varepsilon^{\pi(1)} \Delta_\varepsilon^{\pi(2)} \cdots \Delta_\varepsilon^{\pi(l)}.$$

On peut formuler la construction précédente en disant que tout élément de Nerf_2 peut se décomposer de façon unique en un produit

$$(f, g) = \mathfrak{f}_{\varepsilon_1,l_1,\pi_1} * \mathfrak{f}_{\varepsilon_2,l_2,\pi_2} * \cdots * \mathfrak{f}_{\varepsilon_n,l_n\pi_n},$$

ce qui prouve que $\mathrm{Nerf}_2(\underline{\mathrm{Ty}})$ est le monoïde libre sur les générateurs précédents $\mathfrak{f}_{\varepsilon,l,\pi}$. (**NB** à la suite vide correspond

$$1 \xrightarrow{\mathrm{id}_1} 1 \xrightarrow{\mathrm{id}_1} 1 \qquad .)$$

Si l'objet de Nerf_2 est

$$x \xrightarrow{f} y \xrightarrow{g} z,$$

p. 37
[page 54]

la construction précédente nous dit, en termes de la donnée combinatoire, i.e. de la suite de données

$$(\varepsilon_1, l_1, \pi_1),\ \ldots\ ,\ (\varepsilon_n, l_n, \pi_n),$$

quels sont x, y, z : chacun d'eux est le produit dans $\mathrm{Nerf}_0 = \mathrm{Ty}$ des n facteurs x_i, y_i ou z_i respectivement, pour $i \in [1, n]$, donnés dans la définition des $\mathfrak{f}_{\varepsilon_i,l_i,\pi_i}$, i.e. de

$$\Delta_{\varepsilon_i},\ \Delta_{\varepsilon_i}^{l_i},\ \text{ et } \Delta_{\varepsilon_i}^{\pi_i(1)} \Delta_{\varepsilon_i}^{\pi_i(2)} \cdots \Delta_{\varepsilon_i}^{\pi_i(l_i)} = \Delta_{\varepsilon_i}^{\mathrm{long}(\pi_i)}$$

(où $\mathrm{long}(\pi_i) = \sum_{j \in [1,l_i]} \pi_i(j)$). Donc

$$\begin{cases} x &= \prod_{i\in[1,n]}^{\mathrm{Ty}} \Delta_{\varepsilon_i} \\ y &= \prod_{i\in[1,n]}^{\mathrm{Ty}} \Delta_{\varepsilon_i}^{l_i} \\ z &= \prod_{i\in[1,n]}^{\mathrm{Ty}} \Delta_{\varepsilon_i}^{\mathrm{long}(\pi_i)} \end{cases}$$

([16]), et on trouve de même f, g comme des produits (au sens $*$) de n facteurs f_i resp. g_i ($i \in [1, n]$) explicités dans les formules (1), (2) (p. 52, 53) :

$$\begin{aligned} f_i &= \mathfrak{f}_{\varepsilon_i,l_i} : \ \Delta_{\varepsilon_i} \longrightarrow \Delta_{\varepsilon_i}^{l_i} \\ g_i &= g_{\varepsilon_i,l_i} : \ \Delta_{\varepsilon_i}^{l_i} \longrightarrow \Delta_{\varepsilon_i}^{\mathrm{long}(\pi_i)}, \end{aligned}$$

g_i lui-même étant représenté comme un $*$-produit de l_i facteurs indécomposables, de sorte que f et g apparaissent sous forme de $*$-produits de n, resp. de $\sum_{i\in[1,n]} l_i$ facteurs de la forme $\mathfrak{f}_{\varepsilon,\nu}$. Pour terminer de tenir en mains l'objet semi-simplicial tronqué $(\mathrm{Nerf}_i(\underline{\mathrm{Ty}}))_{0\le i\le 2}$, il reste à

[page 55]

16. attention, les produits doivent être pris en respectant l'ordre des facteurs donné par la notation indicielle en i.

décrire les deux applications de dégénérescence $\mathrm{Nerf}_1 \longrightarrow \mathrm{Nerf}_2$ (cas où f ou g est une flèche identique) et surtout l'application de *composition* des flèches

$$\mathrm{Nerf}_2(\underline{\mathrm{Ty}}) \xrightarrow{\gamma} \mathrm{Nerf}_1(\underline{\mathrm{Ty}}) = \mathrm{Fl}(\underline{\mathrm{Ty}}).$$

Il suffit de donner γ sur les générateurs, et on a tautologiquement, par définition des $\mathfrak{f}_{\varepsilon,l,\pi}$

$$\gamma(\mathfrak{f}_{\varepsilon,l,\pi}) = \mathfrak{f}_{\varepsilon,\mathrm{long}(\pi)}.$$

(**NB** Il n'existe au plus qu'un seul morphisme de Δ_ε (de Δ_+ ou de Δ_-) dans un intervalle I_τ. Il existe si et seulement si τ est de la forme Δ^l_ε, $l \in \mathbf{N}$.)

Commentary · Exposition [ms. 53]

Free monoids in degrees one and two

Grothendieck uses the nerve to keep composition together with concatenation. A string of composable reparametrizations can still be cut along the original source edges. The resulting factors are independent, and this is the reason the monoid in each nerve degree is free.

In degree one, a morphism with source word $\varepsilon_1 \cdots \varepsilon_n$ and weights $(a_1, \ldots, a_n)$ has the unique decomposition

$$f = \mathfrak{f}_{\varepsilon_1,a_1} * \cdots * \mathfrak{f}_{\varepsilon_n,a_n}.$$

The factors are indexed by source edges, even when their weights vanish. A generator $\mathfrak{f}_{\varepsilon,0}$ is therefore not the unit of this free monoid: its source has one edge. The monoid unit is the empty factorization, namely the identity of the point. Nor is $\mathfrak{f}_{\varepsilon,1}$ the monoid unit; it is the identity of a one-edge object and is indecomposable under concatenation. This separates the categorical identity operation from the unit of the tensor product.

Now consider $\tau \xrightarrow{f} \tau' \xrightarrow{g} \tau''$. The ith original edge produces an ordered block of a_i edges after f. Let $\pi_i : [1, a_i] \to \mathbb{N}$ record the weights that g assigns to that block. All descendants have the original sign ε_i. Consequently the pair has the unique factorization

$$(f, g) = \prod_{i=1}^{n,*} \mathfrak{f}_{\varepsilon_i,a_i,\pi_i}.$$

Existence comes from cutting every intermediate word into its descendant blocks; uniqueness comes from the fixed order of the original edges and the unique weight vector of each restriction. The nullary case $a_i = 0$ has one empty function π_i, so it contributes a legitimate generator whose two targets are the point. For $n = 0$ the whole pair is the identity string at the point and is the monoid unit. This proves the claimed freeness in degree two without discarding extinct blocks.

Writing $N_r = N_r(\underline{\mathrm{Ty}})$, the three faces of a degree-two generator are

$$\begin{aligned} d_2(\mathfrak{f}_{\varepsilon,a,\pi}) &= \mathfrak{f}_{\varepsilon,a}, \\ d_1(\mathfrak{f}_{\varepsilon,a,\pi}) &= \mathfrak{f}_{\varepsilon,\sum_{j=1}^{a} \pi(j)}, \\ d_0(\mathfrak{f}_{\varepsilon,a,\pi}) &= \mathfrak{f}_{\varepsilon,\pi(1)} * \cdots * \mathfrak{f}_{\varepsilon,\pi(a)}. \end{aligned}$$

The last line is the empty product when $a = 0$. The two degeneracies of a degree-one generator insert the identity before or after its map:

$$s_0(\mathfrak{f}_{\varepsilon,a}) = \mathfrak{f}_{\varepsilon,1,(a)}, \qquad s_1(\mathfrak{f}_{\varepsilon,a}) = \mathfrak{f}_{\varepsilon,a,1_a}.$$

Here (a) is the one-entry weight vector and 1_a the all-one vector of length a. These formulas recover precisely the composition and degeneracies described on manuscript pages 54–56, while displaying the other two faces as well.

The word "semi-simplicial" in this edition includes degeneracies; in current terminology the nerve is a simplicial monoid. The faces and degeneracies are monoid homomorphisms because concatenation is a bifunctor and is strictly associative and unital. This statement concerns the whole degreewise free monoid. Its distinguished basis need not itself be a simplicial set: d_0 can send one generator to a product of several generators, or to the unit.

p. 38

Le cas $g = \mathrm{id}$ correspond au cas où

$$\pi_i(j) = 1 \qquad \forall j \in [1, l_i],$$

les $\mathfrak{f}_{\varepsilon_i, l_i, \pi_i}$ sont alors détérminés en fonction des $\mathfrak{f}_{\varepsilon_i, l_i}$, et l'application de dégénérescence est

$$\mathfrak{f}_{\varepsilon,l} \longmapsto \mathfrak{f}_{\varepsilon,l,1_l} \qquad (\text{où } 1_l \text{ est la fonction constante de valeur 1 sur } [1,l]).$$

Le $f = \mathrm{id}$ est celui où les l_i sont égaux à 1. Alors chaque $\pi_i : [1,1] \longrightarrow \mathbf{N}$ peut être vu comme un élément de $\mathbf{N}$, la donnée de $(\varepsilon_i, l_i, \pi_i)$ revient à celle des $(\varepsilon_i, n_i) \in \{\pm 1\} \times \mathbf{N}$, i.e. la donnée d'une suite de n générateurs parmi les $\mathfrak{f}_{\varepsilon,l}$. L'application de dégénérescence $\mathrm{Nerf}_1 \longrightarrow \mathrm{Nerf}_2$ est ici donnée sur les générateurs par [page 56]

$$\mathfrak{f}_{\varepsilon,l} \longmapsto \mathfrak{f}_{\varepsilon,1,l}.$$

Heureusement, on n'a plus à prouver l'associativité de la composition.

NB La simplicité de ces descriptions renforce mon sentiment que la catégorie $\underline{\mathrm{Ty}}$ définie à présent, avec les *morphismes d'intervalles orientés croissants* $I_\tau \longrightarrow I_{\tau'}$ comme flèches de $\underline{\mathrm{Ty}}$, est bien 'la bonne'. On va déjà voir si elle donne une description sympa des catégories de fractions $X\Sigma^{-1}$, sans tortillements comme précédemment.

Mais on a promis de déterminer $\mathrm{Nerf}_r(\underline{\mathrm{Ty}})$, pour tout $r \in \mathbf{N}$. Le générateur général de Nerf_r est de la forme (pour $\varepsilon \in \{\pm 1\}$ fixé)

$$\underbrace{\Delta_\varepsilon}_{=\Delta_\varepsilon^{l_0} \text{avec } l_0=1} \xrightarrow{f_1} \Delta_\varepsilon^{l_1} \xrightarrow{f_2} \Delta_\varepsilon^{l_2} \longrightarrow \cdots \xrightarrow{f_r} \Delta_\varepsilon^{l_r},$$

où les $f_i : \Delta_\varepsilon^{l_{i-1}} \longrightarrow \Delta_\varepsilon^{l_i}$, $i \in [1,r]$, sont donnés par des applications

$$\pi_{i-1} : [1, l_{i-1}] \longrightarrow \mathbf{N} \qquad \text{telles que} \quad \underbrace{\mathrm{long}(\pi_{i-1})}_{\overset{\text{déf}}{=} \Sigma_{j \in [1,l_i]} \pi_i(j)} = l_i.$$

(NB $\pi_0 : [1,1] = \{1\} \longrightarrow \mathbf{N}$ est identifié à $\mathrm{long}(\pi_0) = \pi_0(1) = l_1$.)

Pour ne pas faire dépendre la définition du domaine des π_i ($i \in [0, r-1]$) des entiers l_i, on peut aussi considérer les π_i comme des applications [page 57]

$$\mathbf{N}^* \xrightarrow{\pi} \mathbf{N} \qquad (\mathbf{N}^* = \{i \in \mathbf{N} \mid i \geq 1\})$$

à supports finis (i.e. tels que $\pi(i) = 0$ pour i grand), et exiger de façon précise

$$(**) \qquad \begin{aligned} &\mathrm{supp}\,\pi_0 \subseteq \{1\} \\ &\mathrm{supp}\,\pi_1 \subseteq [1, \mathrm{long}(\pi_0)] \\ &\qquad \cdots \\ &\boxed{\mathrm{supp}\,\pi_i \subseteq [1, \mathrm{long}(\pi_{i-1})]}, \qquad \text{pour } \boxed{i \in [0, r-1]} \quad . \end{aligned}$$

Commentary · Exposition [ms. 57]

All nerve degrees as ordered forests

The final assertion of manuscript page 57 is that the same decomposition works for arbitrarily long strings of reparametrizations. It is useful to complete the argument now, since it explains both the support conditions at the bottom of the page and the one face map that behaves differently from the others.

Fix $r \geq 0$. Call an r-step string *rooted* when its initial type has one transition. Every intermediate type is then a power of the same sign, and the string has the form

$$\Delta_\varepsilon^{l_0} \longrightarrow \Delta_\varepsilon^{l_1} \longrightarrow \cdots \longrightarrow \Delta_\varepsilon^{l_r}, \qquad l_0 = 1.$$

For $0 \le a < r$ its ath weight vector is

$$\pi_a : [1, l_a] \longrightarrow \mathbb{N}, \qquad l_{a+1} = \sum_{j=1}^{l_a} \pi_a(j).$$

One can regard this as an ordered rooted tree with r levels of edges: a transition at level a has $\pi_a(j)$ ordered descendants at level $a+1$. A vertex may have no descendants. Once a whole level is empty, all subsequent levels are empty because there is no morphism from the point to a nonpoint type.

For a general string, let its initial word have transitions $1, \dots, n$. At the first stage the descendants of each original transition form a consecutive monochromatic block. At the next stage the descendants of all transitions in one such block again form a consecutive block: concatenate their individual image blocks, allowing zero lengths. Induction gives such a block at every level. Restricting all maps to the descendants of a fixed original edge produces a rooted string, and concatenating the n rooted strings reconstructs the original string. Each boundary is determined by cumulative weights, so this factorization is unique. A rooted string cannot be a product of two nonunit strings, since the lengths of their initial words would be positive integers summing to one. Conversely a string whose initial word has at least two edges splits after its first edge. Thus rooted strings are exactly the indecomposables, and

$$N_r(\underline{\mathrm{Ty}}) \cong \text{the free monoid on rooted } r\text{-step strings.}$$

For $r = 0$ there are exactly two generators, the two signs. For an empty initial word there is only the all-identity string at the point, which is the monoid unit. These boundary cases establish the assertion for every r.

The simplicial operators can now be read directly on these forests. An inner face removes one level and replaces the two successive weight vectors by the sums over consecutive descendant blocks. The last face forgets the last level. A degeneracy repeats a level, inserting weight 1 at each of its transitions. These operations preserve a single root. The first face removes the original root level: a rooted string with l_1 first-generation transitions becomes the concatenation of their l_1 rooted descendant strings. This is the higher-dimensional version of the formula for d_0 above. Since these are exactly restriction and composition of actual functors $[r] \to \underline{\mathrm{Ty}}$, they satisfy all simplicial identities; the unique forest decomposition identifies their formulas with those categorical operators.

For $r > 0$, to use fixed-domain functions as on manuscript page 57, extend each π_a by zero to $\mathbb{N}^*$. The exact conditions are

$$\mathrm{supp}(\pi_0) \subseteq \{1\}, \qquad \mathrm{supp}(\pi_a) \subseteq [1, \mathrm{long}(\pi_{a-1})] \quad (1 \le a < r).$$

The source's final boxed range starts at $a = 0$, although π_{-1} is undefined; it must begin at 1. The preceding display defining $\mathrm{long}(\pi_{i-1})$ likewise needs the indices $j \in [1, l_{i-1}]$ and $\pi_{i-1}(j)$. These printed indexing slips do not affect the argument once the successive domains are kept in view.

One should not infer from this result that the simplicial monoid is freely generated by a simplicial set of indecomposables: the first-face calculation rules that out for this particular basis. Nor does the algebraic freeness make its classifying space complicated. The point is terminal in $\underline{\mathrm{Ty}}$, since every weight vector admits the unique further collapse to zero. Appending that terminal object gives the usual contraction of the nerve. The free presentations describe how all reparametrizations fit together, while this terminal object describes their ordinary homotopy type.

Commentary · Present state [ms. 57]

What the shape calculus does for localization

The free monoids just constructed organize subdivision and concatenation. To obtain mapping spaces, a second ingredient is needed: comparisons of labelled paths must carry the specified weak-equivalence information. For a relative category (C, W) and fixed x, y, let $Z_\tau(C, W)_{x,y}$ be the category of paths of type τ from x to y, with backward arrows in W, and natural transformations whose components lie in W and whose endpoint components are identities. Precomposition makes these categories contravariant in $\underline{\mathrm{Ty}}$. Their nerves, or their groupoid completions, retain comparisons that the set of path components alone would discard.

The analogous construction for relative infinity-categories is developed by Mazel-Gee (2018, Definitions 3.9 and 3.17). Under a homotopical three-arrow calculus, his Theorem 4.4 identifies the geometric realizations of its hammock mapping objects with the groupoid completions of three-arrow zigzag categories. This is an additional hypothesis, not a consequence of the finite normal form in the manuscript. Independently, Mazel-Gee (2019, Theorem 3.8) proves that completing the relative Rezk nerve presents localization. That universal property supplies the criterion with which a proposed path model must be compared.

For the general mapping-space comparison, Arakawa and Cnossen (2026, Theorem 1.9 and Corollary 1.11) prove in their preprint that

$$\mathrm{Map}_{C[W^{-1}]}(x,y) \simeq \operatorname*{colim}_{\tau \in \underline{\mathrm{Ty}}^{\mathrm{op}}} \left| Z_\tau(C,W)_{x,y} \right|,$$

where the colimit is taken in spaces and $|-|$ is groupoid completion. The displayed formula uses the ordinary relative categories just defined; the passage from their strict endpoint fibres to the invariant formula is supplied by Convention 4.2, Definition 4.3, Theorem 4.7, and Proposition 4.8(b) of the same paper. The general infinity-categorical statement uses the corresponding infinity-categories of relative diagrams and their endpoint fibres. Their Corollary 5.7 supplies the localization identification for Mazel-Gee's hammock construction. These references distinguish the established Rezk-nerve theorem from the more recent explicit comparison.

The comparison makes the scope of the present pages clear. They provide the shapes, their functorial changes, and strict concatenation. They do not yet choose W or impose the conditions on vertical arrows used above. No new open conjecture is required to finish their finite combinatorics. The subsequent localization construction still has to be checked with its own morphisms and universal property; the contractibility of an interval, by itself, does not perform that check.

Overview · VII-a

Chapter VII, manuscript pages 1–57: the shapes of paths.

The opening of Chapter VII is a restart. Grothendieck has found the earlier path formalism too cumbersome to serve as a foundation for localization, and he now separates a path from the finite combinatorial object on which it is parametrized. The distinction gives these pages their unity. First one understands intervals independently of any coefficient category; next one regards every operation on paths as a change of interval; finally one assembles all types and makes their concatenation strictly functorial. The later theory of fractions is a test of the construction, not yet a theorem established in these pages. The commentary on localization and path completion in Chapter VI, especially at manuscript pages 64–70, supplies the background; the present chapter changes the finite apparatus on which such arguments are to rest.

An interval of length n is the free category on an oriented path with vertices $0, \dots, n$. Its signature is a word $\tau = (\varepsilon_1, \dots, \varepsilon_n)$ in two signs. There are two orders to remember. The progression order is the linear order of the vertices; the categorical order records the existence of arrows. A path proceeds from vertex 0 to vertex n even when some of its arrows point backwards. Reversing this progression order changes the signature to $(-\varepsilon_n, \dots, -\varepsilon_1)$, whereas taking the opposite category changes it to $(-\varepsilon_1, \dots, -\varepsilon_n)$. Their distinction is already needed to understand why a span is symmetric as an interval but is not isomorphic to its opposite cospan.

