Démonstration de la proposition. Elle se fait par la suite d'implications suivante, toutes (±) tautologiques :

$$(c') \implies (c) \implies (a) \implies (b) \implies (d) \implies (c')\,,$$

dont les quatre premières utilisent seulement l'hypothèse $\Phi \longleftrightarrow \Psi$ (de (a) de la définition [page 30]

9. **N.B.** On utilise seulement que $\Phi \longleftrightarrow \Psi$, et que j peut se mettre sous la forme pi, avec $i \in \Phi$, $p \in \Psi$.

4.1), et la dernière seulement, $(d) \Longrightarrow (c')$, fait appel à l'hypothèse de factorisation de Quillen ((b) dans 4.1) ; et encore il suffit de la supposer pour j seulement !

$(c') \Longrightarrow (c)$ tautologie pure, $(c) \Longrightarrow (a)$ car on sait que $\widetilde{\Phi}$ est stable par facteurs directs (et contient Φ), $(a) \Longrightarrow (b)$ car $\widetilde{\Phi} \subset \Psi^*$ ($\widetilde{\Phi}$ étant par définition la plus petite partie close à gauche de $\mathrm{Fl}(\mathcal{M})$ contenant Φ, et Ψ^* étant close à gauche), $(b) \Longrightarrow (d)$ car on écrit le diagramme donné (4.2.2) (traits pleins) comme

$(*)$

$$\begin{array}{ccc} A & \xrightarrow{u} & X \\ {\scriptstyle j\in\Psi^*}\downarrow & \overset{q}{\nearrow} & \downarrow{\scriptstyle p\in\Psi} \\ B & \xrightarrow{v} & Y\,, \end{array}$$

en y faisant $Y = B$, $v = \mathrm{id}_B$, et en rebaptisant X par B', et u par i : l'hypothèse (b), $j \in \Psi^*$, signifie que dans un diagramme traits pleins $(*)$, il existe toujours q telle que $qj = u$, $pq = v$, et en l'exprimant dans le cas particulier où $v = \mathrm{id}_B$, on trouve (d).

Reste à prouver $(d) \Longrightarrow (c')$, en utilisant cette fois l'hypothèse de factorisation sur j, *i.e.* qu'on peut écrire j sous la forme pi :

$$\begin{array}{ccc} A & \xrightarrow{j} & B \\ & {\scriptstyle i}\searrow \quad \overset{p}{\nearrow} & \\ & B' \quad \overset{q}{\leftarrow} & \end{array}\,,$$

avec $i \in \Phi$, $p \in \Psi$. En vertu de (d), comme $p \in \Psi$, il existe donc $q : B \longrightarrow B'$ satisfaisant

p. 21
[page 31]

$$pq \;=\; \mathrm{id}_B\,, \qquad qj \;=\; i\,,$$

ce qui prouve (c'), puisque $i \in \Phi$.

Commentary · Exposition [ms. 30]

The retraction which completes both classes

The role of Proposition 4.2 is to identify exactly what can be missing from a précouple. Suppose $j : A \to B$ lifts against R, and choose a factorization $j = pi$ with $i : A \to Z$ in L and $p : Z \to B$ in R. Apply the lifting property to

$$\begin{array}{ccc} A & \xrightarrow{i} & Z \\ {\scriptstyle j}\downarrow & \overset{q}{\nearrow} & \downarrow{\scriptstyle p} \\ B & \xrightarrow[\mathrm{id}_B]{} & B. \end{array}$$

The equations are $qj = i$ and $pq = \mathrm{id}_B$. Hence $(\mathrm{id}_A, q) : j \to i$ and $(\mathrm{id}_A, p) : i \to j$ exhibit j as a retract of i. Conversely, a lifting property passes to retracts: extend a proposed lifting square along the section, solve it for the larger arrow, and compose the resulting filler with the retraction. These two observations prove

$$^{\square}R = \mathrm{Retr}(L), \qquad L^{\square} = \mathrm{Retr}(R)$$

whenever (L, R) is a précouple. The dual assertion uses a factorization with target fixed.

This proof requires a factorization only of the particular arrow j under consideration, as footnote 9 correctly emphasizes. There is no induction hidden in the argument and no completeness hypothesis on the category. Once all arrows have factorizations, closing the two classes under retracts therefore produces a weak factorization system without changing any chosen factorization. This is the precise content of the two corollaries on manuscript page 31.

It also explains a useful economy in model-category arguments. One first constructs maps in classes with convenient explicit descriptions, such as relative cell complexes. One then enlarges those classes by retracts. The enlargement does not require repeating the construction: lifting supplies the necessary retraction. The enlargement is nevertheless real, and omitting it from a recognition statement can change that statement's truth value.

Corollaire 1. *Soit* (Φ, Ψ) *un précouple de Quillen. Alors on a*

$$\widetilde{\Phi} \;=\; \Psi^* \;=\; \text{ensemble des objets de } \underline{\mathrm{Fl}}(\mathcal{M}) \text{ qui sont facteurs directs d'éléments de } \Phi\ , \tag{4.3}$$

et dualement

$$\overline{\Psi} \;=\; \Phi_* \;=\; \text{ensemble des objets de } \underline{\mathrm{Fl}}(\mathcal{M}) \text{ qui sont facteurs directs d'éléments de } \Psi\ . \tag{4.4}$$

Corollaire 2. *Les conditions suivantes sur le précouple de Quillen* (Φ, Ψ) *sont équivalentes.*

a) *Le précouple est* clos, i.e. $\Phi = \widetilde{\Phi}$, $\Psi = \overline{\Psi}$.

b) $\Phi = \Psi^*$, $\Psi = \Phi_*$.

c) Φ *et* Ψ *sont stables par facteurs directs.*

Soit maintenant

$$W \;\subset\; \mathrm{Fl}(\mathcal{M}) \tag{4.5}$$

un localiseur, satisfaisant les conditions habituelles

$$\begin{cases} a) & W \text{ contient les isomorphismes.} \\ b) & \text{Si } X \xrightarrow{f} Y \xrightarrow{g} Z \text{ dans } \mathcal{M}, \text{ si deux parmi } f,\ g,\ gf \text{ sont dans } W, \text{ alors le troisième aussi.} \end{cases} \tag{4.6}$$

(W modérément saturé). Supposons de plus données quatre autres parties

$$C\ ,\ TC\ , \qquad F\ ,\ TF \tag{4.7}$$

de $\mathrm{Fl}(\mathcal{M})$, satisfaisant les conditions suivantes.

$$\begin{cases} a) & (C, TF) \text{ et } (TC, F) \text{ sont des précouples de Quillen.} \\ b) & TC \subset C \cap W,\ TF \subset F \cap W. \end{cases} \tag{4.8}$$

Ces propriétés s'explicitent ainsi : [page 32]

M 1 Propriétés de relèvement-prolongement, $C \longleftrightarrow TF$ et $TC \longleftrightarrow F$.

M 2 Propriété de factorisation de toute flèche f de $\mathcal{M}$ en $f = pi$, avec, au choix, $i \in C$, $p \in TF$, ou $i \in TC$, $p \in F$.

M′ $TC \subset C \cap W$, $TF \subset F \cap W$.

C'est donc une partie des axiomes d'une structure de Quillen faible pour W (XIII, p. 27, déf. 1) – il manque les axiomes de stabilité M 3, M 4, et les axiomes de "propreté" (propriety) M″, savoir $F \subset \mathrm{Fib}_W$, $C \subset \mathrm{Cof}_W$. p. 22

Proposition 4.3. *Soient* $\mathcal{M}$ *une catégorie,* (C, TF) *et* (TC, F) *deux précouples de Quillen dans* $\mathcal{M}$*, satisfaisant*

$$TC \;\subset\; C\ , \qquad TF \;\subset\; F\ , \tag{4.3.1}$$

et soit W *une partie de* $\mathrm{Fl}(\mathcal{M})$ *dont on ne suppose pour l'instant que* 4.6, (b) [10]*, et*

$$W \;\supset\; TC\ ,\ TF\ , \tag{4.3.2}$$

10. On utilise seulement que si $X \xrightarrow{f} Y \xrightarrow{g} Z$, et si $gf \in W$, alors $f \in W \iff g \in W$. On n'a pas besoin que W contienne les isomorphismes, ni qu'il soit stable par composition.

donc on a

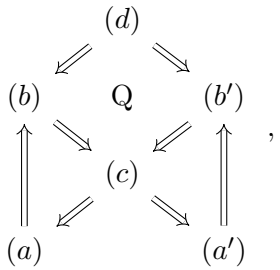
$$TC \subset C \cap W , \qquad TF \subset F \cap W . \tag{4.3.3}$$

Considérons les conditions de prolongement-relèvement suivantes (a), (a′)*, et les conditions de factorisation* (b), (b′), (c), (d) (*en se rappelant que* $\widetilde{TC} = F^*$, $\overline{TF} = C_*$*, en vertu de la proposition* 4.2 (*cor.* 1) *appliquée aux précouples de Quillen* (TC, F), (C, TF)) :

a) $C \cap W \subset \widetilde{TC}$ (*donc* $TC \subset C \cap W \subset \widetilde{TC}$).

a′) $F \cap W \subset \overline{TF}$ (*donc* $TF \subset F \cap W \subset \overline{TF}$).

b) $W \subset TF \circ \widetilde{TC}$.



b′) $W \subset \overline{TF} \circ TC$.

c) $W \subset \overline{TF} \circ \widetilde{TC}$.

d) $W \subset TF \circ TC$ (*donc, par* (4.3.2), $W = TF \circ TC$ *si* W *est stable par composition*). [11]

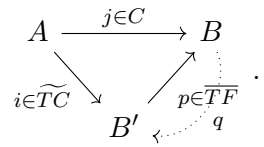
Alors toutes les conditions sauf la dernière sont équivalentes (*et elles sont donc impliquées par cette dernière*)*. Donc lorsque* TC *ou* TF *sont stables par facteurs directs* (*p. ex. si* TC *est clos à gauche, ou* TF *clos à droite*)*, toutes les conditions envisagées sont équivalentes* (*puisque par le corollaire* 2 *à la proposition* 4.2*, on a alors* $TC = \widetilde{TC}$ *resp.* $TF = \overline{TF}$*, donc* (b′) *resp.* (b) *équivaut alors à* (d)). [page 33]

DÉMONSTRATION. Elle se fait par le diagramme d'implications

où les quatre implications du carré supérieur Q sont tautologiques. Il suffit donc d'établir les implications p. 23

$$(c) \implies (a) \implies (b) ,$$

les implications $(c) \Longrightarrow (a') \Longrightarrow (b')$ en résultent par dualité.



Supposons donc (c), *i.e.*

$$W \subset \overline{TF} \circ \widetilde{TC} , \tag{$*$}$$

et prouvons (a), *i.e.* que

$$C \cap W \subset \widetilde{TC} .$$

Mais si $j \in C \cap W$, pour prouver que $j \in \widetilde{TC}$, écrivons $j = pi$, $i \in \widetilde{TC}$, $p \in \overline{TF}$, ce qui est possible par l'hypothèse $(*)$ et $j \in W$.

[page 34]

Utilisons maintenant l'hypothèse $j \in C$ et $C \longleftrightarrow \overline{TF}$, on trouve donc (prop. 3.2, $(a) \Longrightarrow (d)$) une flèche $q : B \longrightarrow B'$ telle que $pq = \mathrm{id}_B$, $qj = i$, donc j apparaît comme facteur direct de i. Comme $i \in \widetilde{TC}$ et que $\widetilde{TC}$ est stable par facteurs directs, on en conclut $j \in \widetilde{TC}$, *q.e.d.*

11. **N.B.** La condition (a) signifie aussi que $(C \cap W, F)$ est encore un précouple de Quillen, resp. (b) signifie que $(C, F \cap W)$ en est un – et alors cette paire de précouples de Quillen satisfait cette fois à (d), *i.e.* $W = TF' \circ TC'$.

$(a) \Longrightarrow (b)$. On suppose donc

$$(*) \qquad C \cap W \ \subset \ \widetilde{TC} \ ,$$

et on veut prouver (b), *i.e.*

$$W \ \subset \ TF \circ \widetilde{TC} \ .$$

Soit donc $f \in W$, et factorisons f en pi, avec $i \in C$, $p \in TF$. (O.K. à cause du précouple de Quillen (C, TF)). Comme $TF \subset W$, on a $p \in W$, et comme $pi \in W$, on en conclut $i \in W$ (saturation modérée de W – on doit quand même l'utiliser !). On a donc $i \in C \cap W$, donc $i \in \widetilde{TC}$ par $(*)$, d'où $f \in TF \circ \widetilde{TC}$, *q.e.d.*

Corollaire 1. *Supposons TC stable par facteurs directs. Alors toutes les conditions de la proposition* 4.3 *sont équivalentes, et équivalent à la relation*

$$(4.3.4) \qquad C \cap W \ = \ TC \ .$$

Dualement, si TF est stable par facteurs directs, les conditions de la proposition 4.3 *sont toutes équivalentes et équivalent à*

$$(4.3.4') \qquad F \cap W \ = \ TF \ .$$

En effet, par le corollaire 2 de la proposition 4.2, l'hypothèse sur TC implique que $TC = \widetilde{TC}$, donc comme $TC \subset C \cap W$, l'hypothèse $C \cap W \subset \widetilde{TC}$ $(= TC)$ équivaut à $C \cap W = TC$.

p. 24
[page 35]

Commentary · Exposition [ms. 34]

Recognition by two compatible factorizations

Grothendieck wants to describe weak equivalences through their two possible factorizations. The names TC and TF are provisional at this stage: the assumptions only give $TC \subset C \cap W$ and $TF \subset F \cap W$. Proposition 4.3 measures what must be added before those inclusions become the desired equalities.

The proof has two different mechanisms. A factorization

$$j = pi, \qquad j \in C \cap W, \quad i \in \widetilde{TC}, \quad p \in \overline{TF}$$

exhibits j as a retract of i, because C lifts against $\overline{TF} = C_*$. This gives $C \cap W \subset \widetilde{TC}$ without using a property of W beyond membership of j in it. In the other direction, factor an arbitrary $w \in W$ using (C, TF). If $w = pi$, then $p \in TF \subset W$; cancellation in W forces $i \in C \cap W$. This is the sole use of the two-out-of-three axiom in that half of the argument. The dual proof exchanges the two factorizations.

Consequently, the equivalences among (a), (a′), (b), (b′), and (c) need only the restricted cancellation condition stated in footnote 10: whenever $gf \in W$, membership of f in W is equivalent to membership of g in W. A displayed equality $W = TF \circ TC$ additionally uses closure of W under composition for the reverse inclusion. The source itself makes this qualification beside (d). There is no need to strengthen the main proposition to a saturation condition involving localization.

The subsequent corollaries must be read with their respective closure hypotheses. If TC is retract closed, then $\widetilde{TC} = TC$, so the recognition condition becomes $C \cap W = TC$. The analogous statement for TF needs retract closure of TF. If C and W are retract closed, there is an even shorter proof of Corollary 2 than the printed one: $TC \subset C \cap W$ gives

$$\widetilde{TC} = \mathrm{Retr}(TC) \subset C \cap W,$$

and condition (a) supplies the reverse inclusion. The printed relation $C \cap W \longleftrightarrow TC$ in this proof is a slip. The lifting relation available here is $C \cap W \longleftrightarrow F$, and the relevant précouple is $(C \cap W, F)$.

Corollaire 2. *Supposons C et W stables par facteurs directs. Alors les conditions équivalentes de la proposition* 4.3 *équivalent à*

$$(4.3.5) \qquad C \cap W \ = \ \widetilde{TC} \ .$$

Dualement, si F, W sont stables par facteurs directs, les conditions équivalentes de la proposition 4.3 *équivalent à*

$$F \cap W \;=\; \overline{TF}\ . \tag{4.3.5$'$}$$

En effet, si C et W sont stables par facteurs directs, il en est de même de $C \cap W$, et dès lors si $C \cap W \subset \widetilde{TC}$, comme $C \cap W$ contient TC, on en conclut $\widetilde{C \cap W} = \widetilde{TC}$. Mais comme $C \cap W \longleftrightarrow TC$ et $C \cap W$ est stable par facteurs directs, $C \cap W$ est clos à gauche par corollaire 2 de la proposition 4.2, *i.e.* $C \cap W = \widetilde{C \cap W}$, d'où $C \cap W = \widetilde{TC}$, *q.e.d.*

Corollaire 3. *Supposons les conditions équivalentes* (a) *à* (c) *de* 4.3 *satisfaites, et de plus* W stable par facteurs directs[12]. *Alors les conditions préliminaires* (4.3.1) *et* (4.3.2) *restent satisfaites quand on remplace* (C, TF) *et* (TC, F) *par leurs clôtures* $(C', TF') = (\widetilde{C}, \overline{TF})$ *et* $(TC', F') = (\widetilde{TC}, \bar{F})$, *et les conditions équivalentes de la proposition* 4.3 *sont encore satisfaites pour ces couples, sous les formes fortes*

$$\begin{cases} C' \cap W \;=\; TC' & (= \widetilde{TC'}) \\ F' \cap W \;=\; TF' & (= \overline{TF'}) \\ \qquad W \;=\; TF' \circ TC'\ . \end{cases} \tag{4.3.6}$$

Le triple (W, C', F') *est un triple de Quillen clos* (*correspondant à une "closed model category" de Quillen, du moins si on suppose* $\mathcal{M}$ *stable par* $\varinjlim$ *finies et* $\varprojlim$ *finies, et que* W *est modérément saturé*).[13] [page 36]

Démonstration. Les relations (4.3.1) impliquent

$$\widetilde{TC} \;\subset\; \widetilde{C} \qquad \text{et} \qquad \overline{TF} \;\subset\; \bar{F}\ ,$$

i.e. p. 25

$$TC' \;\subset\; C'\ , \qquad TF' \;\subset\; F'\ ,$$

i.e. (4.3.1) pour les nouveaux couples de Quillen. La relation 4.3.2, $W \supset TC, TF$, implique

$$W \;\supset\; \widetilde{TC}\ ,\ \overline{TF}\ , \qquad \textit{i.e.} \qquad W \;\supset\; TC'\ ,\ TF'\ ,$$

en vertu du corollaire 2 à la proposition 4.2 et du fait que W est stable par facteurs directs ; donc on a (4.3.2) pour les nouveaux couples. Comme par hypothèse on a

$$W \;=\; \overline{TF} \circ \widetilde{TC}\ ,$$

ceci s'écrit

$$W \;=\; TF' \circ TC'\ ,$$

donc les nouveaux couples satisfont aux mêmes conditions, qui cette fois, les couples étant clos, prennent la forme forte (4.3.6).

---

12. En fait, il suffit de supposer que l'on a $W \supset \widetilde{TC}$, $\overline{TF}$, *i.e.* que tout facteur direct d'un élément de W qui est soit dans C, soit dans F, est encore dans W. Alors $(\widetilde{C}, \widetilde{TC}, \bar{F}, \overline{TF})$ définissent une structure de Quillen close, et on sait que cela implique qu'en fait, W lui aussi est stable par facteurs directs.

13. Il en résulte le

Corollaire 4. *Soient W un localiseur modérément saturé, et (C, TF), (TC, F) deux précouples de Quillen tels que $TC \subset C \cap W$, $TF \subset F \cap W$. Alors les conditions suivantes sont équivalentes.*

a) $TC = C \cap W$.

b) $TF = F \cap W$.

c) $W = TF \circ TC$.

d) (W, C, F) *est un triple de Quillen clos.*

Prouvons que le triple (W, C', F') satisfait aux axiomes de Quillen d'un triple de Quillen clos. On a bien, par (4.3.6),

$$\begin{cases} C' \;=\; (TF')^* \;=\; (F' \cap W)^* \;, & F' \;=\; (TC')_* \;=\; (C' \cap W)_* \;, \\ W \;=\; TF' \circ TC' \;=\; C'_* \circ F'^* \;, \end{cases}$$

qui correspond à la définition des catégories de modèles de Quillen *clos* : les axiomes M 1, M 2, M 3, M 4 de Quillen sont réalisés de façon triviale (M 3 et M 4 parce que C et F, TC et TF sont clos à gauche resp. à droite). L'axiome M 5 est la saturation modérée de W. [page 37]

Commentary · Development (commentators') [ms. 36]

The missing closure hypothesis in the footnote

Grothendieck's main closure result, Corollary 3, deliberately replaces the four provisional classes by their retract closures. Footnote 13 then proposes a shorter Corollary 4 in which that replacement disappears. As printed, its equivalence with a *closed* Quillen structure is false. The following example isolates the defect while retaining invariance of the classes under isomorphism; it is not an objection based merely on a choice of representatives.

A précouple whose two classes have not both been closed. [ours] In the category of sets, with choice, let W be all maps. Let L consist of the injections $i : A \hookrightarrow B$ for which $B \setminus i(A)$ is empty or infinite, and let R consist of all surjections. Set

$$C = TC = L, \qquad F = TF = R.$$

Then both required pairs are précouples, and conditions (a), (b), and (c) of the printed Corollary 4 hold, but (W, C, F) is not closed.

To verify the lifting condition, consider an injection $i : A \hookrightarrow B$ and a surjection $p : X \twoheadrightarrow Y$. A commutative square specifies the filler on $i(A)$; on each remaining element of B, choose an inverse image under p of its prescribed image in Y. This proves $L \longleftrightarrow R$. For factorization, take any $f : A \to B$ and form

$$A \;\longrightarrow\; A \amalg (B \times \mathbb{N}) \;\xrightarrow{[f, \mathrm{pr}_B]}\; B.$$

The first map has empty complement when $B = \varnothing$ and infinite complement otherwise; the second is surjective. Thus it is an (L, R)-factorization. Since W contains every map, the equalities $TC = C \cap W$ and $TF = F \cap W$ hold, and the factorization just given proves $W = TF \circ TC$.

On the other hand, $\varnothing \to \{0\}$ is a retract of $\varnothing \to \mathbb{N}$: use the inclusion selecting 0 and the unique map $\mathbb{N} \to \{0\}$. The larger map belongs to L, whereas the smaller one does not. Therefore L is not retract closed and cannot equal $^{\square}R$. This proves the failure of (d).

The appropriate repair of the footnote is to require the two input pairs to be *couples*, or equivalently to require all four classes to be retract closed. Proposition 4.3 then gives the equivalence of (a), (b), and (c), and the resulting two weak factorization systems give (d), subject to the required existence of limits and colimits. Another valid conclusion under the weaker hypotheses is the one actually stated in Corollary 3: take retract closures first. The general modern formulation, including automatic retract closure of W once the two weak factorization systems exist, is in Riehl (2014, Definition 11.3.1 and Lemma 11.3.3).

We checked those general criteria and the recognition theorems cited below. We did not find this particular isomorphism invariant example in those sources; the claim here is the explicit counterexample and its verification, not a claim of priority for the retract obstruction.

4.4. Voici l'idée pour construire plus ou moins "toutes" les structures de Quillen closes (C, TC, F, TF) associées à un localiseur donné $W \subset \mathcal{M}$. On suppose que $\mathcal{M}$ satisfait aux conditions du paragraphe précédent, concernant l'existence de $\varinjlim$ filtrantes, d'une filtration cardinale, l'accessibilité dans $\mathcal{M}$ (celle des éléments de Filt^{π_0}). On part d'une partie petite

$$C_0 \;\subset\; \mathrm{Fl}(\mathcal{M})$$

telle que

$$C_{0*} \;\subset\; W \;, \tag{4.4.1}$$

et on pose

$$(4.4.2)\qquad \begin{cases} C \;=\; \widetilde{C_0}\;, & TC \;=\; C\cap W\;,\\ TF \;=\; C_* \;=\; C_{0*}\;, & F \;=\; (TC)_*\;. \end{cases}$$

Il y a un problème seulement, vu que l'on sait déjà que (C, TF) est un couple de Quillen par le théorème de factorisation dans §1 (p. 10) : il faut la factorisation pour le couple $(TC, F \;=\; (TC)_*)$. À ce moment là, les conditions préliminaires (4.3.1), (4.3.2) de la proposition 4.3 sont satisfaites :

$$TC \;\subset C\;,\qquad TF \;\subset F\;,\qquad W \;\supset\; TC\;,\, TF\;,$$

ainsi que la condition (a), $C\cap W \;\subset\; \widetilde{TC}$, puisque $C\cap W \;=\; TC$. Donc on trouve, par l'équivalence des conditions (a), (a'), (c), et vu que TC et TF sont clos,

$$TF \;=\; F\cap W\;,\qquad W \;=\; TF\circ TC\;,$$

d'autre part l'hypothèse sur W implique que W est stable par facteurs directs, C l'est aussi, étant close à gauche, donc $TC = C\cap W$ aussi, donc par proposition 4.1, corollaire 2, on a $TC \;=\; \widetilde{TC}$, TC est close à gauche. On gagne donc, par la dernière assertion du corollaire 3, proposition 4.3 (p. 35). p. 26 [page 38]

En fait, indépendamment des conditions particulières sur $\mathcal{M}$, W, on vient de prouver ceci :

Lemme 4.4.1 (corollaire de la proposition 4.3.). *Soient $\mathcal{M}$ une catégorie, W un localiseur dans $\mathcal{M}$ modérément saturé et stable par facteurs directs. Alors les structures de Quillen closes (C, F) associées à W s'obtiennent ainsi : on prend une partie C_0 de* $\mathrm{Fl}(\mathcal{M})$ *telle que*

$$TF \;\overset{\text{déf}}{=}\; C_{0*} \;\subset\; W\;,$$

on pose

$$C \;=\; \widetilde{C_0} \;=\; TF^*\;,\qquad TC \;=\; C\cap W\;,\qquad F \;=\; (TC)_*\;,$$

et on doit se débrouiller pour que (C, TF) et (TC, F) satisfassent à la condition de factorisation de Quillen, i.e. *soient des précouples de Quillen.* (En fait, C, TF et F étant clos par construction, et $TC = C\cap W$ étant stable par facteurs directs (C et W l'étant), ce seront même des *couples* de Quillen.)

Les hypothèses supplémentaires faites tantôt sur $\mathcal{M}$ servaient à assurer que si je prends C_0 petite, alors la factorisation marche pour (C, TF) automatiquement. Il reste le problème pour TC, F. [page 39]

Notons que si elle marche, alors $TC = \widetilde{TC} = F^*$, donc TC est clos à gauche, et *a fortiori* satisfait les conditions de stabilité correspondantes :

$$(4.4.3)\qquad \begin{cases} a) & \text{Stable par cochangement de base, par composition, par}\\ & \text{facteurs directs (ces deux dernières sont assurées auto-}\\ & \text{matiquement, car } C,\ W \text{ sont stables).}\\ b) & \text{Stable par } \varinjlim \text{ ordinales strictes.} \end{cases}$$

L'hypothèse de stabilité sur W sert (entre autres) à garantir la stabilité (b) pour TC (en fait, il suffirait pour cela seulement que W soit stable par $\varinjlim$ ordinales strictes). Il reste la stabilité de $TC = C\cap W$ par cochangement de base, qui est problématique car W n'est en général *pas* stable par cochangement de base. C'est pour assurer cette stabilité que je me vois pratiquement contraint ici à imposer

$$(4.4.4)\qquad C_0 \;\subset\; \mathrm{Cof}_W\;,$$

p. 27 [page 40]

je dis qu'avec l'hypothèse de stabilité faite sur W, cela implique

$$C \overset{\text{déf}}{=} \widetilde{C_0} \subset \mathrm{Cof}_W \ . \tag{4.4.5}$$

En effet, on a :

Commentary · Exposition [ms. 39]

Why preservation under pushout is the right condition

The second factorization cannot be obtained merely by declaring $TC = C \cap W$. Its left class must survive the operations used in the small object construction. Composition and retracts are already available, but an arbitrary weak equivalence need not remain a weak equivalence after pushout. Grothendieck's choice $C_0 \subset \mathrm{Cof}_W$ makes the missing stability a property of the cofibrations along which one pushes out.

With the definition recalled in Chapter XIII, manuscript page 8, a map $i : A \to B$ lies in Cof_W when its pushout functor

$$i_! : A\backslash\mathcal{M} \longrightarrow B\backslash\mathcal{M}, \qquad (A \to X) \longmapsto (B \to B \amalg_A X),$$

preserves weak equivalences. All pushouts mentioned here are assumed to exist. This is often called the condition of being an h-cofibration relative to W. The property automatically passes to cobase changes, by the pasting law for pushout squares. It is defined from W, before a model structure has been chosen.

The distinction between preserving weak equivalences under pushout *along* i and having every pushout *of* i belong to W is essential. The latter condition defines W^{univ}. Two-out-of-three gives $W^{\mathrm{univ}} \subset \mathrm{Cof}_W \cap W$: in the square comparing the cobase changes of i to X and to Y, the two cobase changes and the given map $X \to Y$ are weak equivalences. The reverse inclusion needs a factorization hypothesis. Grothendieck had explicitly used that hypothesis in Chapter XIII, Corollary 1 and Proposition 4, manuscript pages 10–11; it has been dropped from Corollary 4.4.3 here. The next block records the resulting counterexample and restores the hypothesis exactly where it is needed.

The filtered-colimit assertion of Proposition 4.4.2 itself is sound and has a short explicit proof. Let $i_t : A_t \to B_t$ be a filtered diagram in Cof_W, with colimit $i : A \to B$. Given a weak equivalence $u : X \to Y$ under A, restrict it under each A_t. Each map

$$B_t \amalg_{A_t} X \longrightarrow B_t \amalg_{A_t} Y$$

lies in W. Their filtered colimit is $B \amalg_A X \to B \amalg_A Y$, since colimits commute with colimits. Closure of W under filtered colimits proves the required preservation. It also gives retract closure of W: a retract is the colimit of the countable sequence which repeats the associated idempotent. Thus a retract of a map in Cof_W again preserves W, because its pushout comparisons are retracts of the corresponding comparisons for the larger map. Together with pushout and composition, these facts prove the asserted stability under continuous transfinite composition by induction on the ordinal.

Proposition 4.4.2. *Soit $\mathcal{M}$ stable par petites $\varinjlim$ inductives filtrantes, et $W \subset \mathrm{Fl}(\mathcal{M})$ un localiseur* (*modérément saturé*) stable par lesdites limites. *Alors* Cof_W *satisfait les conditions de stabilité* (4.4.3) ("*stabilité de Quillen gauche*"), *et est stable aussi par $\varinjlim$ filtrantes quelconques.*

En effet, la condition (a) est satisfaite sans condition supplémentaire sur W. D'autre part, il est immédiat que cette condition par rapport aux $\varinjlim$ filtrantes implique que Cof_W *est stable par limites inductives filtrantes* dans $\underline{\mathrm{Fl}}(\mathcal{M})$.

Corollaire 4.4.3. *Sous les conditions de la proposition* 4.4.2, $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$ (*ensemble des W-équivalences co-universelles dans $\mathcal{M}$*) *est stable par limites inductives filtrantes, et donc "stable à gauche" en sens de* (4.4.3).

Corollaire 4.4.4. *Sous les conditions de la proposition* 4.4.2, *supposons de plus que les sommes amalgamées simples existent dans $\mathcal{M}$, et soit C_0 une petite partie de* Cof_W *dont les éléments soient accessibles, et considérons*

$$C \ = \ \widetilde{C_0} \ , \qquad TC \overset{\text{déf}}{=} C \cap W \ .$$

Alors on a

$$C \;=\; \mathrm{Cof}_W\ , \qquad TC \;=\; C \cap W^{\mathrm{univ}} \;\subset\; W^{\mathrm{univ}}\ ,$$

et C et TC sont Q-stables à gauche. [page 41]

Commentary · Development (commentators') [ms. 40]

A missing hypothesis in the couniversal-equivalence assertion

The intended application will have a useful factorization available before the second small object argument starts. Remembering that factorization repairs Corollary 4.4.3 and preserves the eventual recognition theorem. Forgetting it makes the intermediate assertion false even in a finite lattice.

A finite counterexample. [ours] Let $\mathcal{M}$ be the diamond lattice, viewed as a category, with $0 < a < 1$ and $0 < b < 1$, and with a, b incomparable. Let W consist of the identity maps and $i : 0 \to a$. Then W satisfies two-out-of-three and is closed under all filtered colimits; all objects of $\mathcal{M}$ are finitely presentable. Nevertheless,

$$i \in \mathrm{Cof}_W \cap W, \qquad i \notin W^{\mathrm{univ}}.$$

Indeed, a filtered diagram in a finite poset has a greatest element in its image, and that element is its colimit. The same observation applies to the finite arrow poset, proving closure of W under filtered colimits. It also shows directly that each representable preserves filtered colimits. To check two-out-of-three, the only nonidentity composable pairs are the two chains from 0 to 1 through a and b; neither chain has two of its three maps in W.

Pushout along i is the operation $x \mapsto a \vee x$. Among the arrows under 0, the only nonidentity weak equivalence is $0 \to a$, and it is sent to id_a. Hence $i \in \mathrm{Cof}_W$. But its pushout along $0 \to b$ is $b \to 1$, which does not belong to W. This verifies every claimed property and disproves the equality in Corollary 4.4.3 under its printed hypotheses. If $C_0 = \{i\}$, then $C = \widetilde{C_0}$ contains i and its pushout $b \to 1$. Thus $TC = C \cap W$ contains i but not that pushout, disproving also the asserted pushout stability of TC in Corollary 4.4.4. The other identities involving W^{univ} in that corollary require the same repair.

The factorization that repairs the argument. Assume that every map factors as a member of Cof_W followed by a member of W. Then $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$. This is the dual form of Grothendieck (1990–1991q, Chapter XIII, Proposition 4, ms. pp. 10–11), and we give the complete argument in the notation used here.

Take $i : A \to B$ in $\mathrm{Cof}_W \cap W$ and any $u : A \to X$. Factor $u = qj$ with $j : A \to Z$ in Cof_W and $q : Z \to X$ in W. Form $P = B \amalg_A Z$ and $Q = B \amalg_A X$. The map $k : Z \to P$ is weak because it is the pushout of the weak equivalence i along the W-cofibration j. It is also a W-cofibration, being a pushout of i. Therefore the induced map $q' : P \to Q$, the pushout of q along k, is weak. The equation $q'k = i'q$, where $i' : X \to Q$ is the desired cobase change, and two-out-of-three imply $i' \in W$. The reverse inclusion was proved in the preceding block.

Proposition 4.4.6 supplies exactly this hypothesis: its first factorization has left map in $C \subset \mathrm{Cof}_W$ and right map in $TF \subset W$. Once that first factorization is constructed, the proof above establishes the pushout stability of TC, and all subsequent uses of Corollary 4.4.4 are justified. The false intermediate generalization therefore does not invalidate the final recognition proposition. The class W^{univ} itself remains closed under filtered colimits and the stated left stability operations even without the extra factorization.

Our literature check covered the earlier manuscript argument and the modern comparison in Batanin and Berger (2017, Lemma 1.10), which distinguishes couniversal weak equivalences from trivial h-cofibrations and gives equality in left proper model categories. We did not find this finite lattice example in those sources.

En effet, par le théorème 1 du paragraphe 1 (p. 10) et son corollaire, $\widetilde{C_0}$ est la plus petite partie de $\mathrm{Fl}(\mathcal{M})$ contenant C_0 et Q-stable à gauche. Comme Cof_W est Q-stable à gauche et contient C_0, on a donc $C = \widetilde{C_0} \subset \mathrm{Cof}_W$. Donc $TC \overset{\text{déf}}{=} C \cap W \subset \mathrm{Cof}_W \cap W \overset{\text{déf}}{=} W^{\mathrm{univ}}$, donc $TC = C \cap W^{\mathrm{univ}}$. Comme W^{univ} est lui aussi Q-stable à gauche (corollaire précédent), il en est de même de $C \cap W$, *q.e.d.*

Corollaire 4.4.5. *Supposons que tout objet de $\mathcal{M}$ soit accessible. Sous les conditions du*

corollaire précédent, posant

$$TF \;=\; C_{0*} \;=\; C_* \;, \qquad F \;=\; (TC)_* \;,$$

le couple (C, TF) *est un couple de Quillen. Pour qu'il en soit de même du couple* (TC, F)*, il suffit qu'il existe une* petite *partie* TC_0 *de* $C \cap W$*, telle que* $\widetilde{TC_0} = TC$ $(\overset{déf}{=} C \cap W)$.

La première assertion est, on l'a vu tantôt, le théorème 1 du paragraphe 1. La deuxième résulte de ce même théorème. On peut préciser dans ce sens :

Commentary · Examples [ms. 41]

An inclusion which cannot be an equality

Grothendieck has established enough closure to apply the small object theorem to a chosen set $C_0 \subset \mathrm{Cof}_W$. The conclusion is that the class it generates stays inside Cof_W. The display in Corollary 4.4.4 prints $C = \mathrm{Cof}_W$, although the proof on the following manuscript page proves $C \subset \mathrm{Cof}_W$. This is a slip in the edition, not in the transcription.

A small example shows why the stronger assertion cannot follow. Take $\mathcal{M} = \mathrm{Set}$, let W consist of the bijections, and take $C_0 = \{\mathrm{id}_{\{0\}}\}$. Every map belongs to Cof_W, since every pushout functor preserves isomorphisms. Every map also has the right lifting property against $\mathrm{id}_{\{0\}}$, so

$$C_0^{\square} = \mathrm{Mor}(\mathrm{Set}), \qquad {}^{\square}(C_0^{\square}) = \mathrm{Iso}(\mathrm{Set}).$$

For the second equality, a map which lifts against every map lifts against itself in the square with identity horizontal maps, and the resulting filler is a two-sided inverse. Thus C consists of the bijections, whereas Cof_W contains, for example, $\varnothing \to \{0\}$. All objects of Set are presentable for some regular cardinal, and the required colimits exist, so the example meets the hypotheses of the corollary.

Under the extra factorization hypothesis explained in the preceding block, the rest of the corollary has its intended force:

$$TC = C \cap W = C \cap W^{\mathrm{univ}}.$$

Both factors in the last intersection have the required stability under pushout, retracts, and continuous transfinite composition. Hence so does TC. This establishes the necessary closure of the proposed trivial cofibrations; the existence of a small set generating them remains the next problem.

Proposition 4.4.6. *Soit* $\mathcal{M}$ *une catégorie stable par petites* $\varinjlim$ *filtrantes, par sommes amalgamées, et dont tous les objets sont accessibles,* W *un localiseur modérément saturé dans* $\mathcal{M}$*, stable par* $\varinjlim$ *filtrantes,* C_0 *une* petite *partie de* $\mathrm{Fl}(\mathcal{M})$*, telle que* [page 42]

$$C_0 \;\subset\; \mathrm{Cof}_W \;, \qquad \underbrace{C_{0*}}_{(=TF)} \;\subset\; W \;,$$

posons p. 28

$$C \;=\; \widetilde{C_0} \qquad TC \;=\; C \cap W \;, \qquad TF \;=\; C_* \;, \qquad F \;=\; (TC)_* \;,$$

et soit TC_0 *une petite partie de* $TC = C \cap W$*. On a alors*

$$(4.4.6) \qquad \begin{cases} C \;\subset\; \mathrm{Cof}_W \;, & TC \;=\; C \cap W^{\mathrm{univ}} \quad (\textit{pour mémoire}) \\ \widetilde{TC_0} \;\subset\; TC \;, & F_0 \supset F \quad (\textit{ce dernier trivial}) \;, \end{cases}$$

et les conditions suivantes sont équivalentes :

a) $\widetilde{TC_0} = TC$ *(on a* $\subset$*)*;

a′) $F_0 = F$ *(on a* $\supset$*)*;

b) $TF = F_0 \cap W$ *(on a* $\subset$*)* [14];

14. **N.B.** On voit facilement que $\boxed{TF = F \cap W,}$ mais ça ne suffit pas pour avoir $TF = F_0 \cap W$ pour TC_0 convenable.

c) $W = TF \circ \widetilde{TC_0}$ $\quad (on\ a \supset)$ [15] ;

et impliquent que (W, C, F) est un triple de Quillen clos.

Démonstration. L'inclusion $\widetilde{TC_0} \subset TC$ résulte de la Q-stabilité à gauche de TC (cor. 4.4.4) et du fait que $TC_0 \subset TC$ est petite (on applique alors le théorème 1 tout comme pour $C \subset \mathrm{Cof}_W \ldots$). L'équivalence de (a), (b), (c) n'est autre que la proposition 4.3 appliquée à W et aux deux couples de Quillen (C, TF), $(\widetilde{TC_0}, F_0)$ (compte tenu du théorème 1 du paragraphe 1). Qu'on a alors un triple de Quillen clos a été vu dans le corollaire 3 de la proposition 4.3 (p. 35). Il reste à prouver l'équivalence de (a) et de (a'). On a $(a) \Longrightarrow (a')$, puisque $(TC_0)_* = (\widetilde{TC_0})_* = F_0$. Inversement, (a') implique $\widetilde{TC_0} = \widetilde{TC}$, donc le théorème de factorisation pour (TC, F) en vertu du théorème de factorisation, corollaire 1 (p. 11) appliqué à $TC_0 \subset TC \subset \widetilde{TC_0}$ et à $F_0 = F = (TC_0)_*$.

Commentary · Exposition [ms. 42]

The two identities already available before the second factorization

Grothendieck's two footnotes on this page separate a formal recognition problem from a problem of size. Put $C = \widetilde{C_0}$, $TF = C^{\square} \subset W$, $TC = C \cap W$, and $F = TC^{\square}$. The first weak factorization system (C, TF) already gives

$$W = TF \circ TC, \qquad TF = F \cap W,$$

without assuming a factorization with left map in TC for every arrow. The missing quantifier concerns arbitrary arrows, not only weak equivalences.

Here are complete proofs. Given $w \in W$, factor it as $w = pi$ using (C, TF). Since $p \in TF \subset W$, two-out-of-three gives $i \in C \cap W = TC$. Conversely, a composite of a member of TC and a member of TF belongs to W. For the second identity, $TF \subset F \cap W$ follows from $TC \subset C$. If $f \in F \cap W$, factor $f = pi$ with $i \in C$ and $p \in TF$. Again $i \in TC$. The square with left arrow i, right arrow f, top arrow the identity of the source of f, and bottom arrow p has a diagonal s satisfying $si = \mathrm{id}$ and $fs = p$. Consequently f is a retract of p in the arrow category. The right lifting class TF is retract closed, so $f \in TF$.

For a candidate set $TC_0 \subset TC$, the notation left implicit in the statement of Proposition 4.4.6 is $F_0 = TC_0^{\square}$. Smallness produces a weak factorization system $(\widetilde{TC_0}, F_0)$, but only the inclusions

$$\widetilde{TC_0} \subset TC, \qquad F \subset F_0$$

are automatic. Proposition 4.4.6 says that the candidate succeeds precisely when $F_0 \cap W = TF$, equivalently when every weak equivalence has the more restrictive factorization with left map in $\widetilde{TC_0}$. If $F_0 = F$, then $\widetilde{TC_0} = {}^{\square}F = \widetilde{TC}$; combined with $\widetilde{TC_0} \subset TC \subset \widetilde{TC}$, this gives equality immediately. Thus the final implication does not assume the desired second factorization in disguise.

To see the distinction concretely, take $\mathcal{M} = \mathrm{Set}$ and W all maps. Let C_0 contain $\varnothing \to \{0\}$ and the fold $\{0,1\} \to \{0\}$. Right lifting against the first map is surjectivity, and right lifting against the second is injectivity. Hence TF consists of bijections and C consists of all maps. Then TC is all maps and F consists of bijections. If the candidate TC_0 contains only $\varnothing \to \{0\}$, its right class F_0 consists of surjections. The projection $\{0,1\} \to \{0\}$ belongs to $F_0 \cap W$ but not to TF. Both identities of the preceding paragraph still hold; the candidate has simply omitted a necessary generating map.

[page 43]

Ainsi, le seul problème, une fois trouvé C_0 (petite) satisfaisant $C_0 \subset \mathrm{Cof}_W$, $C_{0*} \subset W$, c'est de trouver une *petite* partie $TC_0 \subset TC$ qui "engendre $TC = C \cap W$ ", *i.e.* qui satisfasse aux conditions équivalentes (a), (a'), (b), (c) de la proposition précédente. J'ai passé des jours à essayer de prouver l'existence de TC_0, en supposant $\mathcal{M}$ munie d'une filtration cardinale, et W une partie accessible de $\mathcal{M}$, sans y être arrivé. Bien sûr, tout ce qui nous importe vraiment, c'est que (TC, F) satisfasse à la condition de factorisation. Mais je ne vois aucun moyen de le prouver, si ce n'est en "engendrant" à gauche TC par un *petit* sous-ensemble TC_0.

15. **N.B.** On sait que $\boxed{W = TF \circ TC,}$ ce qui n'est nullement suffisant pour impliquer (c) !

Commentary · Later developments [ms. 43]

The generating set supplied by Smith's theorem

The question at the end of Section 4 became a standard recognition theorem for combinatorial model categories. In the locally presentable setting, Smith's theorem, published with proof by Beke (2000, Theorem 1.7), gives the missing set of generating trivial cofibrations. Its hypotheses are precisely organized around the difficulty seen here: W has two-out-of-three and is retract closed, $C_0^{\square} \subset W$, $C \cap W$ is stable under pushout and transfinite composition, and W satisfies a solution set condition at each map of C_0. Accessibility of the full subcategory $W \subset \mathcal{M}^{[1]}$ supplies the last condition by Beke (2000, Proposition 1.15).

The solution set condition says that, for each $i \in C_0$, a set of maps $i \to w_s$ with $w_s \in W$ is weakly initial among all maps from i to members of W in the arrow category. This is the categorical form of the bounded choices Grothendieck is seeking. Smith's argument converts these choices into a set $J \subset C \cap W$ with $\mathrm{cof}(J) = C \cap W$; Beke's Lemmas 1.8 and 1.9 supply the construction and proof.

This answers the existence question under the stated modern hypotheses. A cardinal filtration on its own should not silently be substituted for local presentability, and the claim does not cover every category allowed by the more flexible assumptions on the preceding pages. Nor does the theorem require C itself to be stable under all filtered colimits, the additional route Grothendieck begins to explore in Section 5.

Commentary · Present state [ms. 43]

The form closest to the proposed localizer construction

Grothendieck's use of Cof_W also survives in a recognition theorem whose hypotheses closely follow these pages. In the updated online text of Lurie (2009, Proposition A.2.6.15), a locally presentable category, a perfect class W, and a set of generating cofibrations satisfying the pushout preservation condition and $C_0^{\square} \subset W$ produce a left proper combinatorial model structure. Here "perfect" means that W contains the isomorphisms, satisfies two-out-of-three, is closed under filtered colimits, and is generated under those colimits by a set. The proof first establishes the required stability of $C \cap W$, then applies the small-generation result of Lemma A.2.6.9 and the general recognition Proposition A.2.6.10. These are the numbers in the online revision consulted, not the earlier printed numbering.

The later theorem makes precise both parts of the intended conclusion: the second factorization exists, and the chosen cofibrations preserve weak equivalences under pushout. The latter is left properness. It remains separate from the formal two-factorization axioms studied at the beginning of Section 4; an arbitrary model structure need not have it.

Commentary · Later developments [ms. 43]

The passage from models to diagram homotopy theories

The point of obtaining a model structure is that it can support coherent operations on diagrams. In the combinatorial setting, the later passage is precise: Groth (2013, Theorem 1.28 and Proposition 1.30) constructs projective and injective model structures on diagram categories and proves that $J \mapsto \mathrm{Ho}(\mathcal{M}^J)$ is a strong derivator. The two diagram model structures supply the appropriate derived Kan extensions.

The existence of these diagram model structures is a convenient sufficient route. The broader construction of homotopy right Kan extensions for model categories with small limits is treated by Cisinski (2003, Theorem 6.11), in that paper's left-derivator convention. This later theorem explains why the goal is larger than a particular generating-set argument. Chapter XV builds and controls models; the derivator records their homotopy theories of diagrams and the functors between them. Neither the cardinal estimates nor the two lifting systems alone constitute the passage between the two.

5 Résultats techniques préliminaires sur les parties accessibles de $\mathrm{Ob}\,\mathcal{M}$, stables par limites inductives filtrantes

Je crois pourtant que je peux arriver à quelque chose d'utilisable, en travaillant systématiquement avec des C ($\subset \mathrm{Cof}_W$, Q-closes à gauche, Q-engendrées à gauche par une *petite* partie C_0 de C) qui sont stables par toutes limites inductives filtrantes.

Je suppose à nouveau sur $\mathcal{M}$ les conditions suivantes : p. 29 [page 44]

a) $\mathcal{M}$ stable par petites limites inductives (et pas seulement filtrantes).

b) $\mathcal{M}$ muni d'une filtration cardinale $(\mathrm{Filt}^\pi)_{\pi\geq\pi_0}$.

c) Les objets de $\mathcal{M}$ sont accessibles (**N.B.** Il suffit de le supposer pour les objets de Filt^{π_0}).

La condition (*b*) implique que $\mathcal{M}$ contient une petite famille génératrice par épimorphismes stricts (p. ex. une sous-catégorie $\mathcal{C}$ petite de $\underline{\mathrm{Filt}}^{\pi_0} = \mathcal{M}^{\pi_0}$ telle que l'inclusion $\mathcal{C} \longrightarrow \underline{\mathrm{Filt}}^{\pi_0}$ soit une équivalence de catégories). Par SGA 4 I 8.12.7, il en résulte que $\mathcal{M}$ est stable par petites limites projectives. Il s'ensuit le

Lemme 5.1 (sous les conditions (*a*), (*b*)). *Pour tout objet X de $\mathcal{M}$, l'ensemble* $\mathrm{Ss}(X)$ *des sous-objets de X, muni de la relation d'ordre naturelle "d'inclusion", admet des* inf *et des* sup *quelconques.*

Des inf, car ceux-ci s'expriment comme des limites projectives dans $\mathcal{M}$. Or l'existence des inf implique celle des sup, puisque $\sup_J = \inf_{J'}$, où J' est l'ensemble des majorants de J dans $\mathrm{Ss}(X)$.

Corollaire 5.2. *Pour toute flèche $f : Z \longrightarrow X$ dans $\mathcal{M}$, il existe, parmi les sous-objets X' de X par lesquelles f se factorise, un plus petit (qu'on notera* $\mathrm{Im}\, f$*). Le morphisme $Z \longrightarrow \mathrm{Im}\, f$* [page 45] *est un épimorphisme.*

Commentary · Exposition [ms. 44]

Images and the meaning of a small subobject

Grothendieck now wants the size of an object to be visible inside the object itself. A presentation by a filtered diagram can repeat objects, identify elements, and carry many choices. The ordered collection of its small subobjects is a more geometric presentation: its transition maps are inclusions, and its small directed suprema can be calculated in the ambient category. This change of presentation is the preparation for recognizing a class of objects from its bounded part.

We keep the three conditions on the filtration separate. Essential smallness says that a bounded collection has a set of isomorphism classes; generation says that every object has an appropriately directed presentation by bounded objects; preservation of such colimits by a represented functor is an additional condition on the representing object. In the terminology of these pages, "grand devant π" means that every subset of cardinal at most π has an upper bound. For infinite π, this is the usual π^+-directedness. A π-accessible object is consequently a π^+-presentable object in current terminology. It is not an object with exactly π elements, and the bound is not assumed regular.

The set-sized assertion in Lemma 5.1 also has content. Let G run through a small set of representatives of the base level. A subobject $U \hookrightarrow X$ determines the subsets of $\mathrm{Hom}(G, X)$ consisting of the maps which factor through U. These subsets determine U: a generating presentation of its domain lifts uniquely to any other subobject having the same subsets, and these unique lifts assemble. Thus there is a set of subobjects of X.

The same base level is a conservative generating family. Suppose $f : X \to Y$ induces bijections on maps from its objects. Write $Y = \varinjlim_i G_i$ using the filtration. Each structural map $G_i \to Y$ lifts uniquely to X; uniqueness makes the lifts compatible, so they induce $g : Y \to X$ with $fg = \mathrm{id}_Y$. For a presentation $X = \varinjlim_j H_j$, injectivity of $\mathrm{Hom}(H_j, f)$ gives $gfh_j = h_j$ at every structural map h_j, hence $gf = \mathrm{id}_X$. No accessibility rank is needed. The dual of (Artin et al., 1972, Exposé I, 8.12.7) now supplies completeness: the functor of cones $Z \mapsto \varprojlim_j \mathrm{Hom}(Z, X_j)$ takes colimits to limits and is represented by the desired limit. This argument uses conservative generation, without requiring the stronger density assertion in the source.

Once intersections exist, the image used here is the intersection of *all* subobjects through which the map factors. If $Z \to \mathrm{Im}(f)$ were not epic, two different maps out of its codomain would agree after composition; their equalizer would give a smaller subobject through which f factors. This

proves Corollary 5.2. In fact the first map in this factorization is extremal epic: any factorization through a monomorphism would contradict the minimality of the image unless that monomorphism were invertible.

In Lemma 5.3 the adjective *strict* has the categorical meaning of SGA 4, not merely "different from the whole object"; the latter requirement is written separately. A strict monomorphism which is also epic is invertible. Conversely, failure to be epic is detected by a proper equalizer, which is a strict monomorphism. This proves the stated criterion, after replacing the accidental name g by f. The distinction matters, for example, for the epimorphism $\mathbb{Z} \to \mathbb{Q}$ in commutative rings: it factors through a proper monomorphism, namely itself, but not through a proper strict monomorphism. The terminology is fixed in (Artin et al., 1972, Exposé I, 10.2–10.5).

Cette dernière assertion provient de celle-ci :

Lemme 5.3. *Soient $\mathcal{M}$ une catégorie où les noyaux des doubles flèches existent. Soit $f : Z \longrightarrow Y$ une flèche de $\mathcal{M}$. Alors g est un épimorphisme si et seulement si g ne se factorise pas par un sous-objet* strict Y_0 *de Y différent de Y.*

On va faire une hypothèse supplémentaire (pratiquement anodine) sur les Filt^π :

d) Filt^π est stable par limites inductives indexées par des catégories d'indices I telles que $\operatorname{card} \mathrm{Fl}(I) \leq \pi$ [16]. (Il suffit de supposer la stabilité par objet initial, sommes amalgamées simples, et $\varinjlim$ filtrantes indexées par un ensemble ordonné I de cardinal $\leq \pi$.) De plus, si $f : Z \longrightarrow X$ est une flèche de $\mathcal{M}$ telle que Z ou X est dans Filt^π, alors $\operatorname{Im} f \in \mathrm{Filt}^\pi$.

Cette dernière condition sur $\operatorname{Im} f$ se décompose en deux : [page 46]

d_1) Tout sous-objet d'un objet de Filt^π est dans Filt^π.

d_2) Si Z est dans Filt^π, alors tout quotient Z' de Z tel que $\operatorname{Im} p = Z'$ (où $p : Z \longrightarrow Z'$ est le morphisme canonique) est dans Filt^π. [17]

Bien sûr, pratiquement il sera toujours vrai que Filt^π est stable par passage aux sous-objets et aux quotients d'un objet (pas seulement les quotients particuliers dont il est question dans (d_2). D'ailleurs, lorsque tout bimorphisme (*i.e.* monomorphisme *et* épimorphisme) de $\mathcal{M}$ est un isomorphisme, alors (d_2) équivaut bien à la stabilité de Filt^π par quotients d'objets. p. 30

Proposition 5.3. `[Deux fois 5.3.]` *Supposons les conditions* (a), (b), (d) *vérifiées pour $\mathcal{M}$. Soient π un cardinal $\geq \pi_0$, et X un objet de $\mathcal{M}$. Soit $\mathrm{Ss}_\pi(X)$ l'ensemble des sous-objets de X qui sont dans* Filt^π*. Cet ensemble, ordonné par la relation d'ordre induite par $\mathrm{Ss}(X)$, est grand devant π (et en particulier filtrant). Si de plus, les limites inductives filtrantes de monomorphismes dans $\mathcal{M}$ sont des monomorphismes* [18] *(p. ex. si les limites inductives filtrantes sont exactes à gauche), ou si les objets de* Filt^π *sont π-accessibles, on a $\varinjlim_{\alpha \in \mathrm{Ss}_\pi(X)} Z_\alpha \xrightarrow{\sim} X$* [19].

Démonstration. Soit $(Z_\alpha)_{\alpha \in A}$ une famille de sous-objets de X tels que $Z_\alpha \in \mathrm{Filt}^\pi$, et $\operatorname{card} A \leq \pi$. Soit $Z = \coprod_{\alpha \in A} Z_\alpha$, on a $Z \in \mathrm{Filt}^\pi$ par (c). Le plus petit sous-objet de X majorant les Z_α n'est autre que $\operatorname{Im}(Z \longrightarrow X)$, qui est dans Filt^π par (d_1). Prouvons que $\varinjlim_{\alpha \in \mathrm{Ss}_\pi(X)} Z_\alpha \xrightarrow{\sim} X$ est un isomorphisme, quand on sait que c'est un monomorphisme. Or [page 47]

$$X = \varinjlim_{I} X_i \ ,$$

où $(X_i)_{i \in I}$ est un système inductif filtrant, I ensemble ordonné grand devant π, les X_i dans Filt^π. Soit, pour tout $i \in I$, X'_i l'image de X_i dans X. On a donc $X'_i \in \mathrm{Filt}^\pi$ par (d_2). Utilisant

16. Cette condition sera nommée (d_0) par la suite.

17. Il semblerait qu'on n'aura pas besoin de (d_1), seulement de (d_2). Mais en fait, (d_1) doit être conséquence de (d_2), et (d_2) est conséquence de la première partie de (d) (stabilité par $\varinjlim$ finies) si tout épimorphisme dans $\mathcal{M}$ est strict, donc effectif (si les Filt^π sont stables par $\varprojlim$ finies aussi …).

18. C'est une *condition d'exactitude* de $\mathcal{M}$, que je vais noter comme :

© Les monomorphismes dans $\mathcal{M}$ sont stables par $\varinjlim$ filtrantes dans $\underline{\mathrm{Fl}}(\mathcal{M})$.

19. Dire aussi que $\mathrm{Ss}_\pi(X)$ est π-adapté, et le système inductif $(Z_\alpha)_\alpha$ aussi.

le fait que les $X_i \longrightarrow X'_i$ sont des épimorphismes, on voit de suite que $X = \varinjlim_I X'_i$. Considérons l'application

$$\begin{array}{ccc} I & \longrightarrow & \mathrm{Ss}_\pi(X) \\ i & \longmapsto & X'_i \ . \end{array}$$

C'est une application croissante, soit J son image, partie filtrante grande devant π de $\mathrm{Ss}_\pi(X)$, telle que

$$\varinjlim_{\alpha\in J} Z_\alpha \ \xrightarrow{\sim}\ X \ .$$

On a donc [page 48]

$$\underbrace{\varinjlim_{\alpha\in J} Z_\alpha}_{\simeq X} \ \longrightarrow \ \varinjlim_{\alpha\in \mathrm{Ss}_\pi X} Z_\alpha \ \xrightarrow{\varphi}\ X \ ,$$

le composé étant l'identité. Si on sait que φ est un monomorphisme, il en résulte que c'est un isomorphisme (monomorphisme ayant une section). Or φ sera un monomorphisme si toute $\varinjlim$ filtrante de monomorphismes est un monomorphisme, et alors on gagne.

Commentary · Development (commentators') [ms. 46]

Quotient bounds do not bound subobjects

The two image conditions serve different purposes. The second controls the image of a bounded source; the first controls an arbitrary subobject of a bounded target. The suggestion in footnote 17 that the second should imply the first is false even in a module category with exact filtered colimits. Giving the example explicitly explains why the two conditions must be distinguished, even in arguments where only one of them is used.

A filtration separating (d_1) and (d_2). [ours] Fix an infinite cardinal π, a field k, and a set S of cardinal greater than π. Put

$$R = k[x_s \mid s \in S], \qquad \mathrm{Filt}^\kappa(R\text{-Mod}) = \{N \mid N \text{ is generated by at most } \kappa \text{ elements}\}, \quad \kappa \geq \aleph_0.$$

This is a cardinal filtration satisfying (a), (b), (c), (d_0), (d_2) and (e), but (d_1) fails at π.