The maximal constant runs of the signature are the structural chains. Their endpoints are the critical vertices; retaining just these vertices gives the reduced interval. These notions organize all full subcategories of an interval. A nonempty full subcategory has interval components, and a subset with extreme vertices $i < j$ is connected precisely when it retains every critical vertex between them. The proof is elementary and decisive: two consecutive retained vertices can be joined by an arrow exactly when no change of sign has been omitted between them. Thus reduction remembers the turns while suppressing subdivisions inside a composable run. It does not mean that arbitrary diagrams on the interval may forget the intermediate objects.

Several literal statements near the beginning need repair. Proposition 1(b) asserts that every endpoint-fixing endofunctor is the identity. On [2], the function $(0, 1, 2) \mapsto (0, 0, 2)$ is a counterexample. The proof on the following pages establishes rigidity of endpoint-fixing *isomorphisms*, which is sufficient for the classification of orientations. In fact, the stronger endofunctor assertion holds exactly for reduced intervals. Proposition 3's deletion criterion also needs the vertices incomparable with the deleted vertex to be separated from its incoming and outgoing links. Finally, an interval-shaped subcategory need not be full. All these readings occur in the edition and remain in the source text. The accompanying blocks give counterexamples and prove the repaired assertions, so that subsequent correct arguments do not inherit an unnecessary uncertainty.

Reduction has a useful additional interpretation. For the full inclusion $j : I_{\mathrm{red}} \hookrightarrow I$, send an interior vertex of each run to that run's categorical target or categorical source, and fix all critical vertices. The resulting maps satisfy

$$p_{\mathrm{target}} \dashv j \dashv p_{\mathrm{source}}.$$

The commentary proves these adjunctions by comparing the relevant hom-sets. They give categorical deformation retractions and explain exactly why reduction is harmless for groupoid-valued paths. For a general category X, restriction $X^I \to X^{I_{\mathrm{red}}}$ need not be an equivalence. This is the first place where the geometry of the shape and the information in a labelled diagram must be kept distinct.

Once the shape is fixed, a path of type τ in X is a functor $I_\tau \to X$, and its morphisms are natural transformations. The category is X^{I_τ}; its set of objects is the represented functor

$\mathrm{Hom}_{\mathrm{Cat}}(I_\tau, X)$. Yoneda then says that every operation on paths natural in the coefficient category is precomposition by a unique functor between their shapes, in the reverse direction. The proof evaluates the operation on the identity path in I_τ. This explains both composition of successive arrows and insertion of identities, and supplies their action on morphisms without an additional coherence choice. The manuscript's distinction between the set and the category of paths must therefore survive the typography.

The category of types changes twice while Grothendieck tests it. Initially it permits all functors between intervals; then it retains functors preserving the two endpoints; finally it also requires their vertex functions to be nondecreasing in the progression order. Only the first version is fully faithful in Cat. The second is fully faithful in the category of categories under the discrete two-point category. The final version, denoted $\underline{\mathrm{Ty}}$, is generally not full there either. These are successive definitions, not contradictory assertions about a fixed category. The final restriction preserves directed progress through a path and excludes changes of parameter which backtrack.

For any chosen version T, the strict contravariant functor $\tau \mapsto X^{I_\tau}$ gives a split Grothendieck fibration over T. A morphism from (τ', c') to (τ, c) is a pair

$$\varphi : \tau' \to \tau, \qquad \upsilon : c' \Rightarrow c\varphi.$$

Composition is whiskering followed by composition of transformations. This is the machinery of Grothendieck (1971a, Exposé VI, §§8–10), specialized to restriction along finite shapes. Endpoint-preserving shape maps make evaluation at the two ends into functors on the total category. The commentary also determines the maximal enlargement for which natural endpoint evaluations can still exist, allowing comparison arrows at the ends. That enlargement illustrates why the subsequent requirement of strict gluing is stronger. No colimits in X are needed for the fibration; extending paths in the opposite direction would require Kan extensions, and already a collapsed span asks for a pushout.

The main calculation of the second half has a particularly short modern form. Give the transition set $\mathrm{Tr}(\tau) = \{1, \ldots, n\}$ its order and its signs. If $f : I_\tau \to I_\upsilon$ is a morphism of the final type category, every target transition belongs to the image interval of exactly one source transition. This defines a monotone, sign-preserving map

$$f^* : \mathrm{Tr}(\upsilon) \longrightarrow \mathrm{Tr}(\tau).$$

Conversely, given such a map h, recover the vertex function by

$$f(i) = \#\{j : h(j) \leq i\}.$$

These assignments are inverse and reverse composition. Thus the type category is opposite to the category of finite signed linear orders with monotone sign-preserving maps. Its many normal forms are descriptions of this one correspondence.

For a reduced target, f^* is injective, so a map is specified by a signed subsequence of the source word. In general, a map out of a fixed source is specified by nonnegative integer weights: an edge of sign ε and weight a becomes a run of a edges of sign ε. Weight zero collapses that edge. A map into a fixed target is instead described by its image vertices and by the signatures of the fibers over them. The latter description must use cumulative sums for the target coordinates, and collapsed fibers are components of the graph of collapsed edges, not components of the union of their endpoint vertices with every ambient adjacency restored. The point target is treated separately. These corrections preserve the two classification results.

Concatenation glues the final vertex of one interval to the initial vertex of the next. On standard words and endpoint-preserving maps it is strictly associative and unital, and makes $\underline{\mathrm{Ty}}$ a strict monoidal category. It cannot extend with this object operation to the category allowing *all* interval functors: there $+$ and $-$ are isomorphic, whereas $++$ and $-+$ are not. The

restriction on morphisms is therefore essential to the source's own construction. Through the signed-edge description, Ty is the free strict monoidal category on two counital coassociative comonoids. The one-generator background is the opposite of the augmented simplex category; see Aguiar and Mahajan (2010, Appendix D, Proposition D.2). The two-generator version follows by ordered concatenation, without a symmetry interchanging the letters.

The nerve calculation is now transparent. A chain of r composable type maps splits uniquely according to the edges of its initial word. Each factor begins at a single signed edge; its later stages are successive ordered expansions of that edge, allowing complete disappearance. Consequently every $N_r(\mathrm{Ty})$ is a free monoid. The face deleting the initial object can send a generator to several generators, or to the empty word, so this assertion does not identify the nerve with the free simplicial monoid on its degreewise generators. The commentary gives every face and degeneracy by the corresponding operation on ordered forests and resolves the final support-indexing slip.

The later comparison can be made at the level of the indexing category itself. Marking the negative transitions identifies Ty with the zigzag type category in Mazel-Gee (2018, Definition 3.5). The closing status block distinguishes this finite identification from the additional construction of localization mapping spaces, including the recent comparison in Arakawa and Cnossen (2026, Theorem 1.9 and Corollary 1.11). The development blocks prove explicit consequences left unworked here: the reduction adjunctions and sharp rigidity criterion, the endpoint evaluation criterion, and a criterion with a counting formula for sections of contractions. Their markers record our proofs and limited literature searches, not a claim of priority. The unresolved task at manuscript page 57 is the promised construction of fractions with its precise morphisms; the finite combinatorics considered in these pages has been settled in the commentary.

D'autre part, posant $l_i = \mathrm{long}(\pi_{i-1})$ (pour $i \in [1, r]$), p. 39

$$f_i : \Delta_\varepsilon^{l_{i-1}} \longrightarrow \Delta_\varepsilon^{l_i \ (=\mathrm{long}(\pi_{i-1}))}$$

est défini comme

$$f_i = \mathfrak{f}_{\varepsilon,\pi_{i-1}(1)} * \mathfrak{f}_{\varepsilon,\pi_{i-1}(2)} * \cdots * \mathfrak{f}_{\varepsilon,\pi_{i-1}(l_{i-1})},$$

de sorte que l'élément $(*)$ de $\mathrm{Nerf}_r(\underline{\mathrm{Ty}})$ est déterminé de façon unique par la donnée des $\varepsilon \in \{\pm 1\}$ et de

$$\pi_\bullet = (\pi_i)_{i\in[0,r-1]} \in (\mathrm{Hom}_{\mathrm{Ens}}(\mathbf{N}^*, \mathbf{N}))^r$$

satisfaisant les conditions $(**)$. Soit $F_{\varepsilon,\pi_\bullet}$ cet élément de $\mathrm{Nerf}_r(\underline{\mathrm{Ty}})$, et soit N_r l'ensemble des $\pi_\bullet$ qu'on vient d'expliciter. Alors

$$(F_{\varepsilon,\pi_\bullet})_{(\varepsilon,\pi_\bullet)\in\{\pm1\}\times N_r}$$

est un système de générateurs libre du monoïde $\mathrm{Nerf}_r(\underline{\mathrm{Ty}})$.

Si $l_i = 0$ (i.e. $\boxed{\pi_{i-1} = 0}$), on doit avoir $\mathrm{supp}(\pi_{i+1}) = \emptyset$, i.e. $\pi_{i+1} = 0$, d'où $l_{i+1} = 0$, et de même pour les l_j et π_j suivants. Géométriquement l'hypothèse s'exprime par la condition que le but de f_i est l'élément 1 de Ty (correspondant à l'intervalle ponctuel), et comme $\mathrm{Hom}(1, \tau) = \emptyset$ pour $\tau \neq 1$, cela signifie que les flèches qui suivent f_i doivent être toutes égales à la flèche $\mathrm{id}_1 : 1 \longrightarrow 1$. [page 58]

Commentary · Exposition [ms. 57]

Degreewise free is a precise assertion

Grothendieck has now made the combinatorics of a changing path shape completely explicit. The commentary at manuscript pages 53–57 already explains the free generators in every degree and counts refinement stages. One additional distinction helps us use that calculation correctly: freeness in each degree does not mean that the intrinsic generators themselves form a simplicial set.

To see the distinction, take the generator of degree two represented by

$$\Delta_+ \longrightarrow \Delta^2_+ \xrightarrow{\mathrm{id}} \Delta^2_+.$$

Its first face, which forgets the initial object and first arrow, is $\mathrm{id}_{\Delta^2_+} = f_{+,1} * f_{+,1}$. This is a product of two nonunit elements in the degree-one monoid. It is therefore not a generator. In the notation of the text, the general formula is

$$d_0(f_{\varepsilon,l,\pi}) = f_{\varepsilon,\pi(1)} * \cdots * f_{\varepsilon,\pi(l)},$$

where the empty product for $l = 0$ is the unit. An isomorphism between free monoids preserves their intrinsic indecomposables. Consequently $N_\bullet\underline{\mathrm{Ty}}$ cannot be the degreewise free monoid on a simplicial set: such a construction would send each generator under every face to a generator. The monoid structure maps are determined by generators, as Grothendieck says; their images can be arbitrary words.

There is also a useful boundary case in his finite-support description. The condition on π_0 is separate, namely $\mathrm{supp}\,\pi_0 \subseteq \{1\}$. The recursive condition must then run over $1 \leq i \leq r-1$, since π_{-1} has not been defined. If the length at stage i is zero, the next weighting is $\pi_i = 0$, and every later stage remains the empty interval. The edition instead writes π_{i+1} at this step. Both index slips are retained in the source and registered in the corrections table. They change neither the free decomposition nor its geometric meaning: a path shape which has disappeared cannot reappear under an endpoint-preserving interval map.

Remarque. Dans la description combinatoire de $\underline{\mathrm{Ty}}$ et de $\mathrm{Nerf}_\bullet(\underline{\mathrm{Ty}})$, l'ensemble des 'signatures' $\{\pm 1\}$ joue un rôle assez bidon. Il peut être remplacé par n'importe quel ensemble Σ (dit 'ensemble des signatures'), et on construit alors une catégorie monoïdale (ou un

monoïde catégorique) ayant comme ensemble d'objets le monoïde libre engendré par Σ, interprétés comme des intervalles d'entiers $[0, n]$, munis de 'signatures' dans Σ pour chaque intervalle de transition, ou ce qui revient au même, des 'graphes' orientés Σ-pondérés de type combinatoire un intervalle $\mathbf{\Delta}_i$, ce qui revient à la donnée d'une suite (ordonnée) de n éléments $\varepsilon_1,\ \varepsilon_2,\ \dots\ ,\ \varepsilon_n \in \Sigma$, i.e. d'un 'mot' $\varepsilon_1\varepsilon_2 \dots \varepsilon_n$, qu'on préfère écrire $\Delta_{\varepsilon_1}\Delta_{\varepsilon_2}\cdots\Delta_{\varepsilon_n}$. On peut définir de façon évidente les homomorphismes *croissants* de tels graphes pondérés orientés (sous-entendu : avec l'élément source et l'élément but dans la structure, à respecter par les morphismes), sans avoir besoin d'une interprétation catégorique. La fonctorialité de l'opération de composition des intervalles pondérés, pour cette notion de morphisme, est évidente. Le choix $\Sigma = \{\pm 1\}$ est à ma connaissance le seul utile, à cause de son lien avec la notion de chemins et le calcul de π_0 d'un objet de X `[plutôt d'un objet` X `de` Cat`]`, etc. [page 59]

Commentary · Exposition [ms. 59]

The localization test

Grothendieck is about to test his category of types against a construction whose universal property is already settled: the category obtained by formally inverting specified arrows. This is a demanding first test because literal concatenation gives too much information. It remembers the length of a zigzag, every inserted identity, and every subdivision of a composite. A localization must identify presentations which differ in these ways, while retaining their common source and target.

Let $P(X)$ denote the category whose arrows are literal finite zigzags in X. Length is additive under composition. Thus an invertible arrow of $P(X)$ must have length zero. Moreover the assignment $u \mapsto c(u)$ from arrows of X to one-edge paths does not preserve composition: $c(vu)$ has one edge and $c(v)c(u)$ has two. It does not preserve identities either, since $c(\mathrm{id}_a)$ has length one. These observations concern the literal path construction uniformly in X. For particular categories there can of course be useful functors in one direction: if X is a groupoid, every zigzag has an effect in X, and evaluation is a functor $P(X) \to X$.

The category $\underline{\mathrm{Ch}}(a, b)$ supplies the missing identifications as morphisms. A type map replaces a string of composable arrows by its composite or inserts identity arrows through pullback. A natural transformation compares two paths of the same type by a ladder of commuting squares. Since the endpoints are fixed, the components at a and b must be identities. Passing to π_0 identifies objects joined by a finite zigzag of these morphisms. A single directed natural transformation is enough for this purpose; it need not be invertible.

The desired category therefore has

$$\mathrm{Hom}(a, b) = \pi_0\underline{\mathrm{Ch}}(a, b).$$

Its composition comes from concatenation before taking components. This is legitimate because $\pi_0(A \times B) = \pi_0(A) \times \pi_0(B)$ for categories: a zigzag in a product projects to the factors, while zigzags in the factors can be traversed one coordinate at a time. Associativity and units are then inherited, rather than imposed as further equivalence relations.

The relative version allows only a chosen class Σ of arrows to be traversed backwards. Its aim is the formula

$$\pi_0\underline{\mathrm{Ch}}_\Sigma(a, b) \cong \mathrm{Hom}_{X[\Sigma^{-1}]}(a, b).$$

At this stage the assertion concerns ordinary hom-sets. The homotopy type of the whole path category is a separate, stronger question, and the later pages of the chapter turn precisely to the additional choices and coherence needed for it.

p. 40

7 Explicitation des catégories de fractions $X\Sigma^{-1}$ en termes des $\underline{\mathrm{Ch}}(X; a, b)$

Si X est une catégorie, on désigne par $\underline{\mathrm{Ch}}(X)$ la catégorie des chemins dans X (cf. §4), et pour $a, b \in \mathrm{Ob}\, X$, par

$$\underline{\mathrm{Ch}}(X; a, b) \qquad \text{ou simplement } \underline{\mathrm{Ch}}(a, b)$$

celle des chemins de a vers b, i.e. de source a, but b. L'intuition géométrique (qu'on explicitera), c'est qu'un tel chemin c définit un chemin 'direct' de a vers b (i.e. un chemin de type τ' 'direct', i.e. toutes les flèches de transition sont directes, i.e. τ' de la forme Δ_+^n), de même longueur que le chemin initial c, obtenu en inversant toutes les flèches rétrogrades dans le chemin c. Cette opération est effectivement possible dans X lui-même si et seulement si lesdites flèches sont inversibles. On obtient alors une suite composable de flèches, dont le composé total (qu'on peut appeler 'l'effet utile' du chemin) est une flèche de a vers b. Dans le cas général, les chemins de a vers b peuvent être vus comme une sorte de 'flèches généralisées' allant de a vers b, dont la composition serait la composition évidente, et les identités les 'chemins vides' relatifs aux $a \in \mathrm{Ob}\, X$. On trouve d'ailleurs bien ainsi une catégorie, ayant mêmes objets que X, mais où les [page 60]

$$\mathrm{Hom}_{\mathrm{Ch}}(a,b) = \mathrm{Ch}(a,b) = \mathrm{Ob}\,\underline{\mathrm{Ch}}(a,b)$$

sont prohibitivement gros. Cela s'exprime notamment par le fait que les seules flèches inversibles dans X_{Ch} sont les identités ! On n'a pas de foncteur naturel entre X_{Ch} et X qui soit l'identité sur les objets. Car à un chemin $a \xrightarrow{c} b$ on ne peut associer de X-morphismes $a \longrightarrow b$ (sauf si c `[est]` de type Δ_+), et à un X-morphisme $a \xrightarrow{u} b$ on peut associer un chemin $c(u)$ de type Δ_+, mais si $a \xrightarrow{u} b \xrightarrow{v} c$, $c(vu)$ est encore de type Δ_+ alors que $c(v)c(u)$ est de type Δ_+^2, ils ne sont pas égaux. Par contre, il y a une flèche naturelle entre ces deux éléments de $\underline{\mathrm{Ch}}(a,c)$, flèche au dessus de l'unique homomorphisme

$$\Delta_+ \xrightarrow{\mathfrak{f}_{+,2}} \Delta_+^2.$$

On a alors

$$\mathfrak{f}_{+,2}^*(\underbrace{a \xrightarrow{u} b \xrightarrow{v} c}_{c(v)c(u)}) = (\underbrace{a \xrightarrow{vu} c}_{c(vu)}), \qquad \text{[page 61]}$$

d'où une flèche canonique

$$c(vu) \longrightarrow c(v)c(u) \qquad \text{dans } \underline{\mathrm{Ch}}(a,c).$$

Cela montre que $c(vu)$ et $c(v)c(u)$ sont tout au moins dans une même composante connexe de $\underline{\mathrm{Ch}}(a,c)$, ou (comme on dit encore) qu'ils sont 'homotopes'. Cela suggère ici de modifier la définition de $\mathrm{Hom}_{\mathrm{Ch}}(a,b)$ en

$$\pi(a,b) = \pi_0(\underline{\mathrm{Ch}}(a,b)).$$

Le foncteur de composition des chemins p. 41

$$\begin{array}{ccccc} \underline{\mathrm{Ch}}(a,b) & \times & \underline{\mathrm{Ch}}(b,c) & \longrightarrow & \underline{\mathrm{Ch}}(a,c) \\ (c & , & c') & \longmapsto & c' \circ c \end{array}$$

`[il y a trop de` c`]` ([17]) induit une application sur les π_0, ce qui donne une loi de composition

$$\pi(a,b) \times \pi(b,c) \longrightarrow \pi(a,c)$$

sur les flèches. Il est immédiat qu'elle est associative (la composition des chemins l'étant), et unitaire. Elle admet comme flèche identique en x soit le 'lacet vide en x', lequel est (directement) homotope dans $\underline{\mathrm{Ch}}(x,x)$ au chemin 'dégénéré' $x \xrightarrow{\mathrm{id}} x$ de type Δ_+, ou aussi au chemin dégénéré de n'importe quel type τ, disons [page 62]

$$x \xleftarrow{\mathrm{id}} x \xrightarrow{\mathrm{id}} x \xrightarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x \xleftarrow{\mathrm{id}} x,$$

17. Ce foncteur est déduit des foncteurs

$$\underline{\mathrm{Ch}}_\tau(a,b) \times \underline{\mathrm{Ch}}_{\tau'}(b,c) \longrightarrow \underline{\mathrm{Ch}}_{\tau\tau'}(a,c)$$

évidents, cf. page 77.

un tel chemin n'étant autre que $p_\tau^*(x)$, où

$$p_\tau : \tau \longrightarrow 1$$

est le morphisme de dégénérescence (l'unique morphisme dans $\underline{\mathrm{Ty}}$ vers 1, qui est objet final), d'où

$$p_\tau^* : \underline{\mathrm{Ch}}_1(x,x) = \{x\} \longrightarrow \underline{\mathrm{Ch}}_\tau(x,x) \subseteq \underline{\mathrm{Ch}}(x,x).$$

La catégorie $\Pi(X)$ ainsi obtenu doit s'appeler le *groupoïde fondamental* de X. En effet,

Commentary · Examples [ms. 61]

A span and its fraction

The construction becomes concrete as soon as reversing one arrow creates a morphism which the original category did not contain. Consider the category X generated by the span

$$a \xleftarrow{s} x \xrightarrow{t} b$$

with no nonidentity arrows besides s and t, and put $\Sigma = \{\mathrm{id}_a, \mathrm{id}_x, \mathrm{id}_b, s\}$. The zigzag from a to b is a Σ-path although $\mathrm{Hom}_X(a,b)$ is empty. Its effect after localization is the fraction ts^{-1}.

We can compute the entire localization. It has the same three objects and the following hom-sets, with rows denoting sources:

	a	x	b
a	$\{\mathrm{id}_a\}$	$\{s^{-1}\}$	$\{ts^{-1}\}$
x	$\{s\}$	$\{\mathrm{id}_x\}$	$\{t\}$
b	$\varnothing$	$\varnothing$	$\{\mathrm{id}_b\}$.

Composition is determined by $s^{-1}s = \mathrm{id}_x$, $ss^{-1} = \mathrm{id}_a$, and $(ts^{-1})s = t$. For any functor $F : X \to Y$ with $F(s)$ invertible, there is exactly one extension to this category: it sends s^{-1} to $F(s)^{-1}$ and ts^{-1} to $F(t)F(s)^{-1}$. This verifies the universal property directly.

The same calculation can be read inside the path categories. A path starting at b can only stay at b, because t is not permitted as a backward arrow. A nonconstant path ending at b reaches it by a final occurrence of t; before that it moves between a and x using s in either direction. Adjacent traversals of s in opposite directions cancel by the homotopies on manuscript page 63. After removing identity edges, only one of the entries in the displayed table remains. This proves directly that the connected components of the relative path categories give exactly those hom-sets.

The two objects a and x are isomorphic in the result. Choosing a as their representative identifies a skeleton with the walking arrow $a \to b$. Thus localization has changed the hom-set from a to b, while it has introduced no path from b to a. This is the elementary reason that a relative localization is generally a category rather than a groupoid.

a) toutes les flèches de $\Pi(X)$ sont inversibles, i.e. $\Pi(X)$ est bien un groupoïde, et

b) le foncteur canonique

$$X \longrightarrow \Pi(X)$$

qui est l'identité sur les objets, et qui est défini sur les flèches par $u \longmapsto c(u)$ comme ci-dessus, est *universel* (dans Cat) pour les foncteurs (i.e. les Cat-morphismes) de X vers des *groupoïdes.* (Plus généralement encore, il est universel pour les foncteurs $X \xrightarrow{F} Y$ tels que F transforme toute flèche de X en `[une]` flèche inversible.)

Pour prouver que toute flèche dans $\Pi(X)$ est inversible, comme tout chemin non vide est composé de chemins 'élémentaires' de type Δ_+ ou Δ_-, il suffit de prouver que ces chemins sont inversibles. En fait, ils se correspondent biunivoquement, p. 42 [page 63]

$$\underline{\mathrm{Ch}}_{\Delta_+}(a,b) \simeq \underline{\mathrm{Ch}}_{\Delta_-}(b,a),$$

en associant au chemin de a vers b

$$c(u) : a \xrightarrow{u} b \qquad \text{de type } \Delta_+$$

le chemin

$$c(u)^o : b \overset{u}{\leftarrow} a \qquad \text{de type } \Delta_-$$

de b vers a. Je dis que

$$\begin{array}{rcl} c(u)^o c(u) & \sim & 1_a \\ c(u)c(u)^o & \sim & 1_b \end{array}$$

$$\left.\begin{array}{ccccc} a & \xrightarrow{u} & b & \xleftarrow{u} & a \\ \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle u} & & \uparrow{\scriptstyle \mathrm{id}} \\ a & \xrightarrow{\mathrm{id}} & a & \xleftarrow{\mathrm{id}} & a \end{array}\right\} \text{ on a un homomorphisme dans } \underline{\mathrm{Ch}}_{\Delta_+\Delta_-}(a,a) \text{ de } 1_a \text{ dans } c(u)^o c(u).$$

$$\left.\begin{array}{ccccc} b & \xleftarrow{u} & a & \xrightarrow{u} & b \\ \uparrow{\scriptstyle u} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle u} \\ a & \xleftarrow{\mathrm{id}} & a & \xrightarrow{\mathrm{id}} & a \end{array}\right\} \text{ itou dans } \underline{\mathrm{Ch}}_{\Delta_-\Delta_+}(b,b), \text{ de } 1_b \longrightarrow c(u)c(u)^0$$

`[plutôt` $1_b \longleftarrow c(u)c(u)^0$`, viz.`

$$\begin{array}{ccccc} b & \xleftarrow{u} & a & \xrightarrow{u} & b \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle u} & & \downarrow{\scriptstyle \mathrm{id}} \\ b & \xleftarrow{\mathrm{id}} & b & \xrightarrow{\mathrm{id}} & b \end{array}$$ `].`

Notons que, plus généralement, pour tout chemin p. 43

$$c : a \longrightarrow b, \qquad \text{de type } \tau, \qquad \text{[page 64]}$$

on définit un *chemin opposé*

$$c^o : b \longrightarrow a \qquad \text{de type } \tau^o,$$

où

$$\tau \longmapsto \tau^o : \mathrm{Ty} \longrightarrow \mathrm{Ty}$$

est l'antiïnvolution du monoide libre Ty qui échange les deux générateurs Δ_-, Δ_+, et qui est donc donné sur l'élément général par

$$(\Delta_{\varepsilon_1}\Delta_{\varepsilon_2}\cdots\Delta_{\varepsilon_n})^o = \Delta_{-\varepsilon_n}\Delta_{-\varepsilon_{n-1}}\cdots\Delta_{-\varepsilon_1}.$$

Par récurrence sur la longueur de c ([18]), en utilisant le résultat précédent, que $c(u)$, $c(u)^o$ sont inverses l'un de l'autre dans $\Pi(X)$, on trouve

$$\left.\begin{array}{rcl} c^o c & = & \mathrm{id}_a \\ c c^o & = & \mathrm{id}_b \end{array}\right\} \text{dans } \Pi(X).$$

18. inutile, résulte directement de la formule (∗) `[de la]` page suivante, en décomposant c en composés de chemins 'élémentaires' de type Δ_+ ou Δ_-.

Commentary · Exposition [ms. 63]

Two cancellation homotopies with fixed endpoints

Grothendieck wants reversal of a single edge to give an inverse after taking components. The proof requires two different directions of natural transformation, because the two loops have different shapes. Keeping those directions visible also explains the editors' correction on this page.

For $u : a \to b$, the loop at a is the diagram $L_a = (a \xrightarrow{u} b \xleftarrow{u} a)$. Let K_a be the constant $+-$ diagram at a. The components

$$(\mathrm{id}_a, u, \mathrm{id}_a) : K_a \longrightarrow L_a$$

form a natural transformation. Both endpoint components are identities, so this is a morphism in the fixed-endpoint fibre $\underline{\mathrm{Ch}}_{+-}(a,a)$. The collapse of the type $+-$ to the empty type gives a cartesian arrow from K_a to the empty path at a. We have therefore joined L_a to the empty path by a zigzag in the total fixed-endpoint category.

For the other loop, $L_b = (b \xleftarrow{u} a \xrightarrow{u} b)$, the appropriate constant diagram is K_b at b. This time the transformation goes in the other direction:

$$(\mathrm{id}_b, u, \mathrm{id}_b) : L_b \longrightarrow K_b.$$

It is a morphism in $\underline{\mathrm{Ch}}_{-+}(b,b)$, and K_b again maps to the empty path through the type collapse. The uncorrected diagram in the edition has a constant diagram at a below L_b. Its endpoint components are u, so it is not a morphism in this fixed-endpoint fibre. The bracketed correction supplies exactly the downward transformation just described.

Two conventions are doing work here. First, a constant diagram of nonempty type is an object of its fibre, whereas the empty path belongs to the fibre over the unit type. When the source writes 1_a or 1_b in a fibre, it is temporarily using the constant diagram as a representative of the unit component. Second, connectedness forgets the direction of the arrows used to connect objects. Nothing requires both cancellation homotopies to point the same way.

The relative argument is identical when $u \in \Sigma$: every nonidentity backward edge in these diagrams is then an allowed denominator, and all remaining backward edges are identities. This proves that $\kappa(u)$ is invertible in $\Pi_\Sigma(X)$. There is no condition on a vertical component of a path transformation beyond naturality and the identity endpoint condition.

Exemple. Si

$$\begin{aligned} \tau &= \Delta_+\Delta_-\Delta_+^2\Delta_- \\ \tau^o &= \Delta_+\Delta_-^2\Delta_+\Delta_-, \end{aligned}$$

et si on a un chemin

$$c : a_0 \xrightarrow{u_1} a_1 \xleftarrow{u_2} a_2 \xrightarrow{u_3} a_3 \xrightarrow{u_4} a_4 \xleftarrow{u_5} a_5$$

de type τ, on en déduit le chemin

$$c^o : a_5 \xrightarrow{u_5} a_4 \xleftarrow{u_4} a_3 \xleftarrow{u_3} a_2 \xrightarrow{u_2} a_1 \xleftarrow{u_1} a_0$$

de type τ^o. L'opération $c \longmapsto c^o$ satisfait en effet [pour]

$$\begin{array}{ccccc} a & \xrightarrow{\gamma} & b & \xrightarrow{\gamma'} & c \\ c & \xrightarrow{\gamma'^o} & b & \xrightarrow{\gamma^o} & a \end{array}$$ [page 65]

la relation

$$(*) \qquad (\gamma'\gamma)^o = \gamma^o\gamma'^o,$$

Commentary · Examples [ms. 64]

A circle in a category with two arrows

Grothendieck's reversal operation removes backtracking without destroying genuine loops. A small example distinguishes the two phenomena. Let X have two objects a, b and two distinct nonidentity arrows $f, g : a \to b$, and invert every arrow. The zigzag

$$a \xrightarrow{f} b \xleftarrow{g} a$$

represents the loop $h = g^{-1}f$ at a.

All morphisms in the resulting groupoid have unique expressions of the following forms, with $n \in \mathbf{Z}$:

	a	b
a	h^n	gh^n
b	$h^n g^{-1}$	$gh^n g^{-1}$.

For existence, use g as a chosen path from a to b and replace f by gh. After cancelling adjacent $g^{-1}g$ and gg^{-1}, a word has exactly the indicated form. For uniqueness, consider the functor from X to the one-object group $\mathbf{Z}$ which sends f to 1 and g to 0. Since its target is a groupoid, it extends to the groupoid completion, and it sends h^n to n. Thus different integers cannot give equal arrows. Composition in the table adds the integer exponents, with the displayed g and g^{-1} providing the changes of endpoint.

It follows that $\mathrm{Aut}_{\Pi(X)}(a) \cong \mathbf{Z}$ and $\pi_0 \underline{\mathrm{Ch}}(a,a) \cong \mathbf{Z}$. The nerve supplies a geometric check: the only nondegenerate positive-dimensional simplices of NX are the two edges f, g. There are no composable pairs of nonidentity arrows. Its realization is therefore the graph consisting of two vertices joined by two edges, which is a circle.

If instead Σ consists only of identities, every backward edge is an identity and the effect of a path is already defined in X. The relative localization is then X itself. In particular the two arrows f, g remain distinct and there is no nonidentity loop at a. The difference lies entirely in which arrows may be traversed backwards, not in a choice of representative for the same unrestricted path space.

ce qui est en accord avec l'intuition que l'opération $\gamma \longmapsto \gamma^o$ joue le rôle d'un passage à l'inverse ('à homotopie près'), et on a la formule p. 44

$$(\gamma'\gamma)^{-1} = \gamma^{-1}\gamma'^{-1}$$

pour deux flèches inversibles γ, γ' composables (dans l'ordre γ', γ).

Pour la propriété universelle de

$$X \longrightarrow \Pi(X)$$

(qui permettra d'écrire

$$\Pi(X) \simeq X\Sigma^{-1}, \qquad \text{avec } \Sigma = \mathrm{Fl}(X) \ \ ),$$

autant l'établir tout de suite dans le cadre général où on se donne une partie

$$\Sigma \subseteq \mathrm{Fl}(X),$$

et on définit, pour $\tau \in \underline{\mathrm{Ty}}$,

$$\underline{\mathrm{Ch}}_{\Sigma,\tau}(X) \subseteq \underline{\mathrm{Ch}}_{\tau}(X)$$

comme la sous-catégorie pleine de $\underline{\mathrm{Ch}}_{\tau}(X)$ formée des chemins dans X dont *toutes les flèches rétrogrades*

sont dans X `[plutôt dans Σ]`. On notera que pour qu'un chemin c et son opposé c^o soient tous les deux des Σ-*chemins,* il faut et il suffit que *toutes* les flèches du chemin c soient dans Σ (on dira alors que c est un Σ-*chemin stricte*), puisque les flèches rétrogrades de c^o sont les flèches directes de c. [page 66]

Pour que les sous-catégories pleines $\underline{\mathrm{Ch}}_{\tau,\Sigma}(X)$ soient stables par les foncteurs images inverses

$$f^* : \underline{\mathrm{Ch}}_{\tau'}(X) \longrightarrow \underline{\mathrm{Ch}}_{\tau}(X)$$

associés aux flèches

$$f : \tau \longrightarrow \tau'$$

dans $\underline{\mathrm{Ty}}$, ou simplement pour qu'y ait stabilité pour les deux foncteurs f^* associés à un $f : \Delta_- \longrightarrow 1$ et $\Delta_- \longrightarrow \Delta^2_-$, il faut et il suffit que Σ soit stable par composition et contienne toutes les flèches identiques

$$\begin{cases} x \in \mathrm{Ob}\, X \implies \mathrm{id}_x \in \Sigma \\ u, v \in \Sigma, \quad u,\, v \text{ composables} \Longrightarrow uv \in \Sigma. \end{cases}$$

En effet, les flèches dans un chemin $f^*(c') \in \underline{\mathrm{Ch}}_\tau(X)$ sont soit des flèches identiques (qui correspondent aux flèches de transition de I_τ dégénérées pour f), soit des flèches parmi celles de τ, ou des composés d'une suite de flèches consécutives composables de τ' (qui correspondent aux flèches de transition dans $I_{\tau'}$ incluses dans la partie d'une flèche de transition de I_τ), avec conservation des signatures.

p. 45

Commentary · Exposition [ms. 66] [page 67]

Why denominators must form a subcategory

Grothendieck imposes exactly the closure needed to let every interval map act on relative paths. A backward source edge may cover several consecutive backward target edges, or it may collapse to a vertex. Pullback must therefore allow composition of denominators and insertion of identity denominators. These are the two tests singled out in the text.

The map $\Delta_- \to 1$ pulls the empty path at x back to the one-edge path $x \xleftarrow{\mathrm{id}_x} x$. Stability forces $\mathrm{id}_x \in \Sigma$ for every x. Next, for composable denominators $v : z \to y$ and $u : y \to x$, the backward path

$$x \xleftarrow{u} y \xleftarrow{v} z$$

pulls back along $\Delta_- \to \Delta^2_-$ to $x \xleftarrow{uv} z$. Thus stability forces $uv \in \Sigma$. Conversely, assume these two closure properties. The image of a source edge under an endpoint-preserving increasing type map is either a vertex or a consecutive monochromatic block. A backward source edge consequently becomes either an identity or a composite of backward target arrows. Both belong to Σ. This proves stability under every type map, including maps with both collapses and subdivisions.

The condition says that Σ is the arrow set of a wide subcategory of X. It does not require an Ore condition, saturation, or a two-out-of-three property. If we begin with an arbitrary collection S of arrows to invert, we may first take its closure under identities and finite composition. A functor inverts this closure exactly when it inverts S, so the intended universal localization is unchanged. Saturation is a later operation: it adds every arrow whose image in the localization happens to be invertible.

The adjective "full" in $\underline{\mathrm{Ch}}_{\Sigma,\tau}(X)$ deserves equal attention. The restriction is on backward *horizontal* arrows of the path. Given two such paths, every natural transformation between them remains available, with identity components at prescribed endpoints. Its internal vertical arrows need not lie in Σ. This fullness is consistent with the ordinary localization theorem, as the calculation at manuscript page 68 will show. It must be remembered when making a higher-homotopical comparison with constructions which restrict vertical arrows as well.

Finally, reversal of an individual path remains allowed precisely when its forward arrows also belong to Σ. Closure of the entire path system under reversal therefore forces $\Sigma = \mathrm{Fl}(X)$. This statement concerns literal permitted paths; it does not say that a localization can be a groupoid only in that case. Arrows outside Σ may already be invertible in X, or become invertible after localization.

On suppose ces conditions satisfaites, de sorte que les $\underline{\mathrm{Ch}}_{\tau,\Sigma}(X)$ forment les fibres d'une sous-catégorie fibrée pleine de $\underline{\mathrm{Ch}}(X)$ sur $\underline{\mathrm{Ty}}$, qu'on dénotera par

$$\underline{\mathrm{Ch}}_\Sigma(X) \hookrightarrow \underline{\mathrm{Ch}}(X).$$

Il est évident que cette sous-catégorie est stable par l'opération de composition des chemins (mais non pas, en général, on l'a dit, par passage de c à c^o (il faudrait pour cela que Σ contienne *toutes* les flèches de X, puisque pour toute $u : a \longrightarrow b$, qui est donc dans $\underline{\mathrm{Ch}}_{\Delta_+,\Sigma}(X)$, u^o donné par $b \xleftarrow{u} a$ dans $\underline{\mathrm{Ch}}_{\Delta_-}(X)$ devrait être un Σ-chemin, d'où $u \in \Sigma$)).

On va définir une catégorie canonique

$$\Pi_\Sigma(X),$$

ayant même objets que X, et un foncteur canonique

$$X \longrightarrow \Pi_\Sigma(X)$$

qui est l'identité sur les objets, et qui transforme les $u \in \Sigma$ en flèches inversibles. Pour cela on calque la description du groupoïde fondamental (mais $\Pi_\Sigma(X)$ ne sera pas en général un groupoïde), en posant

$$\mathrm{Hom}_\Sigma(x,y) = \pi_0(\underline{\mathrm{Ch}}_\Sigma(x,y)),$$

et en définissant la composition des 'Σ-flèches' en termes de la composition des chemins. L'argument qui prouvait, dans le cas de $\Pi(X)$, que *toute* flèche de X, vue comme chemin c de type Δ_+, était inversible dans $\Pi(X)$, ayant comme inverse c^o de type Δ_-, est encore valable, pourvu que c^o soit encore bien un Σ-chemin, ce qui exige que $u \in \Sigma$. [page 68]

On va l'interpréter en termes d'un foncteur canonique

$$(*) \qquad \kappa : X \longrightarrow \Pi_\Sigma(X) \qquad ([19])$$

qui se décrit encore comme dans le cas du groupoïde fondamental, en associant à toute flèche u de X la classe d'homotopie du chemin $c(u)$ qu'elle définit. On voit donc que ce foncteur canonique transforme les $u \in \Sigma$ en flèches inversibles.

Quand les flèches de Σ sont déjà inversibles dans X, je dis que le foncteur $(*)$ est un isomorphisme, i.e. que pour tout $a, b \in \mathrm{Ob}\, X$,

$$\alpha : \mathrm{Hom}_X(a,b) \longrightarrow \pi_0 \underline{\mathrm{Ch}}_\Sigma(a,b), \qquad u \longmapsto \underbrace{\mathrm{ch}_\Sigma(u)}_{=\mathrm{ch}(u)}$$

est bijectif. Pour le voir, on va définir

$$\beta : \pi_0(\underline{\mathrm{Ch}}_\Sigma(a,b)) \longrightarrow \mathrm{Hom}_X(a,b),$$

qui sera inverse de β. On définit

p. 46

Commentary · Exposition [ms. 68]

The effect of a zigzag descends to components [page 69]

Grothendieck now uses evaluation in a category where the denominators are already invertible. Before checking that evaluation is inverse to α, we should verify that it is defined on a connected component of the path category. This is a short verification, but it explains why the internal vertical arrows of a path transformation need not be invertible.