Proof. Modules generated by at most κ elements are quotients of $R^{(\kappa)}$, so they have a set of isomorphism classes. A colimit of a diagram with at most κ arrows and κ-generated values is a quotient of the sum of at most κ such modules; it is again κ-generated. This proves (d_0) and the required closure part of the filtration, and quotient closure proves (d_2). Every module is presentable for some sufficiently large regular cardinal: choose a presentation, and bound both its generators and relations; factorization and eventual equality in a sufficiently directed colimit are then checked on those sets. This proves (c). Filtered colimits of modules are exact, giving (e).

For the quantitative generation clause, let N have a chosen generating set T of size at most κ', where $\kappa' \geq \kappa$. The submodules generated by subsets of T of size at most κ form a κ^+-directed diagram with colimit N. Its indexing set has cardinal at most $(\kappa')^\kappa$. This is precisely the bound required of a cardinal filtration, including when the ring itself is much larger than κ.

Finally R is cyclic, whereas its ideal $\mathfrak{a} = (x_s \mid s \in S)$ is not π-generated. Indeed $R/\mathfrak{a} = k$ and

$$\mathfrak{a}/\mathfrak{a}^2 \cong \bigoplus_{s\in S} k\,\overline{x_s}.$$

Any generating set of $\mathfrak{a}$ maps to a spanning set of this k-vector space and therefore has cardinal at least $|S|$. Thus $\mathfrak{a} \hookrightarrow R$ disproves (d_1). □

The example does not challenge the propositions which follow: they assume (d), hence both image conditions. It also explains why increasing the cardinal can remove the difficulty in familiar concrete categories. If $\kappa \geq |R|$, every submodule of a κ-generated module has at most κ underlying elements and is itself κ-generated. We checked the filtration definition and the relevant size arguments in (Artin et al., 1972, Exposé I, 9.12–9.16); the particular counterexample above is our explicit verification of the remark's failure, with no claim of priority.

Si on suppose que les éléments de Filt^π sont π-accessibles, on gagne aussi, car on trouve : p. 31

Corollaire 5.4. *Si les objets de* Filt^π *sont* π*-accessibles (p. ex. si* $\pi \geq \pi_1$ *et* $\pi = \pi^{\pi_0}$*, p. ex.* $\pi \geq \pi_1$ *et* $\pi = 2^c$*, avec* $c \geq \pi_0$*,* cf. (3.2) *p. 16), alors pour toute partie filtrante* J *de* $\mathrm{Ss}(X)$ *grande devant* π*, telle que* $\varinjlim_{\alpha\in J} Z_\alpha \xrightarrow{\sim} X$*,* J *est cofinale dans* $\mathrm{Ss}_\pi(X)$ *(donc* $\varinjlim_{\alpha\in J} Z_\alpha \xrightarrow{\sim} \varinjlim_{\alpha\in \mathrm{Ss}(X)} Z_\alpha$*).*

C'est immédiat.

[page 49]

Scholie 5.5. Quand on fait sur $\mathcal{M}$ l'hypothèse d'exactitude assez anodine que les $\varinjlim$ filtrantes de monomorphismes sont des monomorphismes, *ou* qu'on se borne aux cardinaux π tels que les objets de Filt^π soient π-accessibles, on peut *canoniser* la représentation d'un objet X comme $\varinjlim_{i\in I} X_i$, avec $X_i \in \mathrm{Filt}^\pi$ et I grand devant π, en prenant $I = \mathrm{Ss}_\pi(X)$, et le système inductif correspondant. On a de plus l'agréable propriété supplémentaire que voici : toute partie filtrante J de I, de cardinal $\leq \pi$, admet une borne supérieure i_J, et (si on suppose que $\mathcal{M}$ satisfait la condition (e), page 46, note 18), on aura

$$X_{i_J} \;=\; \varinjlim_{i\in J} X_i \;;$$

en d'autres termes, on a une représentation de X par un système inductif (parfaitement) π*-adapté* (*cf.* XIII, p. 85, 86).

[page 50]

Soit maintenant

$$M \;\subset\; \mathrm{Ob}\,\mathcal{M}$$

une partie de $\mathrm{Ob}\,\mathcal{M}$, stable par la relation d'isomorphie. Si M est π-accessible (suivant la condition b_π de XIII, p. 88), alors en posant

$$M^\pi \;=\; M \cap \mathrm{Filt}^\pi \;,$$

M^π détermine M par la condition suivante sur $X \in \mathrm{Ob}\,\mathcal{M}$.

(5.1) $X \in M \iff$ le sous-ensemble $\mathrm{Ss}_\pi^M(X)$ de $\mathrm{Ss}_\pi(X)$ formé des $X_\alpha \in \mathrm{Ss}_\pi(X)$ tels que $X_\alpha \in M$ ($\iff X_\alpha \in M^\pi$) est cofinal dans $\mathrm{Ss}_\pi(X)$.

Notons que lorsque $X \in \mathrm{Filt}^\pi$, ce critère est trivialement valable, puisque alors $\mathrm{Ss}_\pi(X)$ admet X comme plus grand élément, et les sous-ensembles cofinaux sont ceux qui contiennent cet objet final. Donc (5.1) est intéressant seulement pour les $X \in \mathrm{Ob}\,\mathcal{M}\backslash\mathrm{Filt}^\pi$. Notons que pour *toute* partie M^π de Filt^π, on peut définir une partie M de $\mathrm{Ob}\,\mathcal{M}$ par la condition (5.1), et on aura trivialement

(5.2) $$M^\pi \;=\; M \cap \mathrm{Filt}^\pi \;.$$

Mais sans doute, bien que M satisfasse (5.1), il n'est pas pour autant nécessairement π-accessible. En effet, pour qu'il le soit, il faut qu'il soit stable par $\varinjlim$ grandes devant π d'éléments de M^π, ce qui implique que tout facteur direct d'un élément de M^π est dans M, donc aussi dans M^π, d'après la condition de stabilité (d) sur Filt^π. C'est là une condition particulière sur la partie M^π de Filt^π. Aussi, on devra avoir une condition sur $\mathcal{M}$ plus forte que la validité de (5.1), savoir :

p. 32

[page 51]

(5.3) Pour tout $X \in \mathrm{Ob}\,\mathcal{M}$ et pour toute partie J de $\mathrm{Ss}_\pi(X)$, telle que
- *a)* J est cofinale dans $\mathrm{Ss}_\pi(X)$ et
- *b)* Si $J' \subset J$ est une partie filtrante de J, de cardinal $\leq \pi$, alors sa borne supérieure $\alpha_{J'}$ dans $\mathrm{Ss}_\pi(X)$ appartient à J,

on a $X \in M$ si et seulement si $J^M \overset{\text{déf}}{=} J \cap \mathrm{Ss}_\pi^M(X)$ est cofinal dans J (ou ce qui revient au même, dans $\mathrm{Ss}_\pi(X)$)[20].

Commentary · Exposition [ms. 49]

The canonical directed union

The gain in Proposition 5.3 is a canonical presentation whose indexing order has actual suprema. Write $\mathrm{Sub}_\pi(X)$ for Grothendieck's $\mathrm{Ss}_\pi(X)$. Given at most π members $U_a \hookrightarrow X$, form their coproduct and then its image in X. The coproduct belongs to Filt^π by (d_0), and its image belongs to Filt^π by (d_2). It is their least upper bound in the full subobject lattice. These are the two assumptions used in the proof; the printed references to (c) and (d_1) on manuscript page 47 are misplaced.

Here is the colimit argument in a form that also explains the role of epimorphisms. Choose a generating presentation $X = \varinjlim_i X_i$ by Filt^π-objects, and factor each map to X as

$$X_i \twoheadrightarrow U_i \hookrightarrow X.$$

A compatible family $U_i \to T$ gives, by composition, a compatible family $X_i \to T$ and hence a unique map $X \to T$. Its restriction to U_i is the given map because $X_i \to U_i$ is epic. Therefore $\varinjlim_i U_i = X$. Passing to the image of the indexing order in $\mathrm{Sub}_\pi(X)$ does not change this colimit: above any chosen U_i, the original directed order supplies a common upper bound for every finite family of representatives.

There is consequently a section of the canonical map

$$q : \varinjlim_{U \in \mathrm{Sub}_\pi(X)} U \longrightarrow X.$$

Under (e) this map is monic, being the filtered colimit of the monomorphisms $U \to X$; a monomorphism with a section is invertible. Alternatively, if every Filt^π-object is π-accessible, any small subobject $V \hookrightarrow X$ factors through some U_i, and the factorization is a map of subobjects. The U_i are then cofinal in $\mathrm{Sub}_\pi(X)$, proving the same result without (e).

For the stronger continuity assertion of Scholie 5.5, (e) is used again. If $K \subset \mathrm{Sub}_\pi(X)$ is directed and $|K| \le \pi$, its colimit belongs to Filt^π by (d_0), and its map to X is monic by (e). It is the supremum of K. Thus the canonical diagram carries small directed suprema to colimits. This is the precise content of a *perfectly π-adapted* representation. It is stronger than the mere requirement that its index be π^+-directed.

In a presheaf category on a small category A, this construction has a concrete form once π bounds $|\mathrm{Fl}(A)|$. Use the filtration by presheaves whose total set of elements has cardinal at most π. Closing at most π chosen elements under all restriction maps still gives at most π elements. The poset of such subpresheaves is π^+-directed, its small directed suprema are unions, and their union is the whole presheaf. This familiar example is the geometric picture underlying the abstract image argument.

Si on admet déjà le "il suffit" de (5.1), alors il suffit dans (5.3) de supposer $X \in M$ et exiger qu'alors J^M soit cofinal dans J.

Mais notons la [page 52]

Commentary · Exposition [ms. 51]

Accessibility tests every adapted presentation

The word "accessible" now applies to a *class of objects*. Its meaning must be recovered from the definition to which Grothendieck refers, since it is more specific than simply saying that the corresponding full subcategory is accessible in the modern sense. The relevant condition b_π in (Grothendieck, 1990–1991q, Chapter XIII, manuscript pp. 88–89) is this: for every perfectly π-adapted presentation

$$X = \varinjlim_{i \in I} X_i, \qquad X_i \in \mathrm{Filt}^\pi,$$

20. Au lieu de J cofinale dans $\mathrm{Ss}_\pi(X)$, il suffit même que l'on ait $\varinjlim_{\alpha \in J} X_\alpha \xrightarrow{\sim} X$ – la condition correspondante sur M devient donc plus exigeante. Mais si les objets de Filt^π sont π-accessibles, cette condition est en fait équivalente à la condition plus faible.

one has $X \in M$ if and only if $\{i \mid X_i \in M\}$ is cofinal in I. Thus the test concerns all such presentations, including presentations whose maps identify elements.

Formula (5.1) applies this test to the canonical subobject presentation. It records a necessary condition, and gives a way to reconstruct a candidate class from any chosen bounded part M^π. On bounded objects the recovery formula is automatic: X itself is the largest element of $\mathrm{Sub}_\pi(X)$, so a cofinal subset must contain it. This explains (5.2), but supplies no invariance under changing the presentation.

Condition (5.3) asks for that invariance among the continuous cofinal subdiagrams of the canonical diagram. The closure requirement on J says that it contains the supremum of every directed subset of itself of cardinal at most π. It makes the induced diagram perfectly adapted. It does not turn a nonmonic presentation into a subobject presentation, and this is where the first version of Proposition 5.6 overreaches. The source itself identifies the obstruction and inserts the correction in footnote 21.

The repair on manuscript page 55 asks that M^π be closed under filtered colimits of diagrams of cardinal at most π. Then the good indices in a perfectly adapted diagram are themselves closed under the same directed suprema. They form another perfectly adapted presentation whenever they are cofinal. Lemma 5.7 can therefore be applied to that presentation, reducing its colimit to a continuous cofinal family of monomorphic stages. This is why the extra closure condition repairs the converse: it allows the comparison lemma to be used a second time, on the good part of the diagram.

Proposition 5.6.[21] *Supposons π choisi de telle façon que les objets de* Filt^π *soient π-accessibles (p. ex. $\pi = 2^c$, avec $c \geq \pi_1$,* cf. (3.2)*, p. 16). Alors, pour une partie M de* $\mathrm{Ob}\,\mathcal{M}$*, M est π-accessible si et seulement si elle satisfait au critère* (5.3).

On a vu que c'est nécessaire (tautologiquement, compte tenu de la proposition 5.3 et du scholie 5.5, bas de la page 49). Prouvons que c'est suffisant, en établissant d'abord le

Lemme 5.7. *Sous les conditions de* 5.6 *sur π, et la condition* (e) *sur $\mathcal{M}$* (p. 46)*, pour toute représentation π-adaptée $X = \varinjlim_{i\in I} X_i$ d'un objet X de $\mathcal{M}$, le sous-ensemble I' des $i \in I$ tels que $X_i \longrightarrow X$ soit un monomorphisme, est cofinal dans I. De plus, I' est stable par bornes supérieures dans I de parties filtrantes J de I' de cardinal $\leq \pi$.*

Montrons comment ce lemme 5.7 implique le "il suffit" de la proposition 5.6. Soit donc $X = \varinjlim_{i\in I} X_i$ une représentation π-adaptée de X ($X_i \in \mathrm{Filt}^\pi$, I grand devant π, *etc.*). Il faut prouver que, si 5.3 est valable, alors $X \in M$ si et seulement si l'ensemble I_M est cofinal dans I.

[page 53]

Supposons $X \in M$. Considérons le sous-ensemble $I' \subset I$ décrit dans le lemme. On a une application $I' \longrightarrow \mathrm{Ss}_\pi(X)$, soit $i \longmapsto X'_i = \mathrm{Im}\,(X_i \hookrightarrow X)$, et on a

$$X \simeq \varinjlim_{i\in I} X_i \;\simeq\; \varinjlim_{i\in I'} X_i \;\simeq\; \varinjlim_{i\in I'} X'_i \;\simeq\; \varinjlim_{\alpha\in J} Z_\alpha\ ,$$

où J est l'image de I' dans $\mathrm{Ss}_\pi(X)$. Comme les objets de Filt^π sont π-accessibles, on en conclut que J est cofinal dans $\mathrm{Ss}_\pi(X)$. Par 5.3, il s'ensuit que l'ensemble J_M des $\alpha \in J$ tels p. 33
que $Z_\alpha \in M$ est cofinal dans J, donc $\neq \emptyset$. Donc I'_M, qui est l'image inverse de J_M dans I', est en tous cas non vide. Appliquant le même résultat en remplaçant I' par le sous-ensemble $I'_{\geq i'_0}$, on voit que I'_M est cofinal dans I', donc aussi dans I, puisque I' est cofinal dans I ; donc $I_M \supset I'_M$ est cofinal dans I, *q.e.d.*

Inversement, supposons que I_M soit cofinal dans I, et prouvons $X \in M$. La difficulté ici provient du fait que la représentation $X = \varinjlim_{i\in I_M} X_i$ n'est plus adaptée à $\pi - I_M$ n'est pas nécessairement stable dans I par bornes supérieures (dans I) de parties filtrantes dans I_M, I' de cardinal $\leq \pi$. En somme, il faut prouver que M est stable par $\varinjlim$ grandes devant π sans [page 54]

21. Faux tel quel, vrai si on suppose que M^π est stable par $\varinjlim$ filtrantes.

plus, et je doute maintenant que ça résulte des seules hypothèses faites ici, qui ne concernent que les systèmes inductifs où les morphismes de transition sont des monomorphismes.

Voici, je crois, un contre-exemple. Prenons

(5.4) M = ensemble des objets de $\mathcal{M}$ isomorphes à un objet fixe $X_0 \in \mathrm{Filt}^\pi$, tel que X_0 n'ait pas d'endomorphisme qui soit un monomorphisme autre que l'identité.

Alors la condition 5.3 est satisfaite. Car :

a) Si $X \in M$, *i.e.* $X \simeq X_0$, alors $X \in \mathrm{Filt}^\pi$, donc $\mathrm{Ss}_\pi(X)$ admet X comme objet final, et J, étant cofinal, contient cet élément, donc J_M (qui le contient aussi) est cofinal.

Et :

b) Si J_M est cofinal, l'hypothèse (5.4) implique que l'ensemble des morphismes de transition entre les Z_α ($\alpha \in J_M$) est formé d'isomorphismes, donc la limite inductive X des Z_α en question est isomorphe à chacun d'eux, donc $X \simeq X_0$, *i.e.* $X \in M$.

Pourtant, M n'est π-accessible que s'il est stable par $\varinjlim$ grandes devant π, ce qui implique qu'il est stable par *facteurs directs.* Mais l'hypothèse (5.4) n'exclut nullement que X_0 admette [page 55]
un projecteur p ($p^2 = p$) non trivial. Celui-ci aura une image X' dans $\mathcal{M}$, qui sera facteur direct de X_0 non isomorphe à X_0, *i.e.* non dans M.

Ces difficultés disparaissent si on suppose que M^π est stable par $\varinjlim$ filtrantes indexées par des ensembles ordonnés I de cardinal $\leq \pi$. En effet, dans ce cas, dans la démonstration précédente, le sous-ensemble I_M est stable par bornes supérieures (dans I) de parties J de I_M filtrantes et de cardinal $\leq \pi$. Donc le système inductif $(X_i)_{i \in I_M}$ est encore π-adapté, et on peut lui appliquer le lemme 5.7, pour trouver un sous-ensemble cofinal $I'_M \subset I_M$, tel que les $X_i \longrightarrow X$ pour $i \in I'_M$ soient des monomorphismes. L'image J de I'_M dans $\mathrm{Ss}_\pi(X)$ est alors une partie de $\mathrm{Ss}_\pi(X)$ telle que $\varinjlim_{\alpha \in J} Z_\alpha = X$, donc (par l'hypothèse faite sur π) cofinale dans $\mathrm{Ss}_\pi(X)$ (5.4), avec $Z_\alpha \in M^\pi$ pour tout $\alpha \in J$. Donc par 5.3 on a $X \in M$, *q.e.d.*

Il reste à prouver le lemme 5.7. Avec les hypothèses et notations du lemme, soit donc [page 56]
$i_0 \in I$, il faut trouver $i' \in I'$ tel que $i' \geq i_0$. Considérons l'image X'_i de X_i dans X, et

Commentary · Development (commentators') [ms. 55]

A two-point model of the retract obstruction

Grothendieck's proposed counterexample asks for an object which has no proper monic self-map, but does have a nontrivial retract. The walking arrow provides such an object in an elementary ambient category, and also makes the failure visible in a perfectly adapted presentation. This gives a concrete completion of the mechanism proposed in (5.4).

A class satisfying (5.3) but failing b_π. [ours] Let $\mathcal{M} = \mathrm{Pos}$ be the category of small partially ordered sets and monotone maps. For an infinite cardinal π, use the filtration by underlying cardinality at most π, and let M consist of the objects isomorphic to the two-element chain $P = \{0 < 1\}$. Then M satisfies (5.3) but is not π-accessible.

Proof. Monomorphisms in Pos are the injective monotone maps, so every monic endomorphism of P is the identity. The constant map $P \to P$ with value 0 is nevertheless an idempotent whose image is the one-point poset 1. The ambient hypotheses are satisfied: a colimit is obtained from a disjoint union by generating the order relations and quotienting by the resulting equivalence relation, so a diagram of cardinal at most π with π-small values has a π-small colimit. Subobjects and image quotients have the same cardinal bound. Filtered colimits have underlying set the filtered colimit of the underlying sets, and an order relation between two representatives holds exactly when it holds at some later common stage. This description proves (*e*). A poset of cardinal at most π has at most π order relations; choosing representatives for its elements and making those relations hold at one common stage proves its π-accessibility. The eventual-equality part follows by the same argument on the at most π elements.

To check (5.3), first suppose $X \cong P$. Every cofinal subset of $\mathrm{Sub}_\pi(X)$ contains its largest member X, so its good members are cofinal. Conversely, suppose J^M is cofinal in a continuous cofinal subset J of $\mathrm{Sub}_\pi(X)$. Then X is the filtered colimit of the subobjects indexed by J^M. Each

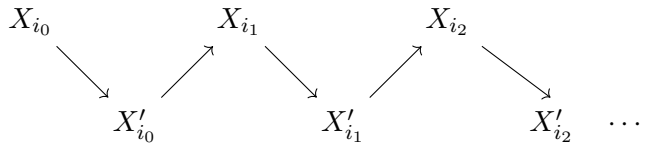
has type P, and every transition between them is an isomorphism. The index is nonempty and directed, so its colimit is again P. This establishes both directions of (5.3).

For a direct failure of the actual definition b_π, put $\lambda = \pi^+$ and index a diagram by the ordinals $\alpha < \lambda$. Take $X_\alpha = P$ at 0 and at every successor ordinal, and $X_\alpha = 1$ at every nonzero limit ordinal. Give each X_α its distinguished least element. For $\alpha < \beta$, let the transition map be the constant map to that element of X_β. These maps compose as required. The colimit is 1, since every element is identified with a distinguished element at a later stage.

This diagram is perfectly π-adapted. The ordinal λ is π^+-directed. Every nonempty directed subset of cardinal at most π has a supremum below λ; if it has a maximum, the colimit is its final stage, and otherwise its supremum is a nonzero limit ordinal and both the colimit and that stage are 1. Yet the good indices, namely 0 and the successor ordinals, are cofinal, while the colimit is not in M. Thus b_π fails. □

The same phenomenon can be described as splitting an idempotent by a long filtered diagram. The continuous version above shows why replacing arbitrary presentations by subobject presentations loses precisely the needed information. We checked the definition in Chapter XIII, manuscript pp. 85–97, and the treatment of idempotents in (Artin et al., 1972, Exposé I, 8.6.5 and 10.6). We did not find this specified two-point diagram in those sources; it is an elaboration of the manuscript's counterexample, not a claim of priority.

p. 34



l'inclusion

$$\underbrace{X'_{i_0}}_{\in \mathrm{Filt}^\pi} \longrightarrow X \simeq \varinjlim X_i \,.$$

Comme $X'_{i_0} \in \mathrm{Filt}^\pi$, donc est π-accessible, il existe un $i_1 > i_0$ tel que $X'_{i_0} \longrightarrow X$ se factorise par

$$X'_{i_0} \longrightarrow X_{i_1} \,.$$

Appliquant ce même résultat à X_{i_1}, X'_{i_1} *etc.*, on trouve une suite infinie de morphismes

telle que les morphismes composés de deux en deux soient, sur la ligne supérieure, les transitions

$$X_{i_m} \longrightarrow X_{i_n} \qquad (\, i_m < i_n \,) \,,$$

et sur la ligne inférieure, les inclusions

$$X'_{i_m} \hookrightarrow X'_{i_n} \qquad (\hookrightarrow X) \,.$$

Soit $i_\omega = \sup_n i_n$ dans I, donc

$$X_{i_\omega} = \varinjlim_n X_{i_n} \simeq \varinjlim_n X'_{i_n} \simeq X'_{i_\omega} \,,$$

donc $X_{i_\omega} \longrightarrow X$ est un monomorphisme.

La dernière assertion de 5.7 résulte aussitôt du fait qu'une limite inductive filtrante de monomorphismes dans $\mathcal{M}$ est un monomorphisme (condition (e), p. 46). [page 57]

On peut préciser la proposition 5.6 obtenue ainsi :

Proposition 5.7. `[Deux fois 5.7.]` *Soient $\mathcal{M}$ une catégorie satisfaisant les conditions* (a), (b), (c), (d) (p. 44, 45) et (e) (p. 46). *Soit $\mathcal{M}$ une partie de* $\mathrm{Ob}\,\mathcal{M}$, *stable par isomorphie, π un cardinal tel que les objets de* Filt^π *soient π-accessibles. Les conditions suivantes sont équivalentes :*

a) *M est π-accessible, et stable par $\varinjlim$ filtrantes.*

b) *M est π-accessible, et $M \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrante de cardinal $\leq \pi$.*

c) *Il existe une partie M^π de Filt^π, stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$ et telle que pour tout $X \in \mathrm{Ob}\,\mathcal{M}$, on ait $X \in M$ si et seulement si l'ensemble J_M des $Z_\alpha \in J$ tels que $Z_\alpha \in M^\pi$ est cofinal dans J.*

(*De plus, sous la condition* (c), *on a* $M^\pi = M \cap \mathrm{Filt}^\pi$.) p. 35

c′) *Il existe une partie M_0 de Filt^π telle que M soit la plus petite partie de $\mathcal{M}$ stable par limites inductives filtrantes.* (*De plus, on peut alors prendre M_0* petite.)[22]. [page 58]

Commentary · Exposition [ms. 57]

Making the image factorization a transition

Lemma 5.7 is the comparison that makes the repaired recognition theorem work. Its diagonal construction is sound once one supplies an eventual-equality step. That step uses the accessibility of X_i as well as the accessibility of its image; factorization of the image alone does not identify the resulting composite with a transition of the original diagram.

Write $q_i : X_i \twoheadrightarrow U_i$ for the image factorization of the structural map to X. Given i_0, accessibility of $U_{i_0} \in \mathrm{Filt}^\pi$ gives $j \geq i_0$ and a factorization

$$U_{i_0} \xrightarrow{a} X_j \longrightarrow X.$$

The two maps aq_{i_0} and $X(i_0 \leq j)$ from X_{i_0} to X_j have the same composite to X. Accessibility of X_{i_0} therefore gives a further stage $i_1 \geq j$ at which these maps agree. After replacing a by its composite to X_{i_1}, the upper composite in Grothendieck's zigzag really is the transition $X_{i_0} \to X_{i_1}$. Its lower composite is the inclusion $U_{i_0} \hookrightarrow U_{i_1}$, since both maps are over X and the latter image maps monomorphically to X.

Repeating gives an interleaving of the chains (X_{i_n}) and (U_{i_n}). A cocone on either chain extends uniquely to a cocone on the other, so their colimits agree. Let $i_\omega = \sup_n i_n$. Perfect adaptation identifies X_{i_ω} with that colimit, while (e) makes the map $\varinjlim_n U_{i_n} \to X$ monic. Thus i_ω is a monomorphic stage above i_0. The same use of (e) and continuity proves that the monomorphic stages are closed under directed suprema of cardinal at most π. The choices may be non-strictly increasing; the proof does not require that the index have no maximal element.

There is a second detail in applying this lemma on manuscript page 53. The image of a continuous cofinal map of directed posets need not itself be closed under directed suprema, as the example below shows. Consequently, the image J of the monomorphic stage indices cannot simply be inserted into (5.3) without checking its closure requirement.

The correction already adopted on manuscript page 55 supplies the repair. If $X \in M$, the good small subobjects form a cofinal subset closed under small directed unions, because M^π has that closure. Starting with any monomorphic stage, choose a good small subobject containing it, then a later monomorphic stage containing that subobject, and continue alternately. At the countable supremum the stage and the union of the good subobjects agree, so the resulting stage is good. Hence good stages are cofinal. In the converse direction, if good stages are cofinal, their closure under small directed suprema makes their restricted diagram perfectly adapted. Applying Lemma 5.7 to it produces cofinally many good monomorphic stages; their subobjects are cofinal in $\mathrm{Sub}_\pi(X)$, so (5.1) gives $X \in M$. This proves the corrected assertion without imposing a closure property on the raw image of an indexing map.

22. **N.B.** On a

$$\begin{array}{ccc} (a) & \Longleftrightarrow & (b) \\ \Downarrow & & \Downarrow \\ (c') & \overset{?}{\Longrightarrow} & (c) \end{array},$$

sans conditions sur π (sauf $\pi \geq \pi_0$).

Commentary · Development (commentators') [ms. 57]

A continuous image need not be closed

The distinction just used is easy to miss because the indexing map preserves every supremum which can be formed upstairs. The difficulty is that a directed family of image values need not have coherently ordered representatives. The following example isolates that point in sets.

A perfectly adapted diagram with nonclosed image. [ours] Let I be the countable subsets of the successor ordinals below ω_1, ordered by inclusion. Choose $e \notin \omega_1$, put $X = \omega_1 \cup \{e\}$, and define subobjects of X by

$$X_S = \bigcup_{\alpha \in S} \alpha \ \cup \ \{e \mid |S| \geq 2\}.$$

With inclusion maps this is a perfectly $\aleph_0$-adapted presentation of X, and its image is cofinal among the countable subobjects of X, but that image is not closed under countable directed suprema.

Proof. The union of countably many countable subsets is countable, so I is $\aleph_1$-directed, and countable directed suprema in I are unions. If $\mathcal{K} \subset I$ is directed, its union contains two distinct ordinals exactly when some member of $\mathcal{K}$ contains both: direct the two witnesses to a common member. It follows that

$$X_{\bigcup \mathcal{K}} = \bigcup_{S \in \mathcal{K}} X_S.$$

Every X_S is countable, and the union of the whole diagram is X, proving perfect adaptation. Any countable subset of X is contained in X_S for a two-element S containing a successor ordinal above its ordinal elements; this proves cofinality. Finally every positive finite ordinal n is $X_{\{n\}}$. Their directed supremum is ω without e. No S with two or more elements gives this value, because its value contains e; a singleton gives a successor ordinal, and the empty set gives the empty set. Thus ω is not in the image. □

The literature check here was bounded to the adapted-presentation discussion in Chapter XIII, manuscript pp. 85–97, and SGA 4, Exposé I, 9.1–9.3 and 9.12–9.16. This explicit example supplies a missing verification in the present argument; we make no assertion that the observation is new.