The useful statement is slightly more general. Let $F : X \to Y$ send every arrow of Σ to an isomorphism. For a Σ-path $c = (x_0, \ldots, x_n)$, let $e_i : F(x_{i-1}) \to F(x_i)$ be $F(u_i)$ if its ith edge is forward and $F(u_i)^{-1}$ if that edge is backward. Define

$$E_F(c) = e_n \cdots e_1, \qquad E_F(\text{empty path at } a) = \mathrm{id}_{F(a)}.$$

This formula is defined solely by the inversion hypothesis.

First compare paths c, c' of the same type by a natural transformation with components $\eta_i : F(x_i) \to F(x'_i)$. For a forward edge the commuting square reads $\eta_i e_i = e'_i \eta_{i-1}$. For a backward edge the original square is

$$\eta_{i-1} F(u_i) = F(u'_i)\eta_i.$$

Multiplication by the inverses of $F(u_i)$ and $F(u'_i)$ gives exactly the same formula

$$\eta_i e_i = e'_i \eta_{i-1}.$$

Successively composing these equations yields

$$\eta_n E_F(c) = E_F(c')\eta_0.$$

At fixed endpoints, η_0 and η_n are identities. Hence the two effects agree. No inverse of any η_i has been taken.

19. Sur les flèches, κ est défini, pour $u : a \longrightarrow b$, par $\kappa(u)$ = classe d'homotopie de $\mathrm{ch}(u)$ dans $\underline{\mathrm{Ch}}_\Sigma(a,b)$, où $\mathrm{ch}(u)$ est le chemin de type Δ_+ de a vers b défini par u.

We must also compare different types. If $q : \tau \to \tau'$ and c' is a path of type τ', then each edge of q^*c' is a composite over the corresponding consecutive block of edges of c', or an identity for an empty block. A forward block has the same effect as its composite. A backward block does too, because inversion reverses the order of composition. The blocks partition the target edges in their traversal order, so

$$E_F(q^*c') = E_F(c').$$

A general morphism in the total path category factors into a morphism within a fibre followed by a cartesian morphism of this form. We have therefore proved invariance under every morphism and hence under every connecting zigzag. Evaluation defines a map on $\pi_0\underline{\mathrm{Ch}}_\Sigma(a,b)$.

Taking $F = \mathrm{id}_X$ gives the missing descent check for β in the text. The identity $\beta\alpha = \mathrm{id}$ is immediate. For the other identity, a backward traversal of an invertible $u \in \Sigma$ represents the inverse of $\kappa(u)$; this is also $\kappa(u^{-1})$, since κ is a functor. Replacing each backward edge in this way gives the all-forward path $c^\natural$, and repeated composition identifies its class with the elementary path of its composite. These equalities take place in $\Pi_\Sigma(X)$. The omitted subscripts in equations (1) and (2) on manuscript page 69 should not lead us to infer equality in a relative localization merely from equality in its groupoid completion.

$\beta(c)$, pour une Σ-flèche de type τ, le longueur n, en inversant toutes les flèches rétrogrades (ce qui est possibles, puisqu'elles sont dans Σ), de façon à obtenir un chemin $c^\natural$ de type Δ_+^n, et en prenant le composé (dans X) des flèches de ce chemin $c^\natural$. Il est évident alors que $\beta\alpha = \mathrm{id}$, il faut prouver que l'on a aussi $\alpha\beta = \mathrm{id}$, i.e. que dans $\Pi_\Sigma(X)$, les flèches $u = \int c^\natural$ et c sont égales, i.e. u et c sont homotopes dans $\underline{\mathrm{Ch}}_\Sigma(a,b)$. Considérons le chemin $c^\natural$, de type Δ_+^n :

$$a = a_0 \xrightarrow{u_1} a_1 \xrightarrow{u_2} a_2 \longrightarrow \cdots \longrightarrow a_{n-1} \xrightarrow{u_n} a_n = b,$$

et soit u_i ($i \in [1,n]$) une flèche de ce chemin, correspondant à une flèche de transition $\underline{u_i}$ *rétrograde* de τ, donc par construction

$$u_i = v_i^{-1} \qquad \text{dans } X, \text{ avec } v_i \in \Sigma$$

la flèche d'indice i dans le chemin initial c de type τ. Si $\underline{u_i}$ par contre est directe, on aura

$$u_i = v_i.$$

(NB On désigne par v_i la i-flèche dans le chemin c.) Or on a

$$(*) \qquad c = c_n * c_{n-1} * \cdots * c_1 \qquad \text{dans } \Pi_\Sigma(X)$$

et le facteur c_i est soit la classe d'homotopie de $\mathrm{ch}(v_i) = \mathrm{ch}(u_i)$ (cas où la flèche de transition $\underline{u_i}$ de τ est directe), soit celle du chemin *opposé* au chemin $\mathrm{ch}(v_i) : a_i \xrightarrow{v_i} a_{i-1}$ de type Δ_+, donc le chemin $\mathrm{ch}(v_i)^o : a_{i-1} \xleftarrow{v_i} a_i$ de type Δ_-. Je dis que

$$(1) \qquad \boxed{\mathrm{ch}(v_i)^o = \mathrm{ch}(u_i) \qquad \textit{dans } \Pi(X),}$$

ce qui prouve que dans $\Pi_\Sigma(X)$, c est égal au composé des $\mathrm{ch}(u_i)$ ($i \in [1,n]$), donc à $c^\natural$. Il faut prouver de plus que

$$(2) \qquad c^\natural = \mathrm{ch}(u) \qquad (u = u_n u_{n-1} \cdots u_1) \qquad \text{dans } \Pi(X).$$

Commentary · Context [ms. 69] [page 70]

Relations before higher homotopies

Grothendieck's path construction is testing the same universal problem as the classical category of fractions, while retaining the witnesses for its elementary relations. In Gabriel and Zisman (1967, Chapter I, §1.1 and Lemma 1.2), localization is constructed from paths with formal reverse arrows by

imposing composition, identity, and inverse relations. Lemma 1.2 also gives the universal property on functor categories and natural transformations. Here composition and identity relations come from type changes; the inverse relations come from the two fixed-endpoint ladders. The evaluation calculation above shows that arbitrary path ladders respect these relations. The universal property on the following pages will prove that taking components introduces no additional identifications.

This is also the appropriate scale on which to read the connection with the derivator programme. In Grothendieck (1983, §69, pp. 1–4 of the separately edited text), the diagramwise construction

$$I \longmapsto \mathrm{Fun}(I, M)[W_I^{-1}]$$

retains a whole family of localized diagram categories, where W_I consists of pointwise weak equivalences. The present calculation makes morphisms in such ordinary localizations accessible by diagrams of arrows and commuting squares. It does not by itself supply the homotopy Kan extensions or the higher comparisons required for a derivator.

The chronological comparison with Dwyer and Kan is particularly instructive, since their simplicial localization papers appeared in 1980, before these manuscript pages. Their hammock construction restricts every vertical arrow to the chosen subcategory of weak equivalences, as well as every backward horizontal arrow; its component category is the ordinary localization, and it is weakly equivalent to their standard simplicial localization (Dwyer and Kan, 1980a, Definition 2.1 and Propositions 2.2, 3.1). Grothendieck's full relative path fibres allow arbitrary internal vertical arrows. Agreement of component categories is therefore a common starting point, not an automatic comparison theorem for the entire nerves. The stronger assertions later in the chapter must be justified with the actual path category and its actual indexing maps.

Donc il y a deux vérifications à faire (où je suppose à nouveau Σ quelconque) :

1°) Soit $u \in \Sigma$, $u : a \longrightarrow b$, supposons Σ inversible dans X. Alors

$$\mathrm{ch}(u)^o = \mathrm{ch}(u^{-1}) \qquad \text{dans } \Pi_\Sigma(X),$$

i.e. les deux chemins de b vers

$$\begin{array}{lll} b & \xleftarrow{u} & a \quad \text{de type } \Delta_- \\ b & \xrightarrow{u^{-1}} & a \quad \text{de type } \Delta_+ \end{array}$$

sont homotopes dans $\underline{\mathrm{Ch}}_\Sigma(b, a)$. Or on sait déjà, comme $\kappa : X \longrightarrow \Pi_\Sigma(X)$ est un foncteur, que p. 47

$$\mathrm{hot}\,\mathrm{ch}(u^{-1}) = (\mathrm{hot}\,\mathrm{ch}(u))^{-1} \qquad \text{dans } \Pi_\Sigma(X)$$

où $\mathrm{hot}(\bullet)$ désigne la classe d'homotopie d'une chaine (ici classe dans $\underline{\mathrm{Ch}}_\Sigma(b, a)$ et dans $\underline{\mathrm{Ch}}_\Sigma(a, b)$ respectivement). Donc l'énoncé à prouver c'est que $\mathrm{hot}(\mathrm{ch}(u)^o)$ est égal à l'*inverse* de $\mathrm{hot}(\mathrm{ch}(u))$ dans $\Pi_\Sigma(X)$. C'est donc ce qu'on a prouvé pour *tout* $u \in \mathrm{Fl}(X)$, dans le cas de $\Pi(X)$. L'argument doit marcher, du moment qu'il a un sens, i.e. que $\mathrm{ch}(u)^o$ est bel et bien un Σ-chemin, i.e. $u \in \Sigma$.

2°) La formule (2) signifie que pour tout chemin c de type Δ_+^n (donc tautologiquement un Σ-chemin), allant de a vers b, sa classe dans $\mathrm{Hom}_\Sigma(a, b)$ n'est autre que celle de $\mathrm{ch}(u)$, où u est le composé $u_n u_{n-1} \cdots u_1$. Mais on a [page 71]

$$c = c_1 * c_2 * \cdots * c_n,$$

d'où dans $\Pi_\Sigma(X)$

$$\mathrm{hot}(c) = \mathrm{hot}(c_n)\mathrm{hot}(c_{n-1}) \cdots \mathrm{hot}(c_1),$$

or $\mathrm{hot}(c_i) = \mathrm{hot}\,\mathrm{ch}(u_i) = \kappa(u_i)$, donc

$$\begin{aligned} \mathrm{hot}(c) &= \kappa(u_n)\kappa(u_{n-1}) \cdots \kappa(u_1) \\ &= \kappa(\underbrace{u_n u_{n-1} \cdots u_1}_{u}), \end{aligned}$$

puisque κ est un foncteur, donc

$$\mathrm{hot}(c) = \mathrm{hot}\,\mathrm{ch}(u),$$

c.q.f.d.

Notons maintenant que si (X', Σ') est un deuxième couple d'une catégorie X' et d'un ensemble *'admissible'* de flèches de X', et si

$$f : X \longrightarrow X'$$

est un foncteur tel que

$$f(\Sigma) \subseteq \Sigma',$$

alors il existe un *unique* foncteur

$$\bar{f} = \Pi_\Sigma(f) : \Pi_\Sigma(X) \longrightarrow \Pi_{\Sigma'}(X')$$

qui 'prolonge' f, i.e. tel que le carré p. 48

$$\begin{array}{ccc} X & \xrightarrow{\kappa_X} & \Pi_\Sigma(X) \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle \bar{f}=\Pi_\Sigma(f)} \\ X' & \xrightarrow{\kappa_{X'}} & \Pi_{\Sigma'}(X') \end{array} \qquad \text{[page 72]}$$

soit commutatif. L'unicité résulte du fait que sur les objets $\bar{f}$ doit être donné par f, et que sur les flèche la commutativité du carré implique que $\bar{f}$ est connu sur les flèches de la forme $\kappa_X(u)$, ainsi donc que sur les inverses de telles flèches, quand ces inverses sont inversibles, donc en particulier sur les $\kappa_X(u)^{-1}$ pour $u \in \Sigma$. Or toute flèche de $\Pi_\Sigma(X)$, provenant d'un chemin, est composé d'une suite de flèches de cette forme. Pour l'existence de $\bar{f}$, on note que f induit des foncteurs

$$\underline{\mathrm{Ch}}_\tau(X; a, b) \longrightarrow \underline{\mathrm{Ch}}_\tau(X'; f(a), f(b))$$

qui commutent aux opérations φ^* sur les chemins associées aux foncteurs

$$\varphi : \tau \longrightarrow \tau',$$

d'où un homomorphisme de catégories fibrées sur $\underline{\mathrm{Ty}}$

$$f_{a,b} : \underline{\mathrm{Ch}}(X; a, b) \longrightarrow \underline{\mathrm{Ch}}(X'; f(a), f(b)).$$

D'où une application sur les π_0, i.e.

$$\bar{f}_{a,b} : \mathrm{Hom}_\Sigma(a, b) \longrightarrow \mathrm{Hom}_\Sigma(f(a), f(b)), \qquad \text{[page 73]}$$

donnée par

$$\bar{f}_{a,b}(\mathrm{hot}(c)) = \mathrm{hot}(f_{a,b}(c)).$$

On a évidemment, pour deux chemins $\gamma : a \longrightarrow b$ et $\gamma' : b \longrightarrow c$,

$$f_{a,c}(\gamma\gamma') = f_{b,c}(\gamma')f_{a,b}(\gamma),$$

ce qui prouve que $\bar{f}$ est compatible avec la composition. Il est trivial qu'il est compatible avec les identités (car $f_{a,a}$ transforme le chemin vide en a en le chemin vide en $f(a)$), donc on a un foncteur $\bar{f}$, et il rend bel et bien le carré commutatif.

On peut maintenant prouver la propriété universelle de $\Pi_\Sigma(X)$ et de p. 49

$$X \xrightarrow{\kappa} \Pi_\Sigma(X), \qquad \text{[page 74]}$$

savoir que tout foncteur $f : X \longrightarrow X'$ tel que $u \in \Sigma \Longrightarrow f(u)$ inversible, se factorise *de façon unique* par $\Pi_\Sigma(X)$. L'unicité se voit comme tantôt ([20]). Pour l'existence, on note que f applique Σ dans l'ensemble Σ'

des flèches inversibles de X' (lequel ensemble satisfait bien aux deux conditions d'admissibilité). Donc par ce qui précède on a un diagramme commutatif

$$\begin{array}{ccc} X & \xrightarrow{\kappa} & \Pi_\Sigma(X) \\ {\scriptstyle f}\downarrow & \overset{\tilde{f}}{\searrow} & \downarrow{\scriptstyle \bar{f}=\Pi_\Sigma(f)} \\ X' & \xrightarrow[\sim]{\kappa'} & \Pi_{\Sigma'}(X'), \end{array}$$

où $\bar{f}$ est uniquement déterminé. Comme κ' est un isomorphisme (comme on a vu tantôt, puisque Σ' `[est]` formé des flèches inversibles), l'existence et l'unicité de $\bar{f}$ équivaut à la conclusion annoncée,

c.q.f.d.

Encore un sorite sur les classes d'homotopie d'éléments d'une catégorie X. De façon générale, on voit que X et $\Pi_\Sigma(X) = X\Sigma^{-1}$ ont mêmes composantes connexes, car si a et b dans X sont reliés par une flèche de $X\Sigma^{-1}$, i.e. par un Σ-chemin, alors ils sont dans une même composante connexe de X. Mais l'inverse est également vrai, comme on voit p. ex. en prenant $\Sigma = \mathrm{Fl}(X)$, et en disant que dans le *groupoïde* $\Pi(X)$, où deux sommets sont dans une même composante `[connexe]` si et seulement si $\exists\ x \longrightarrow y$ (relation qui est non seulement transitive et reflexive, mais aussi symétrique dans un groupoïde). Un chemin [page 75]

$$a \xrightarrow{c} b$$

sera appelé aussi une *homotopie* de a vers b. On dit que a et b sont *homotopes* s'il existe une homotopie c de a vers b, auquel cas il existe aussi une homotopie 'inverse' c^o de b vers a. Cela signifie aussi que a et b sont dans la même composante connexe de X, i.e. définissent le même élément de $\pi_0(X)$.

Commentary · Exposition [ms. 74]

The universal property includes natural transformations

Grothendieck has now brought the path construction back to the familiar category of fractions. The work with arbitrary lengths and their changes of parameter pays for a universal property requiring only that the denominators contain identities and be closed under composition. No condition allowing fractions to be shortened to spans has entered the argument. This is the general localization of Gabriel and Zisman (1967, Chapter I, §1.1 and Lemma 1.2); a calculus of left or right fractions is additional structure that can simplify its representatives.

Write $Q : X \longrightarrow L = \Pi_\Sigma(X)$. A functor $F : X \longrightarrow Y$ carrying Σ into isomorphisms must send a zigzag

$$a = x_0 \xrightarrow{u_1} x_1 \xleftarrow{s_2} x_2 \xrightarrow{u_3} \cdots \xleftarrow{s_n} x_n = b$$

to the corresponding composite of the $F(u_i)$ and $F(s_j)^{-1}$, in their order of traversal. The preceding discussion of the evaluation map proves that this prescription is constant on components of the path category. It therefore defines $\overline{F} : L \longrightarrow Y$. Every arrow of L is represented by a zigzag, so these prescribed values also prove uniqueness. The factorization through $\Pi_{\mathrm{Iso}(Y)}(Y) \simeq Y$ used in the text packages precisely this argument.

There is a useful categorical refinement, already part of the classical universal property. Precomposition induces an isomorphism

$$Q^* : \mathrm{Fun}(L, Y) \xrightarrow{\sim} \mathrm{Fun}_\Sigma(X, Y),$$

where the right side is the full subcategory of $\mathrm{Fun}(X, Y)$ on the functors inverting Σ. The statement concerns all natural transformations, not merely natural isomorphisms. To see the extra assertion

20. C'est inutile, cf. ci-dessous.

directly, let $\eta : F \Rightarrow G$ be a natural transformation between such functors. Since Q is the identity on objects, the only possible extension has components $\overline{\eta}_x = \eta_x$. Naturality for $s : x \to y$ gives

$$\eta_y F(s) = G(s)\eta_x, \qquad \eta_x F(s)^{-1} = G(s)^{-1}\eta_y.$$

The second equality supplies naturality for the formal inverse of s. Naturality then passes to every composite representing an arrow of L. These components define the required transformation, and uniqueness follows again from the identity on objects. This also explains why relative functors induce functors on localizations without further choices: both their action on arrows and their action on transformations are determined before any presentation of a fraction is chosen.

For the present chapter, this refinement matters because a path whose vertices are themselves functors is a diagram of natural transformations. The later passage to diagram categories will repeatedly use the same distinction between determining objects and controlling the morphisms between them. The localization established here already supplies both at the ordinary categorical level.

L'homotopie sera dite *simple* si c est de type Δ_+ ou Δ_-, i.e. si elle est donnée par une flèche $u : a \longrightarrow b$ ou $v : b \longrightarrow a$. Si on cherche une homotopie entre a et b, on essaiera de la trouver la plus 'courte' possible. Si on a une homotopie c de longueur l de a vers b, alors en remplaçant τ par $\tau_{\text{réd}}$, donc I_τ par $I_{\tau\,\text{réd}}$, le sous-intervalle réduit correspondant, on trouve une homotopie de a à b de type $\tau_{\text{réd}}$, dont la longueur est égale à la *'longueur utile'* du type τ de c (ce qui justifie la terminologie). Notons que si [page 76]

$$\tau = \Delta_\varepsilon^{l_1}\Delta_{-\varepsilon}^{l_2}\Delta_\varepsilon^{l_3}\cdots\Delta_{(-1)^r\varepsilon}^{l_r},$$

alors

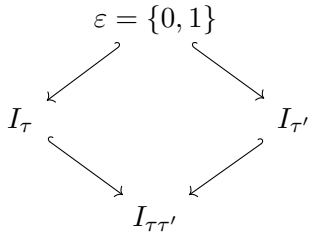
$$\tau_{\text{réd}} = \Delta_\varepsilon\Delta_{-\varepsilon}\Delta_\varepsilon\cdots\Delta_{(-1)^r\varepsilon},$$

`[plutôt deux fois` $(-1)^{r-1}$`]` où r est la longueur utile de τ (la longueur pas utile étant $n = \sum_{i\in[1,r]} l_i$). p. 50

Quand on part d'une homotopie entre *foncteurs*

$$X \longrightarrow Y,$$

il est entendu qu'il s'agit d'homotopies dans la catégorie $\underline{\mathrm{Hom}}(X, Y)$. (Ou, suivant le contexte, dans une sous-catégorie précisée de $\underline{\mathrm{Hom}}(X, Y)$.)



À la page 61, j'ai invoqué l'existence d'un *foncteur* de *'composition des chemins'* [page 77]

$$\underline{\mathrm{Ch}}_\Sigma(X; a, b) \times \underline{\mathrm{Ch}}_\Sigma(X; b, c) \longrightarrow \underline{\mathrm{Ch}}_\Sigma(X; a, c),$$

qui sur la fibre du premier membre au dessus de $(\tau, \tau') \in \mathrm{Ob}(\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}})$, serait donné par

$$(*) \qquad \underline{\mathrm{Ch}}_{\Sigma,\tau}(X; a, b) \times \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X; b, c) \longrightarrow \underline{\mathrm{Ch}}_{\Sigma,\tau\tau'}(X; a, c),$$

la composition des chemins de types précisés τ, τ'. Qu'on ait là un *foncteur,* pas seulement une application sur les ensembles d'objets, est assez évident, et peut s'exprimer par exemple à l'aide du diagramme d'amalga`[ma]`tion

en le transformant par $\underline{\mathrm{Hom}}(\cdot, X)$ (au lieu de le transformer par $\mathrm{Hom}_{\mathrm{Cat}}(\cdot, X)$ seulement), du moins dans le cas particulier où $\Sigma = \mathrm{Fl}(X)$ (qui était celui de la page 61). Mais le passage aux flèches est assez évident - pour deux composés $c_1' \circ c_1$ et $c_2' \circ c_2$, de

$$\begin{array}{ccccc} a & \xrightarrow{c_1} & b & \xrightarrow{c_1'} & c \\ \| & & \| & & \| \\ a & \xrightarrow[c_2]{} & b & \xrightarrow[c_2']{} & c \end{array} \qquad \begin{array}{c} \\ w \\ \\ w' \\ \\ \end{array}$$

[on] voit que les homomorphismes w'' du premier dans le second, dans $\underline{\mathrm{Ch}}_{\Sigma}(X; a, c)$, qui sont l'identité sur le sommet d'indice $n+1$ des deux chemins (où $n = \log \tau$), correspondant à 1_τ et à $0_{\tau'}$, 'sont' exactement les couples formés d'un homomorphisme $w : c_1 \longrightarrow c_2$ et p. 51
$w' : c_1' \longrightarrow c_2'$ dans $\underline{\mathrm{Ch}}_{\Sigma,\tau}(a, b)$ et $\underline{\mathrm{Ch}}_{\Sigma,\tau'}(b, c)$ respectivement, et si w'', w, w' se correspondent ainsi, on posera [page 78]

$$w'' = w * w'.$$

Il y a une transitivité évidente à vérifier pour voir que ça définit un *foncteur* $(*)$. On peut exprimer la situation à l'aide du diagramme

$$\begin{array}{ccccc} & & \underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}} & \xrightarrow{\pi \text{ (composition)}} & \underline{\mathrm{Ty}} \\ & \swarrow^{p_1} & & \searrow_{p_2} & \\ \underline{\mathrm{Ty}} & & & & \underline{\mathrm{Ty}}, \end{array}$$

où p_1, p_2 sont les deux projections. On considère sur $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$ les trois catégories fibrés

$$p_1^*(\underline{\mathrm{CH}}_{\Sigma,\tau}(a, b)), \quad p_2^*(\underline{\mathrm{CH}}_{\Sigma,\tau'}(b, c)), \quad \pi^*(\underline{\mathrm{Ch}}_{\Sigma,\tau\tau'}(a, c))$$

[plutôt $\pi^*(\underline{\mathrm{CH}}_{\Sigma,\tau\tau'}(a, c))$], dont les fibres en (τ, τ') sont respectivement

$$\underline{\mathrm{Ch}}_{\Sigma,\tau}(a, b), \quad \underline{\mathrm{Ch}}_{\Sigma,\tau'}(b, c), \quad \underline{\mathrm{Ch}}_{\Sigma,\tau\tau'}(a, c).$$

(On écrit $\underline{\mathrm{CH}}$ au lieu de $\underline{\mathrm{Ch}}$, pour indiquer que l'on considère les catégories envisagées comme des catégories (fibrées) *au dessus de* ($\underline{\mathrm{Ty}}$) ([21]).) Au dessus de $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$, on a un homomorphisme (cartésien) de catégories fibrées

$$(**) \qquad p_1^*(\underline{\mathrm{CH}}_{\tau}(a, b)) \times_{\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}} p_2^*(\underline{\mathrm{CH}}_{\tau}(b, c)) \longrightarrow \pi^*(\underline{\mathrm{CH}}_{\tau}(a, c))$$

[plutôt $p_1^*(\underline{\mathrm{CH}}_{\tau}(a, b)) \times_{\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}} p_2^*(\underline{\mathrm{CH}}_{\tau'}(b, c)) \longrightarrow \pi^*(\underline{\mathrm{CH}}_{\tau\tau'}(a, c))$], car c'est OK sur les fibres ($(*)$ page 77), et si

$$(\varphi, \varphi') : (\tau_1, \tau_1') \longrightarrow (\tau, \tau') \qquad (\varphi : \tau_1 \longrightarrow \tau,\ \varphi' : \tau_1' \longrightarrow \tau') \qquad \text{[page 79]}$$

est une flèche dans $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$, on en déduit un diagramme commutatif

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{\Sigma,\tau}(a, b) \times \underline{\mathrm{Ch}}_{\Sigma,\tau'}(b, c) & \xrightarrow{\text{comp.}} & \underline{\mathrm{Ch}}_{\Sigma,\tau}(a, c) \\ \downarrow{\scriptstyle \varphi_{a,b}^* \times (\varphi'_{b,c})^*} & & \downarrow{\scriptstyle (\varphi * \varphi')^*_{a,c}} \\ \underline{\mathrm{Ch}}_{\Sigma,\tau_1}(a, b) \times \underline{\mathrm{Ch}}_{\Sigma,\tau_1'}(b, c) & \xrightarrow{\text{comp.}} & \underline{\mathrm{Ch}}_{\Sigma,\tau_1\tau_1'}(a, c) \end{array}$$

[plutôt $\underline{\mathrm{Ch}}_{\Sigma,\tau\tau'}(a, c)$], i.e. la composition des chemins d'extrémités fixés est compatible avec les images inverses de chemins par flèches entre les types de chemins.

p. 52

21. Mais il s'agit pour p_1^*, p_2^* et π^* de produits cartésiens ordinaires dans Cat, il n'y a pas à avoir peur et à écrire des $\underline{\mathrm{CH}}$ …

Commentary · Examples [ms. 76]

Connectedness does not impose an orientation

Grothendieck next isolates the least information carried by his paths: whether two objects belong to one component. For any admissible Σ, the map $Q : X \to X[\Sigma^{-1}]$ induces a bijection on connected components. Indeed, every arrow of X supplies an edge between its two objects in the localization, so a zigzag in X remains a zigzag there. Conversely, an arrow of the localization is represented by a Σ-zigzag in X; forgetting which of its arrows were designated denominators gives an ordinary zigzag in X. Applying this observation to the finitely many arrows of a zigzag in the localization proves the converse on components.

The orientation must be kept separate from this argument. Let $X = [1]$, with its single nonidentity arrow $0 \to 1$, and let Σ contain only identities. Then $X[\Sigma^{-1}] = X$ and $0, 1$ belong to the same component, although there is no arrow $1 \to 0$ in the localization. Thus the phrase about the converse on manuscript page 75 is read as a statement about connected components. It would be false if read as the assertion that connectedness supplies a directed Σ-path in every prescribed direction. When $\Sigma = \mathrm{Fl}(X)$, reversal is available, and the groupoid formulation does permit that stronger assertion.

Reduction of a type has an equally concrete meaning. A string

$$a_0 \longrightarrow a_1 \longrightarrow a_2 \longleftarrow a_3 \longleftarrow a_4 \longrightarrow a_5$$

can be replaced by

$$a_0 \longrightarrow a_2 \longleftarrow a_4 \longrightarrow a_5$$

by composing the arrows in each maximal run. The signs of the three remaining edges are $+, -, +$. For r runs beginning with ε, their signs are $(-1)^{j-1}\varepsilon$, $1 \le j \le r$; this is the reason for the edition's correction of the last exponent on pages 76–77. If the original backward arrows belong to Σ, closure under composition ensures that the reduced backward arrows still do. The same construction in $\mathrm{Fun}(A, B)$ composes successive natural transformations of the same direction. Here a homotopy between functors means a finite zigzag of natural transformations; its endpoints need not be naturally isomorphic.

Mais l'homomorphisme cartésien $(**)$ de catégories fibrées sur $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$ n'est pas tout à fait la même chose qu'un anodin foncteur

$$(*) \qquad \underline{\mathrm{Ch}_\Sigma}(a,b) \times \underline{\mathrm{Ch}_\Sigma}(b,c) \longrightarrow \underline{\mathrm{Ch}_\Sigma}(a,c).$$

La formule $(*)$ définit en tout cas une application sur les ensembles d'objets, puisque les ensembles d'objets de chacune des trois catégories envisagées se décompose en somme d'ensembles $\underline{\mathrm{Ch}_{\Sigma,\tau}}(\bullet,\bullet)$, où τ parcourt $\mathrm{Ty} = \mathrm{Ob}\,\underline{\mathrm{Ty}}$. Mais cela se prolonge-t-il de façon naturelle aux morphismes?

Mais voilà que je me rappelle que ce fameux produit cartésien $p_1^*(\text{fourbi}) \times p_2^*(\text{machin})$ n'est autre que le produit cartésien tout bête [page 80]

$$\underline{\mathrm{Ch}_\Sigma}(a,b) \times \underline{\mathrm{Ch}_\Sigma}(b,c),$$

envoyé sur $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$ par le produit cartésien des deux foncteurs de projection

$$\begin{aligned} p_{a,b} : \underline{\mathrm{Ch}_\Sigma}(a,b) &\longrightarrow \underline{\mathrm{Ty}} \\ p_{b,c} : \underline{\mathrm{Ch}_\Sigma}(b,c) &\longrightarrow \underline{\mathrm{Ty}}, \end{aligned}$$

d'où

$$\begin{array}{c} \underline{\mathrm{Ch}_\Sigma}(a,b) \times \underline{\mathrm{Ch}_\Sigma}(b,c) \\ \big\downarrow{\scriptstyle p_{a,b} \times p_{b,c}} \\ \underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}} \end{array}$$

qui est bel et bien fibrant (comme produit cartésien de deux foncteurs fibrants) et a les fibres [page 81]

qu'il faut! On trouve donc bien, par le sorite général sur les foncteurs fibrants (ici sur $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$) un foncteur de catégories fibrées sur $\underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}}$

$$\underline{\mathrm{Ch}_\Sigma}(a,b) \times \underline{\mathrm{Ch}_\Sigma}(b,c) \longrightarrow \underbrace{\pi^*(\underline{\mathrm{CH}_\Sigma}(a,c))}_{=(\underline{\mathrm{Ty}}\times\underline{\mathrm{Ty}})\times_{\underline{\mathrm{Ty}}}\underline{\mathrm{Ch}_\Sigma}(a,c)} \quad (22) \qquad .$$

Comme on a d'autre part un foncteur du dernier membre (produit fibré) vers le facteur $\underline{\mathrm{Ch}_\Sigma}(a,c)$, on gagne. (On l'aurait retrouvé par le raisonnement direct que je m'apprêtais de faire, et que j'ai biffé - mais je suis plus heureux comme ça!)

Pour bien faire, il faudrait prouver l'*associativité* des foncteurs de composition, pas seulement au niveau des objets, par des arguments comme ceci, mais ça revient simplement à une relation du type p. 53

$$(w'' * w') * w = w'' * (w' * w)$$

pour un système de trois flèches dans

$$\underline{\mathrm{Ch}_\Sigma}(a,b),\ \underline{\mathrm{Ch}_\Sigma}(b,c) \text{ et } \underline{\mathrm{Ch}_\Sigma}(c,d)$$

respectivement. Ça ne peut être que trivialement vrai, mais fastidieux à expliciter.

[page 82]

Commentary · Exposition [ms. 81]

The total composition and its associativity

Grothendieck returns to composition because the localization argument uses a functor on the total path categories, including morphisms that change the type. The commentary at manuscript pages 48–50 describes the fixed-type operation. The additional verification here is that this operation respects the arrows of the Grothendieck construction. Writing these arrows explicitly also settles the associativity left to the reader on pages 81–82.

For fixed endpoints, put $P_{a,b}(\tau) = \underline{\mathrm{Ch}_{\Sigma,\tau}}(X; a, b)$. An arrow in its total category,

$$(\tau, c) \longrightarrow (\sigma, d),$$

is a pair (φ, η) with $\varphi : \tau \to \sigma$ and an endpoint-fixed natural transformation $\eta : c \Rightarrow d\varphi$. If a second arrow is $(\psi, \theta) : (\sigma, d) \to (\rho, e)$, its composite with the first is

$$(\psi\varphi, (\theta\varphi)\eta).$$

This is the concrete form of the fibred-category formalism used in the text.

To concatenate two such arrows, concatenate the type maps and glue their transformations at the common endpoint:

$$((\varphi, \eta), (\varphi', \eta')) \longmapsto (\varphi * \varphi', \eta * \eta').$$

Both components at the joining object are the identity. Hence the two definitions there agree, and the naturality square for every edge comes from exactly one of the two given naturality squares. The resulting objects remain Σ-paths because concatenation does not change an edge or its direction. A vertical component of a transformation is unrestricted: $P_{a,b}(\tau)$ is a full subcategory on its allowed objects, with the endpoint condition imposed on transformations.

Compatibility with composition is checked at vertices. On the first interval the two possible composites have component $(\theta\varphi)_i\eta_i$; on the second they have the corresponding primed component; at the joining vertex both have the identity. They are therefore equal. The base maps agree by functoriality of concatenation in $\underline{\mathrm{Ty}}$. Thus the formula defines the desired functor on total categories. Equivalently,

$$p_1^*\underline{\mathrm{Ch}_\Sigma}(a,b) \times_{\underline{\mathrm{Ty}}\times\underline{\mathrm{Ty}}} p_2^*\underline{\mathrm{Ch}_\Sigma}(b,c) \cong \underline{\mathrm{Ch}_\Sigma}(a,b) \times \underline{\mathrm{Ch}_\Sigma}(b,c),$$

and the cartesian functor to the pullback along concatenation can be followed by the projection to $\underline{\mathrm{Ch}_\Sigma}(a,c)$. This is the recognition made on page 80.

For associativity, number the vertices of three paths of lengths n, m, l by successive blocks in $[0, n+m+l]$. The first block keeps its indices, the second is shifted by n, and the third by $n+m$.

22. produit fibré par $\pi : \underline{\mathrm{Ty}} \times \underline{\mathrm{Ty}} \longrightarrow \underline{\mathrm{Ty}}$.

Either parenthesization produces those same indices, objects, and arrows. The same statement holds for the components of a glued transformation and for the underlying type map. Consequently both parenthesizations agree as functors, and the length-zero path is a strict unit. With these standard representatives, no later strictification is required.

One diagrammatic slip deserves explicit repair. The amalgamation on page 77 is

$$I_\tau \amalg_{\{1_\tau = 0_{\tau'}\}} I_{\tau'},$$

a pushout over a singleton category. The displayed $\varepsilon = \{0, 1\}$ would glue two pairs of endpoints. Already for two forward one-edge intervals, that different pushout has two parallel arrows between two objects, rather than the two successive arrows of $I_{\Delta^2_+}$. The joining vertex has index n in the numbering $0, \dots, n+m$; the printed $n+1$ uses the wrong index. Neither slip affects the correct componentwise construction.

Les sueurs froides sont terminées!

En résumé, le formalisme des $\underline{\mathrm{Ch}}_\Sigma(X)$ et des $\underline{\mathrm{Ch}}_\Sigma(X; a, b)$ développé jusqu'à présent donne satisfaction complète sur les points suivants :

a) Bon formalisme de composition des chemins (qui était dégueulasse avant).

b) Traitement élégant de la construction des catégories de fractions $\mathcal{M}\Sigma^{-1}$. Mais je m'attends que ce sera moins joli qu'avant, quand il s'agira de remplacer un $(\mathcal{M}, \Sigma)$ par des $(\underbrace{\mathcal{M}(X)}_{=\underline{\mathrm{Hom}}(X,\mathcal{M})}, \Sigma_X)$ (X une catégorie d'indices) `[plutôt` $\underline{\mathrm{Hom}}(X^o, \mathcal{M})$`]`. C'est pour y pallier qu'il me faudra développer des énoncés de comparaison, entre la catégorie $\underline{\mathrm{Ch}}_\Sigma$ construite ici, et d'autres dont le type dans Hot se prête aux calculs de façon plus directe, comme dans l'état premier de la question. De plus, on sera sûrement obligé d'en venir à des Ind-catégories, pour pouvoir suivre la variance de $\mathcal{M}(X)\Sigma_X^{-1}$ pour X variable.

c) Bon formalisme des 'homotopies' et des compositions des homotopies (ce qui est une autre façon de parler des chemins et de leur composition).

p. 54

Commentary · Context [ms. 82] [page 83]

Why the category of diagrams returns

The reservation at the end of this section brings the calculation back to the purpose of a derivator. Localizing $\mathcal{M}$ answers the question at one point. To vary coefficients over an indexing category A, one must also localize

$$\mathcal{M}(A) = \mathrm{Fun}(A^{\mathrm{op}}, \mathcal{M}), \qquad \Sigma_A = \{\eta \mid \eta_a \in \Sigma \text{ for every } a \in A\}.$$

The opposite in the edition's correction records the presheaf convention. It is a variance convention, not an alteration of the localization theorem: the latter applies to either functor category once its convention is fixed.

There is a small but decisive issue of uniformity. An object of a path category for $\mathcal{M}(A)$ is a finite zigzag of natural transformations with one common word of signs over all $a \in A$. An arbitrary family of zigzags in $\mathcal{M}$ may use a different word, or require an unbounded length, as a varies. Thus a description that works perfectly for individual objects still has work to do before it describes localization naturally in the parameter A. The ind-objects considered later organize precisely the freedom to enlarge a finite path type while retaining its functorial meaning.

This interpretation agrees with Grothendieck's subsequent account in his letter to Thomason of 2 April 1991. In §2, printed page 9, he explicitly defines the associated prederivator by $A \mapsto \mathcal{M}(A)[\Sigma_A^{-1}]$, with presheaf diagrams and objectwise denominators; on printed page 8 he emphasizes the transformations between restriction functors as part of the structure (Grothendieck, 1991a). The present concern about types is a concrete instance of that requirement. It asks for controlled variation of the entire diagram theory, beyond the universal property of a single localization.

8 Le lemme d'homotopie pour les morphismes d'intervalles

C'est le suivant :

Lemme 1. *Soient $\tau, \tau' \in \mathrm{Ty}$, et $f, g : \tau \rightrightarrows \tau'$ deux morphismes dans $\underline{\mathrm{Ty}}$. Alors f, g sont homotopes dans la catégorie $\underline{\mathrm{Hom}}\,\underline{\mathrm{int}}(I_\tau, I_{\tau'})$ des morphismes croissants d'intervalles orientés de I_τ dans $I_{\tau'}$.*

Cette catégorie pourrait licitement se désigner par $\underline{\mathrm{Hom}}_{\underline{\mathrm{Ty}}}(\tau, \tau')$, ou $\underline{\mathrm{Hom}}(\tau, \tau')$. C'est une sous-catégorie de la catégorie $\underline{\mathrm{Hom}}(I_\tau, I_{\tau'})$ de *tous* les foncteurs de I_τ dans $I_{\tau'}$, et une sous-catégorie pleine de la catégorie $\underline{\mathrm{Hom}}^\varepsilon(I_\tau, I_{\tau'})$ des foncteurs f qui sont compatibles avec la donnée des sources et des buts, i.e. qui rendent commutatif le diagramme

$$\begin{array}{ccc} & \varepsilon = \{0,1\} & \\ {\scriptstyle (\sigma_\tau, \beta_\tau)} \swarrow & & \searrow {\scriptstyle (\sigma_{\tau'}, \beta_{\tau'})} \\ I_\tau & \xrightarrow{\quad f \quad} & I_{\tau'}. \end{array}$$

Si f, g sont dans cette catégorie (pas forcément morphismes croissants d'ailleurs), une flèche de f dans g est donc la donnée, pour tout $i \in I_\tau$, d'une flèche $f(i) \xrightarrow{w_i} g(i)$ dans $I_{\tau'}$, avec les deux conditions :

a) Si $i \in \{0_\tau, 1_\tau\}$, $w_i = \mathrm{id}$, et

b) le carré commutatif habituel pour une flèche $i \longrightarrow j$ dans I_τ. (Il suffit d'avoir cette compatibilité pour les flèches de transition $\underline{u_i} : i - 1 \longrightarrow i$ dans I_τ $(i \in [1, \log \tau])$.)