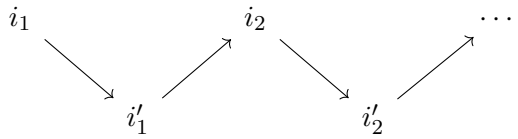
Corollaire 5.8. *Les applications*

$$M \ \longmapsto \ M^\pi = M \cap \mathrm{Filt}^\pi \ ,$$

$$M^\pi \quad \longmapsto \quad \begin{array}{l} \textit{l'ensemble des } X \in \mathrm{Ob}\,\mathcal{M} \textit{ tels que l'ensemble} \\ \mathrm{Ss}_\pi^{M^\pi}(X) \textit{ des } Z_\alpha \in \mathrm{Ss}_\pi(X) \textit{ qui sont dans } M^\pi \\ \textit{soit cofinal } (= \textit{plus petit sous-ensemble de} \\ \mathrm{Ob}\,\mathcal{M} \textit{ stable par } \varinjlim \textit{ filtrantes}) \end{array}$$

établissent des bijections, inverses l'une de l'autre, entre l'ensemble des $M \subset \mathrm{Ob}\,\mathcal{M}$ satisfaisant les conditions équivalentes de la proposition 5.7*, et l'ensemble des parties M^π de* Filt^π *stables par* $\varinjlim$ *filtrantes de cardinal $\leq \pi$.*

Démonstration de 5.7. L'implication $(b) \Longrightarrow (c)$ est tautologique, compte tenu de la définition de la π-accessibilité de M, et de la proposition 5.3. Et $(a) \Longrightarrow (b)$ provient de la stabilité de Filt^π par $\varinjlim$ filtrantes de cardinal $\leq \pi$ (condition (d)).



Il reste donc à prouver $(c) \Longrightarrow (a)$. (C'est ici qu'on doit utiliser l'hypothèse particulière sur π.) Une fois ceci vu, on saura l'équivalence de (a), (b), (c), et d'autre part, il est immédiat que $(a) \Longrightarrow (c')$, en prenant $M_0 = M \cap \mathrm{Filt}^\pi$. D'autre part, $(c') \Longrightarrow (c)$ (sans hypothèses sur π ?), car on peut supposer que la partie M_0 de Filt^π est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$. Mais alors, connaissant l'équivalence de (a), (b) (c), d'où aussitôt le corollaire, il s'ensuit que l'enveloppe stable par $\varinjlim$ filtrantes de M_0 dans $\mathcal{M}$ n'est autre que la partie accessible déduite de M_0 dont il est question dans (c), et on gagne. [page 59]

Donc tout revient à prouver que, si tous les objets de Filt^π sont accessibles, alors (c) implique (a). Montrons d'abord que (c) implique le critère d'appartenance (5.3) (p. 51), donc par la proposition 5.6 "revue et corrigée" dans la note 21, il s'ensuit déjà que $(c) \Longrightarrow (b)$, et il restera à établir $(b) \Longrightarrow (a)$, *i.e.* que (b) implique la stabilité de M par $\varinjlim$ filtrantes quelconques (pas seulement grandes devant π).

Que (c) implique (5.3) va résulter du lemme suivant, appliqué à $I = \mathrm{Ss}_\pi(X)$:

Lemme 5.8. [Deux fois 5.8.] *Soit I un ensemble ordonné* π-adapté, i.e. *filtrant et tel que toute partie filtrante K de I, de cardinal $\leq \pi$, ait une borne supérieure i_K dans I. Je dis qu'une partie J de I est* π-cofinale, *si elle est cofinale, et si pour toute partie filtrante K de J de cardinal $\leq \pi$, sa borne supérieure i_K dans I est dans J. (Il s'ensuit donc que J est lui aussi π-adapté, pour la structure d'ordre induite.) Ceci dit, l'intersection de deux parties π-cofinales de I est encore π-cofinale.* p. 36 [page 60]

Il suffit de voir qu'elle est cofinale, car sa stabilité par bornes supérieures dans I de parties filtrantes de cardinal $\leq \pi$ est tautologique (si elle est vraie pour des J_α, elle est vraie pour $\bigcap_\alpha J_\alpha$). Soit $i_0 \in I$, et construisons un élément de $J \cap J'$ qui majore i_0. On construit de proche en proche une double suite

avec les i_α dans J, les i'_α dans J', et $i_1 \geq i_0$. On a donc

$$\sup i_\alpha \;=\; \sup i'_\alpha \,,$$

et si i est la valeur commune des deux membres, on a $i \in J \cap J'$.

Ceci vu, pour prouver la validité de (5.3), on note que la partie $J' = \mathrm{Ss}_\pi^{(M^\pi)}(X)$ de $I = \mathrm{Ss}_\pi(X)$, formée des $Z_\alpha \subset X$ tels que $Z_\alpha \in M^\pi$, est stable par bornes supérieures de parties filtrantes de cardinal $\leq \pi$, vu que M^π est stable par $\varinjlim$ de cardinal $\leq \pi$. Donc si J est une partie π-cofinale de $\mathrm{Ss}_\pi(X)$, $J \cap J'$ est cofinale dans J, *i.e.* dans I, si et seulement si J' est cofinale dans I (*i.e.* si et seulement si $X \in M$, par la condition (c)). Car $J \cap J'$ cofinale $\Longrightarrow$ J' cofinale tautologiquement, et J' cofinale implique J' π-cofinale, donc $J \cap J'$ π-cofinale par le lemme 5.8, donc cofinale. [page 61]

Commentary · Exposition [ms. 60]

Closed cofinal families and the four descriptions

The alternating construction in Lemma 5.8 is a small version of the closed-unbounded argument familiar in set theory. Its purpose here is representation independence. Two canonical-looking systems of small subobjects need not meet cofinally merely because each is cofinal. Closure under countable directed suprema is what allows an alternating sequence to finish in both systems.

For example, the even and odd natural numbers are cofinal in $\mathbb{N}$ and disjoint. That order lacks the required countable suprema. In a π-adapted order, with π infinite, start above any prescribed element and alternate choices in two closed cofinal subsets. The supremum of the even subsequence equals that of the odd subsequence, and belongs to both. The intersection is therefore cofinal; closure of the intersection is immediate. This gives exactly the assertion used in the manuscript, without any assumption that π itself is regular.

We can now organize the corrected Proposition 5.7. Let $S \subset \mathrm{Filt}^\pi$ be invariant under isomorphism and closed under filtered colimits with at most π arrows. Define M_S by cofinality of its S-subobjects in $\mathrm{Sub}_\pi(X)$. Under (e) these good subobjects are closed under small directed suprema. Their intersection with any other closed cofinal family is cofinal by the preceding argument. Thus M_S satisfies (5.3), and the corrected Proposition 5.6 identifies it as a π-accessible class when the Filt^π-objects are π-accessible. Proposition 5.9, in this same range of cardinals, supplies closure under all filtered colimits.

Conversely, a π-accessible class closed under all filtered colimits has bounded part $S = M \cap \mathrm{Filt}^\pi$ with the required small-colimit closure, by (d_0), and (5.1) reconstructs M. These two operations are inverse because on a bounded object cofinality is equivalent to containing the largest subobject, namely the object itself. This is Corollary 5.8.

The description by an arbitrary generating set $M_0 \subset \mathrm{Filt}^\pi$ follows by first closing M_0 under the filtered colimits of cardinal at most π which exist inside the bounded level, and under isomorphism.

Call the resulting class S. It remains essentially small because it is contained in Filt^π. The class M_S is filtered-colimit closed and contains M_0. Any filtered-colimit closed class containing M_0 contains S, and then contains M_S, since every object of M_S is a filtered colimit of its good small subobjects. Hence M_S is precisely the filtered-colimit closure of M_0.

The printed condition (c'), and the matching parenthesis in Corollary 5.8, omit the words saying that the smallest closed class must *contain* the proposed generators. Those words are indispensable: without them the smallest class closed under nonempty filtered colimits is the empty class. The intended statement and its proof are unambiguous from the surrounding discussion. The stronger question in footnote 22 concerns retaining the same rank without the special assumption on the bounded objects; it is not resolved merely by the proof at the admissible ranks used in the proposition.

Reste à prouver seulement que $(b) \Longrightarrow (a)$, *i.e.* la stabilité de M par limites inductives filtrantes quelconques, moyennant (b). Ici à nouveau, cela ne doit pas utiliser l'hypothèse particulière sur π, ni même l'hypothèse d'exactitude (e) sur $\mathcal{M}$, mais être une histoire générale d'accessibilité :

Proposition 5.9. *Soit $\mathcal{M}$ une catégorie satisfaisant* (a), (b), (c), (d_0) (pages 44, 45), *$\pi \geq \pi_0$ un cardinal, M une partie π-accessible de* $\mathrm{Ob}\,\mathcal{M}$, i.e. *satisfaisant la condition b_π de* XIII, p. 88. *Alors M est stable par $\varinjlim$ filtrantes si et seulement si $M^\pi \overset{déf}{=} M \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$.*

Je n'ai pas envie d'expliciter ici la démonstration, ayant l'impression pénible de refaire à perpette la même démonstration (ici et dans XIII). Je devrai revenir là-dessus dans une situation plus décantée.

Je vais quand même esquisser la démonstration. Soit $X = \varinjlim_I X_i$, I filtrant, les X_i dans [page 62]
M, il faut prouver que $X \in M$ (moyennant l'hypothèse de stabilité sur $M^\pi = M \cap \mathrm{Filt}^\pi$). p. 37

$$\begin{array}{ccc} \mathcal{C} & \longrightarrow & I \\ \downarrow & \text{cart.} & \downarrow \varphi \\ \underline{M}^\pi \text{ “source”} & \underline{M}^\pi/\underline{M} \xrightarrow[\text{“but”}]{} & \underline{M} \end{array}$$

$\mathcal{C}$ est une catégorie cofibrée sur I, dont les fibres sont

$$\mathcal{C}_i \simeq M^\pi/X_i\ ,$$

or comme $X_i \in M$, on voit, à cause de la condition de π-accessibilité, que M^π/X_i est *filtrante.* On va le dégager en

Lemme 5.10. *Soit M une partie π-accessible de $\mathcal{M}$. Alors pour tout $Y \in M$, M^π/Y est une catégorie* filtrante, *et $\mathrm{Ss}_\pi(Y)$ y est cofinale.*

Considérons le foncteur canonique [page 63]

$$I \;=\; \mathrm{Ss}_\pi(Y) \xrightarrow{\varphi} \underline{M}^\pi/Y \;=\; I'\ ,$$

où la catégorie source I est filtrante. Par SGA 4 I 8.1.3, ce foncteur est cofinal si et seulement s'il satisfait deux conditions F 1, F 2, et alors I' est également filtrante. La condition F 1 est la condition habituelle que tout $i' \in \mathrm{Ob}\,I'$ est “majoré” par un $\varphi(i)$, *i.e.* tout $Z \longrightarrow Y$, avec $Z \in M^\pi$, est “majoré” par un *monomorphisme* $Z_\alpha \hookrightarrow Y$, avec $Z_\alpha \in M^\pi$, ce qui résulte du fait que c'est majoré par $Z_\alpha \hookrightarrow Y$ avec $Z_\alpha \in \mathrm{Filt}^\pi$, *i.e.* $Z_\alpha \in \mathrm{Ss}_\pi(Y)$, et que parmi ces Z_α ceux qui sont dans M^π sont cofinaux (vu que $Y \in M$). L'autre condition [23] est qu'une double flèche $i' \overset{f'}{\underset{g'}{\rightrightarrows}} \varphi(i)$ peut s'égaliser par une flèche $\varphi(h)$, avec $h : i \longrightarrow j$. Mais en fait, pour un $i' \in \mathrm{Ob}\,I'$, [page 64]
i.e. un $Z \longrightarrow Y$ donné ($Z \in M^\pi$), et un $i \in \mathrm{Ob}\,I$, *i.e.* un $Z_\alpha \hookrightarrow Y$ donné ($Z_\alpha \in M^\pi$), il existe

23. Comme I est filtrante.

au plus *une* flèche dans $I' = \underline{M}^\pi/Y$ de $Z \longrightarrow Y$ dans $Z_\alpha \hookrightarrow Y$. Donc la condition F 2 est trivialement satisfaite (on prend $h = \mathrm{id}_i$).

Corollaire 5.11. *Si $(X_i)_{i\in I}$ est un système inductif filtrant, avec les X_i dans M^π, alors la catégorie $\mathcal{C} = \underline{M}^\pi/\underline{M} \times_{\underline{M}} (I, \varphi)$, construite page* 62, *est filtrante, et le foncteur canonique (fibrant) $\mathcal{C} \longrightarrow I$ est cofinal.*

Que $\mathcal{C}$ soit filtrante et $\mathcal{C} \longrightarrow I$ cofinal résulte formellement du fait que I l'est, que les fibres de $\mathcal{C}$ le sont, et que $\mathcal{C}$ est cofibrée sur I. (Mérite un lemme, à toutes fins utiles.)

N.B. On peut remplacer $\mathcal{C}$ par $\mathcal{C}_0$ dont les fibres sont les

$$\mathrm{Ss}_\pi^{M^\pi}(X_i) \ \subset \ \underline{M}^\pi \ ; \qquad \text{cofinale dans } \mathcal{C}_i = \underline{M}^\pi/X_i \ ,$$

on trouve une sous-catégorie de $\mathcal{C}$ cofinale dans $\mathcal{C}$, et qui est cette fois ordonnée tout comme I. [page 65]

Commentary · Exposition [ms. 64]

The slice category that must be integrated

The final argument returns from subobjects to maps, because maps assemble functorially when the target moves. Its fibre over $Y \in M$ is M^π/Y, the category of maps $A \to Y$ with $A \in M^\pi$. The poset naturally included in this fibre is

$$\mathrm{Sub}_\pi^M(Y) = \{U \hookrightarrow Y \mid U \in M \cap \mathrm{Filt}^\pi\}.$$

The unrestricted $\mathrm{Ss}_\pi(Y)$ printed in Lemma 5.10 and its first display must be restricted in this way. An arbitrary small subobject of an object of M need not itself belong to M, so the printed unrestricted functor is not defined in general.

Under the image and continuity hypotheses used earlier in this section, the corrected assertion follows directly from (5.1). Given $A \to Y$, its image is small by (d_2), and is contained in a good small subobject by cofinality. Hence every object of M^π/Y maps to an object of $\mathrm{Sub}_\pi^M(Y)$. There is at most one map over Y into any fixed subobject. The good subobjects form a directed poset, and their inclusion in the slice is final: the relevant comma category is nonempty, and two of its objects have a common upper bound. This also proves that M^π/Y is filtered. Its source diagram has colimit Y, because the final subobject diagram does.

For a filtered diagram $i \mapsto Y_i$ in M, the total category $\mathcal{E}$ has objects (i, A, a), where $A \in M^\pi$ and $a : A \to Y_i$. A morphism to (j, B, b) is a pair (u, v) with $u : i \to j$, $v : A \to B$, and $bv = Y(u)a$. Postcomposition gives an opfibration $\mathcal{E} \to I$. The adjective "fibrant" in Corollary 5.11 has the wrong variance for this construction; no pullback closure of M^π is assumed.

The total category is filtered. Two objects can first be moved to a common base index and then given a common successor in that fibre. For two parallel arrows, first equalize their base arrows in I, then equalize the resulting two vertical arrows in the target fibre. The same argument shows that $\mathcal{E} \to I$ is final. More particularly, a cocone on the source objects A of $\mathcal{E}$ is exactly a compatible family of cocones on the fibres. Taking their colimits gives

$$\varinjlim_{(i,A,a)\in\mathcal{E}} A \cong \varinjlim_{i\in I} \left(\varinjlim_{(A\to Y_i)\in M^\pi/Y_i} A \right) \cong \varinjlim_i Y_i.$$

This is an ordinary colimit calculation; no homotopy-cofinality theorem is being used.

Corollary 5.11 prints $Y_i \in M^\pi$, a stronger hypothesis than the argument needs. The same proof works for $Y_i \in M$, and this is the form required on manuscript page 62. If the base index is a poset, the full subcategory consisting of good subobjects in each fibre is again a poset and is final in $\mathcal{E}$. Its projection need not remain an opfibration: the image of a good subobject after postcomposition need not be good. The proof requires only finality of this subcategory, which the preceding factorization through good subobjects establishes.

p. 38

On a

$$X_i \ = \ \varinjlim_{Z_\alpha \in \mathcal{C}_i} Z_\alpha \ ,$$

donc

$$X \;=\; \varinjlim_{\alpha\in\mathcal{C}} Z_\alpha \;,$$

au total on est arrivé à représenter X comme $\varinjlim$ filtrante d'éléments Z_α qui sont (non seulement dans M, mais même) dans M^π.

Changeons la notation, en prenant

$$X \;=\; \varinjlim_{i\in I} X_i \;, \qquad I \text{ ensemble ordonné filtrant, } X_i \in M^\pi \;\; \forall\, i \in I \;,$$

soit I' l'ensemble des parties *filtrantes* $J \subset I$ telles que $\operatorname{card} J \leq \pi$, I' ordonné par inclusion. Alors I' est grand devant π, et on a un système inductif

$$(X_J)_{J\in I'} \;, \qquad X_J \;=\; \varinjlim_{i\in J} X_i \;.$$

Par l'hypothèse de stabilité de M^π (qui n'a pas encore servi), les X_J sont dans M^π. On a donc

$$X \;=\; \varinjlim_{J\in I'} X_J \;, \qquad \text{les } X_J \text{ dans } M^\pi,\ I' \text{ grande devant } \pi \;,$$

donc $X \in M$ puisque M est π-admissible, *q.e.d.*

[page 66]

Commentary · Exposition [ms. 65]

Completing the filtered-colimit closure argument

The last reindexing in Proposition 5.9 is the right way to pass from bounded filtered colimits to arbitrary ones. There is, however, a scope issue in the preceding reduction. The proposition drops the image hypotheses $(d_1), (d_2)$ and the exactness hypothesis (e), whereas the proof of Lemma 5.10 as printed uses the earlier subobject presentation. We give a complete proof under the additional assumption that every Filt^π-object is π-accessible. This is the assumption already present in Proposition 5.7 and suffices for every application to the four equivalent descriptions above. The printed general assertion for an arbitrary rank is not certified by the image proof alone.

Put $A = M \cap \mathrm{Filt}^\pi$, and suppose that A is closed under filtered colimits indexed by categories with at most π arrows. When forming slices, replace this essentially small class by a small full set of representatives; this does not change their colimits. The necessary direction of Proposition 5.9 is immediate from (d_0), so consider a filtered diagram $Y_i \in M$ with colimit Y. For each Y_i, choose a perfectly π-adapted presentation by objects of Filt^π. Such presentations exist under $(b), (d_0)$: apply the reindexing by small filtered subcategories given below to any bounded generating presentation. Condition b_π makes its A-stages cofinal. Thus Y_i is a π^+-directed colimit of objects of A.

Smallness of the domains now supplies the slice argument without images. Any finite diagram in A/Y_i factors through one stage of the chosen A-presentation: factor the finitely many structural maps, choose a common stage, and then pass further until its finitely many commutativity equations hold. The same reasoning works for a diagram with at most π arrows. Hence A/Y_i is π^+-filtered. The chosen presentation is final in it, since every map from an A-object factors through a stage and two factorizations become equal at a later stage. In particular

$$Y_i \cong \varinjlim_{A/Y_i} A.$$

The opfibration argument in the preceding block then expresses Y as a filtered colimit of A-objects, say $Y = \varinjlim_{e\in E} A_e$ with E small and filtered.

To make this presentation perfectly adapted, let P be the poset of filtered subcategories $J \subset E$ with at most π arrows. Every set of at most π arrows of E is contained in such a subcategory: repeatedly adjoin identities, composites, cocones for finite diagrams and equalizers of parallel pairs. There are at most π choices at each step, and countably many repetitions suffice, since π is infinite. This also shows that P is π^+-directed. A directed family of at most π members of P has its union as supremum; that union is still filtered and has at most π arrows.

Define $A_J = \varinjlim_{e\in J} A_e$. By the assumed bounded closure, $A_J \in A$. Colimits commute with this directed union of indexing categories: a cocone on the union is exactly a compatible family of cocones on the pieces. Consequently

$$Y \cong \varinjlim_{J\in P} A_J, \qquad A_{\bigcup K} \cong \varinjlim_{J\in K} A_J \quad (K \subset P \text{ directed},\ |K| \le \pi).$$

This is a perfectly π-adapted presentation with every stage in M. Applying b_π gives $Y \in M$, which completes the proof in the stated range.

The proof also makes the remaining issue precise. To remove the extra presentability assumption one needs, under the proposition's weaker hypotheses, a replacement for the slice factorization and density argument. The statement on manuscript page 44 about generation by strict epimorphisms would provide such density if established at the required bounded level, but it should not be inferred merely from a choice of colimit presentations. Density and generation under colimits are distinct notions. The earlier discussion already flags this difficulty: Chapter XIII, manuscript p. 92, questions the asserted strict generation, and footnote 44 on manuscript p. 93 explicitly identifies the tacit hypothesis that the bounded objects are π-accessible (Grothendieck, 1990–1991q). We have not settled that unrestricted fixed-rank step here; this is a limit of the present verification, not a claim that it is an open problem in the literature.

Définition 5.12.

1) Soit $\mathcal{M}$ une catégorie satisfaisant les conditions (a), (b), (c), (d) (p. 44-46). Soit $\pi \ge \pi_0$ un cardinal. Une partie M de $\operatorname{Ob}\mathcal{M}$ est dite *L-π-accessible,* si elle est π-accessible et stable par petites $\varinjlim$ filtrantes[24], ou ce qui revient au même (5.9), si elle est π-accessible et si $M^\pi = M \cap \operatorname{Filt}^\pi$ est stable par $\varinjlim$ filtrantes de cardinal $\le \pi$. (**N.B.** Si les objets de Filt^π sont π-accessibles, 5.8 nous dit que cela signifie aussi qu'il suffit pour cela qu'il existe une partie M_0 de Filt^π telle que M soit la L-enveloppe (enveloppe stable par $\varinjlim$ filtrantes) de M_0 – condition qui est de toutes façons toujours nécessaire, en prenant $M_0 = M^\pi$.)
2) Soit M une partie de $\operatorname{Ob}\mathcal{M}$. On dit qu'elle est *L-accessible,* si elle satisfait à l'une des quatre conditions équivalentes suivantes :
   - a) Il existe un cardinal π tel que M soit L-π-accessible.
   - a') M est accessible et L-stable.
   - b) Il existe une petite partie M_0 de $\operatorname{Ob}\mathcal{M}$, telle que M soit la L-enveloppe de M_0[25].
   - b') Il existe une partie M_0 de $\mathcal{M}$ contenue dans une partie Filt^π (ou ce qui revient au même, telle que la sous-catégorie pleine $\underline{M}_0$ de $\mathcal{M}$ soit essentiellement petite, *i.e.* équivalente à une petite catégorie, telle que M soit la *L*-enveloppe de M_0).

Commentary · Later developments [ms. 66]

Filtered-colimit classes and modern accessible categories

Definition 5.12 isolates the feature needed for the intended application: a class is generated by bounded objects and is closed under *all* filtered colimits. At the good cardinals used in Proposition 5.7, its full subcategory is π^+-accessible in the current sense, and its inclusion into $\mathcal{M}$ preserves filtered colimits. Indeed its bounded objects are π^+-presentable even in the ambient category, every object has a π^+-directed presentation by them, and the required colimits exist in the full subcategory because they are computed in $\mathcal{M}$. This is the familiar small-generation description of accessible categories; see (Adámek and Rosický, 1994, Definition 2.1 and Theorem 2.26). The manuscript's b_π also controls every continuous bounded presentation, so one should not identify its fixed-rank definition with the modern definition without the comparison just proved.

A simple example shows that L-accessibility does not mean local presentability of the full subcategory. In Set, let M be the nonempty sets. Its bounded part consists of the nonempty sets of

24. On dit alors que M est *L-stable.*
25. Cette condition ne dépend pas de la filtration cardinale choisie de $\mathcal{M}$.

cardinal at most π and is closed under filtered colimits of cardinal at most π. For a nonempty X, every small subset can be enlarged to a nonempty small subset; for $X = \varnothing$ there is no good subobject at all. Thus the small-subobject criterion recovers exactly M. Filtered colimits of nonempty sets are nonempty, so this is an L-accessible class. Its full subcategory has no initial object: a singleton has more than one map to a two-element set, and a larger set does not have a unique map either. It is therefore accessible but not cocomplete.

Under the hypotheses of Proposition 5.7, the statement independent of a chosen filtration is the existence of an essentially small family whose filtered-colimit closure is the given class. To pass from a small family to a bounded one, bound the filtration indices of its representatives. To pass back, take representatives of the bounded level. At a sufficiently large cardinal satisfying the accessibility requirement, Proposition 5.7 identifies this closure with the class detected by cofinally many good small subobjects. The cardinal filtration is then a means of making the construction uniform; the resulting notion of L-accessibility does not retain that choice.

There is a final scope convention to keep visible. Definition 5.12 restates $(a), (b), (c), (d)$ but omits (e). The definition of L-π-accessibility itself makes sense with those hypotheses. Its cited classification through Proposition 5.7, however, was proved using (e), and our small-subobject argument retains that hypothesis. We have not supplied a proof removing it from the classification, just as we have not removed the rank restriction from Proposition 5.9. These qualifications concern the claimed equivalences under weaker hypotheses, not the definition or the preceding example.

This is the part of the chapter which is closest to the later theory of accessible and accessibly embedded subcategories. It supplies a method for obtaining a small amount of generating data, while the earlier factorization argument turns small generating *maps* into lifting factorizations. These are different passages: existence of a small generating family under filtered colimits does not by itself assert that the same maps generate a weak factorization system. The additional closure and lifting arguments remain necessary.

Overview · XV-a

Grothendieck devotes these pages to the passage from a small amount of generating data to a factorization theory on a large category. The point is not merely to factor an individual map. The construction must vary with that map, remain compatible with enlargement of the generators, and admit a bound which is independent of the particular object being treated. Only then can it contribute to the construction of categories of models and, through them, to the homotopy theories of diagrams which the manuscript seeks to organize.

The chapter brings together two kinds of control. Lifting properties say what a factorization must accomplish; cardinal filtrations say when the construction has accomplished enough and how large its intermediate objects can become. The former belongs to the language of model categories, while the latter continues the systematic treatment of generation and accessibility in SGA 4, Exposé I. Their interaction is the mathematical subject of this part of Chapter XV. The later discussion of accessible classes is therefore not a digression. It addresses the problem of replacing a class of prospective generators by a set to which the preceding construction can be applied.

Attaching solutions and taking a sufficiently long limit. For a set C_0 of arrows and a map $f : X \to Y$, the first stage attaches, simultaneously, one solution for every square from an element of C_0 to f. Grothendieck realizes this simultaneous attachment as the filtered colimit of the finite amalgamations. This permits him to work with the relevant pushouts and filtered colimits, without assuming arbitrary coproducts at the outset. The residual map to Y is then subjected to the same operation, and limit stages are formed by filtered colimits. The result is the classical small object construction, expressed as a transfinite sequence of functorial factorizations; compare Riehl (2014, Chapter 12).

The decisive step is a factorization of a map from the domain of a generator through an earlier stage. If these domains are π-accessible in the manuscript's convention, a limit ordinal of cofinality greater than π suffices. A square reaching the limit then already occurs at some stage and receives its solution at the next. The word *limit* is necessary: an ordinal with a last predecessor can satisfy the order-theoretic definition of "grand devant π" while providing no further stage in which to attach the required solution. The printed statements omit this qualification. Their usual successor-cardinal choice of stopping ordinal has the required property and repairs them.

The cellular left class is compared with the left lifting class by the familiar retract argument. Factoring a map which already has the left lifting property exhibits it as a retract of its cellular factor. The commentary also supplies the functoriality arguments left to the reader, including compatibility with inclusions of generating sets. One should not confuse completion of the lifting task with stabilization of the sequence: for the sole generator $\varnothing \to 1$ in sets, the stages have the form $X \amalg (Y \times \alpha)$. They continue growing after the residual map has become surjective. Garner's algebraic refinement treats the additional structure of chosen fillers and its composition laws (Garner, 2009); that structure is stronger than the functoriality established here.

The arithmetic behind a uniform factorization. A cardinal filtration presents a large object by sufficiently directed diagrams of smaller ones. The two base cardinals have distinct roles: π_0 bounds the complexity of these presentations, while π_1 provides a uniform accessibility bound for the first bounded level. The estimates then depend on a small category of representatives and on its actual arrows. Counting only isomorphism classes in the arrow category loses the automorphisms and cannot bound individual Hom sets. The one-object category of an arbitrarily large small group gives a particularly short counterexample: its arrows have one isomorphism class, although its unique Hom set has the cardinality of the group.

Choose a small full skeleton K_1 of the π_1-level and put

$$\chi = \max(\aleph_0, \pi_1, |\operatorname{Mor}(K_1)|), \qquad \mu = r^{\pi_0}, \qquad r, s \geq \chi.$$

The corrected counting argument gives the intended forms of the bounds: at most 2^μ isomorphism classes of objects and arrows at level r, and at most s^μ maps from an r-bounded object to an s-bounded one. The number of choices of a diagram must be counted by exponentiation, not by the printed products. With that change the final estimates still follow. The asserted universal sharpness of the two-coloured-set example does not: under GCH its arrow-orbit count at $r = \aleph_1$ is smaller than 2^r.

The fixed-point device is robust. Taking a sufficiently large $\rho = 2^c$ makes $\rho^{\pi_0} = \rho$ and absorbs the repeated attachment bounds. The manuscript's alternative GCH shortcut needs a cofinality condition: GCH does not imply $\rho^{\pi_0} = \rho$ at singular cardinals of cofinality at most π_0. The commentary separates these two choices and proves a bound retaining the actual number of generators. If their endpoints lie at level r, the input endpoints at level s, and the construction is followed through α, then

$$B = \left(\max(2, r, s, |C_0|, |\alpha|)\right)^{r^{\pi_0}}$$

bounds every stage, under the stated closure hypotheses. Thus the principal uniform-factorization conclusion survives the correction of its numerical threshold. Low's later analysis identifies regular-cardinal conditions under which factorization functors preserve presentable objects and a small subcategory detects a combinatorial model structure (Low, 2016, Theorem 4.4, Theorem 5.9, Proposition 5.12).

Recognizing a category of models. Section 4 separates the elementary logic of lifting from the smallness needed to produce the factorizations. A precouple supplies lifting and factorization; closing its two classes under retracts gives the corresponding weak factorization system. Two compatible systems, together with the cancellation properties of W, provide the model-category identities. This distinction explains both the strength of Proposition 4.2 and the defect in the later footnote which treats unclosed precouples as though they were already closed. A set-theoretic counterexample in the commentary satisfies the displayed equalities but fails retract closure.