Une autre façon de décrire cette catégorie $\underline{\mathrm{Hom}}^\varepsilon$, c'est de dire que c'est la catégorie

[page 84]

$$\underline{\mathrm{Ch}}_\tau(I_{\tau'}; 0_{\tau'}, 1_{\tau'}) \qquad (\simeq \underline{\mathrm{Hom}}^\varepsilon(I_\tau, I_{\tau'})),$$

mais $\underline{\mathrm{Hom}}_{\underline{\mathrm{Ty}}}(\tau, \tau')$ est la sous-catégorie pleine de cette catégorie formée des *chemins croissants* dans $I_{\tau'}$. Le lemme d'homotopie signifie aussi que cette catégorie $\underline{\mathrm{Hom}}_{\underline{\mathrm{Ty}}}(\tau, \tau')$ est toujours *connexe.* Elle n'est d'ailleurs pas forcément 0-connexe, car elle peut être vide. Notons ici, pour plus tard, la

Proposition 1 : *Soient $\tau, \tau' \in \mathrm{Ty}$, soient r, r' leurs longueurs utiles. Pour que $\mathrm{Hom}_{\underline{\mathrm{Ty}}}(\tau, \tau')$ soit non vide, il faut et il suffit que l'une ou l'autre des deux conditions suivantes soit satisfaite :*

a) $r \geq r' + 1$

b) $r = r'$, *et (si $r \neq 0$) τ et τ' ont même direction initiale (de sorte que $\tau_{\text{réd}} = \tau'_{\text{réd}}$).*

p. 55

(Démonstration ± immédiate.)

Notons que si τ, τ' n'ont pas même direction initiale, alors tout morphisme $\tau \longrightarrow \tau'$ est forcément dégénéré sur le premier intervalle critique de I_τ. On aura donc $\tau = \Delta_\varepsilon^{l_0} \cdot \tau_0$ (où l_0 est la longueur du premier intervalle critique, et où τ_0 a `[la]` direction initiale opposée de celle de τ), et un isomorphisme

$$\underline{\mathrm{Hom}}(\tau, \tau') \simeq \underline{\mathrm{Hom}}(\tau_0, \tau'),$$

où cette fois τ_0, τ' ont même direction initiale. On supposera donc désormais que *la direction initiale de τ, τ' est la même.* La condition $\underline{\mathrm{Hom}}(\tau, \tau') \neq \emptyset$ équivaut maintenant à $\underline{r \geq r'}$, ce que nous pouvons supposer. Je vais alors décrire un élément canonique F_0 de $\underline{\mathrm{Hom}}(\tau, \tau')$, ainsi. Soient

[page 85]

$$I_1, I_2, \ldots, I_r$$

les intervalles critiques de I_τ, et

$$I'_1, I'_2, \ldots, I'_{r'} \qquad (r' \leq r)$$

ceux de $I_{\tau'}$. Le foncteur F_0 proviendra de morphismes d'intervalles orientés (comme

$$\left\{\begin{array}{lcl} I_1 & \xrightarrow{f_1} & I'_1 \\ I_2 & \xrightarrow{f_2} & I'_2 \\ & \cdots & \\ I_{r'} & \xrightarrow{f_{r'}} & I'_{r'} \end{array}\right. \quad)$$

et sera donc forcément trivial sur les intervalles critiques I_α pour $r' < \alpha \leq r$ (il y en a si et seulement si $r > r'$). Comme I_τ, $I_{\tau'}$ ont même direction initiale, il s'ensuit que pour $\alpha \in [1, r']$, I_α et I'_α ont même signature (à savoir $\varepsilon_\alpha = (-1)^{\alpha+1}\varepsilon_1$, où ε_1 est la signature commune de I_1 et I'_1). Donc

$$I_\alpha = \Delta^{l_\alpha}_{\varepsilon_\alpha}, \qquad I'_\alpha = \Delta^{l'_\alpha}_{\varepsilon_\alpha},$$

et on définit f_α comme

$$f_\alpha = \mathfrak{f}_{\varepsilon_\alpha, l'_\alpha} * \mathrm{triv}_\alpha,$$

où

$$\mathfrak{f}_{\varepsilon_\alpha, l'_\alpha} : \Delta_{\varepsilon_\alpha} \longrightarrow \Delta^{l'_\alpha}_{\varepsilon_\alpha}$$

et où

$$\mathrm{triv}_\alpha : \Delta^{l_{\alpha-1}}_{\varepsilon_\alpha} \longrightarrow 1.$$

En d'autres termes, pour $\varepsilon = +1$ (p. ex.) on doit définir un morphisme des intervalles type $\underbrace{\mathbf{\Delta}^+_{l_\alpha}}_{=[0,l_\alpha]} \longrightarrow \underbrace{\mathbf{\Delta}^+_{l'_\alpha}}_{=[0,l'_\alpha]}$, et on pose (avec les numérotations internes à $\mathbf{\Delta}_{l_\alpha}$, $\mathbf{\Delta}_{l'_\alpha}$)

$$f_\alpha(0) = 0, \qquad f_\alpha(i) = l'_\alpha \ \text{ pour } i \in [1, l_\alpha].$$

Commentary · Exposition [ms. 84]

The two orders in the interval lemma

Grothendieck now wants the choice of a type map to disappear after homotopy. The statement is about a particularly constrained mapping category, and its constraints explain both the nonemptiness criterion and the proof. Number the source and target vertices by $[0, n]$ and $[0, m]$, and write their edge signs as ε_i and δ_j. An object is a nondecreasing function $F : [0, n] \to [0, m]$ satisfying $F(0) = 0$, $F(n) = m$, and

$$F(i-1) < F(i) \quad \Longrightarrow \quad \delta_{F(i-1)+1} = \cdots = \delta_{F(i)} = \varepsilon_i.$$

The condition says that one source edge can traverse a run of target edges only when their directions agree. It cannot cross a change of direction in the target. An arrow $F \to G$ is instead defined by the categorical order of the target: for every i, there must be an arrow $F(i) \to G(i)$ in $I_{\tau'}$. Such arrows, when present, are unique, and their naturality is automatic because the target is a poset. In particular the ordering of maps is generally different from pointwise numerical comparison.

Let r, r' count the maximal constant-sign runs. Each target run must be traversed using at least one source edge of the same sign. Distinct target runs require distinct source runs in the same order, because their signs alternate and a source run cannot pass a target turning vertex. This proves $r \geq r'$ when the initial signs agree. If the initial signs disagree, the whole first source run is forced to be constant at the initial target vertex, and the necessary inequality is $r - 1 \geq r'$. Conversely, under either inequality, map the first edge of each of the earliest matching source runs across the corresponding whole target run, collapse its remaining edges, and collapse every unused source run at the final target vertex. This constructs an admissible map and proves Proposition 1. If the target has no edges, there is exactly one map from every source; if the source has no edges and the target has an edge, there is none.

These observations also clarify the word "connected" in the text. Its assertion is that any two objects are connected by a finite zigzag of transformations; it allows the mapping category to be empty. For a nonempty mapping category, the lemma asserts that its nerve is connected.

Grothendieck then asks whether a stronger contraction exists. The following example separates that question from the proposed terminal-object argument, and the development after it gives a uniform contraction.

L'idée donc, c'est d'être dans les dispositions d'un voyageur qui, tenu à un plan de voyage par étapes décrit par τ, voudrait arriver aussi vite que possible à $1_{\tau'}$, en partant de $0_{\tau'}$. Il va dès la première étape $\Delta_\varepsilon \subseteq I_1$, se porter jusqu'au bout de I_1', regrettant ne pas pouvoir aller plus loin (à cause du plan de voyage). Il doit rester inactif jusqu'à ce qu'il soit arrivé au moment marqué par l'extrémité finale de I_1 (si celle-ci est au delà de celle de sa première flèche de transition, i.e. si $l_1 > 1$), puis il fait son deuxième grand pas jusqu'à l'extrémité terminale de I_2' etc. Il peut espérer, à chaque moment de son voyage, être en avance (ou du moins pas en retard) sur les autres voyageurs, qui auraient suivi de tactiques de progression différentes. Si cet espoir était justifié, cela signifierait que F_0 serait un plus grand élément de $\underline{\mathrm{Hom}}(\tau, \tau')$ (**NB** toutes ces catégories $\underline{\mathrm{Hom}}$ entre intervalles sont 'ordonnées', i.e. il y a au plus une flèche entre deux objets), i.e. un objet final. Cela impliquerait que $\underline{\mathrm{Hom}}(\tau, \tau')$ serait même contractile - chose peut-être vraie, mais sûrement pas de façon si simpliste je crains. Je me suis d'ailleurs canulé : F_0 est sans doute bien un 'plus grand' élément, mais pour l'ordre défini par la numérotation des sommets de $I_{\tau'}$ (donc $F \leq G$ si et seulement si $F(i) \leq G(i)$ $\forall i \in I_\tau$), et nullement pour l'ordre défini par la structure de catégorie de $\underline{\mathrm{Hom}}(\tau, \tau')$.

p. 56

[page 86]

L'idée pour prouver la connexité de $\underline{\mathrm{Hom}}(\tau, \tau')$, c'est de ramener tout $F \in \mathrm{Hom}(\tau, \tau')$, par une suite d'homotopies simples, à la forme normale. Rappelons que F est donné par une suite croissante de flèches de transition

[page 87]

$$\underline{u}_{i_1},\ \underline{u}_{i_2},\ \dots\ ,\ \underline{u}_{i_s}, \qquad i_1 < i_2 < \cdots < i_s,$$

et une suite d'entiers ≥ 1

$$\lambda_1,\ \lambda_2,\ \dots\ ,\ \lambda_s$$

avec la condition que

$$(*) \qquad \Delta_{\varepsilon_{i_1}}^{\lambda_1} \Delta_{\varepsilon_{i_2}}^{\lambda_2} \cdots \Delta_{\varepsilon_{i_s}}^{\lambda_s} = \tau'.$$

Les $\underline{u}_{i_\alpha}$ sont les flèches de transition de I_τ *critiques* pour F, i.e. non dégénérées pour F, et λ_α est la *partie* de $\underline{u}_{i_\alpha}$ pour F. Le foncteur normalisé ('pressé') F_0 est distingué par les conditions suivantes a) et b) `[et c)]`. Tout d'abord :

Commentary · Examples [ms. 86]

A quickest map that is neither initial nor terminal

The normal form reaches each target turning vertex as early as the source permits. It maximizes numerical progress, but the categorical direction reverses whenever the target changes direction. A four-object mapping category makes the distinction visible without any large diagram.

Take

$$\tau = \Delta_+^2 \Delta_-^2, \qquad \tau' = \Delta_+ \Delta_-.$$

The target is $0 \to 1 \leftarrow 2$. Every increasing endpoint-preserving functor has vertex list

$$F_{a,b} = (0, a, 1, b, 2), \qquad a \in \{0, 1\}, \quad b \in \{1, 2\}.$$

Indeed the middle source vertex must map to the target turning vertex 1: it cannot lie below 1, since the remaining negative edges could not reach 2, and it cannot lie above 1, since the initial positive edges could not reach it. The choices of a, b are then unrestricted in the displayed ranges. The exact arrow relation is

$$F_{a,b} \longrightarrow F_{a',b'} \quad \Longleftrightarrow \quad a \leq a' \ \text{ and } \ b \geq b',$$

where the inequalities on the right are numerical. The reversal of the second inequality is forced by $2 \to 1$ in the target.

The quickest functor is $F_0 = F_{1,2}$. It is numerically greater than or equal to every other functor, but the terminal object of this mapping category is $F_{1,1}$ and its initial object is $F_{0,2}$. In particular $F_{1,1}$ has no arrow to F_0, and F_0 has no arrow to $F_{0,2}$. The objection on manuscript page 86 is therefore exact, even in this small case.

Nevertheless a contraction to F_0 is immediate once we normalize one target run at a time. Define $R(F_{a,b}) = F_{1,b}$. There is a natural transformation $\mathrm{id} \Rightarrow R$, and another $\mathrm{const}_{F_0} \Rightarrow R$. Hence

$$\mathrm{id} \implies R \impliedby \mathrm{const}_{F_0}.$$

This is the pattern of the general argument: each step advances across only one constant-sign target run, so all its components have one common categorical direction. The entire numerical maximum need not define a single transformation.

Commentary · Development (commentators') [ms. 86]

A uniform contraction of the interval mapping category

Grothendieck's proposed normal form can be made into a contraction by advancing across one target run at a time. This answers the question on page 86 for the increasing endpoint-preserving mapping categories used in this section. We did not find this particular argument in the literature checked for the present commentary: the source's §8 proves connectedness, while the institutional abstract of Fernandes et al. (2019) concerns order-preserving self-transformations of a fence, without these simultaneous endpoint and linear-order constraints. We checked that abstract and metadata; its manuscript could not be retrieved. The result below is an elementary supplement, without a claim of priority.

Proposition (run-by-run contraction).[ours] *Let $P(\tau, \tau')$ be the category of nondecreasing endpoint-preserving functors $I_\tau \to I_{\tau'}$, with endpoint-fixed natural transformations. If $P(\tau, \tau')$ is nonempty, its identity functor is connected to the constant functor at the quickest map by a finite zigzag of natural transformations. In particular its nerve is contractible. One can use at most r' transformations, where r' is the number of target runs.*

Proof. We induct on r'. When the target has no edges, every functor is the same constant functor and $P(\tau, \tau')$ is the terminal category. Assume that the target is nontrivial. The source is then nontrivial too. If its initial sign differs from the target's, every map is constant on the entire first source run, as proved above. Every transformation is the identity at those vertices. Restriction past that run is consequently an isomorphism of mapping categories. We may use this isomorphism to assume that the first source and target runs have the same sign ε.

Let the first source run have vertices $0, \dots, a$, and the first target run have vertices $0, \dots, b$, where $a, b \geq 1$. The numerical clamping map

$$h : [0, m] \longrightarrow [0, m], \qquad h(j) = \max\{j, b\},$$

is a functor of the target interval category. On its first run it collapses every arrow to an identity at b; on every later edge it is the identity. These checks on generating edges prove functoriality, including at the turning vertex b.

For each $F \in P(\tau, \tau')$, define

$$(RF)(0) = 0, \qquad (RF)(i) = h(F(i)) \quad (1 \leq i \leq n).$$

The first source run cannot pass the first target turning vertex. Thus $F(i) \leq b$ for $0 \leq i \leq a$, and $(RF)(i) = b$ for $1 \leq i \leq a$. The new first edge is an allowed traversal from 0 to b of sign ε; all later edges are obtained by applying the functor h to their old images. This proves that RF is a functor. Its vertex map remains nondecreasing, it fixes both endpoints, and hence it is again an object of $P(\tau, \tau')$.

For a transformation $F \Rightarrow G$, apply h to its components at vertices $i \geq 1$ and use the identity at vertex 0. The resulting components define a transformation $RF \Rightarrow RG$. Indeed both functors are already valid interval functors, their target is thin, and each component exists by functoriality of h. Identities and composites are preserved componentwise. We have therefore constructed an endofunctor R of $P(\tau, \tau')$.

The comparison with the identity has one uniform direction. If $\varepsilon = +$, the unique arrows $j \to h(j)$ give $\mathrm{id}_P \Rightarrow R$; if $\varepsilon = -$, the arrows $h(j) \to j$ give $R \Rightarrow \mathrm{id}_P$. At vertex 0 the component is

the identity, and at the final vertex it is also the identity. Naturality in the source interval and in F follows from thinness of the target and of the mapping category. Only values in the first target run have changed, which is why this comparison exists despite the failure of a global numerical-maximum argument.

Let $Q \subseteq P$ be the full subcategory of maps with values $0, b, \dots, b$ on the first source run. The endofunctor R takes values in Q and restricts to the identity there. Delete the first source run, retain its last vertex as the new initial vertex, and do the same for the target. Restriction identifies Q with the endpoint-preserving mapping category of these two remaining intervals. To verify this identification on morphisms, observe that every component over the deleted prefix is forced to be an identity; restriction and the prescribed extension are inverse functors. The remaining target has $r' - 1$ runs. Since Q contains RF for every F, it is nonempty, so induction applies.

Compose the inductive zigzag on Q with $R : P \to Q$ and the inclusion $Q \hookrightarrow P$. Adjoining the single comparison between id_P and R gives a zigzag to the constant functor at the map that crosses the first target run on the first available source edge and then follows the inductively quickest map. This is exactly Grothendieck's normal form, after the forced initial deletion when necessary. The number of comparisons increases by one, hence is at most r'. A natural transformation induces a simplicial homotopy after taking nerves, so this categorical contraction contracts the nerve as asserted. □

The proposition supplies more than a path joining two chosen maps: its choices of intermediate functors are simultaneous and natural in the object of the mapping category. It concerns the increasing subcategory. No conclusion about all endpoint-preserving functors, without numerical monotonicity, is being used here.

a) La suite des signes $\varepsilon_{i_1}, \varepsilon_{i_2}, \dots, \varepsilon_{i_s}$ est 'alternée', i.e. $\varepsilon_{i_\alpha} \neq \varepsilon_{i_{\alpha+1}}$ ($\alpha \in [1, s-1]$). (Cela traduit le fait que le voyageur pressé ne fait pas en plusieurs pas ce qu'il pourrait faire en un seul.) Comme le premier de ces signes est forcément $\varepsilon'_1 = \varepsilon_1$, cela signifie que la suite des signes est la même que celle des ε_1, ε_2, ..., $\varepsilon_{r'}$ (à la longueur près). Mais mieux, que l'expression $(*)$ de τ' est son unique expression réduite, donc que $s = r'$ (longueur utile de τ'), et que les λ_i sont les longueurs l'_i des intervalles critiques de $I_{\tau'}$.
Soit donc $\alpha \in [1, s = r']$, et considérons la flèche de transition F-critique $\underline{u}_{i_\alpha}$, soit j_α l'indice marquant l'intervalle critique de I_τ contenant la partie de $\underline{u}_{i_\alpha}$ dans I_τ, p. 57 [page 88]

$$\underline{u}_{i_\alpha} \in \mathrm{Fl}(I_{j_\alpha}),$$

alors F induit des morphismes (croissants) d'intervalles orientés

$$F_\alpha = F|I_{j_\alpha} : I_{j_\alpha} \longrightarrow I'_\alpha$$

et est trivial sur les autres intervalles critiques (ceux pas de la forme I_{j_α}). La donnée des F_α détermine donc F sur les I_{j_α}, donc sur *tous* les I_j, donc partout (par l'opération $*$ de composition par recollement). De plus la condition a) assure que chaque F_α est de nature assez particulière : une seule flèche de transition critique $\underline{u}_{i_\alpha}$. De plus, pour qu'on ait $F = F_0$, il faudra :

b) $\forall \alpha \in [1, r']$, $\underline{u}_{i_\alpha}$ est la *première* flèche de transition de l'intervalle critique I_{j_α} qui la contient. Et enfin :

c) La suite des intervalles critiques de I_τ

$$I_{j_1},\ I_{j_2},\ \dots\ ,\ I_{j_{r'}} \qquad \text{(de signes alternés } \varepsilon_1,\ -\varepsilon_1,\ \varepsilon_1,\ \dots)$$

associés aux flèches F-critiques, n'est autre que celle

$$I_1,\ I_2,\ \dots\ ,\ I_{r'}$$

des r' premiers intervalles critiques de I_τ, i.e.

$$(j_1, j_2, \dots, j_{r'}) = (1, 2, \dots, r'). \qquad \text{[page 89]}$$

Ceci vu, l'idée naturelle pour 'déformer' F en F_0, c'est de trouver une suite d'homotopies qui transforment F de façon à lui faire acquérir successivement les caractéristiques a), b), c) du voyageur pressé. Au besoin, pour aller plus vite au but, on utilisera l'hypothèse de récurrence sur $n = \log \tau$, que le théorème de connexité est déjà prouvé quand I est de longueur $\leq n-1$. (NB Ce théorème est trivial pour $n \leq 1$, car alors les catégories $\underline{\mathrm{Hom}}(\tau, \tau')$ sont toutes ou bien vides, ou bien ponctuelles.)

1) On veut assurer a). Pour ceci, on utilise l'hypothèse de récurrence, pour remplacer un groupe de `[mot illisible]` flèches critiques consécutives de même signe, par une seule flèche critique. Cette méthode ne foire que si les flèches critiques sont toutes de même signe ε et incluent $\underline{u}_1$ et $\underline{u}_n$. Mais l'hypothèse de récurrence appliquée à $I = [1, n-1] \subseteq I_\tau$ nous ramène au cas où il n'y a que deux flèches critiques $\underline{u}_1$ et $\underline{u}_n$. Si le premier intervalle critique n'est pas réduit à Δ_ε, i.e. soit de longueur 2, alors l'hypothèse de récurrence appliquée à $I = [1, n] \subseteq I_\tau$ nous ramène au cas où les deux flèches critiques sont $\underline{u}_1$ et $\underline{u}_2$, et on est alors ramené au cas où $\boxed{I = \Delta^2_\varepsilon,\ \tau' = \Delta^2_\varepsilon.}$ Sinon, au cas où $\boxed{\tau = \Delta_\varepsilon \Delta^{l_2}_{-\varepsilon} \Delta_\varepsilon,\ \tau' = \Delta^2_\varepsilon,}$ et où les deux flèches critiques sont encore la première et la dernière, et $\tau' = \Delta^2_\varepsilon$. Ce sont là les deux cas irréductibles, qu'il faudra traiter à part.

[page 90] p. 58 [page 91]

Ces cas admis, on a donc moyen pour définir F de façon à satisfaire a). Ensuite on veut :

2) Assurer que la suite des intervalles critiques I_{j_1}, I_{j_2}, …, $I_{j_{r'}}$ qui contient les flèches critiques $\underline{u}_{i_1}$, …, $\underline{u}_{i_{r'}}$, soit la suite I_1, …, $I_{r'}$. C'est encore immédiat par l'hypothèse de récurrence, le seul cas irréductible étant celui où $r' = 1$ (une seule flèche critique), et où il s'agit de faire descendre cette flèche critique jusqu'à $\underline{u}_1$. Si I_1 est de longueur > 1, alors on fait descendre en $\underline{u}_2$ par hypothèse de récurrence, et le cas irréductible est celui où $\boxed{\tau = \Delta^2_\varepsilon,\ \tau' = \Delta_\varepsilon,}$ une flèche critique $\underline{u}_2$, la faire descendre en $\underline{u}_1$. Si par contre I_1 `[est]` de longueur 1, le cas irréductible est $\boxed{\tau = \Delta_\varepsilon \Delta^{l_2}_{-\varepsilon} \Delta_\varepsilon,\ \tau' = \Delta_\varepsilon,}$ une flèche critique $\underline{u}_{l_2+2}$, la faire descendre en $\underline{u}_1$.

Sous réserve de traiter les deux nouveaux cas irréductibles, on peut déformer F en un foncteur qui satisfait à a) et à c). Reste à normaliser chacun des $F_\alpha : I_\alpha \longrightarrow I'_\alpha$ ($\alpha \in [1, r']$). Donc on est ramené à $\Delta^n_\varepsilon \longrightarrow \Delta_\varepsilon$: une seule flèche critique $\underline{u}_\alpha$, $\alpha \in [1, n]$, à faire descendre en $\underline{u}_1$. Si $n \geq 2$, par hypothèse de récurrence elle descend en $\underline{u}_2$, cas supposé traité en 2°). Donc on gagne, sous réserve de traiter les 4 cas irréductibles.

A) Cas $\tau = \Delta^2_\varepsilon$, $\tau' = \Delta^2_\varepsilon$ ou Δ_ε. [page 92]

La catégorie $\underline{\mathrm{Hom}}(\Delta^2_\varepsilon, \Delta_\varepsilon)$ a deux éléments, les morphismes $\Delta^2_\varepsilon \longrightarrow \Delta_\varepsilon$ correspondent aux flèches de transition de Δ^2_ε ($= \mathbf{\Delta}^+_2$ ou $\mathbf{\Delta}^-_2$). Dans le cas $\varepsilon = +1$, ce sont les deux applications de $\{0, 1, 2\}$ dans $\{0, 1\}$, qui appliquent 0 en 0, 2 en 1, et 1 soit en 1 (F_0), soit en 1 `[plutôt en 0]` (F_1).

$$0 \longrightarrow 1 \longrightarrow 2$$

$$0 \longrightarrow 1$$

On a évidemment une flèche $F_1 \longrightarrow F_0$ (le voyageur pressé arrive plus vite …). Similaire pour $\varepsilon = -1$,

$$\underline{\mathrm{Hom}}(\Delta^2_\varepsilon, \Delta_\varepsilon) \simeq \mathbf{\Delta}^1, \qquad \text{catégorie 0-connexe.}$$

La catégorie $\underline{\mathrm{Hom}}(\Delta^2_\varepsilon, \Delta^2_\varepsilon)$ a trois éléments, s'identifiant à l'ensemble des parties non vide de l'ensemble $\mathrm{Tr}(\tau)$ à deux éléments des flèches de transition $\underline{u}_1$, $\underline{u}_2$ de τ : il y a $F_{\underline{u}_1} = F_0$, $F_{\underline{u}_2}$, $F_{\underline{u}_1, \underline{u}_2}$. Si $\varepsilon = +1$, il s'agit des applications croissantes (sans plus) de $\{0, 1, 2\}$ dans $\{0, 1, 2\}$, appliquant 0 en 0, 2 en 2, et 1 en ce qu'elle voudra.

Donc $1 \longmapsto 2$ correspond à F_0 p. 59

$1 \longmapsto 1$ correspond à F_1

$1 \longmapsto 0$ correspond à F_2

et on a bien sur $F_2 \longrightarrow F_1 \longrightarrow F_0$,

$$\underline{\mathrm{Hom}}(\Delta^2_\varepsilon, \Delta^2_\varepsilon) \simeq \mathbf{\Delta}^2, \qquad \text{catégorie 0-connexe.}$$

Dans ces deux cas, deux éléments de $\mathrm{Hom}(\tau, \tau')$ sont reliés par une homotopie *simple.*
B) Cas $\tau = \Delta_\varepsilon \Delta^l_{-\varepsilon} \Delta_\varepsilon$, $\tau' = \Delta^2_\varepsilon$ ou Δ_ε.
Notons que l'on a, pour $\tau, \tau' \in \underline{\mathrm{Ty}}$ quelconque, un isomorphisme de catégories [page 93]

$$\underline{\mathrm{Hom}}(\tau, \tau') \longrightarrow \underline{\mathrm{Hom}}(\tau'^o, \tau^o),$$

exprimant simplement que

$$\tau \longmapsto \tau^o$$

est un `[2]`-foncteur de $\underline{\mathrm{Ty}}$ dans $\underline{\mathrm{Ty}}$, et même un automorphisme de cette `[2]`-catégorie. Donc dire que $\underline{\mathrm{Hom}}(\tau, \tau')$ est connexe revient à dire que $\underline{\mathrm{Hom}}(\tau^o, \tau'^o)$ l'est. Donc on peut supposer ci-dessus que $\varepsilon = +1$ (et pareil dans A!).

$$\tau : \quad \longrightarrow \underbrace{\longleftarrow \longleftarrow \cdots \longleftarrow}_{l} \longrightarrow$$

$$\tau' : \quad \longrightarrow \longrightarrow \quad \text{ou} \quad \longrightarrow .$$

Mais tous les morphismes $\tau \longrightarrow \tau'$ sont triviaux sur l'intervalle critique I_2 (rétrograde), ce qui implique que

$$\underline{\mathrm{Hom}}(\tau, \tau') \xleftarrow{\sim} \underline{\mathrm{Hom}}(\Delta^2_\varepsilon, \tau'),$$

via le foncteur de contraction canonique

$$I_\tau \longrightarrow I_{\Delta^2_\varepsilon} = \mathbf{\Delta}^2.$$

Or dans A on a vu que $\underline{\mathrm{Hom}}(\Delta^2_\varepsilon, \tau')$ est connexe (pour τ' de la forme Δ_ε ou Δ^2_ε).
On a gagné!

Commentary · Exposition [ms. 93] p. 60

The four small cases and the completed proof [page 94]

Grothendieck's induction reduces the normalization to two monotone cases and two cases with one intervening run of the opposite sign. The local calculations are sound; the reversal formula printed at the start of case B needs its arguments restored to their original order. Reversal of the numbered interval gives

$$P(\tau,\tau') \cong P(\tau^o,\tau'^o), \qquad F \longmapsto r_{\tau'} F r_\tau^{-1},$$

where $r_\tau : I_\tau \to I_{\tau^o}$ reverses the vertex numbering. It is a covariant isomorphism of the underlying categories, since the reversed word also changes every sign. The displayed $P(\tau'^o,\tau^o)$ in the edition would reverse the direction of a functor and is not this operation. The next sentence in the source already has the correct order.

For $\tau = \Delta^2_+$ and target Δ^k_+ with $k = 1$ or 2, a map is determined by $F(1) = j$, $0 \le j \le k$. There is a unique transformation from j to j' exactly when $j \le j'$. Thus the two mapping categories are the chains [1] and [2]. With negative signs the order reverses, producing isomorphic chains. In particular any two objects are joined by one simple homotopy. These are the calculations on pages 92–93, including the edition's correction of the repeated value 1 in the first example.

For $\tau = \Delta_+\Delta^l_-\Delta_+$ and a positive target, every edge of the negative middle run must collapse: a nondecreasing map cannot carry a negative source edge to a nonconstant positive target arrow. It therefore factors uniquely through the contraction $I_\tau \to I_{\Delta^2_+}$. The factorization also holds for transformations, because all components over the collapsed middle run coincide. This proves the displayed isomorphism of mapping categories and reduces the remaining cases to the preceding chains. Two small corrections clarify the longer induction on page 90. A first source run that is not a singleton has length at least two; the printed "length two" omits that qualification. More substantially, to concentrate all activity except the final edge, the inductive subinterval must be $[0, n-1]$, not the printed $[1, n-1]$. The latter fixes both interior boundary values, and cannot eliminate a nonzero traversal between them: the identity on a positive three-edge interval already demonstrates the problem. On the prefix $[0, n-1]$, induction instead leaves its first edge active and its remaining edges constant, while the final edge is unchanged. The following use of $[1, n]$ then moves the tail activity to the second edge when the first run has length at least two. With these corrections the stated reductions have their intended meaning. The run-by-run contraction above gives a full alternative proof of their connectedness conclusion.

Commentary · Later developments [ms. 93]

The path model and simplicial localization

The interval lemma makes changes of parameter homotopically harmless in a precise local sense. It is natural to compare the resulting path constructions with Dwyer–Kan localization, but the categories being compared must first be specified. In the present text, $\underline{\mathrm{Ch}}_{\Sigma,\tau}(X; a, b)$ is full on the diagrams whose backward edges lie in Σ; its interior vertical transformations are arbitrary arrows of X. In the hammock construction, the vertical arrows are required to lie in the chosen weak-equivalence subcategory as well. These prescriptions agree when $\Sigma = \mathrm{Fl}(X)$, and can differ for a proper subcategory of denominators.

Dwyer and Kan (1980a, Definition 2.1, Proposition 2.2 and Proposition 3.1) construct the hammock mapping simplicial sets, compare them with simplicial localization, and identify their components with ordinary localization. Their definition also permits strict composition by concatenation followed by reduction. This gives a useful historical comparison: their work appeared in 1980, before these notes of 1990. It supplies an established construction retaining homotopical information about fractions, but its comparison theorem does not identify the nerve of the particular full path category in this manuscript without an additional argument.

Here the elementary result is already valuable on its own. It says that a category of allowed parameter maps carries a contraction whenever it has an object. The next section transports natural transformations between such maps through precomposition on path diagrams. That step explains why Grothendieck needed the homotopies to remain inside the increasing endpoint-preserving category, rather than merely to exist between maps of the underlying realizations.

9 Théorème d'homotopie pour les catégories de chemins

Soient X une catégorie, $\Sigma \subseteq \mathrm{Fl}(X)$ `[un]` ensemble admissible de flèches dans X, $a, b \in \mathrm{Ob}\, X$. Considérons pour $\tau \in \mathrm{Ty}$ variable, les catégories

$$\underline{\mathrm{Ch}}_{\Sigma,\tau}(X), \qquad \underline{\mathrm{Ch}}_{\Sigma,\tau}(X; a, b),$$

qui forment les fibres des catégories Cat-fibrées

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{\Sigma}(X) & \xleftarrow{\text{incl.}} & \underline{\mathrm{Ch}}_{\Sigma}(X; a, b) \\ & \searrow \quad \swarrow & \\ & \underline{\mathrm{Ty}} & \end{array}$$

sur la catégorie $\underline{\mathrm{Ty}}$. Ainsi, pour $\tau, \tau' \in \mathrm{Ty}$, et pour toute

$$\varphi : \tau \longrightarrow \tau',$$

on a un carré commutatif d'homomorphismes

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X) & \xleftarrow{\text{incl.}} & \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X; a, b) \\ {\scriptstyle \varphi_X^*}\downarrow & & \downarrow{\scriptstyle \varphi_{a,b}^*} \\ \underline{\mathrm{Ch}}_{\Sigma,\tau}(X) & \xleftarrow{\text{incl.}} & \underline{\mathrm{Ch}}_{\Sigma,\tau}(X; a, b), \end{array}$$

avec transitivité pour φ variable (composition $\psi \circ \varphi$ de flèches dans $\underline{\mathrm{Ty}}$).

En fait, pour φ variable dans $\underline{\mathrm{Hom}}(\tau, \tau')$, les foncteurs images inverses φ_X^*, $\varphi_{a,b}^*$ dépendent *fonctoriellement* de φ; i.e. on a des *foncteurs*

$$(*) \qquad \underline{\mathrm{Hom}}(\tau, \tau') \longrightarrow \begin{cases} \underline{\mathrm{Hom}}(\underline{\mathrm{Ch}}_{\Sigma,\tau'}(X), \underline{\mathrm{Ch}}_{\Sigma,\tau}(X)) \\ \underline{\mathrm{Hom}}(\underline{\mathrm{Ch}}_{\Sigma,\tau'}(X; a, b), \underline{\mathrm{Ch}}_{\Sigma,\tau}(X; a, b)) \end{cases}$$

p. 61

Commentary · Exposition [ms. 94]

[page 95]

Why a homotopy of types acts on every path

Grothendieck now uses the interval calculation to remove a choice from the theory: the operation induced on paths should depend on the source and target types, rather than on the particular subdivision or collapse chosen between them. The relevant assertion concerns natural transformations, not merely the induced maps of connected components. This stronger form is what will allow a diagram of categories to descend to a diagram in Cat hot.

Write $P_\tau = \underline{\mathrm{Ch}}_{\Sigma,\tau}(X)$ and let $\mathcal{T}(\tau,\tau')$ be the category of endpoint-preserving type maps used in the preceding section. If $\eta : \varphi \Rightarrow \psi$ is a morphism of this category and $F : I_{\tau'} \to X$ is a permitted path, the transformation

$$F\eta : F\varphi \Longrightarrow F\psi$$

is a morphism in P_τ. Indeed, both its objects are permitted paths because φ and ψ carry backward arrows to backward arrows or identities. The fibre P_τ is the *full* subcategory of the functor category on these objects: the components of $F\eta$ need not belong to Σ. Naturality in F is precisely the interchange law for natural transformations. Thus whiskering gives a functor

$$\mathcal{T}(\tau,\tau') \longrightarrow \underline{\mathrm{Hom}}(P_{\tau'}, P_\tau), \qquad \varphi \longmapsto \varphi^*.$$

This is the elementary two-dimensional mechanism behind the theorem.

The endpoint condition does a second piece of work. For a transformation of type maps its two endpoint components are identities, so $(F\eta)_0 = \mathrm{id}_{F(0)}$ and $(F\eta)_1 = \mathrm{id}_{F(1)}$. The displayed functor therefore lands in the category of functors and vertical transformations over $X \times X$. Restriction to the strict fibre at (a,b) consequently preserves the entire homotopy. An arbitrary homotopy of functors over an unspecified base would not have this property. The words "au dessus de X" on manuscript page 97 should here be understood as "over $X \times X$", as the following diagram makes explicit.

Finally, connectedness of $\mathcal{T}(\tau,\tau')$, proved by the interval homotopy lemma, supplies a finite zigzag from φ to ψ. Applying the whiskering functor supplies the required finite zigzag of natural transformations. Taking nerves turns each transformation into a simplicial homotopy. No assertion that the individual pullback functors are equivalences is made: the theorem compares parallel operations, and this is exactly what the next construction needs.

Cela provient de l'inclusion

$$\underline{\mathrm{Hom}}(\tau,\tau') \hookrightarrow \underline{\mathrm{Hom}}^{\varepsilon}(I_\tau, I_{\tau'})$$

et de la description des catégories $\underline{\mathrm{Ch}}_\tau$, $\underline{\mathrm{Ch}}_{\tau'}$ comme catégories de foncteurs, telle

$$\underline{\mathrm{Ch}}_{\Sigma,\tau}(X) \simeq \underline{\mathrm{Hom}}_{\Sigma_\tau,\Sigma}(I_\tau, X),$$

où Σ_τ désigne l'ensemble des flèches dans I_τ qui sont soit inversibles, soit *rétrogrades.* (Cet ensemble de flèches est admissible, car stable par composition.) On désigne par $\underline{\mathrm{Hom}}_{\Sigma_\tau,\Sigma}$ la sous-catégorie pleine de $\underline{\mathrm{Hom}}$ formée des foncteurs qui appliquent Σ_τ dans Σ. Or de façon générale, si

$$(I,\Sigma_I), \quad (I',\Sigma_{I'}), \quad (X,\Sigma)$$

sont trois catégories, munies d'ensembles admissibles de flèches, considérant les foncteurs $\varphi : I \longrightarrow I'$ avec $\varphi(\Sigma_I) \subseteq \Sigma_{I'}$, alors le foncteur familier

$$\underline{\mathrm{Hom}}(I,I') \longrightarrow \underline{\mathrm{Hom}}(\underline{\mathrm{Hom}}(I',X), \underline{\mathrm{Hom}}(I,X))$$

(transposé du foncteur de composition

$$\begin{array}{ccccc} \underline{\mathrm{Hom}}(I,I') & \times & \underline{\mathrm{Hom}}(I',X) & \longrightarrow & \underline{\mathrm{Hom}}(I,X) \\ (\varphi & , & F') & \longmapsto & F'\circ\varphi \quad), \end{array}$$

se généralise en un foncteur

$$(*) \qquad \underline{\mathrm{Hom}}_{\Sigma_I,\Sigma_{I'}}(I,I') \longrightarrow \underline{\mathrm{Hom}}(\underline{\mathrm{Hom}}_{\Sigma_{I'},\Sigma}(I',X), \underline{\mathrm{Hom}}_{\Sigma_I,\Sigma}(I,X)),$$

transposé du foncteur de composition

$$\underline{\mathrm{Hom}}_{\Sigma_I,\Sigma_{I'}}(I,I') \times \underline{\mathrm{Hom}}_{\Sigma_{I'},\Sigma}(I',X) \longrightarrow \underline{\mathrm{Hom}}_{\Sigma_I,\Sigma}(I,X)$$

induit par $(*)$.