The class Cof_W records preservation of weak equivalences by pushout. An arrow in $W \cap \mathrm{Cof}_W$ need not, under the hypotheses printed at that point, remain in W after every cobase change. A four-object diamond lattice makes the difference explicit. The omitted sufficient hypothesis is already present in Chapter XIII: every map must factor as a W-cofibration followed by a weak equivalence. The commentary proves the resulting identification with couniversal weak equivalences. The eventual recognition theorem, Proposition 4.4.6, supplies this factorization through its first weak factorization system, so its principal conclusion is preserved.

For the existence of the second small generating family, modern accessibility hypotheses give a precise answer. Smith's theorem as published by Beke (2000, Theorem 1.7 and Proposition 1.15) supplies the relevant solution-set argument in a locally presentable category. The formulation in Lurie (2009, Proposition A.2.6.15, updated online version) is especially close to the proposed construction from W and Cof_W. These results resolve the problem in their stated setting; they do not justify deleting hypotheses from an arbitrary cardinally filtered category. Once such a combinatorial model category is obtained, its diagram homotopy categories form a strong derivator (Groth, 2013, Proposition 1.30). This identifies the later destination of the machinery without treating this portion of the manuscript as a proof of every derivator axiom.

Recovering a class from its bounded part. Section 5 replaces presentations by maps with presentations by small subobjects. Images, closure of bounded levels under suitable

colimits, and exactness of filtered colimits make the poset of small subobjects into a continuous, sufficiently directed presentation of the object. The hypotheses on images are independent in the direction questioned by the source: a cyclic module may contain a submodule needing arbitrarily many generators. The commentary gives the complete polynomial-ring example, and distinguishes a strict monomorphism from an arbitrary proper monomorphism in the preceding image lemmas.

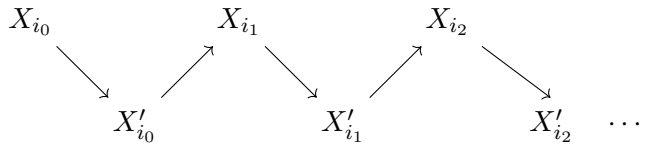
The definition of an accessible class used here tests *every* perfectly adapted presentation. Recognizing membership from cofinally many good small subobjects is therefore initially only a necessary condition. The first version of Proposition 5.6 misses the information carried by nonmonic presentations; Grothendieck himself corrects it in footnote 21. A continuous diagram of two-point and one-point posets makes the retract obstruction explicit. Closure of the bounded part under small filtered colimits repairs the assertion. The remaining comparison is a closed-cofinal-set argument: two cofinal families meet cofinally when both contain the relevant directed suprema. The supplied proofs include the eventual-equality step in Lemma 5.7 and avoid assuming that the image of a continuous cofinal indexing map is itself closed.

At cardinals where the bounded objects are themselves π-accessible, these arguments give the four descriptions in the corrected Proposition 5.7, the recovery bijection of Corollary 5.8, and filtered-colimit closure. Proposition 5.9 is printed in wider generality. Its proof invokes a slice argument whose supplied justification uses hypotheses no longer retained. We prove the proposition at the cardinals required for the preceding recognition theorem, but do not certify the unrestricted fixed-rank assertion. This is a stated limit of the present verification, not a designation of an open problem. In the verified range, the resulting full subcategory is accessible and accessibly embedded; it need not be cocomplete, as the nonempty sets show (Adámek and Rosický, 1994, Definition 2.1).

The commentary keeps these distinctions visible in its apparatus. The edition remains the authority for the historical text; genuine transcription corrections are applied, while slips visible in the edition are retained and explained. The claim register records the source's proof status separately from the repair. Results developed here carry the marker [ours] in their commentary blocks and no claim of priority.

XV-b · Chapter XV, part 2 of 2 · manuscript pages 57–137

p. 34



l'inclusion

$$\underbrace{X'_{i_0}}_{\in \mathrm{Filt}^\pi} \longrightarrow X \simeq \varinjlim X_i \,.$$

Comme $X'_{i_0} \in \mathrm{Filt}^\pi$, donc est π-accessible, il existe un $i_1 > i_0$ tel que $X'_{i_0} \longrightarrow X$ se factorise par

$$X'_{i_0} \longrightarrow X_{i_1} \,.$$

Appliquant ce même résultat à X_{i_1}, X'_{i_1} *etc.*, on trouve une suite infinie de morphismes

telle que les morphismes composés de deux en deux soient, sur la ligne supérieure, les transitions

$$X_{i_m} \longrightarrow X_{i_n} \qquad (\, i_m < i_n \,) \,,$$

et sur la ligne inférieure, les inclusions

$$X'_{i_m} \hookrightarrow X'_{i_n} \qquad (\hookrightarrow X) \,.$$

Soit $i_\omega = \sup_n i_n$ dans I, donc

$$X_{i_\omega} = \varinjlim_n X_{i_n} \simeq \varinjlim_n X'_{i_n} \simeq X'_{i_\omega} \,,$$

donc $X_{i_\omega} \longrightarrow X$ est un monomorphisme.

La dernière assertion de 5.7 résulte aussitôt du fait qu'une limite inductive filtrante de monomorphismes dans $\mathcal{M}$ est un monomorphisme (condition (e), p. 46). [page 57]

On peut préciser la proposition 5.6 obtenue ainsi :

Commentary · Exposition [ms. 57]

Small pieces and recognition of a class

Grothendieck wants a supply of small generators which remains useful after one imposes several conditions on an object or on a morphism. The immediate example will be a class of cofibrations intersected with a class of weak equivalences. Before asking whether such an intersection generates a factorization system, he separates the more elementary question: can membership be recognized on sufficiently many small pieces? This is the purpose of the end of §5. Its positive results survive the failure of the proposed factorization theorem in §6.

Here and below all indexing categories are small in the fixed universe, and π is infinite. Put $\mathcal{K}_\pi = \underline{\mathrm{Filt}}^\pi(\mathcal{M})$ and write $\mathrm{Ss}_\pi(X)$ for the poset of subobjects of X whose domains belong to $\mathcal{K}_\pi$. A poset is "large with respect to π" when every subset of cardinal at most π has an upper bound; in current terminology it is π^+-directed. A π-adapted presentation has the additional continuity property

$$X_{\sup J} \simeq \varinjlim_{j \in J} X_j \quad \text{for every directed } J \text{ with } |J| \leq \pi, \qquad X_i \in \mathcal{K}_\pi.$$

The last requirement is part of the definition. It will be precisely the requirement lost on manuscript page 83. The term "π-accessible object" means that its covariant hom functor preserves these large filtered colimits, hence means π^+-presentable in the modern cardinal convention. Accessibility of a *class* in these pages is the stronger, explicitly embedded recognition condition b_π: in every adapted presentation of X, the object X belongs to M exactly when the indices with $X_i \in M$ are cofinal. It must not be replaced without argument by the assertion that the full category on M is accessible. The definition is recorded explicitly in Chapter XIII, manuscript pages 86–89 (Grothendieck, 1990–1991e).

The standing assumptions from the preceding pages have concrete roles. Cocompleteness supplies the colimits. The cardinal filtration makes each $\mathcal{K}_\pi$ essentially small and supplies presentations. Condition (d) on manuscript pages 45–46 includes closure under colimits of diagrams with at most π arrows, under subobjects, and under images of maps with small source. Condition (e) says that filtered colimits in the arrow category preserve monomorphisms. Consequently the union of small subobjects is computed by their filtered colimit, and $\mathrm{Ss}_\pi(X)$ itself gives an adapted presentation. These hypotheses concern ordinary colimits, before homotopy enters the discussion.

There are two independent meanings of generation to keep in view. The L-envelope of M_0 is its closure under arbitrary small filtered colimits. The class $\widetilde{C}$ of arrows is a lifting closure, namely ${}^{\square}(C^{\square})$. A filtered presentation of a morphism need not be a sequence of pushout attachments. Nothing in Proposition 5.7 identifies these two closure operations.

The proposition compares three descriptions of an L-accessible class: an intrinsic recognition condition; closure of its bounded part under bounded filtered colimits; and a cofinality test on small subobjects. In condition (c), J is $\mathrm{Ss}_\pi(X)$. In condition (c′), the phrase "containing M_0" is absent from the edition and has to be understood; otherwise the smallest filtered-colimit-closed class is the empty class. The same omission occurs in the parenthesis of Corollary 5.8. We retain these printed readings and record their intended meaning in the audit. The duplicate numbers 5.7 and 5.8 likewise belong to the edition: the proposition and corollary here are distinct from the lemmas with those numbers.

Proposition 5.7. [Deux fois 5.7.] *Soient $\mathcal{M}$ une catégorie satisfaisant les conditions* (a), (b), (c), (d) (p. 44, 45) et (e) (p. 46). *Soit $\mathcal{M}$ une partie de* $\mathrm{Ob}\mathcal{M}$*, stable par isomorphie, π un cardinal tel que les objets de* Filt^π *soient π-accessibles. Les conditions suivantes sont équivalentes :*

a) *M est π-accessible, et stable par $\varinjlim$ filtrantes.*

b) *M est π-accessible, et $M \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrante de cardinal $\leq \pi$.*

c) *Il existe une partie M^π de* Filt^π*, stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$ et telle que pour tout $X \in \mathrm{Ob}\mathcal{M}$, on ait $X \in M$ si et seulement si l'ensemble J_M des $Z_\alpha \in J$ tels que $Z_\alpha \in M^\pi$ est cofinal dans J.*

(*De plus, sous la condition* (c), *on a* $M^\pi = M \cap \mathrm{Filt}^\pi$.) p. 35

c′) *Il existe une partie M_0 de* Filt^π *telle que M soit la plus petite partie de $\mathcal{M}$ stable par limites inductives filtrantes.* (*De plus, on peut alors prendre M_0* petite.) [22]. [page 58]

Corollaire 5.8. *Les applications*

$$M \longmapsto M^\pi = M \cap \mathrm{Filt}^\pi ,$$

$$M^\pi \longmapsto \begin{array}{l} \text{l'ensemble des } X \in \mathrm{Ob}\mathcal{M} \text{ tels que l'ensemble} \\ \mathrm{Ss}_\pi^{M^\pi}(X) \text{ des } Z_\alpha \in \mathrm{Ss}_\pi(X) \text{ qui sont dans } M^\pi \\ \text{soit cofinal } (= \text{plus petit sous-ensemble de } \mathrm{Ob}\mathcal{M} \\ \text{stable par } \varinjlim \text{ filtrantes}) \end{array}$$

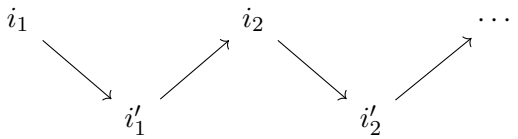
établissent des bijections, inverses l'une de l'autre, entre l'ensemble des $M \subset \mathrm{Ob}\mathcal{M}$ satisfaisant les conditions équivalentes de la proposition 5.7*, et l'ensemble des parties M^π de* Filt^π *stables par $\varinjlim$ filtrantes de cardinal $\leq \pi$.*

Démonstration de 5.7. L'implication $(b) \Longrightarrow (c)$ est tautologique, compte tenu de la définition de la π-accessibilité de M, et de la proposition 5.3. Et $(a) \Longrightarrow (b)$ provient de la stabilité de Filt^π par $\varinjlim$ filtrantes de cardinal $\leq \pi$ (condition (d)).

22. **N.B.** On a

$$\begin{array}{ccc} (a) & \Longleftrightarrow & (b) \\ \Downarrow & & \Downarrow \\ (c') & \overset{?}{\Longrightarrow} & (c) \end{array} ,$$

sans conditions sur π (sauf $\pi \geq \pi_0$).



Il reste donc à prouver $(c) \Longrightarrow (a)$. (C'est ici qu'on doit utiliser l'hypothèse particulière sur π.) Une fois ceci vu, on saura l'équivalence de (a), (b), (c), et d'autre part, il est immédiat que $(a) \Longrightarrow (c')$, en prenant $M_0 = M \cap \mathrm{Filt}^\pi$. D'autre part, $(c') \Longrightarrow (c)$ (sans hypothèses sur π ?), car on peut supposer que la partie M_0 de Filt^π est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$. Mais alors, connaissant l'équivalence de (a), (b) (c), d'où aussitôt le corollaire, il s'ensuit que l'enveloppe stable par $\varinjlim$ filtrantes de M_0 dans $\mathcal{M}$ n'est autre que la partie accessible déduite de M_0 dont il est question dans (c), et on gagne. [page 59]

Donc tout revient à prouver que, si tous les objets de Filt^π sont accessibles, alors (c) implique (a). Montrons d'abord que (c) implique le critère d'appartenance (5.3) (p. 51), donc par la proposition 5.6 "revue et corrigée" dans la note 21, il s'ensuit déjà que $(c) \Longrightarrow (b)$, et il restera à établir $(b) \Longrightarrow (a)$, *i.e.* que (b) implique la stabilité de M par $\varinjlim$ filtrantes quelconques (pas seulement grandes devant π).

Que (c) implique (5.3) va résulter du lemme suivant, appliqué à $I = \mathrm{Ss}_\pi(X)$:

Lemme 5.8. `[Deux fois 5.8.]` *Soit I un ensemble ordonné* π-adapté, i.e. *filtrant et tel que toute partie filtrante K de I, de cardinal $\leq \pi$, ait une borne supérieure i_K dans I. Je dis qu'une partie J de I est* π-cofinale, *si elle est cofinale, et si pour toute partie filtrante K de J de cardinal $\leq \pi$, sa borne supérieure i_K dans I est dans J. (Il s'ensuit donc que J est lui aussi π-adapté, pour la structure d'ordre induite.) Ceci dit, l'intersection de deux parties π-cofinales de I est encore π-cofinale.* p. 36 [page 60]

Il suffit de voir qu'elle est cofinale, car sa stabilité par bornes supérieures dans I de parties filtrantes de cardinal $\leq \pi$ est tautologique (si elle est vraie pour des J_α, elle est vraie pour $\bigcap_\alpha J_\alpha$). Soit $i_0 \in I$, et construisons un élément de $J \cap J'$ qui majore i_0. On construit de proche en proche une double suite

avec les i_α dans J, les i'_α dans J', et $i_1 \geq i_0$. On a donc

$$\sup i_\alpha \;=\; \sup i'_\alpha \;,$$

et si i est la valeur commune des deux membres, on a $i \in J \cap J'$.

Ceci vu, pour prouver la validité de (5.3), on note que la partie $J' = \mathrm{Ss}_\pi^{(M^\pi)}(X)$ de $I = \mathrm{Ss}_\pi(X)$, formée des $Z_\alpha \subset X$ tels que $Z_\alpha \in M^\pi$, est stable par bornes supérieures de parties filtrantes de cardinal $\leq \pi$, vu que M^π est stable par $\varinjlim$ de cardinal $\leq \pi$. Donc si J est une partie π-cofinale de $\mathrm{Ss}_\pi(X)$, $J \cap J'$ est cofinale dans J, *i.e.* dans I, si et seulement si J' est cofinale dans I (*i.e.* si et seulement si $X \in M$, par la condition (c)). Car $J \cap J'$ cofinale $\Longrightarrow J'$ cofinale tautologiquement, et J' cofinale implique J' π-cofinale, donc $J \cap J'$ π-cofinale par le lemme 5.8, donc cofinale. [page 61]

Commentary · Exposition [ms. 60]

Why a closed cofinal set is the right index

Grothendieck strengthens cofinality because it is not preserved by intersection alone. Two cofinal subsets of a directed set can be disjoint: the even and odd natural numbers already show this. His extra condition is continuity under bounded directed suprema. It ensures that alternating between two sets eventually produces a point belonging to both.

For clarity, the indexing hypotheses imply more than finite directedness. If $S \subset I$ has cardinal at most π, start with S, choose upper bounds for all pairs, repeat this operation countably many times, and call the union K. Since π is infinite, $|K| \leq \pi$; the set K is directed. Its supremum exists by π-adaptedness and bounds S. Thus I is π^+-directed. If $J \subset I$ is cofinal and closed under the specified suprema, the same construction, with each new upper bound subsequently enlarged into J, shows that J has the corresponding properties.

Now let J, J' be closed and cofinal, and fix $i_0 \in I$. Choose

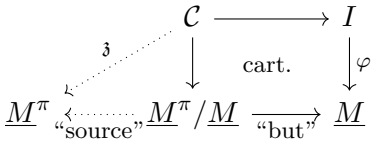
$$i_0 \le j_0 \le j_0' \le j_1 \le j_1' \le \cdots, \qquad j_n \in J, \quad j_n' \in J'.$$

Both subsequences have the same supremum. Closure places that supremum in both sets, and it still lies above i_0. This proves cofinality of $J \cap J'$; closure is immediate. The argument uses only a countable supremum, so no regularity assumption on π is needed. The ambient convention $\pi \ge \aleph_0$ matters: the result, isolated from that convention and read for finite π, would fail for the even and odd subsets of $\mathbb{N}$.

Apply this observation to the small subobjects of an object X. If $N \subset \mathrm{Filt}^\pi$ is closed under filtered colimits of cardinal at most π, then

$$J_N(X) = \{Z \in \mathrm{Ss}_\pi(X) : Z \in N\}$$

is closed under the corresponding suprema. Therefore, whenever $J \subset \mathrm{Ss}_\pi(X)$ is closed and cofinal, $J_N(X)$ is cofinal if and only if $J \cap J_N(X)$ is cofinal. Membership is independent of the chosen continuous cofinal subsystem. This is the precise reason for the closure assumption on M^π in the corrected version of Proposition 5.6.



The opening zigzag of these pages explains the remaining comparison with an arbitrary adapted presentation. At a cardinal for which the X_i and their images are π-accessible, a map from $\mathrm{Im}(X_i \to X)$ into the colimit factors through a later stage. One must also enlarge that stage so that the composite from X_i equals the transition map, rather than merely having the same composite to X. Preservation of the filtered colimit by $\mathrm{Hom}(X_i, -)$ supplies this equality. Repeating the construction gives the interlacing diagram printed on p. 34. At its countable supremum the two colimits agree; the image-side colimit maps monomorphically to X by condition (e). Hence there are cofinally many monomorphic stages. This fills the implicit equality step without changing Grothendieck's argument.

Reste à prouver seulement que $(b) \Longrightarrow (a)$, *i.e.* la stabilité de M par limites inductives filtrantes quelconques, moyennant (b). Ici à nouveau, cela ne doit pas utiliser l'hypothèse particulière sur π, ni même l'hypothèse d'exactitude (e) sur $\mathcal{M}$, mais être une histoire générale d'accessibilité :

Proposition 5.9. *Soit $\mathcal{M}$ une catégorie satisfaisant* (a), (b), (c), (d_0) (pages 44, 45), *$\pi \ge \pi_0$ un cardinal, M une partie π-accessible de* Ob$\mathcal{M}$, i.e. *satisfaisant la condition b_π de* XIII, p. 88. *Alors M est stable par $\varinjlim$ filtrantes si et seulement si $M^\pi \overset{déf}{=} M \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrantes de cardinal $\le \pi$.*

Je n'ai pas envie d'expliciter ici la démonstration, ayant l'impression pénible de refaire à perpette la même démonstration (ici et dans XIII). Je devrai revenir là-dessus dans une situation plus décantée.

Je vais quand même esquisser la démonstration. Soit $X = \varinjlim_I X_i$, I filtrant, les X_i dans [page 62]
M, il faut prouver que $X \in M$ (moyennant l'hypothèse de stabilité sur $M^\pi = M \cap \mathrm{Filt}^\pi$). p. 37

$\mathcal{C}$ est une catégorie cofibrée sur I, dont les fibres sont

$$\mathcal{C}_i \simeq M^\pi/X_i\,,$$

or comme $X_i \in M$, on voit, à cause de la condition de π-accessibilité, que M^π/X_i est *filtrante.* On va le dégager en

Lemme 5.10. *Soit M une partie π-accessible de $\mathcal{M}$. Alors pour tout $Y \in M$, M^π/Y est une catégorie* filtrante, *et* $\mathrm{Ss}_\pi(Y)$ *y est cofinale.* [page 63]

Considérons le foncteur canonique

$$I \;=\; \mathrm{Ss}_\pi(Y) \xrightarrow{\varphi} \underline{M}^\pi/Y \;=\; I' \;,$$

où la catégorie source I est filtrante. Par SGA 4 I 8.1.3, ce foncteur est cofinal si et seulement s'il satisfait deux conditions F 1, F 2, et alors I' est également filtrante. La condition F 1 est la condition habituelle que tout $i' \in \mathrm{Ob}I'$ est "majoré" par un $\varphi(i)$, *i.e.* tout $Z \longrightarrow Y$, avec $Z \in M^\pi$, est "majoré" par un *monomorphisme* $Z_\alpha \hookrightarrow Y$, avec $Z_\alpha \in M^\pi$, ce qui résulte du fait que c'est majoré par $Z_\alpha \hookrightarrow Y$ avec $Z_\alpha \in \mathrm{Filt}^\pi$, *i.e.* $Z_\alpha \in \mathrm{Ss}_\pi(Y)$, et que parmi ces Z_α ceux qui sont dans M^π sont cofinaux (vu que $Y \in M$). L'autre condition [23] est qu'une double flèche $i' \overset{f'}{\underset{g'}{\rightrightarrows}} \varphi(i)$ peut s'égaliser par une flèche $\varphi(h)$, avec $h : i \longrightarrow j$. Mais en fait, pour un $i' \in \mathrm{Ob}I'$, [page 64]
i.e. un $Z \longrightarrow Y$ donné ($Z \in M^\pi$), et un $i \in \mathrm{Ob}I$, *i.e.* un $Z_\alpha \hookrightarrow Y$ donné ($Z_\alpha \in M^\pi$), il existe au plus *une* flèche dans $I' = \underline{M}^\pi/Y$ de $Z \longrightarrow Y$ dans $Z_\alpha \hookrightarrow Y$. Donc la condition F 2 est trivialement satisfaite (on prend $h = \mathrm{id}_i$).

Corollaire 5.11. *Si $(X_i)_{i\in I}$ est un système inductif filtrant, avec les X_i dans M^π, alors la catégorie $\mathcal{C} = \underline{M}^\pi/\underline{M} \times_{\underline{M}} (I, \varphi)$, construite page* 62, *est filtrante, et le foncteur canonique (fibrant) $\mathcal{C} \longrightarrow I$ est cofinal.*

Que $\mathcal{C}$ soit filtrante et $\mathcal{C} \longrightarrow I$ cofinal résulte formellement du fait que I l'est, que les fibres de $\mathcal{C}$ le sont, et que $\mathcal{C}$ est cofibrée sur I. (Mérite un lemme, à toutes fins utiles.)

N.B. On peut remplacer $\mathcal{C}$ par $\mathcal{C}_0$ dont les fibres sont les

$$\mathrm{Ss}_\pi^{M^\pi}(X_i) \;\subset\; \underline{M}^\pi \;; \qquad \text{cofinale dans } \mathcal{C}_i = \underline{M}^\pi/X_i \;,$$

on trouve une sous-catégorie de $\mathcal{C}$ cofinale dans $\mathcal{C}$, et qui est cette fois ordonnée tout comme [page 65]
I.

Commentary · Exposition [ms. 64]

Integrating small presentations

Grothendieck now wants to flatten a filtered diagram of objects which themselves admit small presentations. His category $\mathcal{C}$ remembers both the outer index and a small object mapping into that stage. Keeping these maps, rather than choosing presentations separately and hoping they are compatible, makes the construction functorial.

The notation in Lemma 5.10 needs a restriction. The subobjects which form a subcategory of $\underline{M}^\pi/Y$ are

$$\mathrm{Ss}_\pi^{M^\pi}(Y) = \{Z \hookrightarrow Y : Z \in M^\pi\},$$

not all of $\mathrm{Ss}_\pi(Y)$. For example, in sets let M be the class of nonempty sets and let Y be nonempty. The empty subobject of Y belongs to $\mathrm{Ss}_\pi(Y)$ but is not an object of $\underline{M}^\pi/Y$. The proof and the subsequent displayed formula use the restricted collection, so the repair is unambiguous.

Under the standing subobject and image hypotheses the intended lemma has a short proof. Any $Z \to Y$ with $Z \in M^\pi$ factors through its image, a small subobject by condition (d). Since $Y \in M$, the recognition criterion enlarges this image to a subobject $T \hookrightarrow Y$ with $T \in M^\pi$. Such subobjects form a directed poset: first bound finitely many small subobjects in $\mathrm{Ss}_\pi(Y)$ and then enlarge the bound into the cofinal subset. Finally two maps $Z \rightrightarrows T$ over Y are equal because $T \to Y$ is monic. Thus every finite diagram in the slice has a cone through this poset, and the inclusion is final. Its colimit is Y because the small subobjects are cofinal among all small subobjects.

The formal lemma requested after Corollary 5.11 can also be made explicit. Let $p : E \to I$ be an opfibration, with I filtered and every fibre nonempty and filtered. Given finitely many objects of E, move them by opcartesian arrows to one common fibre and take a cone there. Given parallel arrows of E, first equalize their images by moving farther in I, then use filteredness of the new fibre to equalize the resulting vertical arrows. Hence E is filtered. For every $i \in I$, the category $(i \downarrow p)$ is nonempty, and the same argument makes it filtered; therefore p is final. These are ordinary finality statements and do not require a homotopical version of Theorem A.

23. Comme I est filtrante.

For the category used here, objects are triples $(i, Z, u : Z \to X_i)$; a morphism to (j, Z', u') consists of $a : i \to j$ and $v : Z \to Z'$ satisfying $u'v = X(a)u$. Postcomposition gives the opcartesian transport. Its tautological source functor is the dotted $\mathfrak{z}$ of the diagram. A cocone from this source functor to T is exactly a compatible family of cocones on the fibres. Consequently

$$\varinjlim_{(i,Z,u)\in\mathcal{C}} Z \simeq \varinjlim_{i\in I}\left(\varinjlim_{Z\to X_i} Z\right) \simeq \varinjlim_{i\in I} X_i.$$

This proves the interchange actually needed on page 65. Corollary 5.11 is printed with $X_i \in M^\pi$; the argument works for $X_i \in M$, which is the case required for Proposition 5.9. Its word "fibrant" should be "cofibrant", in the older terminology for an opfibration.

p. 38

On a

$$X_i \;=\; \varinjlim_{Z_\alpha\in\mathcal{C}_i} Z_\alpha \;,$$

donc

$$X \;=\; \varinjlim_{\alpha\in\mathcal{C}} Z_\alpha \;,$$

au total on est arrivé à représenter X comme $\varinjlim$ filtrante d'éléments Z_α qui sont (non seulement dans M, mais même) dans M^π.

Changeons la notation, en prenant

$$X \;=\; \varinjlim_{i\in I} X_i \;, \qquad I \text{ ensemble ordonné filtrant, } X_i \in M^\pi \;\; \forall\, i \in I \;,$$

soit I' l'ensemble des parties *filtrantes* $J \subset I$ telles que $\operatorname{card} J \leq \pi$, I' ordonné par inclusion. Alors I' est grand devant π, et on a un système inductif

$$(X_J)_{J\in I'} \;, \qquad X_J \;=\; \varinjlim_{i\in J} X_i \;.$$

Par l'hypothèse de stabilité de M^π (qui n'a pas encore servi), les X_J sont dans M^π. On a donc

$$X \;=\; \varinjlim_{J\in I'} X_J \;, \qquad \text{les } X_J \text{ dans } M^\pi,\ I' \text{ grande devant } \pi \;,$$

donc $X \in M$ puisque M est π-admissible, *q.e.d.*

Commentary · Exposition [ms. 65] [page 66]

The cardinal regrouping in Proposition 5.9

The last step of the proof turns an unrestricted filtered colimit into an adapted colimit whose stages remain bounded. This is a useful construction independently of the subobject description. Suppose

$$X = \varinjlim_{i\in I} Z_i, \qquad Z_i \in M^\pi,$$

where I is a directed poset. Let $P_\pi(I)$ consist of its nonempty directed subsets of cardinal at most π. Every subset of I of cardinal at most π lies in such a directed subset: adjoin chosen upper bounds of all pairs repeatedly and take the countable union. It follows that $P_\pi(I)$ is π^+-directed. The supremum of a directed family of at most π members is its union, again a member of $P_\pi(I)$.

Set $Z_J = \varinjlim_{j\in J} Z_j$. Bounded filtered-colimit closure puts Z_J in M^π. If $\mathcal{J} \subset P_\pi(I)$ is directed with $|\mathcal{J}| \leq \pi$, the universal property of a cocone gives

$$\varinjlim_{J\in\mathcal{J}} Z_J \simeq \varinjlim_{j\in\bigcup\mathcal{J}} Z_j = Z_{\bigcup\mathcal{J}}.$$

Moreover $\varinjlim_{J\in P_\pi(I)} Z_J \simeq X$, because every object and every comparison in the original diagram occurs in some J. Thus the regrouped presentation is adapted and every one of its stages belongs

to M. Condition b_π now implies $X \in M$. This supplies the continuity check implicit in the last displayed formula of page 65.

There is a genuine distinction between the hypotheses of Proposition 5.9 as printed and those used by its subsequent proof. The proposition lists only (a), (b), (c), and (d_0), whereas Lemma 5.10 is proved using images and the canonical subobject presentation from the stronger standing assumptions. The regrouping argument itself uses neither images nor exactness. Its preceding flattening step does. One complete version of the stated weakening is obtained by requiring that the objects of Filt^π be π-accessible. Then, for $Y \in M$, start with an adapted presentation of Y. The good indices are cofinal, and bounded filtered-colimit closure makes them closed under the required suprema. Maps from objects of M^π into Y factor through this subsystem, and equalities of maps hold at a sufficiently late stage, by presentability. These two properties show directly that M^π/Y is filtered, that the chosen subsystem is final in it, and that its colimit is Y. The preceding block and the regrouping then prove Proposition 5.9 using (d_0) and this presentability assumption, without (d_1), (d_2), or (e).