Comme toute

$$\varphi : \tau \longrightarrow \tau' \qquad \text{[page 96]}$$

induit

$$\varphi : I_\tau \longrightarrow I_{\tau'},$$

transformant flèches rétrogrades en flèches identiques ou rétrogrades, i.e.

$$\varphi(\Sigma_\tau) \subseteq \Sigma_{\tau'},$$

on trouve le premier des deux foncteurs $(*)$ annoncés page 94, qui est associé par transposition au foncteur γ p. 62

$$(*) \qquad \begin{array}{ccc} \underline{\mathrm{Hom}}(\tau,\tau') \times \underbrace{\underline{\mathrm{Ch}}_{\Sigma,\tau'}(X)}_{\simeq \underline{\mathrm{Hom}}_{\Sigma_{\tau'},\Sigma}(I_{\tau'},X)} & \xrightarrow{\quad\gamma\quad} & \underline{\mathrm{Ch}}_{\Sigma,\tau}(X) \\ {\scriptstyle \mathrm{can.}}\downarrow & & \| \\ \underline{\mathrm{Hom}}_{\Sigma_\tau,\Sigma_{\tau'}}(I_\tau,I_{\tau'}) \times \underline{\mathrm{Hom}}_{\Sigma_{\tau'},\Sigma}(I_{\tau'},X) & \xrightarrow{\quad\gamma_0\quad} & \underline{\mathrm{Hom}}_{\Sigma_\tau,\Sigma}(I_\tau,X) \end{array}$$

déduit du foncteur composition γ_0 dans ce diagramme : $\gamma = \gamma_0 \circ \mathrm{can}$. D'autre part, ce foncteur de composition γ induit visiblement un foncteur sur les sous-catégories de chemins à source et but fixés

$$\underline{\mathrm{Hom}}(\tau,\tau') \times \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X;a,b) \longrightarrow \underline{\mathrm{Ch}}_{\Sigma,\tau}(X;a,b),$$

d'où la deuxième des deux flèches annoncées dans $(*)$ p. 94.

Cela montre donc que si

$$\varphi_1, \varphi_2 : \tau \rightrightarrows \tau'$$

sont deux morphismes de τ dans τ' homotopes dans $\underline{\mathrm{Hom}}(\tau,\tau')$, alors les foncteurs induits entre catégories de Σ-chemins ou entre catégories de Σ-chemins à extrémités précisés :

$$\begin{array}{rrcl} \varphi_{1\,X}^*, \varphi_{2\,X}^* : & \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X) & \rightrightarrows & \underline{\mathrm{Ch}}_{\Sigma,\tau}(X), \\ (\varphi_1)_{a,b}^*, (\varphi_2)_{a,b}^* : & \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X;a,b) & \rightrightarrows & \underline{\mathrm{Ch}}_{\Sigma,\tau}(X;a,b) \end{array}$$

sont également homotopes. [page 97]

Or le lemme d'homotopie nous assure que l'hypothèse $\varphi_1 \sim \varphi_2$ est *toujours* satisfaite. Donc :

Théorème d'homotopie sur les opérations universelles sur les chemins. *Soient X, Σ, a, b comme dessus, et $\tau, \tau' \in \mathrm{Ty}$ telles que $\mathrm{Hom}(\tau,\tau') \neq \emptyset$. Alors les foncteurs φ_X^*, $\varphi_{X;a,b}^*$ induits par un $\varphi \in \mathrm{Hom}(\tau,\tau')$*

$$\begin{cases} \varphi_X^* : & \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X) & \longrightarrow & \underline{\mathrm{Ch}}_{\Sigma,\tau}(X) \\ \varphi_{X;a,b}^* : & \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X;a,b) & \longrightarrow & \underline{\mathrm{Ch}}_{\Sigma,\tau}(X;a,b) \end{cases}$$

ne dépendent pas de φ, à homotopie près.

On peut préciser cet énoncé, de telle façon que l'énoncé pour les $\varphi_{X;a,b}^*$ apparaisse, comme il devrait, comme corollaire pour celui sur φ_X^*. Pour ceci, on va regarder les catégories de chemins dans X comme catégories *au dessus de X,* par les foncteurs 'source et but' :

$$\begin{array}{ccc} \underline{\mathrm{Ch}}_{\Sigma,\tau}(X) & & \underline{\mathrm{Ch}}_{\Sigma,\tau'}(X) \\ & {\scriptstyle (\sigma_\tau,\beta_\tau)} \searrow \quad \swarrow {\scriptstyle (\sigma_{\tau'},\beta_{\tau'})} & \\ & X \times X & \end{array}$$

Alors le foncteur $(*)$ (p. 94) se factorise par la sous-catégorie $\underline{\mathrm{Hom}}_{\mathrm{Cat}/X\times X}(\cdot,\cdot)$ de $\underline{\mathrm{Hom}}_{\mathrm{Cat}}(\cdot,\cdot)$ formée des foncteurs qui commutent aux foncteurs de projection dans $X \times X$, et les homomorphismes entre tels foncteurs qui s'effectuent par des flèches 'verticales' de la catégorie but (i.e. par des flèches au dessus de flèches identiques de la catégorie base $X \times X$) : p. 63 [page 98]

$$\underline{\mathrm{Hom}}(\tau,\tau') \longrightarrow \underline{\mathrm{Hom}}_{\mathrm{Cat}/X\times X}(\underline{\mathrm{Ch}}_{\Sigma,\tau'}(X), \underline{\mathrm{Ch}}_{\Sigma,\tau}(X)).$$

Donc dans l'énoncé du théorème d'homotopie, on peut préciser que l'homotopie se fait dans cette sous-catégorie, i.e. s'effectue par une suite d'homotopies simples qui sont des morphismes de foncteurs entre catégories au dessus de $X \times X$. Cela implique alors l'énoncé d'homotopie sur les $\varphi^*_{X;a,b}$.

p. 64

10 Question de comparaison pour les catégories Cat-fibrées satisfaisant au 'théorème d'homotopie' (base filtrante) [page 99]

Nous allons généraliser maintenant au cas d'une catégorie (Cat)-fibrée sur une autre

$$\begin{array}{c} C \\ {\scriptstyle\pi}\big\downarrow \\ T, \end{array}$$

en pensant surtout au cas $T = \underline{\mathrm{Ty}}$, $C = \underline{\mathrm{Ch}}_{\Sigma}(X; a, b)$. L'hypothèse essentielle est la suivante :

(Hypothèse d'homotopie) Si $t, t' \in \mathrm{Ob}\, T$ sont tels que $\mathrm{Hom}(t,t') \neq \emptyset$, alors les foncteurs $\varphi^* : C_{t'} \longrightarrow C_t$ associés aux $\varphi \in \mathrm{Hom}(t,t')$ sont homotopes.

Ils définissent donc une seule et même flèche dans Cat hot. Je désigne par T_{ord} ou T_{o} l'ensemble $\mathrm{Ob}\,(T)$, avec comme relation d'ordre celle déduite de la structure de catégorie :

$$t \leq t' \qquad \Longleftrightarrow \qquad \mathrm{Hom}_T(t,t') \neq \emptyset,$$

de sorte qu'on a un foncteur

$$T \longrightarrow T_{\mathrm{o}}$$

qui est *universel* pour les foncteurs de T dans des catégories 'ordonnées' (i.e. où toute flèche est monomorphique [non, cf. • ⇉ •; plutôt, où toujours $\#\mathrm{Hom}(a,b) \leq 1$ (admettant des isomorphismes non identiques)]) ou pour les foncteurs F sur T tels que F soit constant sur tout $\mathrm{Hom}(t,t')$. L'hypothèse d'homotopie peut s'exprimer en disant que le foncteur composé

$$T^o \longrightarrow \mathrm{Cat} \longrightarrow \mathrm{Cat\,hot}$$

$$t \longmapsto C_t$$

se factorise (évidemment de façon unique) en un foncteur

$$H_C : T_{\mathrm{o}}^o \longrightarrow \mathrm{Cat\,hot},$$

[page 100]

i.e. qu'on a un diagramme commutatif

p. 65

$$\begin{array}{ccc} T^o & \xrightarrow{t \longmapsto C_t} & \mathrm{Cat} \\ \big\downarrow & & \big\downarrow \\ T_{\mathrm{o}}^o & \xrightarrow{H_C} & \mathrm{Cat\,hot}. \end{array}$$

Commentary · Exposition [ms. 99]

The preorder remembers existence, not multiplicity

Grothendieck's purpose is to retain the common value of all operations between two fibres while discarding their multiplicity. Let $q : T \to P$ be the identity on objects, with

$$P(t,t') = \begin{cases} \{*\}, & T(t,t') \neq \varnothing, \\ \varnothing, & T(t,t') = \varnothing. \end{cases}$$

The category P is a preorder; distinct objects may be mutually comparable. Its universal property is among thin categories, whose hom-sets have at most one element. Having every arrow monic is a different condition: the category with two parallel arrows already separates the two notions, as the editors' correction observes.

Let $F : T^{\mathrm{op}} \to \mathrm{Cat}$ describe the fibration. In this discussion

$$\mathrm{Cat\,hot}(A,B) = \pi_0 \underline{\mathrm{Hom}}(A,B)$$

means functors modulo finite zigzags of natural transformations. It is not the localization Hot of categories at weak equivalences of nerves. Natural transformations become equalities in Cat hot, and hence also in Hot, but not every weak equivalence of nerves has a functorial homotopy inverse. The distinction matters throughout the comparison problem.

The homotopy hypothesis says exactly that the composite of F with $\mathrm{Cat} \to \mathrm{Cat\,hot}$ factors through P^{op}. If P is nonempty and any two objects have a common lower bound, P^{op} is filtered and the resulting diagram defines an ind-object H_C. Here nonemptiness is part of the usual convention for "filtrant". The displayed pairwise condition in the manuscript must be read with that convention; otherwise the empty base would satisfy it vacuously and would have no cofinal sequence of the proposed form.

One must keep this modest hypothesis distinct from T being cofiltered. A cofiltered category must also admit a common precomposition equalizing any pair of parallel arrows. Nothing of that kind is assumed here. The usual definition and its role in finite-limit arguments are recorded in The Stacks Project Authors (2026i, Categories, Definition 4.19.1 and Lemma 4.19.2). For $\underline{\mathrm{Ty}}$, concatenation supplies common lower bounds because either factor can be collapsed to the empty type. It does not identify the different ways to perform a collapse. The homotopy theorem, rather than strict equalization, is what allows those different ways to be forgotten in H_C.

Nous allons supposer de plus :

(Hypothèse de filtration) L'ensemble ordonné T_{o} associé à T est *filtrant* décroissant (filtrant à gauche), i.e. si $t, t' \in \mathrm{Ob}\, T$, il existe $t'' \in \mathrm{Ob}\, T$ et des flèches $t'' \longrightarrow t$, $t'' \longrightarrow t'$.

Cette hypothèse est bien satisfaite dans $\underline{\mathrm{Ty}}$, car pour $\tau, \tau' \in \mathrm{Ob}\, \underline{\mathrm{Ty}} = \mathrm{Ty}$, il suffit de prendre $\tau\tau'$, qui s'envoie dans τ par $\mathrm{id}_\tau * p_{\tau'}$, dans τ' par $p_\tau * \mathrm{id}_{\tau'}$, où $p_\tau : \tau \longrightarrow 1$ est le morphisme de τ dans l'objet final.

Ainsi, H_C définit un ind-objet de Cat hot, que nous allons désigner par $\underline{\underline{C}}$. Si on suppose de plus :

(Hypothèse de dénombrabilité, toujours satisfaite si $\mathrm{card}\, T_{\mathrm{o}} \leq \aleph_0$) T_{o} admet un sous-ensemble *dénombrable* cofinal à gauche.

alors cet ind-objet de Cat hot peut être défini, de beaucoup de façons, en termes d'un système inductif dans Cat (pas seulement dans Cat hot) [page 101]

$$(C_n)_{n \in \mathbf{N}},$$

d'où on récupère l'ind-objet $\underline{\underline{C}}$ dans Cat hot en passant au système inductif correspondant dans Cat hot, puis à l'ind-objet associé.

Pour construire le système inductif C_n, il suffit de prendre une chaîne infinie

$$t_0 \longleftarrow t_1 \longleftarrow t_2 \longleftarrow \cdots \longleftarrow t_n \longleftarrow t_{n+1} \longleftarrow \cdots$$

de morphismes dans T, telle que l'ensemble des t_i soit cofinal à gauche dans T_o. On va supposer de plus C *strictement fibrée* sur T (i.e. provenant d'un véritable foncteur $T^o \longrightarrow$ Cat, i.e. on peut choisir les foncteurs images inverses

$$\varphi^* : C_{t'} \longrightarrow C_t$$

de façon transitive stricte, pas seulement transitive à isomorphisme près) - cas auquel on peut toujours se ramener d'ailleurs par l'astuce de Giraud. Cette hypothèse est d'ailleurs vérifiée dans le cas $\underline{\mathrm{Ch}}_{\Sigma}(X; a, b)$ sur $\underline{\mathrm{Ty}}$. Ainsi, les

$$(C_{t_i})_{i\in\mathbf{N}}$$

forment un système inductif de catégories indexées par $\mathbf{N}$, le morphisme de transition

$$C_n \longrightarrow C_{n'} \qquad \text{i.e. } C_{t_n} \longrightarrow C_{t_{n'}}$$

étant le foncteur image inverse $\varphi^*_{n,n'}$, où p. 66

$$\varphi_{n,n'} : t_{n'} \longrightarrow t_n \qquad \text{[page 102]}$$

est le composé des $t_{n'} \longrightarrow t_{n'-1} \longrightarrow \cdots \longrightarrow t_n$. (Si on n'avait pas transitivité stricte, on définirait $\varphi^*_{n,n'}$ comme le composé des foncteurs image inverse par des flèches de transition successives $t_{n'} \longrightarrow t_{n'-1} \longrightarrow \cdots \longrightarrow t_{n+1} \longrightarrow t_n$, ce ne serait $\varphi^*_{n,n'}$ qu'à isomorphisme canonique près.)

Commentary · Context [ms. 101]

Making a sequence strict

Grothendieck wants an actual category as a sequential colimit, so he temporarily makes the reindexing functors strictly composable. This is a familiar issue from the theory of fibred categories: a cleavage supplies canonical comparison isomorphisms, whereas a splitting makes those comparisons identities. The distinction is already developed in Grothendieck (1971b, Exposé VI, §§8–9). The replacement invoked here is an equivalence of fibred categories; it is not a claim that a chosen cleavage on the original total category can always be made split without changing that category.

There is a concrete construction behind the reference to Giraud. For $t \in T$, let $\widetilde{F}(t)$ be the category of cartesian functors $T/t \to C$ over T, with vertical natural transformations. Precomposition along $T/s \to T/t$, induced by $s \to t$, is strictly associative. Evaluation at the terminal object id_t gives an equivalence $\widetilde{F}(t) \simeq C_t$: a cartesian functor is reconstructed from its value there by cartesian lifts, and any morphism between those values extends uniquely to a vertical transformation. Thus $\widetilde{F}$ is a strict replacement of the original pseudofunctor. The right splitting and its equivalence property are treated explicitly in Emmenegger et al. (2024, Theorem 5.4 and Remark 5.5); this gives a precise modern reference for the "astuce de Giraud".

Countability has a different role. Enumerate a cofinal family $s_0, s_1, \ldots$ in P. Choose t_0 below s_0, then choose t_{n+1} below both t_n and s_{n+1}, together with an arrow $t_{n+1} \to t_n$. The resulting chain is cofinal in the preorder. Pullback produces

$$C_{t_0} \longrightarrow C_{t_1} \longrightarrow C_{t_2} \longrightarrow \cdots .$$

Even without replacing the entire fibration, this particular sequence can be made strict simply by defining its long transition maps as composites of its adjacent ones. There are no competing paths in the freely generated chain to compare. The arrow $C_{t_n} \to C_{t_{n-1}}$ printed on manuscript page 102 runs in the wrong direction; the intended transition is $C_{t_{n-1}} \to C_{t_n}$.

Soit

$$C_\infty = \varinjlim_n C_n = \varinjlim_n C_{t_n}$$

la catégorie $\varinjlim$. (Elle sera surtout sympathique si on a pu choisir le système $(t_n)_{n\in\mathbf{N}}$ de telle façon que les foncteurs de transition

$$C_{t_n} \longrightarrow C_{t_{n-1}}$$

soient pleinement fidèles, et peut-être même [des] monomorphismes, de telle façon que les C_n s'identifient à des sous-catégories pleines de leur limite inductive C_∞.) Je voudrais comprendre les relations précises entre les trois genres d'objets suivants :

ⓐ C elle-même (comme objet dans Cat, pas de Cat/T), et surtout les objets de Cat hot et de Hot qui lui correspondent.

ⓑ C_∞, et les objets de Cat hot et de Hot qui lui correspondent. Dans quelle mesure ces deniers sont-ils indépendant du choix du système projectif cofinal à gauche $(t_n)_{n\in\mathbf{N}}$ dans T? Quel est le rôle de C_∞? Est-elle canoniquement isomorphe à C dans Cat hot, ou dans Hot? (Auquel cas la question de son 'rôle' me semblerait résolue!) [page 103]

ⓒ Le ind-objet H_C dans Cat hot, et l'ind-objet de Hot qu'il définit.

Je note que l'ind-objet H_C, et aussi les catégories C_∞ construites comme dessus, ne changent pas quand on remplace T par une sous-catégorie T' cofinale à gauche, ou aussi par une catégorie de la forme T/t_0 ($t_0 \in \mathrm{Ob}\, T$), qui donne lieu à l'ensemble ordonnée associé

$$(T/t)_\mathrm{o} = T_\mathrm{o}/t = \{t \in T_\mathrm{o} \mid t \leq t_0\}$$

[plutôt $(T/t_0)_\mathrm{o} = T_\mathrm{o}/t_0 = \{t \in T_\mathrm{o} \mid t \leq t_0\}$]. Si la relation entre les objets dans a), et ceux dans b) et dans c), est très étroite, on en concluerait que le 'type' de C dans Cat hot, ou dans Hot suivant le cas, ne change pas en remplaçant C par $C \times_T T'$ ou par $C/t_0 \simeq C \times_T T/t_0$. Bien mieux, elle ne changerait pas en remplaçant T par $(\mathbf{N})^o$, la catégorie (ordonnée) opposée à $\mathbf{N}$ (ayant donc un unique objet final), et la catégorie fibrée C sur T par la catégorie $C_{\underline{t}}$ induite par C sur $(\mathbf{N})^o$, via le foncteur p. 67 [page 104]

$$\underline{t} : (\mathbf{N})^o \longrightarrow T$$

défini par le système projectif $\underline{t} = (t_n)_{n\in\mathbf{N}}$ dans T. Cela signifierait donc que pour comprendre le type homotopique (au sens strict, i.e. dans Cat hot, ou large, i.e. dans Hot) de C, on peut le 'nettoyer' de façon draconienne, la base T étant vue comme une sorte de gangue un peu vaseuse, ou du moins pléthorique.

Commentary · Development (commentators') [ms. 103]

A slice does not have the same preorder

Grothendieck proposes restricting the construction to types below a chosen type. This is sound for a lower ideal of the preorder, but a slice category retains the actual arrow to the chosen object. The equality of preorders printed here therefore needs a correction that affects the proposed argument.

A slice obstruction. [ours] There is a finite category T whose associated preorder is cofiltered, while the associated preorder of T/t_0 is not cofiltered.

Proof. Take two objects s, t_0, their identities, and exactly two further arrows $f, g : s \rightrightarrows t_0$. The preorder P has $s < t_0$, so s is a lower bound for every pair. The slice T/t_0 has three objects

$$(s, f), \qquad (s, g), \qquad (t_0, \mathrm{id}_{t_0}),$$

with one arrow from each of the first two objects to the last. An arrow between the first two would have to be id_s and would force $f = g$. There is no fourth object that could map to both. Its preorder is consequently not cofiltered, although the lower ideal $P/t_0 = P$ is. This proves the assertion. □

The example also prevents interpreting the displayed equality as an equivalence after removing duplicate isomorphic objects: the two incomparable objects remain distinct in the skeletal

preorder. It does not dispute the connectedness of the slice, which has a terminal object, nor the separate construction of H_C over P^{op}.