Alternatively, under the full standing assumptions (a)–(e), the subobject proof in the preceding block works at the given cardinal. The assertion that both sets of additional hypotheses may be removed simultaneously is not established by the written sketch. This is a gap in its claimed generality, not a counterexample to its conclusion. Chapter XIII, manuscript pages 90–97, explicitly retains the corresponding presentability condition when flattening slices (Grothendieck, 1990–1991e). The operative form of Proposition 5.7 uses good cardinals, so its proof is unaffected by this distinction.

To finish that proposition, start with a class $M_0 \subset \mathrm{Filt}^\pi$ and close it under bounded filtered colimits inside Filt^π, obtaining N. Define M_N by cofinality of $\mathrm{Ss}^N_\pi(X)$. The preceding arguments show that M_N is L-stable and, at a good cardinal, π-accessible. It contains M_0, while each of its objects is a filtered colimit of objects of N, themselves in the L-envelope of M_0. Therefore M_N is exactly that envelope. On a bounded object X, the poset $\mathrm{Ss}_\pi(X)$ has largest element X, so the recognition condition gives $M_N \cap \mathrm{Filt}^\pi = N$. This proves the inverse correspondence of Corollary 5.8, including its uniqueness assertion.

Définition 5.12.

1) Soit $\mathcal{M}$ une catégorie satisfaisant les conditions (a), (b), (c), (d) (p. 44-46). Soit $\pi \geq \pi_0$ un cardinal. Une partie M de $\mathrm{Ob}\mathcal{M}$ est dite *L-π-accessible,* si elle est π-accessible et stable par petites $\varinjlim$ filtrantes [24], ou ce qui revient au même (5.9), si elle est π-accessible et si $M^\pi = M \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$. (**N.B.** Si les objets de Filt^π sont π-accessibles, 5.8 nous dit que cela signifie aussi qu'il suffit pour cela qu'il existe une partie M_0 de Filt^π telle que M soit la L-enveloppe (enveloppe stable par $\varinjlim$ filtrantes) de M_0 – condition qui est de toutes façons toujours nécessaire, en prenant $M_0 = M^\pi$.)
2) Soit M une partie de $\mathrm{Ob}\mathcal{M}$. On dit qu'elle est *L-accessible,* si elle satisfait à l'une des quatre conditions équivalentes suivantes :
   - a) Il existe un cardinal π tel que M soit L-π-accessible.
   - a') M est accessible et L-stable.
   - b) Il existe une petite partie M_0 de $\mathrm{Ob}\mathcal{M}$, telle que M soit la L-enveloppe de M_0 [25].
   - b') Il existe une partie M_0 de $\mathcal{M}$ contenue dans une partie Filt^π (ou ce qui revient au même, telle que la sous-catégorie pleine $\underline{M}_0$ de $\mathcal{M}$ soit essentiellement petite, *i.e.* équivalente à une petite catégorie, telle que M soit la L-enveloppe de M_0).

L'équivalence de (a) et (a'), ou de (b) et (b') est plus ou moins tautologique. L'équivalence de (a) et (b) résulte aussitôt du N.B. inclus dans 1°, compte tenu que les cardinaux π tels que les objets de Filt^π soient π-accessibles sont cofinaux dans l'ensemble des cardinaux dans $\mathfrak{U}$. (*Cf.* 3.2, page 16). p. 39 [page 67]

Proposition 5.13. *Toute réunion finie de parties L-π-accessibles de* $\mathrm{Ob}\mathcal{M}$ *est L-π-accessible. L'intersection d'une famille* $(M_\alpha)_{\alpha\in A}$ *de parties L-π-accessibles, avec* $\operatorname{card} A \leq \pi$*, est L-π-accessible.*

24. On dit alors que M est *L-stable.*
25. Cette condition ne dépend pas de la filtration cardinale choisie de $\mathcal{M}$.

Démonstration. La première assertion provient du fait qu'une réunion *finie* de parties L-stables de M est L-stable, et qu'on a itou pour la notion de π-accessibilité. Les deux choses se prouvent d'ailleurs pratiquement de la même façon, en utilisant le

Lemme 5.14. *Soit I un ensemble ordonné filtrant, $(I_\alpha)_{\alpha\in A}$ une famille* finie *non vide de parties de I, telle que $\bigcup I_\alpha = I$. Alors il existe $\alpha \in A$ tel que I_α soit cofinal.*

Démonstration par l'absurde. Si pour aucun α, I_α n'était cofinal, on en conclurait [page 68] que pour tout α il existe un i_α tel que $I/i_\alpha \cap I_\alpha = \emptyset$. Soit i majorant les i_α, on aura donc $I/i \cap I_\alpha = \emptyset \ \ \forall\, \alpha \in A$, contrairement à l'hypothèse que $\bigcup I_\alpha = I$.

Commentary · Exposition [ms. 67]

Two closure operations on accessible classes

Grothendieck's letter L records a deliberate strengthening of accessibility: the class is closed under *all* small filtered colimits, including ordinary sequential colimits. Increasing the accessibility cardinal does not remove that requirement. Conversely, once a class is generated under filtered colimits by a small family, one may choose a cardinal bounding that family and then a good cardinal for the ambient filtration. Proposition 5.7 supplies the recognition condition at that cardinal. This is why the absolute notion in Definition 5.12 does not depend on the particular cardinal filtration.

The equivalence between a small generating family and a bounded essentially small family also has a precise size content. Each filtration stage is essentially small, so its members have a small set of representatives. Conversely, choose one representative of every isomorphism class in a given essentially small family. Each representative belongs to some stage, and the small set of those cardinal bounds has a common bound in the universe. Replacing the family by its isomorphism closure changes none of its colimits. These are the size reductions used in clauses (b) and (b′), rather than an assertion that a potentially large collection of literally equal objects is a set.

The finite-union statement may at first seem surprising, since diagrams can contain objects from different classes. Its explanation is entirely about the index. If a directed set is covered by finitely many subsets, one subset is cofinal. Otherwise choose, for each subset, a point above which it never occurs, and then bound those finitely many points. No subset can contain that upper bound, a contradiction. A cofinal subset of a directed poset is itself directed, so a filtered diagram whose objects lie in $M_1 \cup \cdots \cup M_n$ has a cofinal subdiagram lying in one M_r. If every M_r is L-stable, its colimit lies in that M_r and hence in the union.

The same finite-colour argument proves the recognition property in an adapted presentation. If the union of the good-index subsets is cofinal, apply the lemma inside that union; one good-index subset is then cofinal in the union and hence in the original index. The individual good-index subsets need not all be filtered before one knows that they are cofinal. The parenthesis "filtrantes" on page 72 is therefore unnecessary and, if read as an unconditional assertion, incorrect. For example a diagram of sets indexed by the fork $a, b \le t$, with two singleton stages mapping to the two different elements of a two-element terminal stage, has two singleton indices without a common singleton upper bound. The finite-cover lemma does not require that additional assertion.

For intersections, a different argument is needed. If X belongs to every M_α, each corresponding good-index subset is both cofinal and closed under bounded directed suprema, because M_α^π is closed under the matching colimits. The required common presentation is therefore obtained by intersecting closed cofinal subsets. This is the role of Lemma 5.15.

Le cas d'une *intersection* de parties L-π-accessibles : elle est bien sûr L-stable, donc il reste à prouver qu'elle est π-accessible, *i.e.* satisfait la condition b_π de *loc. cit.*

Soit donc [page 69]

$$X \;=\; \varinjlim_{i\in I} X_i\ , \qquad\qquad X_i \in \mathrm{Filt}^\pi\ ,$$

une représentation π-adaptée de X, avec I un ensemble ordonné π-adapté. Donc on a

$$(*) \qquad X \in M_\alpha \iff \begin{array}{c}\text{l'ensemble } I_{M_\alpha} \text{ des } i \in I \text{ tels que } X_i \in M_\alpha \\ \text{est cofinal dans } I.\end{array}$$

D'ailleurs, comme $M_\alpha^\pi = M_\alpha \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrante de cardinal $\le \pi$, on voit tout de suite que la partie I_{M_α} de I est stable par bornes supérieures dans I de parties J de I_{M_α}

filtrantes et de cardinal $\leq \pi$. Donc I_{M_α} cofinal équivaut à I_{M_α} π-*cofinal* (*cf.* 5.8, page 59). Soit $M = \bigcap_{\alpha\in A} M_\alpha$, je veux prouver que

$(**)$ $\qquad X \in M \iff$ l'ensemble I_M $(= \bigcap I_{M_\alpha})$ est cofinal dans I.

Or $(*)$ implique que $X \in M$ $(= \bigcap M_\alpha)$ équivaut à I_{M_α} π-cofinal pour tout α. Donc au total on veut prouver

$(***)$ $\qquad I_{M_\alpha}$ cofinal dans I pour tout $\alpha \iff \bigcap I_{M_\alpha}$ est cofinal dans I.

On a bien sûr $\Longleftarrow$, donc il reste à prouver $\Longrightarrow$. Si l'ensemble d'indices A est fini, cela résulte du lemme 5.8, compte tenu que la cofinalité des I_{M_α} implique leur π-cofinalité. On doit donc simplement améliorer 5.8, par le [page 70]

Lemme 5.15. *Soient π un cardinal, I un ensemble ordonné filtrant π-adapté, et soit $(I_\alpha)_{\alpha\in A}$ une famille de parties I_α π-cofinales* (cf. 5.8), *telle que* $\operatorname{card} A \leq \pi$. *Alors $\bigcap I_\alpha$ est π-cofinale.* p. 40

Il suffit de prouver qu'elle est cofinale, car la propriété de stabilité par bornes supérieures de parties filtrantes de cardinal $\leq \pi$ est évidente. Quitte à remplacer I par I/i_0, et les I_α par leurs traces sur I/i_0, la question est simplement de prouver que $\bigcap_\alpha I_\alpha \neq \emptyset$. On va construire un élément s de $\bigcap I_\alpha$ par induction transfinie. Prenons un bon ordre sur A, et prouvons par récurrence transfinie que pour tout $\alpha \in A$, l'ensemble [page 71]

$$J_\alpha \;=\; \bigcap_{\beta<\alpha} I_\beta$$

est cofinal. Si on sait que J_α est cofinal, il en est de même de $J_{\alpha+1} = J_\alpha \cap I_\alpha$, par 5.8. Donc on est ramené à prouver que J_α est cofinal si α est un ordinal limite, donc à prouver le lemme 5.15 pour une suite transfinie *décroissante* de parties π-cofinales J_β $(\beta < \alpha)$ quand $\operatorname{card}\alpha \leq \pi$, telle que $J_\beta = \bigcap_{\beta'<\beta} J_{\beta'}$ quand β est limite. À prouver que l'intersection est π-cofinale – et on est réduit à prouver qu'elle est non vide. On va construire par récurrence transfinie une suite *croissante* d'éléments

$$i_\beta \;\in\; J_\beta \qquad (\,\beta \;\leq\; \alpha\,)\,.$$

Si i_β est construit, comme $J_{\beta+1}$ est cofinal, il existe $i_{\beta+1} \geq i_\beta$ dans $J_{\beta+1}$, O.K. Si β est un ordinal limite, on prend

$$i_\beta \;=\; \sup_{\beta'<\beta} i_{\beta'}\;,$$

i_β est dans chaque I_{β_0} pour $\beta_0 < \beta$, puisque les $i_{\beta'}$ pour $\beta_0 \leq \beta' < \beta$ sont tous dans $J_{\beta_0} \supset J_{\beta'}$, donc aussi leur limite, donc [page 72]

$$i_\beta \;\in\; \bigcap_{\beta_0<\beta} J_{\beta_0} \;=\; J_\beta\;.$$

Donc la récurrence transfinie marche, et nous donne donc un élément s_α de J_α !

Commentary · Exposition [ms. 71]

The transfinite intersection argument and its bound

Grothendieck is arranging one approximation which satisfies every condition at once. The induction works because a limit of approximations eventually satisfying a fixed condition still satisfies that condition. Here is the proof with its terminal index included, so that the last intersection is obtained as well as all its proper initial intersections.

Write the indexing set as an ordinal λ with $|\lambda| \leq \pi$, and put

$$K_\alpha = \bigcap_{\beta<\alpha} I_\beta \qquad (\alpha \leq \lambda).$$

We prove by transfinite induction that every K_α is closed and cofinal. For $\alpha = 0$ it is I. Closure holds for every intersection. At a successor ordinal it follows from the two-set lemma that $K_{\alpha+1} = K_\alpha \cap I_\alpha$

is cofinal. Suppose now that $\delta \leq \lambda$ is a nonzero limit and that all the earlier intersections are cofinal. Given $i \in I$, construct an increasing family $(x_\beta)_{\beta<\delta}$ with $x_0 \geq i$ and $x_\beta \in K_\beta$. At a successor stage enlarge x_β into $K_{\beta+1}$. At a limit stage $\eta < \delta$, take the supremum of the previous terms. This supremum exists since the chain has cardinal at most π. For each $\gamma < \eta$, its tail from γ onward lies in K_γ; closure therefore places the supremum in every K_γ, hence in K_η.

Finally take $x = \sup_{\beta<\delta} x_\beta$. The same tail argument puts x in K_γ for every $\gamma < \delta$, and hence in K_δ. It also lies above i. This proves the limit step and gives cofinality of K_λ, the desired full intersection. In the manuscript's version the line referring to I_{β_0} is naturally read with J_{β_0}, as in the following line; alternatively one starts the tail after β_0. Neither adjustment changes the proof. What matters is to run the induction through the order type of the entire indexing set, not merely through its elements.

The cardinal restriction is exact at this level of generality. Let T be a set of cardinal strictly larger than π, and let I be the poset of subsets of T of cardinal at most π. It is directed, and a directed family of at most π such subsets has its union as supremum. For $t \in T$, the set

$$I_t = \{S \in I : t \in S\}$$

is cofinal and closed under these suprema. Yet $\bigcap_{t\in T} I_t$ is empty, because no member of I contains all of T. Thus one cannot intersect an arbitrarily large family at a fixed cardinal by this argument.

Corollary 5.16 is nevertheless an absolute small-intersection theorem. Given a small family of L-accessible classes, choose a common sufficiently large good cardinal witnessing their accessibility and bounding the size of the family. Apply Proposition 5.13 there. The witness cardinal may change; the absolute class does not. This is the flexibility that will allow several properties of arrows to be imposed simultaneously.

Je vais prouver aussi en forme l'assertion pour $\bigcup_{\alpha\in A} M_\alpha$, quand A est fini. Posant cette fois $M = \bigcup_\alpha M_\alpha$, il faut prouver, moyennant les relations $(*)$ (p. 68), qu'on a

$$(**) \qquad \begin{array}{lcl} X \in M & \iff & \text{l'ensemble } I_M \ (= \bigcup_\alpha I_{M_\alpha}) \\ (\textit{i.e. } \exists\ \alpha \text{ avec } X \in M_\alpha) & & \text{est cofinal dans } I\ , \end{array}$$

et moyennant $(*)$ le premier terme de cette équivalence à établir signifie qu'il existe α avec I_{M_α} cofinal dans I. Bien sûr, si un des I_{M_α} est cofinal dans I, a fortiori leur réunion. Mais inversement, si la réunion est cofinale, elle est filtrante et réunion des parties (filtrantes) I_{M_α}, dont l'une doit donc être cofinale dans elle par le lemme 5.14, donc aussi dans I, *q.e.d.*

Corollaire 5.16 (de la proposition 5.13). *Toute réunion finie de parties L-accessibles de $\mathcal{M}$ est L-accessible. Toute intersection $\bigcap M_\alpha$ d'une famille petite de parties L-accessibles de $\mathcal{M}$, est L-accessible.*

[page 73]

p. 41

6 Essai avorté pour un critère d'engendrement des parties L-accessibles de $\mathrm{Fl}(\mathcal{M})$.

Soit $\mathcal{M}$ une catégorie munie d'une filtration cardinale $(\mathrm{Filt}^\pi)_{\pi\geq\pi_0}$, et soit S un objet de Cat, considérons

$$\mathcal{M}(S) \ = \ \underline{\mathrm{Hom}}(S, \mathcal{M})\ ,$$

et munissons $\mathcal{M}(S)$ de la filtration par les

$$\mathcal{M}^\pi(S) \ = \ \underline{\mathrm{Hom}}(S, \mathcal{M}^\pi = \underline{\mathrm{Filt}}^\pi(\mathcal{M}))\ .$$

Je dis que c'est là une filtration cardinale de $\mathcal{M}(S)$. Il faut vérifier les conditions (a), (b), (c) de SGA 4 I 9.12. Les conditions (a) (Filt^π essentiellement petite) et (b) (condition L_{π_0}, et stabilité de Filt^π par $\varinjlim_I$, I filtrante grande devant π_0 et de cardinal $\leq \pi$) passent aussitôt de $\mathcal{M}$ à $\mathcal{M}(S)$. La condition (c) est plus délicate (représentation d'un objet comme $\varinjlim$ filtrante

[page 74]

grande devant π d'objets de Filt^{π}). Je ne vais pas refaire le travail, fait dans un cas beaucoup plus général et plus délicat dans SGA 4 I §9, savoir dans le corollaire 9.24 du théorème 9.22 (p. 177). La seule restriction, c'est qu'on y suppose les objets de $\mathcal{M}$ accessibles, et désignant par π_1 le plus petit cardinal tel que $\pi_1 \geq \pi_0$ et que les objets de Filt^{π_0} soient π_1-accessibles, on se borne pour la filtration cardinale de $\underline{\mathrm{Hom}}(S, \mathcal{M})$ aux cardinaux $\boxed{\pi \geq c = 2^{c_0},}$ où

$$c_0 \;=\; \sup(\pi_1, \operatorname{card} \mathrm{Fl}(S)) \;.$$

C'est une restriction raisonnable et anodine.

Commentary · Examples [ms. 73]

Why finite unions are the natural statement

Grothendieck's finite-union theorem has a useful algebraic test. Fix a prime p and work in abelian groups with the cardinal filtration by underlying sets of cardinal at most π, where π is infinite. For $n \geq 1$, let

$$M_n = \{A : p^n A = 0\}.$$

The class is closed under filtered colimits: every element of a filtered colimit is represented by an element of a stage, and multiplication by p^n is zero at that stage. It is also recognized by small subgroups. If $p^n A = 0$, all subgroups satisfy the same equation. Conversely, if small subgroups annihilated by p^n are cofinal, every element of A belongs to one of them, so it is annihilated by p^n. These good subgroups are closed under bounded directed unions. At this cardinal the bounded groups are π^+-presentable: a group with at most π elements has a presentation with at most π generators and relations, and a map or an equality out of such a presentation is settled at one stage of a π^+-filtered diagram. Thus Proposition 5.7 applies and each M_n is L-π-accessible.

The increasing union $\bigcup_n M_n$ is the class of groups annihilated by some finite power of p, with a bound allowed to depend on the whole group. It is not L-stable. Consider

$$\mathbb{Z}/p \longrightarrow \mathbb{Z}/p^2 \longrightarrow \mathbb{Z}/p^3 \longrightarrow \cdots, \qquad [a] \longmapsto [pa].$$

All arrows are injective. Sending $[a] \in \mathbb{Z}/p^n$ to $a/p^n + \mathbb{Z}$ identifies its colimit with $\mathbb{Z}[1/p]/\mathbb{Z}$. For every n this group has an element of order p^{n+1}; consequently no power p^n kills the whole colimit. Every stage is in the union and the colimit is not. This computes the failure of an infinite-union analogue without any size pathology.

The example also explains the distinction between a global bound and a local condition. The class of *all* p-primary torsion groups is L-stable: each element is annihilated by some power of p, and an element in a filtered colimit comes from a stage. Its small subgroups give the same cofinality test. Passing from bounded exponent to elementwise finite exponent changes the class, and is exactly what happens in the displayed colimit. Accessibility alone does not authorize exchanging these two quantifiers.

Pour l'instant, je suis intéressé surtout au cas où $S = \mathbf{\Delta}_1$, donc à

$$\underline{\mathrm{Hom}}(\mathbf{\Delta}_1, \mathcal{M}) \;=\; \underline{\mathrm{Fl}}(\mathcal{M}) \;,$$

auquel cas on a $c_0 = \pi_1$, donc il suffit de se borner aux cardinaux $\pi \geq 2^{\pi_1}$ pour avoir une bonne filtration cardinale sur $\underline{\mathrm{Fl}}(\mathcal{M})$.

C'est donc l'ensemble des deux conditions (b), (c) sur $\mathcal{M}$ (p. 44) qui est stable par passage aux $\underline{\mathrm{Hom}}(S, \mathcal{M}) = \mathcal{M}(S)$. Il en est de même de la condition (a) (stabilité par petites limites inductives), et aussi de la condition (d) (p. 45). De même la condition d'exactitude (e) (p. 46) [page 75]
sur les $\varinjlim$ filtrantes (elles doivent transformer les monomorphismes en monomorphismes).

Commentary · Context [ms. 74]

The passage to diagrams comes from SGA 4

Grothendieck needs the preceding theory in an arrow category, since weak equivalences and cofibrations are classes of arrows. His citation is precise: SGA 4, Exposé I, Corollary 9.24 gives

the objectwise cardinal filtration on categories of sections, under the stated accessibility and filtered-colimit hypotheses, after the bound $\pi \geq 2^{\aleph_0}$ (Artin et al., 1972, Exposé I, 9.22–9.24). Ordinary functor categories are the case of a constant fibred category. The enlarged bound pays for simultaneously choosing the objects, the structure maps, and the equations making them a diagram; small approximations of individual values alone do not provide those equations.

The other transferred properties can be checked directly. Colimits in $\mathcal{M}^S$ are computed at each object of S. A sufficiently small colimit of diagrams whose values lie in Filt^π again has its values there. Essential smallness follows by choosing a small skeleton of Filt^π: a functor assigns one of its objects to each object of S and one of its arrows to each arrow of S, subject to equations. Since S is small, the resulting set of choices is small. Images and subobjects are also computed pointwise under the standing hypotheses. For images, the arrow induced from $\mathrm{Im}(F(s) \to G(s))$ to $\mathrm{Im}(F(t) \to G(t))$ is forced by the image factorization and is unique after the monomorphic inclusion into $G(t)$; these unique arrows satisfy functoriality. This checks the part of condition (d) that is easy to overlook.

A natural transformation is monic exactly when each component is monic in this setting. One direction follows directly from the definition. For the other, evaluation at s has a left adjoint sending A to the diagram $t \mapsto \coprod_{S(s,t)} A$; testing monicity against these diagrams detects monicity of the s-component. Filtered colimits therefore preserve monomorphisms objectwise whenever they do so in $\mathcal{M}$. The same pointwise argument transfers commutation of filtered colimits with finite limits when that stronger exactness condition is available.

For $S = [1]$, a bounded object of the arrow category is a map *whose source and target are both bounded*. This concrete description should remain visible throughout §6. A map from a small object into a fixed large object is not a bounded object of the arrow category. Nor does a family of such maps become a bounded presentation merely because it is continuous and its indexing poset has the correct suprema.

The relationship with modern accessible categories is easiest at good cardinals: the bounded diagram objects can then be compared with presentable objects, and the categorical smallness of all their structure maps is absorbed by increasing the regular cardinal. The historical filtration language retains this choice explicitly. It gives uniform control over several classes in the same ambient category, which is exactly the control required for $C \cap W$.

Pour être tranquille, je vais faire sur $\mathcal{M}$ les hypothèses (a) à (e) inclus (bien que (e) me semble un peu artificielle, on devrait pouvoir l'éliminer, dans un second souffle !). Ces conditions ont donc la propriété de stabilité souhaitable par passage aux $\mathcal{M}(S)$, et en particulier par passage à $\mathrm{Fl}(\mathcal{M})$. Quitte à augmenter π_0, on peut donc supposer que les $\mathrm{Fl}^\pi(\mathcal{M}) = \mathrm{Hom}(\mathbf{\Delta}_1, \mathcal{M}^\pi)$ $(\pi \geq \pi_0)$ forment aussi une filtration cardinale de $\underline{\mathrm{Fl}}(\mathcal{M})$.

On dispose donc des notions de parties π-accessibles, accessibles, L-π-accessibles, L-accessibles de $\mathrm{Fl}(\mathcal{M}) = \mathrm{Ob}\underline{\mathrm{Fl}}(\mathcal{M})$. Ces notions sont stables par réunions et intersections finies, et les notions absolues (sans π) stables par intersections "quelconques" (*i.e.* pour des *petites* familles de parties). Ce sera là une chose particulièrement cruciale, le cas d'une intersection $C \cap W$! p. 42 [page 76]

Le résultat principal, pour lequel j'ai fait les gammes du paragraphe précédent, est le suivant :

Théorème 6.1 [26]. *Soit $\mathcal{M}$ une catégorie satisfaisant les conditions dites :*

a) *Stabilité par petites $\varinjlim$ (pas nécessairement filtrantes).*

b) *$\mathcal{M}$ munie d'une filtration cardinale* $(\mathrm{Filt}^\pi)_{\pi \geq \pi_0}$.

c) *Les objets de $\mathcal{M}$ sont accessibles.*

d) *Les* Filt^π *sont stables par $\varinjlim$ indexées par des catégories I telles que* $\operatorname{card}\mathrm{Fl}(I) \leq \pi$, *et si $Z \in \mathrm{Filt}^\pi$, tout quotient Z' de Z (tel que $Z \longrightarrow Z'$ ne se factorise pas par un sous-objet Z'_0 de Z', différent de Z') est dans* Filt^π.

e) *Les limites inductives filtrantes dans $\mathcal{M}$ transforment les monomorphismes en monomorphismes.*

26. Démonstration canulée, énoncé peut-être *faux* !!

Soit C une partie L-accessible de $\mathrm{Fl}(\mathcal{M}) = \mathrm{Ob}\underline{\mathrm{Fl}}(\mathcal{M})$, i.e. (5.12) *une partie stable par* $\varinjlim$ *filtrantes, et accessible. Supposons de plus C formée de monomorphismes*[27]*, et que C contient les* isomorphismes. *Alors il existe une partie petite $C_0 \subset C$, telle que $C \subset \widetilde{C_0}$. Plus précisément, si π est un cardinal tel que C soit π-accessible, et si on pose $C^\pi = C \cap \mathrm{Fl}^\pi(\mathcal{M})$, alors on a* [page 77]

$$C \subset \widetilde{C^\pi} = \widetilde{C_0}\,, \tag{6.1.1}$$

où C_0 est n'importe quelle petite partie de C^π telle que tout objet de C^π soit isomorphe à un objet de C_0.

Corollaire 6.2. *On a $C_* = C_{0*}$, $\widetilde{C} = \widetilde{C_0}$.*

Corollaire 6.3. *Conditions équivalentes sur la partie L-accessible C de* $\mathrm{Fl}(\mathcal{M})_{\mathrm{mono}}$*, contenant les isomorphismes :*

a) *$C = \widetilde{C}$.*

b) *C est stable par cochangement de base et par composition.*

b′) *C est stable par cochangement de base, et par sommes amalgamées simples,* i.e. *si $A \longrightarrow B_1$, $A \longrightarrow B_2$ sont dans C, alors $A \longrightarrow B_1 \amalg_A B_2$ aussi.*

c) *C^π est stable dans $\mathrm{Fl}^\pi(\mathcal{M}) = \mathrm{Fl}(\mathcal{M}^\pi)$ par cochangement de base et par composition.*

c′) *C^π est stable dans $\mathrm{Fl}(\mathcal{M}^\pi)$ par cochangement de base et par sommes amalgamées* (cf. b′).

Quand ces conditions sont satisfaites, alors (C, C_*) est un couple de Quillen, justiciable du théorème 1 *du paragraphe* 1 (p. 10).

La dernière assertion résulte du théorème 6.1 et du corollaire au théorème 1 du paragraphe 1. On a d'autre part tautologiquement p. 43 [page 78]

$$\begin{array}{ccccc} (a) & \Longrightarrow & (b) & \Longrightarrow & (b') \\ & & \Downarrow & & \Downarrow \\ & & (c) & \Longrightarrow & (c')\,, \end{array}$$

et il reste à prouver $(c') \Longrightarrow (a)$, ce qu'on fera plus bas.

Commentary · Exposition [ms. 77]

What the proposed generation theorem would have supplied

Grothendieck wants the accessibility calculation to finish the existence problem for factorizations. If every arrow in C lay in the lifting closure of a small bounded part C_0, the small object construction from §1 would provide factorizations controlled by C. This is a substantially stronger assertion than saying that C is a filtered-colimit closure of C_0.

Recall the order-reversing operations

$$C^\square = \{p : p \text{ has the right lifting property against } C\},$$
$$^\square R = \{i : i \text{ has the left lifting property against } R\}.$$

In the manuscript $C_* = C^\square$ and $\widetilde{C} = {}^\square(C^\square)$. From $C_0 \subset C \subset \widetilde{C_0}$ one obtains

$$C^\square \subset C_0^\square = (\widetilde{C_0})^\square \subset C^\square.$$

Thus Corollary 6.2 is a correct formal consequence of the proposed inclusion. It supplies no independent evidence for that inclusion. The source itself marks the proof of Theorem 6.1 as withdrawn.

The distinction between lifting closure and closure under elementary constructions is also relevant to Corollary 6.3. Every left lifting class contains the isomorphisms and is closed under pushouts,

27. Finalement, on se débarrasse de cette hypothèse.

composition, transfinite composition, and retracts. If a class is already closed under all filtered colimits, its closure under retracts can be proved without a separate hypothesis: an idempotent $e : f \to f$ in the arrow category has its image as the colimit of the sequence

$$f \xrightarrow{e} f \xrightarrow{e} f \xrightarrow{e} \cdots .$$

A splitting of the idempotent identifies that image with the desired retract. Closure under filtered colimits and finite composition likewise supplies the limit stages of transfinite composition. These observations explain why the hypotheses in (b) look close to being sufficient. They do not produce a *set* of lifting generators. The implication promised from (c′) to (a), and the assertion of a Quillen factorization obtained from §1, cannot be certified by the cancelled proof of 6.1.

For comparison, modern "accessible weak factorization system" refers to accessibility of a chosen functorial factorization, not to an arbitrary class satisfying the manuscript's recognition condition. Rosický's example of split monomorphisms and split epimorphisms in abelian groups gives an accessible weak factorization system which is not generated by a set (Rosický, 2017, Example 2.8). It is not by itself a counterexample to Theorem 6.1: split monomorphisms are not closed under all filtered colimits. An argument about this theorem must verify the additional L-condition and the embedded recognition condition.

The later counterexample discussed at manuscript page 84 does verify those conditions: pure monomorphisms in a finite presheaf diagram category provide the required separation between filtered generation and generation by lifting. Theorem 6.1 is therefore false in its proposed generality, rather than merely lacking the particular proof attempted here. The many valid cardinal and cofinality calculations of §5 remain available; what fails is their conversion into uniformly small relative attachments.

Prouvons donc 6.1. Dans (6.1.1) l'égalité $\widetilde{C_0} = \widetilde{C^\pi}$ est tautologique. Donc tout revient à prouver

$$C \subset \widetilde{C^\pi} .$$

Une difficulté ici, c'est qu'on ne sait *pas* que $\widetilde{C^\pi}$ soit stable par $\varinjlim$ filtrantes – on le sait seulement pour C. Soit donc

$$A \hookrightarrow B$$

une flèche dans C, prouvons qu'elle est dans $\widetilde{C^\pi}$. Pour ceci, on va construire, par induction transfinie, une suite transfinie *strictement* croissante de sous-objets A_α de B contenant $A = A_0$,

$$\underbrace{A}_{=A_0} \xhookrightarrow{i_\alpha} A_\alpha \xhookrightarrow{i_{\beta,\alpha}} A_\beta \xrightarrow{j_\beta} B ,$$

telle que l'on ait

$$i_\alpha \in \widetilde{C^\pi} , \qquad \text{plus généralement les } i_{\beta,\alpha} \in \widetilde{C^\pi} , \qquad j_\alpha \in C ,$$

et que l'on ait

$$A_\alpha = \varinjlim_{\beta<\alpha} A_\beta \qquad \text{si } \alpha \text{ ordinal limite} .$$

Cela précise déjà la définition récurrente pour $\alpha = \alpha_0$ ordinal limite. Notons que le A_{α_0} construit en termes des A_β ($\beta < \alpha_0$) satisfait bien aux conditions que [page 79]

a) les $i_{\alpha_0,\beta} : A_\beta \longrightarrow A_{\alpha_0}$ sont dans $\widetilde{C^\pi}$, car $\widetilde{C^\pi}$ est stable par "limites inductives ordinales strictes" (*cf.* 1.19, p. 8),

b) $j_{\alpha_0} : A_{\alpha_0} \longrightarrow B$ est dans C, car c'est la limite inductive filtrante du système des $A_\beta \longrightarrow B$ ($\beta < \alpha_0$) qui sont dans C, et C est stable par ces limites.

Il reste donc à préciser comment on passe de A_α à $A_{\alpha+1}$. Cela revient à prouver le

Lemme 6.4. *Soit $f : A \hookrightarrow B$ dans C, telle que f ne soit pas un isomorphisme. Alors il existe un sous-objet A_1 de B,* distinct de A, *tel que $A \longrightarrow A_1$ soit dans $\widetilde{C^\pi}$, et $A_1 \longrightarrow B$ dans C.*

Si ce lemme est admis, cela signifie que la construction transfinie se continue aussi longtemps que l'on trouve des A_α tels que $A_\alpha \neq B$, *i.e.* $A_\alpha \hookrightarrow B$ ne soit pas un isomorphisme. Mais comme les A_α sont tous différents, si π est l'ensemble des sous-objets de B (on sait que c'est un

ensemble petit, à cause des hypothèses faites sur $\mathcal{M}$), les ordinaux α pour lesquels A_α existe satisfont $\operatorname{card} A_\alpha \leq \pi$. Donc il doit exister un α tel que $A_\alpha = B$. Mais alors $i_\alpha : A \longrightarrow A_\alpha$ est égal à f, donc $f \in \widetilde{C^\pi}$, *q.e.d.* p. 44 [page 80]

Il reste donc à prouver 6.4. Pour ceci, soit I l'ensemble des sous-objets de B qui sont dans Filt^π, ordonné par inclusion. (Si B est dans Filt^π, A aussi, donc f est déjà dans $C^\pi \subset \widetilde{C^\pi}$, et il n'y a rien à prouver.) C'est un ensemble filtrant grand devant π (et même π-*adapté*), dont la $\varinjlim$ est B (5.3, p. 46). Considérons les

$$A_i \;=\; B_i \cap A\;,$$

ils sont dans Filt^π, comme sous-objets d'objets de Filt^π (condition (d) sur la filtration cardinale). Ainsi, la flèche f apparaît comme limite inductive filtrante des flèches

$$f_i \;:\; A_i \longrightarrow B_i\;.$$

Il est trivial que le système des A_i est cofinal dans $\mathrm{Ss}_\pi(A)$, donc $A = \varinjlim A_i$, d'où $f = \varinjlim f_i$.

D'autre part, je dis que le système inductif des f_i dans $\underline{\mathrm{Fl}}(\mathcal{M})$ est *bien adapté à π*. On sait déjà que I est bien adapté à π, le sup dans I d'une partie filtrante J de cardinal $\leq \pi$ étant le sup dans l'ensemble ordonné $\mathrm{Ss}(B)$ (lequel sup se trouve dans $\mathrm{Ss}_\pi(B)$). Il est essentiel, pour notre argument, de savoir que si $i_J = \sup J$, alors non seulement $B_{i_J} = \varinjlim_{i\in J} B_i$, mais aussi $A_{i_J} = \varinjlim_{i\in J} A_i$, de sorte que le système inductif des f_i est π-adapté dans $\underline{\mathrm{Fl}}(\mathcal{M})$. Il semble qu'il faille donc une condition d'exactitude sur $\mathcal{M}$ voisine de (e), savoir : [page 81] ‖

(e′) Les foncteurs $\varinjlim$ filtrantes commutent au changement de base.

(Il le suffit ici dans le cas très particulier d'un changement de base par un monomorphisme $A \longrightarrow B$, et d'une limite inductive filtrante de sous-objets de B pour des morphismes d'inclusion comme transitions.) Notons que (e), (e′) se trouvent généralement comme conséquence de la condition

(e_0) Les $\varinjlim$ filtrantes dans I sont exactes à gauche.

Ceci posé, on voit donc, C étant π-accessible et I grand devant π, que l'ensemble I_C des $i \in I$ tels que $f_i \in C$ est *cofinal* dans I. Mais comme $f_i \in \mathrm{Filt}^\pi$, $f_i \in C$ équivaut à $f_i \in C^\pi$. [page 82] Comme $A \longrightarrow B$ n'est pas un isomorphisme, il existe un i_0 tel que $B_{i_0} \not\subset A$, puis un $i \geq i_0$ tel que $f_i \in C^\pi$, et aussi $B_i \not\subset A$ (puisque $B_i \supset B_{i_0}$). Ainsi on a prouvé ceci :

Commentary · Examples [ms. 81]

Exact filtered unions do not make every amalgam a subobject

Grothendieck identifies two different requirements while trying to construct the next subobject of B. First, the approximating intersections $A \cap B_i$ must commute with bounded filtered unions. Second, after attaching B_i to A along that intersection, the pushout must still map monomorphically into B. The first requirement concerns a limit followed by a filtered colimit; the second concerns a pushout followed by an image comparison. They have different answers even in familiar algebraic categories.

Under condition (e′), the identity

$$A \times_B \left(\varinjlim_i B_i \right) \simeq \varinjlim_i (A \times_B B_i)$$

provides the desired continuity. Only this pullback along the fixed monomorphism $A \to B$ and filtered diagrams of subobjects of B are needed. Commutation of filtered colimits with finite limits is

sufficient. It also implies condition (e): a map is monic exactly when its diagonal to its self-pullback is an isomorphism, and filtered colimits then preserve that characterization. The phrase "dans I" in the printed condition (e_0) should be read as "dans $\mathcal{M}$".

For the second requirement consider groups. Let $B = \mathbb{Z} \times \mathbb{Z}$, let $A = \mathbb{Z} \times 0$, and let $B' = 0 \times \mathbb{Z}$. Both maps into B are monomorphisms and $A \cap B'$ is the trivial group. Their pushout in groups is

$$A * B' \cong F(a, b),$$

the free group on two generators. The canonical map to B sends a and b to its two coordinate generators. It sends the commutator $aba^{-1}b^{-1}$ to zero, but that reduced word is nontrivial in the free group. Hence the canonical comparison $A * B' \to B$ is not monic. Meanwhile filtered colimits of groups commute with finite limits: both are formed on underlying sets, and a finite list of equations or a finite tuple of representatives is settled in one sufficiently late filtered stage. Thus even condition (e_0) does not repair this pushout problem.

In sets and presheaves of sets the corresponding pushout of two subobjects over their intersection is their union and does embed into B. The proof is componentwise: two elements in the disjoint union are identified precisely when they represent the same element in the intersection. This favourable geometry removes the obstruction just exhibited for groups. It still does not force the residual inclusion $A \cup B' \to B$ to remain in an arbitrarily chosen accessible class C. The pure-monomorphism counterexample later in the commentary occurs in such a favourable presheaf category, and therefore isolates that remaining obstruction.

A further hypothesis has slipped between the statement and this proof. The version of condition (d) restated in Theorem 6.1 omits closure under subobjects, although page 80 uses it to conclude $A \cap B_i \in \mathrm{Filt}^\pi$. The original condition on manuscript pages 45–46 includes that closure. Retaining it makes this approximation step valid; it does not mend the final inference on page 84.

(∗) Sous les hypothèses de (6.4) et moyennant l'hypothèse (e′) sur $\mathcal{M}$, il existe un sous-objet B' de B satisfaisant les conditions suivantes.

a) $B' \in \mathrm{Filt}^\pi$.

b) $B' \not\subset A$.

c) Posant $A' = B' \cap A$, l'inclusion

$$i' \ : \ A' \ \longrightarrow \ B'$$

est dans C^π.

De plus, l'ensemble des $J \subset \mathrm{Ss}_\pi(B)$ formé des B' en question est cofinal dans $\mathrm{Ss}_\pi(B)$, et même π-cofinal. p. 45

Il faut prouver encore ce dernier point – que J (dont on sait qu'il est cofinal) est même π-cofinal, *i.e.* stable par sup (dans $\mathrm{Ss}_\pi(B)$) des parties filtrantes $J' \subset J$ telles que $\mathrm{card}\, J' \leq \pi$. Mais cela résulte aussitôt du fait que C étant stable par

limites inductives filtrantes, $C^\pi = C \cap \mathrm{Filt}^\pi$ est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$, [page 83] en vertu de la condition (*d*) sur Filt^π. Considérons maintenant le carré cocartésien

$$\begin{array}{ccc} A' & \xhookrightarrow{\ i'\ } & B' \\ \downarrow & & \downarrow \\ A & \xrightarrow{\ i\ } & C' = A \amalg_{A'} B' \end{array} \xrightarrow{\ j\ } B \ .$$

Comme $i' \in C^\pi$, on a $i \in \widetilde{C^\pi}$ (car $\widetilde{C^\pi}$ stable par cochangement de base). D'autre part, j'ai besoin du fait que j soit dans C, et je ne sais pas même qu'il est un monomorphisme ! Aussi il faut repasser aux notations indicielles

$$\begin{array}{ccc} A_i & \xhookrightarrow{\ \alpha_i\ } & B_i \\ \downarrow & & \downarrow \\ A & \xrightarrow{\ \beta_i\ } & C_i \end{array} \xrightarrow{\ \gamma_i\ } B \ .$$

Comme la formation des sommes amalgamées commute aux limites inductives filtrantes, on voit que $\varinjlim C_i \simeq A \amalg_{\varinjlim A_i} \varinjlim B_i = A \amalg_A B = B$, donc la limite inductive des γ_i est un isomorphisme (essentiellement id_B). D'autre part, le même argument montre que le système inductif des C_i ($i \in J$) dans $\mathcal{M}$ est π-adapté, donc aussi celui des γ_i [28] dans $\underline{\mathrm{Fl}}(\mathcal{M})$. Comme [page 84]
$\varinjlim \gamma_i$ est un isomorphisme, il est dans C. Comme C est π-accessible, il s'ensuit que l'ensemble J' formé des $i \in J$ tels que $\gamma_i \in C$ est lui aussi cofinal [29]. Donc on trouve i avec $\alpha_i \in C^\pi$, $\gamma_i \in C$, ce qui établit le lemme 6.4, et achève la démonstration du théorème 6.1.

Commentary · Development (commentators') [ms. 83]

A continuous diagram outside the cardinal bound

Grothendieck's footnote 28 locates the decisive obstruction accurately: the arrows $\gamma_i : C_i \to B$ are not known to be bounded objects of the arrow category. The following explicit test shows that the omitted bound cannot be recovered from continuity and an isomorphic colimit. We give the construction to isolate the inference, without making it serve as a counterexample to the entire theorem.

An unbounded counterdiagram. [ours] Let π be an infinite cardinal, let B be a set with $|B| > \pi$, and let $I = [B]^{\leq \pi}$, ordered by inclusion. In the arrow category of sets consider

$$\gamma_S : S \hookrightarrow B \qquad (S \in I),$$

with transition squares given by inclusion on sources and the identity on B. The poset I is π-adapted, the diagram preserves suprema of nonempty directed subsets of cardinal at most π, and its colimit is the identity of B. Nevertheless no γ_S is an isomorphism.

Proof. A family of at most π subsets of cardinal at most π has union of cardinal at most π. Thus I is π^+-directed and directed unions of that size are its suprema. Colimits of the source sets in such a directed family are their unions. The target is the constant diagram at B, whose colimit is B because the indexing category is nonempty and connected. Colimits in the arrow category are pointwise, proving the asserted continuity. Taking the union of all $S \in I$ gives B, and the colimit arrow is consequently id_B. Finally every S is a proper subset of B, so every stage fails to be an isomorphism. □

For completeness, the class of isomorphisms has exactly the accessibility properties relevant here. It is closed under filtered colimits in the arrow category, since a compatible family of inverse maps induces the inverse of the colimit map. Its bounded part is closed under bounded filtered colimits. For an isomorphism $f : A \to D$, a small subarrow $A_0 \to D_0$ can be enlarged to the isomorphism $f^{-1}(D_0) \to D_0$, still small; hence bounded isomorphic subarrows are cofinal. Conversely, if isomorphic subarrows are cofinal, their filtered colimit is f, so f is an isomorphism. The standard cardinal filtration of the arrow category of sets has bounded objects π^+-presentable, and Proposition 5.7 therefore makes this class L-π-accessible in the manuscript's sense.

The displayed diagram does not contradict that recognition property: its target B is too large, so none of its arrows belongs to $\mathrm{Fl}^\pi(\mathbf{Set})$. It does contradict the proposed inference after deleting precisely that hypothesis. Even the strongest possible conclusion about the colimit, namely that it is an identity, says nothing about cofinally many isomorphic stages in this situation.

This is an elementary diagnostic construction supplied here. We checked the bounded-presentation requirements in Chapter XIII, manuscript pages 86–89, and the diagram-filtration statement of SGA 4 I 9.24; neither licenses the deleted hypothesis. We do not claim priority for this example. Its purpose is to make the cancelled inference visible before discussing a counterexample to the generation theorem itself.

Commentary · Development (commentators') [ms. 84]

A presheaf counterexample to the abandoned generation theorem

Grothendieck has isolated the precise defect of his argument, but he still asks whether the theorem might survive it. There is now a negative answer in a particularly elementary presheaf

28. *Sauf* qu'on ne sait pas que les C_i soient dans Filt^π – en fait, ils ne seront pas en général, puisqu'on ne suppose pas que $A, B \in \mathrm{Filt}^\pi$.

29. *Canulé, cf.* annotation précédente.

category. The modern obstruction is a theorem about pure monomorphisms. To apply it here, however, we must verify the manuscript's bounded cofinality condition; replacing that condition by the modern word "accessible" would leave the essential comparison undone.

Let P be the three-object category with its two nonidentity arrows

$$1 \longleftarrow 0 \longrightarrow 2, \qquad \mathcal{E} = \mathrm{Set}^{P}.$$

Thus an object is a span of sets $E_1 \leftarrow E_0 \rightarrow E_2$. This is the presheaf category on P^{op}. Give $\mathcal{E}$ the filtration by the total cardinality of its three sets. For every infinite π, the objects of size at most π are π^+-presentable: a natural transformation out of one of them is specified by at most π elements and equations, all of which can be represented simultaneously at one stage of a π^+-filtered diagram. Subobjects, quotients, and colimits with at most π arrows preserve this bound. All colimits and finite limits are computed on the three underlying sets. In particular, this example satisfies even the strengthened exactness assumptions introduced after Theorem 6.1.

An inclusion $U \hookrightarrow V$ in $\mathcal{E}$ is *pure* if every finite system of equations in the three sorts, with parameters in U, that has a solution in V already has a solution in U. Equivalently, for every commutative square

$$\begin{array}{ccc} K & \xrightarrow{u} & U \\ {\scriptstyle a}\downarrow & & \downarrow \\ L & \xrightarrow[v]{} & V \end{array}$$

with K, L finite, there is $t : L \to U$ with $ta = u$; the other triangle is not required to commute. Indeed, the finitely many elements and structure equations of L, together with $t(a(k)) = u(k)$, give exactly such a system. Conversely, a finite system and its parameters can be encoded by a morphism between finite spans. Write $\mathcal{P}$ for the class of pure monomorphisms.

Proposition (comparison with the manuscript). [ours] *The class $\mathcal{P}$ is L-π-accessible for every infinite cardinal π in this filtration. It contains the isomorphisms and is stable under pushouts, composition, transfinite composition, and retracts. Nevertheless there is no set $S \subset \mathcal{P}$ with $\mathcal{P} \subset \widetilde{S}$. Consequently the assertion of Theorem 6.1 is false, even for a presheaf category.*

We give the comparison and closure arguments, and use the published non-generation theorem only at the last step. First, filtered colimits preserve purity. Given a finite system with parameters in the source of a filtered colimit arrow and a solution in its target, represent its parameters and solution at a common stage. The finitely many equations hold at a further common stage. Purity there supplies a solution in that stage's source, which gives the required solution in the colimit. The colimit arrow is a monomorphism because filtered colimits of sets preserve monomorphisms. This argument permits arbitrary transition squares; it is not restricted to diagrams of inclusions.

Next fix a pure inclusion $A \subset B$ and a subarrow $U_0 \subset V_0$ of size at most π. Thus $U_0 \subset A$, $V_0 \subset B$, and $U_0 \subset V_0$, but there is no requirement that $U_0 = A \cap V_0$. We construct increasing subarrows $U_n \subset V_n$. For every finite equation system with parameters in U_n that is solvable in V_n, choose a solution in A, using the purity of $A \subset B$. There are at most π systems to consider. Adjoin all their chosen solutions to U_n and close under the two structure maps of the span, obtaining U_{n+1} of size at most π. Let V_{n+1} be the subspan of B generated by $V_n \cup U_{n+1}$. Its size is still at most π. At the countable union,

$$U = \bigcup_{n<\omega} U_n, \qquad V = \bigcup_{n<\omega} V_n,$$

the inclusion $U \subset V$ is pure. A finite list of parameters and a finite solution in V both occur at some stage, so its required solution was added at the next stage. Hence the pure subarrows of size at most π are cofinal among all subarrows of that size. They are also closed under filtered unions with at most π members, by the preceding paragraph. Conversely, an arrow whose bounded pure subarrows are cofinal is their filtered colimit and is pure. This is precisely the cofinal small-subobject recognition condition of Proposition 5.7(c), applied to $\underline{\mathrm{Fl}}(\mathcal{E})$. That proposition therefore gives the manuscript's L-π-accessibility, with its original, stronger meaning.

For completeness, pushout stability can be proved without a further smallness assumption. Every pure arrow is a filtered colimit of split monomorphisms between finite spans. To see this, the category of finite arrows mapping to a fixed arrow $f : A \to B$ is filtered, and its colimit is f: finite sets of elements and relations can be put into one finite subarrow. If $a : K \to L$ is such an arrow, purity gives $t : L \to A$ extending its map $K \to A$. Form

$$D = L \amalg_K L, \qquad j_0, j_1 : L \longrightarrow D.$$

The arrow j_0 is split by the fold $D \to L$. There is a morphism $a \to j_0$ in the arrow category with source component a and target component j_1. There is also a morphism $j_0 \to f$: its source component is t, and its target component is induced by ft on the first copy of L and the original $L \to B$ on the second. These two maps agree on K. Thus every finite arrow over f maps to a finite split monomorphism over f. The full subcategory of such split monomorphisms is filtered: any finite diagram first has a cone in the category of finite arrows over f, and the construction just given replaces that cone by a split one. For any fixed finite arrow $a \to f$, the same construction, keeping the map from a as part of the diagram, makes its comma category of split targets nonempty and filtered. This proves finality, so the colimit of the split subcategory is f.

Now push out this filtered presentation of f along any $A \to A'$. The resulting arrow is a filtered colimit of pushouts of split monomorphisms, each of which is split. It is pure by filtered-colimit stability. Composition of pure inclusions follows by reflecting a finite system twice. Retract stability follows by composing a finite square with the section into the larger arrow, taking its pure extension, and composing with the retraction. Transfinite composition follows by induction, using composition at successor stages and filtered-colimit stability at limit stages. These arguments establish every closure property asserted above.

The external ingredient is now exact and short. Cox et al. (2026b, Theorem 5.1) prove that pure monomorphisms in Set^D are cofibrantly generated if and only if every coslice d/D is linearly preordered. For our P, the two objects $0 \to 1$ and $0 \to 2$ of $0/P$ admit no morphism in either direction. Thus $\mathcal{P}$ is not cofibrantly generated. If Theorem 6.1 held, it would give a set $S \subset \mathcal{P}$ with $\mathcal{P} \subset \widetilde{S}$. The small object argument in $\mathcal{E}$ identifies $\widetilde{S}$ with the closure of S under pushouts, transfinite composition, and retracts. The closure properties just proved give the reverse inclusion $\widetilde{S} \subset \mathcal{P}$. This would make $\mathcal{P}$ cofibrantly generated, a contradiction. □

This also explains why the successful theorem of the next section has genuinely more structure. Purity has cancellation in the direction "gf pure implies f pure". Grothendieck's construction in Section 7 needs the other cancellation: from f and gf in W, it must recover $g \in W$. That step keeps the residual inclusion in the desired class after a small attachment. It is precisely what the preceding argument cannot obtain for a general L-accessible class.

The non-generation theorem and its presheaf classification belong to Cox, Feigert, Kamsma, Mazari-Armida, and Rosický; no priority claim is made here. Our contribution is the explicit check of the manuscript's bounded recognition condition and the resulting application to Theorem 6.1. We checked Theorem 5.1 and its reduction to the preceding results, Definition 2.7, Remark 2.8, Fact 2.9, and Example 5.3 in the 26-page third arXiv version, dated 29 April 2026. We did not find this specific application to *Les Dérivateurs* stated there.

7 Construction de triples de Quillen clos avec $C = \mathbf{Mon} \subset \mathbf{Cof}_W$

Finalement, tous les beaux développements des paragraphes 5, 6 ne me donnent pas le "sweeping result" souhaité. Peut-être est-il faux – peut-être la propriété d'engendrement "~" p. 46
par une petite partie (pour les ensembles accessibles, ou L-accessibles) est-elle beaucoup plus rarement satisfaite, que je ne l'aurais imaginé. Pour bien faire, il faudrait que je traite jusqu'au bout quelques exemples, p. ex. celui de Cof_W, et de W^{univ} dans Cat, pour un localiseur [page 85]
fondamental plus ou moins général, et surtout dans le cas $W = \mathbf{W}_\infty$. Sûrement Cof_W et W^{univ} sont accessibles (il faudrait que je le vérifie pourtant), et si le "théorème" hypothétique du paragraphe 6 est faux pour eux, du moins en aurai-je le cœur net. Mais il reste pourtant la question : si $C = \widetilde{C}$ est stable par $\varinjlim$ filtrantes, et de la forme $\widetilde{C_0}$, C_0 petit, et si W est L-accessible également, alors $C \cap W$ est-il aussi de la forme $\widetilde{TC_0}$, avec TC_0 petit ? Je viens encore d'essayer de le prouver, en supposant de plus $C \subset$ mono, et ne vois aucun moyen d'y parvenir. Il faudrait donc un contre-exemple pour dissiper ces perplexités ! Et le mieux serait dans Cat, tant qu'à faire.

Il surnage pourtant un résultat tangible positif, que je vais maintenant essayer de bien cerner et prouver : [page 86]

Théorème 7.1. *Soit $\mathcal{M}$ une catégorie stable par petites $\varinjlim$ filtrantes, $M_0 \subset \mathrm{Ob}\,\mathcal{M}$ un sous-ensemble de $\mathrm{Ob}\,\mathcal{M}$ générateur par monomorphismes stricts, plus précisément on suppose ceci :*

Commentary · Exposition [ms. 85]

What the generation argument must preserve

Grothendieck now changes the question in a decisive way. The unsuccessful argument of §6 tried to recover a lifting class from accessibility alone. The useful extra information is that an arrow in the desired class can be enlarged a little while its remaining part stays in the same class. This is a geometric condition on a factorization, and it is stronger than the assertion that the arrow is a filtered colimit of small arrows. A filtered presentation allows both its source and its target to vary. A cellular construction keeps the original source fixed and attaches successive pieces to it. The discrepancy between those two operations was precisely what invalidated the preceding proof.

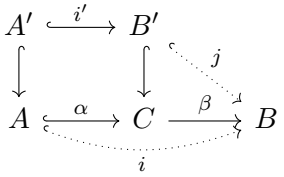
We use modern lifting notation to make the goal explicit. For a class S of arrows, $S^{\square}$ consists of arrows having the right lifting property against every member of S, and ${}^{\square}T$ denotes the corresponding left lifting class. Grothendieck's S_* is $S^{\square}$, and his left Q-closure $\widetilde{S}$ is ${}^{\square}(S^{\square})$. When S is a set and the small object argument applies, this is the closure of S under pushouts, transfinite composition and retracts. A proof that $C \subset \widetilde{C_0}$ must therefore account for this particular closure; being generated by filtered colimits is a different assertion.

The property in Theorem 7.1 supplies the missing control. Suppose $A \hookrightarrow B$ is not yet an isomorphism. A small subobject $B' \hookrightarrow B$ detects something outside A, and the union

$$D = A \amalg_{A\cap B'} B'$$

still embeds in B. Thus $A \subsetneq D \subset B$ is a genuine enlargement, obtained by one permitted attachment. For trivial cofibrations one must additionally keep $D \hookrightarrow B$ a weak equivalence. This is where cancellation in W enters: once $A \to D$ and $A \to B$ lie in W, so does $D \to B$. The hypotheses that look separate in the statement are arranged to secure these two facts, geometric containment and homotopical cancellation.

The question on manuscript page 85 has a precise later answer in the setting of model recognition. If $\mathcal{M}$ is locally presentable, $C = \mathrm{cof}(I)$ for a set I, W is an accessible full subcategory of the arrow category with an accessible inclusion, W has two-out-of-three and is closed under retracts, $I^{\square} \subset W$, and $C \cap W$ is closed under pushouts and transfinite compositions, then $C \cap W$ is generated by a set. This is Smith's theorem, published with proof by Beke (2000, Theorem 1.7 and Lemmas 1.8–1.9). Its solution-set hypothesis is supplied by accessibility. It does not assert that the intersection of an arbitrary accessible class with a lifting class is automatically a lifting class: the closure and compatibility hypotheses remain part of the theorem. Consequently it resolves the model-structure problem which motivates this passage, without turning the tentative claim of §6 into a general theorem.



Pour tout monomorphisme $i : A \hookrightarrow B$ dans $\mathcal{M}$ qui n'est pas un isomorphisme, il existe un monomorphisme $B' \overset{j}{\hookrightarrow} B$ ayant les propriétés suivantes :

a) *$B' \in M_0$.*

b) *j ne se factorise pas par i.*

c) *$A' = A \times_B B'$ existe dans $\mathcal{M}$, ainsi que $C = A \amalg_{A'} B'$, A' est dans M_0, et dans le diagramme canonique*

(7.1.1)

la flèche β est un monomorphisme.

(**N.B.** Ces conditions sont satisfaites si on suppose, en plus de la condition que M_0 soit générateur pour les monomorphismes, que M_0 contient, avec tout objet B', et pour tout objet A' qui est soit un quotient, soit un sous-objet de B', un objet A'_0 isomorphe à A' ; et si de plus $\mathcal{M}$ satisfait aux conditions d'exactitude suivantes :

1°) Toute flèche f de $\mathcal{M}$ se factorise en ip, avec i monomorphisme, p épimorphisme, et :

2°) Si A_1, A_2 sont deux sous-objets d'un objet B de $\mathcal{M}$, alors l'intersection $A_0 = A_1 \times_B A_2$ existe, ainsi que la somme amalgamée $C = A_1 \amalg_{A_0} A_2$, et le morphisme canonique $C \longrightarrow B$ est un monomorphisme.) p. 47 [page 87]

Supposons de plus que $\mathcal{M}$ satisfait la condition ©, p. 76, i.e. *que toute* $\varinjlim$ *filtrante de monomorphismes est un monomorphisme.*

1°) *Soit* $\mathrm{Mon} \subset \mathrm{Fl}(\mathcal{M})$ *l'ensemble des monomorphismes, et* Mon_0 *le sous-ensemble de* Mon *formé des* $i \in \mathrm{Mon}$ *tels que source et but appartiennent à* M_0. *On a alors*

$$\text{(7.1.2)} \qquad \mathrm{Mon} \subset \widetilde{\mathrm{Mon}_0} \quad , \qquad d'où \quad \begin{cases} \widetilde{\mathrm{Mon}} & = & \widetilde{\mathrm{Mon}_0} \\ (\mathrm{Mon})_* & = & (\mathrm{Mon}_0)_* \end{cases} .^{30}$$

2°) *Si* M_0 *est* petit *et si les objets de* M_0 *sont accessibles* (p. ex. $\mathcal{M}$ satisfait ©, p. 76), *et si* Mon *est stable par cochangement de base, alors il existe une factorisation fonctorielle de toute flèche* f *de* $\mathcal{M}$ *en*

$$f = p\,i\,,$$

avec $i \in \mathrm{Mon}$, $p \in (\mathrm{Mon})_*$. (**N.B.** Une flèche $p : X \longrightarrow Y$ de $\mathcal{M}$ est dans $(\mathrm{Mon})_*$ si et seulement si elle fait de X un objet *injectif* de $\mathcal{M}/Y$ – donc l'assertion de factorisation assure que dans les catégories induites $\mathcal{M}/Y$ "il y a assez d'injectifs".) *De plus, on a*

$$\text{(7.1.3)} \qquad \mathrm{Mon} = \widetilde{\mathrm{Mon}_0} \quad .$$

3°) *Soit* W *une partie de* $\mathrm{Fl}(\mathcal{M})$ *qui est* L-accessible (i.e. *accessible, et stable par limites inductives filtrantes*). (*On suppose à présent que* $\mathcal{M}$ *satisfait les conditions* (a), (b), (c), (d), (e) *de la page 76, d'où une bonne théorie des parties L-accessibles de* $\mathrm{Ob}\,(\mathcal{M})$ *ou de* $\mathrm{Fl}(\mathcal{M})$.) *On suppose, plus précisément, que* W *satisfait les conditions :* [page 88]

$$\text{(7.1.4)} \qquad \begin{cases} \text{a)} & W \textit{ est L-accessible } (\textit{i.e.} \text{ stable par } \varinjlim \text{ filtrantes, et accessible}). \\ \text{b)} & \textit{Soient } \alpha, \beta \textit{ composables, avec } \beta\alpha \textit{ et } \alpha \textit{ dans } W, \textit{ alors } \beta \in W. \text{ (\textbf{N.B.} Cette condition sera satisfaite si } W \text{ est un localiseur modérément saturé, et c'est à cette situation que nous allons appliquer notre énoncé.)} \\ \text{c)} & \mathrm{Mon} \cap W \textit{ est stable par cochangement de base.} \end{cases}$$

et que $\mathcal{M}$ *satisfait les conditions supplémentaires*

$$\text{(7.1.5)} \qquad \begin{cases} \text{e}') & \textit{Les } \varinjlim \textit{ filtrantes commutent au changement de base.} \\ \text{f)} & \textit{La condition d'exactitude } (7.2.1) \textit{ ci-dessous.} \end{cases}$$

Soit π *un cardinal tel que* W *soit* π*-accessible, et* $M_0 \subset \mathrm{Filt}^\pi$ (*donc* M_0 *essentiellement petite*). *Alors on a*

$$\text{(7.1.6)} \qquad W \cap \mathrm{Mon} \subset \widetilde{(W \cap \mathrm{Mon})^\pi}$$

(*où pour toute partie* C *de* $\mathrm{Fl}(\mathcal{M})$, *on pose* $C^\pi = C \cap \mathrm{Fl}^\pi(\mathcal{M})$), *donc*

30. **N.B.** On a là un critère d'injectivité d'objets dans les catégories $\mathcal{M}/Y$ – il suffit de tester la condition d'injectivité par des monomorphismes i qui sont dans Mon_0. p. 48

(7.1.7) $$\widetilde{W \cap \mathrm{Mon}} \;=\; (\widetilde{W \cap \mathrm{Mon}})^{\pi}\ ,$$

donc $\widetilde{W \cap \mathrm{Mon}}$ *est Q-engendré par une* petite *partie de* $W \cap \mathrm{Mon}$.

Commentary · Examples [ms. 87]

Small attachments in presheaves and in group actions

Grothendieck's generator condition has an especially concrete meaning for presheaves. Let A be small and choose an infinite cardinal $\kappa \geq |\operatorname{Mor} A|$. For $F \in \widehat{A}$, put $|F| = \sum_{a \in \operatorname{Ob} A} |F(a)|$. Up to isomorphism the presheaves of cardinal at most κ form a set. Let M_0 be a skeleton of this class, and let I contain all monomorphisms between its objects.

Given a proper inclusion $U \subset V$, choose a and $v \in V(a) \setminus U(a)$. The associated map $h_a \to V$ has image B', a subpresheaf of cardinal at most κ, and B' is not contained in U. Its intersection $A' = U \cap B'$ again has cardinal at most κ. Since unions and intersections are computed objectwise, the canonical map

$$U \amalg_{A'} B' \longrightarrow V$$

is a monomorphism, with image $U \cup B'$. This verifies every part of (7.1.1). The image is essential: $h_a \to V$ need not itself be a monomorphism, so directly attaching h_a need not produce a subobject of V. Passing to its quotient image is exactly the reason for allowing quotients among the small pieces.

There is a more explicit calculation when $\widehat{A}$ is the category of left G-sets. Every monomorphism $U \hookrightarrow V$ identifies U with a union of G-orbits in V, and its complement is a disjoint union of orbits G/H. Thus the set

$$I_G = \{\varnothing \longrightarrow G/H \mid H \leq G\}$$

generates all monomorphisms by coproducts and transfinite attachments; retracts are unnecessary for this particular generation. A map $p : X \to Y$ belongs to $I_G^{\square}$ precisely when, for every subgroup $H \leq G$, the map on fixed points

$$X^H \longrightarrow Y^H$$

is surjective. Indeed, an equivariant map $G/H \to Y$ is determined by an H-fixed element y, and a lift is exactly an H-fixed x with $p(x) = y$. Conversely the fixed-point condition solves every orbit attachment and hence every monomorphism lifting problem.

This example explains the word "injective" in the source. It refers to an injective object of the slice, tested against all monomorphisms in that slice. Ordinary surjectivity need not suffice. If G is nontrivial, the equivariant map $G \to *$ is surjective as a map of sets, but G^G is empty, so it fails the test for $H = G$. The small object factorization adds precisely the missing equivariant extensions; it does not merely repair the underlying map of sets.

Corollaire 7.2. *Soit* $\mathcal{M}$ *satisfaisant* (a), (b), (c), (d), (e) *et aux conditions supplémentaires :*

(7.2.1)
- e′) *Les* $\varinjlim$ *filtrantes commutent au changement de base.*
- f) *Si* A_1, A_2 *sont deux sous-objets d'un objet* B *de* $\mathcal{M}$, *et* $A_0 = A_1 \cap A_2$, *alors* $A_1 \amalg_{A_0} A_2 \hookrightarrow B$ *est un monomorphisme*[31].

31. Une autre façon de le dire : si $C = \sup_{\mathrm{Ss}(B)}(A_1, A_2)$, le carré cartésien

$$\begin{array}{ccc} A_0 & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_2 & \longrightarrow & C \end{array}$$

est aussi cocartésien.

Soit W une partie de $\mathrm{Fl}(\mathcal{M})$ *satisfaisant les conditions suivantes.*

(7.2.3)
- a) *W est un localiseur modérément saturé.*
- b) *W est L-accessible,* i.e. *il est stable par* $\varinjlim$ *filtrantes, et est accessible.*
- c) $\mathrm{Mon} \cap W$ *est stable par cochangement de base,* i.e. *si on a un diagramme* cocartésien

$$\begin{array}{ccc} A & \xrightarrow{i} & B \\ {\scriptstyle\alpha}\downarrow & \text{cocart.} & \downarrow{\scriptstyle\beta} \\ A' & \xrightarrow{i'} & B' \end{array}$$

avec i monomorphisme appartenant à W, alors i' est un monomorphisme appartenant à W.[32]

[page 89]

Sous ces conditions, on a

$$\underbrace{\mathrm{Mon}}_{C} \cap W \;=\; \widetilde{W \cap \mathrm{Mon}} \quad , \qquad \text{i.e. } \mathrm{Mon} \cap W \text{ est Q-clos à gauche} \, , \tag{7.2.4}$$

et p. 49

$$\text{il existe une petite partie } TC_0 \subset \mathrm{Mon}, \text{ telle que } \mathrm{Mon} \cap W = \widetilde{TC_0} \, . \tag{7.2.5}$$

(De façon plus précise, si $\pi \geq \pi_0$ est un cardinal tel que W soit π-accessible, on peut prendre $TC_0 = (\mathrm{Mon} \cap W)^{\pi}$ (ou une partie petite *de $(\mathrm{Mon} \cap W)^{\pi}$ ayant les mêmes classes d'isomorphie).) Donc* (th. 1 de §1) *le couple $(TC = \mathrm{Mon} \cap W,\ F = (TC)_*)$ est un couple de Quillen clos, et il y a même une factorisation* fonctorielle *de toute flèche f en*

$$f \;=\; p\,i \, ; \qquad i \;\in\; TC \, , \qquad p \;\in\; F \, . \tag{7.2.4}$$

Si on pose

$$C \;=\; \mathrm{Mon} \, , \qquad TC \;=\; \mathrm{Mon} \cap W \, , \qquad F \;=\; (TC)_* \, , \qquad TF \;=\; C_* \, , \tag{7.2.5}$$

le triple (W, C, F) est un triple de Quillen clos, si et seulement si on a les conditions supplémentaires suivantes.

- (7.2.6) ⓖ *(sur $\mathcal{M}$ seulement)* Mon *stable par cochangement de base.*
- (7.2.7) $\underbrace{TF}_{\overset{\text{déf}}{=} (\mathrm{Mon})_*} \;\subset\; W$ i.e. *si* d) *toute $f : X \longrightarrow Y$ qui fait de X un objet injectif de $\mathcal{M}/Y$, est dans W (donc aussi dans W_{univ}).*

Démonstration de 7.1. On peut donner un énoncé un peu plus délicat, en supposant d'emblée donnée, non une partie M_0 de $\mathrm{Ob}\mathcal{M}$, mais une partie [page 90]

$$\mathrm{Mon}_0 \;\subset\; \mathrm{Mon} \, , \tag{7.1}$$

satisfaisant la condition suivante

32. *Cf.* plus bas pour une quatrième condition (*d*) sur W, qui assure que W s'insère dans un triple de Quillen.

Pour tout monomorphisme $i : A \longrightarrow B$ dans $\mathcal{M}$, il existe $i' \in \mathrm{Mon}_0$, $i' : A' \longrightarrow B'$, et une flèche $i' \longrightarrow i$ dans $\underline{\mathrm{Fl}}(\mathcal{M})$,

(7.2)
$$\begin{array}{ccc} A' & \xrightarrow{i'} & B' \\ \downarrow & & \downarrow \\ A & \xrightarrow{i} & B\ , \end{array}$$

telle que la flèche correspondante

$$C \;=\; A \amalg_{A'} B' \;\longrightarrow\; B$$

soit un monomorphisme, et que $B' \longrightarrow B$ ne se factorise pas par A.

C'est cela qui était visé par la condition (7.1.1) sur M_0, qui implique (7.2) sur Mon_0 défini en termes de M_0 comme dit dans 1°.

Dans ce qui suit, on suppose donnée une partie $\mathrm{Mon}_0 \subset \mathrm{Fl}(\mathcal{M})$ satisfaisant (7.2). En pratique, elle sera souvent déduite d'une partie M_0 de $\mathrm{Ob}\mathcal{M}$, génératrice pour les monomorphismes, comme explicité dans 1°, mais on n'a pas besoin du fait que $i' \longrightarrow i$ soit un monomorphisme (*i.e.* (7.1.1) est plus forte que ce qu'il nous faut). P. ex. si $B' \in M_0$ et $B' \longrightarrow B$ est donné, ne se factorisant pas par A, on pourra prendre $A' = B' \times_B A$ et $i' : A' \longrightarrow B'$ (pour assurer $i' \in \mathrm{Mon}_0$, il faudra donc supposer M_0 stable par passage aux sous-objets), et il y a des chances p. 50

que $C \longrightarrow B$ sera alors bel et bien un monomorphisme … [page 91]

1°) Il faut prouver

$$\mathrm{Mon} \;\subset\; \widetilde{\mathrm{Mon}_0}$$

moyennant (7.2) (et la stabilité de $\mathcal{M}$ par $\varinjlim$ filtrantes). Cela va résulter directement du

Lemme 7.3. *Soient $\mathcal{M}$ une catégorie stable par limites inductives filtrantes, et C_0, C des parties de* $\mathrm{Fl}(\mathcal{M})$. *On supposera*

ⓐ *C formée de monomorphismes, et*

ⓑ *que la condition suivante (généralisant* (7.2) *ci-dessus) soit vérifiée.*

Pour toute flèche $i : A \hookrightarrow B$ dans C telle que i ne soit pas un isomorphisme, il existe $i' : A' \longrightarrow B'$ dans $\widetilde{C_0}$, et une flèche $i' \longrightarrow i$ dans $\underline{\mathrm{Fl}}(\mathcal{M})$, telle que dans le diagramme

(7.3.1)
$$\begin{array}{ccccc} A' & \xrightarrow{i'} & B' & & \\ \downarrow & & \downarrow & \searrow^{\beta} & \\ A & \xrightarrow{\alpha} & D \;=\; A \amalg_{A'} B' & \xrightarrow{\beta} & B\ , \\ & \searrow_{i} & & \nearrow & \end{array}$$

la flèche β soit dans C, et que $B' \longrightarrow B$ ne se factorise pas par A (ou, ce qui revient au même, que le sous-objet de B défini par D et β ne soit pas égal à celui défini par A et i).

On suppose de plus

ⓒ *C stable par $\varinjlim$ filtrantes, et*

ⓓ *que pour tout $B \in \mathrm{Ob}\mathcal{M}$, l'ensemble des sous-objets de B est petit.* (Condition des plus anodines! C'est une condition *sur* $\mathcal{M}$, n'impliquant pas C). [page 92]

Alors on a

$$C \subset \widetilde{C_0}\ , \qquad \textit{donc } \widetilde{C} \subset \widetilde{C_0}\ , \tag{7.3.2}$$

donc, si $C_0 \subset C$, on conclut

$$\widetilde{C} = \widetilde{C_0}\ . \tag{7.3.3}$$

(Ce lemme implique aussitôt la première assertion de 7.1, 1°.) Prouvons ce lemme, *i.e.* que toute $i \in C$ est dans $\widetilde{C_0}$, en construisant par récurrence transfinie une suite strictement croissante de sous-objets de B, p. 51

$$A_\alpha \overset{j_\alpha}{\hookrightarrow} B\ , \qquad \text{avec les } j_\alpha \in C\ ,$$

et avec :

① $A_0 = A$. On prouvera que $A \xrightarrow{i_\alpha = i_{\alpha,0}} A_\alpha$ dans $\widetilde{C_0}$, et il y aura un ordinal final α tel que $A_\alpha = B$; on en conclura donc que $i = i_\alpha$ est dans $\widetilde{C_0}$.

Si i est un isomorphisme, on sait que $i \in \widetilde{C_0}$, il n'y a rien à prouver (la construction transfinie s'arrête au cran 0). Les deux pas de la construction, après le pas initial 1°, sont :

② Soit A_α construit. Si $A_\alpha = B$, la construction est arrêtée. Si $A_\alpha \xrightarrow{j_\alpha} B$ n'est pas un isomorphisme, on applique (7.3.1) à $j_\alpha \in C$, pour trouver un $D \overset{j}{\hookrightarrow} B$, donc $j \in C$ et $D \supsetneqq A_\alpha$. De plus,

$$i_{\alpha+1,\alpha} : A_\alpha \longrightarrow A_{\alpha+1} \overset{\text{déf}}{=} D \qquad \text{est dans } \widetilde{C_0}\ , \tag{7.3.4}$$

car déduit de $i' \in \widetilde{C_0}$ par cochangement de base.

③ Si α est ordinal limite, on pose

$$A_\alpha = \varinjlim_{\beta<\alpha} A_\beta\ , \tag{7.3.5}$$

et la flèche canonique [page 93]

$$A_\alpha \xrightarrow{j_\alpha} B$$

est dans C, car les j_β le sont et C est stable par limites inductives filtrantes.

On a ainsi achevé la description des systèmes transfinis. Pour tout α, on a

$$\operatorname{card}\alpha \leq \operatorname{card}\operatorname{Ss}(B)\ ,$$

puisque l'application $\beta \longmapsto A_\beta$ de l'ensemble $I_\alpha = \{\beta \mid \beta < \alpha\}$ dans $\operatorname{Ss}(B)$ est *strictement* croissante. Donc il existe un cardinal α tel que $\operatorname{card}\alpha \leq \operatorname{card}\operatorname{Ss}(B)$, tel que $A_\alpha = B$. Mais alors $i \in \widetilde{C_0}$, comme limite inductive (ou composé) transfinie de flèches appartenant à $\widetilde{C_0}$. (Il suffit de la condition $\forall\ \beta$, $i_{\beta+1,\beta} \in \widetilde{C_0}$ pour impliquer que tous les morphismes de transition $i_{\beta',\beta}$ sont dans $\widetilde{C_0}$.)

Revenons à 7.1, 2°. Il reste à prouver que si Mon est stable par cochangement de base, alors on a

$$\operatorname{Mon} = \widetilde{\operatorname{Mon}_0}\ .$$

Mais comme Mon est déjà stable par composition, et par limites inductives filtrantes quelconques (donc aussi par facteurs directs), il s'ensuit par le corollaire 2 du théorème 1, §1 (p. 11), que $\operatorname{Mon} = \widetilde{\operatorname{Mon}_0}$. L'énoncé de factorisation est le théorème 1 du §1.

p. 52
[page 94]

Commentary · Exposition [ms. 93]

The transfinite argument and its stopping condition

The strength of Lemma 7.3 is that its proof never guesses a universal set of cells. It assumes that a permissible next cell can be found whenever a remainder is nontrivial, and then proves that the process reaches the target. Here is the full argument, including its size condition.

Fix $i : A \hookrightarrow B$ in C, and let $\mathcal{S}(B)$ be the set of subobjects of B. Choose an ordinal θ whose cardinal is strictly greater than $|\mathcal{S}(B)|$. Starting with $A_0 = A$, apply condition (b) whenever $A_\alpha \hookrightarrow B$ is not invertible, obtaining a pushout attachment $A_\alpha \to A_{\alpha+1}$ in $\widetilde{C_0}$ and a proper inclusion $A_\alpha \subsetneq A_{\alpha+1} \subset B$ whose remainder lies in C. At a nonzero limit ordinal λ, form $A_\lambda = \varinjlim_{\alpha<\lambda} A_\alpha$. The arrows $A_\alpha \to B$ form a filtered diagram in the arrow category with constant target; condition (c) puts its colimit $A_\lambda \to B$ in C, and hence makes it monic. This identifies A_λ with the union of the preceding subobjects.

If the construction had not stopped before θ, it would give more distinct subobjects of B than $\mathcal{S}(B)$ contains. Therefore $A_\lambda = B$ at some stage. Every successor attachment is in $\widetilde{C_0}$, so transfinite closure gives $A \to B \in \widetilde{C_0}$. This also proves the claimed equality of closures when $C_0 \subset C$.

The printed phrase asserting the existence of a "cardinal α" is an ordinal/cardinal slip. The argument produces a stopping *ordinal* λ with $|\lambda| \le |\mathcal{S}(B)|$, not necessarily a stopping stage which is itself an initial ordinal. The distinction changes no conclusion. More substantively, well-poweredness is explicitly assumed in Lemma 7.3, but is absent from the short list at the start of Theorem 7.1(1). Its proof needs this hypothesis, or another smallness argument that forces termination. It holds in all the presheaf applications here. We retain it when stating the general result; we have not obtained a counterexample to the theorem with that hypothesis omitted.

A second small point explains the retract assertions used subsequently. If f is a retract of g in the arrow category, with section s and retraction r, then $e = sr$ is an idempotent endomorphism of g. The sequential diagram $g \xrightarrow{e} g \xrightarrow{e} \cdots$ has colimit f: a cocone is exactly a map out of g invariant under e, and these are exactly maps out of its splitting f. Thus closure under filtered colimits implies closure under retracts. This observation justifies the source's parenthesis without importing a model structure that has not yet been constructed.

Prouvons 7.1, 3°, *i.e.* la formule (7.1.6),

$$W \cap \mathrm{Mon} \;\subset\; \widetilde{(W \cap \mathrm{Mon})^\pi} \ .$$

Pour ceci, on applique encore le lemme 7.3 à

$$C_0 \;=\; (W \cap \mathrm{Mon})^\pi \ , \qquad C \;=\; W \cap \mathrm{Mon} \ .$$

Les conditions (a), (b), (c), (d) du lemme sont vérifiées. C'est clair pour toutes, sauf pour (b), qui demande une vérification non tautologique. Soit donc

$$f \;:\; A \hookrightarrow B \ , \qquad f \in \mathrm{Mon} \cap W,\ f \text{ non isomorphisme} \ .$$

On considère B comme limite inductive [33]

$$B \;=\; \varinjlim_{I} B_i \ , \qquad I \;=\; \mathrm{Ss}_\pi(B) \ .$$

Pour tout i, on pose

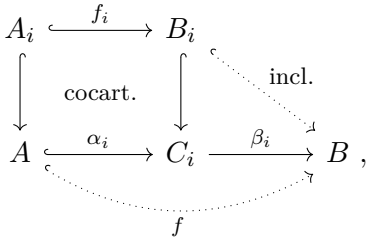
$$A_i \;=\; A \cap B_i \;=\; A \times_B B_i \ ,$$

et

$$f_i \;:\; A_i \;\hookrightarrow\; B_i \ ,$$

donc

$$f \;=\; \varinjlim_{i \in I} f_i \ .$$



[page 95]

On a besoin de savoir que le système inductif des flèches f_i est π-adapté, ce qui nous amène à postuler la condition d'exactitude supplémentaire suivante sur $\mathcal{M}$:

(7.4) e') les $\varinjlim$ filtrantes dans $\mathcal{M}$ commutent au changement de base ,

il suffit même de le supposer dans le cas très particulier qu'on a envisagé ici.

Comme W est π-accessible, et $(f_i)_{i\in I}$ est π-adapté, comme $\varinjlim f_i \in W$, il s'ensuit que l'ensemble I_W des $i \in I$ tels que $f_i \in W$ est cofinal. Comme $A \overset{f}{\hookrightarrow} B$ n'est pas un isomorphisme, il existe donc un $i \in I_W$ tel que $B_i \hookrightarrow B$ ne se factorise pas par A. On a alors le diagramme

avec $f_i \in (C \cap W)^\pi = C_0$, donc $\alpha_i \in \widetilde{C_0}$. On a besoin de savoir que $\alpha_i \in W$, donc une condition supplémentaire sur W : p. 53

Si on a un carré cocartésien

(7.5)
$$\begin{array}{ccc} A & \xrightarrow{\ i\ } & B \\ \downarrow & & \downarrow \\ A' & \xrightarrow{\ i'\ } & B' \ , \end{array}$$

avec $i \in \mathrm{Mon} \cap W$, alors $i' \in W$ [34].

(j'ai renforcé (7.1.4) en conséquence).

Comme par hypothèse $f = \beta_i\alpha_i$ est dans W, et $\alpha_i \in W$, il s'ensuit par (7.1.4), (a) que $\beta_i \in W$. Il faudra que nous sachions de plus que β_i est un monomorphisme, donc $\beta_i \in \mathrm{Mon} \cap W = C$, ce qui achèvera d'établir la condition manquante (b) de 7.3. C'est la condition d'exactitude (7.2.1), qu'il me faut visiblement rajouter aux hypothèses dans 7.1, 3°. Ayant fait cela, le lemme 7.3 s'applique et établit 7.1, 3°. [page 96]

Démonstration de 7.2. Posons

$$C \ = \ \mathrm{Mon} \ , \qquad TC \ = \ C \cap W \ , \qquad TC_0 \ = \ TC^\pi \ ,$$

donc par 7.1, 3°, on a

$$\underbrace{TC_0}_{\substack{\text{essentiellement}\\ \text{petite}}} \quad \subset \ TC \ \subset \ \widetilde{TC_0} \ = \ \widetilde{TC} \ ,$$

et par le théorème 1, §1 (p. 10-12), cor. 2, pour vérifier que $TC = \widetilde{TC_0}$ (*i.e.* TC est Q-clos à gauche), il revient au même de voir qu'il est Q-stable à gauche, *i.e.* stable par composition, par cochangement de base, par $\varinjlim$ ordinales strictes, par facteurs directs. Or les deux derniers sont impliqués par le fait que $\widetilde{TC} = C \cap W$ est stable par $\varinjlim$ filtrantes, vu que W l'est, et C aussi par la condition ⓔ (p. 76) sur $\mathcal{M}$. D'autre part, $C = \mathrm{Mon}$ et W étant stables par composition, itou pour $C \cap W$. Donc il reste le cochangement de [page 97]

33. *D'un système inductif π-adapté.*

34. **N.B.** Cette condition est vérifiée.

Commentary · Exposition [ms. 96]

Keeping the remainder a weak equivalence

Theorem 7.1(3) succeeds because it repairs the precise defect of §6. Let $f : A \hookrightarrow B$ lie in W. Use the full filtration hypothesis (d) from manuscript pages 45–46, including closure under subobjects; its abbreviated restatement in 6.1 omitted this clause. Write B as the π-adapted union of its π-small subobjects B_i, and put $A_i = A \cap B_i$. Subobject closure gives $A_i \in \mathrm{Filt}^{\pi}$, and preservation of filtered colimits by pullback gives

$$f = \varinjlim_i (A_i \hookrightarrow B_i).$$

The same preservation proves continuity at the small filtered suprema in the index poset. Thus this is a π-adapted presentation in the arrow category, rather than merely an arbitrary filtered presentation.

Accessibility now has a legitimate input: it says that the indices for which $f_i : A_i \hookrightarrow B_i$ belongs to W are cofinal. If $A \neq B$, some B_i meets the complement of A; cofinality permits choosing such an index with $f_i \in W$. Form

$$A \xrightarrow{\alpha_i} D_i = A \amalg_{A_i} B_i \xrightarrow{\beta_i} B.$$

The first arrow is a pushout of a small trivial monomorphism, so it lies both in $\widetilde{(W \cap \mathrm{Mon})}^{\pi}$ and in W. Effective unions, condition (f), say that β_i is monic. Since $\beta_i \alpha_i = f \in W$, the cancellation clause (7.1.4)(b) gives $\beta_i \in W$. The attachment is proper because B_i was not contained in A. These facts verify precisely the successor-step hypothesis of Lemma 7.3 for $C = W \cap \mathrm{Mon}$.

No assertion that the large remainder $D_i \to B$ is itself π-small has been used. In §6 that assertion was needed to apply accessibility to a second diagram, and it was unavailable. Here the remainder is put in W by cancellation instead. This is the mathematical reason why the new theorem survives the failure of the earlier one.

Once $TC = W \cap \mathrm{Mon}$ is generated by its small members, the additional closure properties make it equal to its left Q-closure. Composition follows from composition in W and in Mon; pushout stability is assumed; transfinite composition and retract closure follow from filtered-colimit stability, with identities supplying the degenerate cases. The small object argument then constructs the weak factorization system $(TC, TC^{\square})$. Its ordinal length must be chosen large enough for the domains of the chosen generating set to be small relative to the construction. Merely saying that the generating set is small is not itself this domain-smallness assertion; the accessibility hypotheses supply it.

base, et c'est assuré par 7.2.3, (c) (dont on avait déjà besoin dans 7.1, 3°, pour établir $C \cap W \subset \widetilde{TC_0}$). (**N.B.** les hypothèses de 7.2 sont pratiquement celles de 7.1, 3°, sauf qu'on suppose que W est un localiseur (sous-entendu : modérément saturé), de façon précise on n'a utilisé, jusqu'à présent, comme hypothèse supplémentaire, que la stabilité de W par composition.)

Il reste à établir que $(W, C = \mathrm{Mon}, F = (TC)_*)$ est un triple de Quillen clos, si et seulement si les conditions (7.2.6) et (7.2.7), *i.e.*

$$\begin{cases} C = \mathrm{Mon} \ \text{ stable par cochangement de base,} \\ TF = C_* = (\mathrm{Mon})_* \subset W, \end{cases}$$

sont satisfaites. La nécessité est évidente, par définition des triples de Quillen clos, et pour la suffisance, on note qu'il résulte du théorème 7.1, 2°, et de la partie déjà prouvée de 7.2, que p. 54
(C, TF), (TC, F) sont des couples de Quillen clos, et on a de plus

$$TC \ = \ C \cap W \ , \qquad TF \ \subset \ F \cap W$$

(puisque $TF \subset W$ par (7.2.7), et $TF \subset F$ puisque $TC \subset C$). On sait (paragraphe 4.3, corollaire 4, page 36) qu'il en résulte que (W, C, F) est un triple de Quillen clos. Cela achève la démonstration de 7.1 et 7.2. [page 98]

Résumons l'essentiel :

Corollaire 7.4.[35] *Soit $\mathcal{M}$ une catégorie satisfaisant les conditions* (a), (b), (c), (d), (e) (p. 76) *et* (e′), (f) ((7.2.1), p. 88), *enfin* (g) (7.2.6), i.e. *stabilité de l'ensemble* Mon *des*

35. **N.B.** C'est finalement ce corollaire qui est le résultat principal de la présente section.

monomorphismes de $\mathcal{M}$ par cochangement de base. Soit $W \subset \mathrm{Fl}(\mathcal{M})$ un localiseur dans $\mathcal{M}$, qui est stable par $\varinjlim$ filtrantes *et de plus* (*condition plus subtile, mais pratiquement anodine*) accessible. *On pose*

$$C = \mathrm{Mon}\,, \qquad TC = C \cap W\,, \qquad TF = C_*\,, \qquad F = (TC)_*\,.$$

Alors :

1°) (C, TF) *est un couple de Quillen* (*énoncé indépendant de la donnée de W*), *et même un couple de Quillen à factorisation fonctorielle.*

2°) *Pour que (TC, F) soit un couple de Quillen, il faut et il suffit que TC soit stable par cochangement de base.* (*Et alors il y a factorisation fonctorielle.*) [36].

3°) *Pour que (W, C, F) soit un triple de Quillen clos, il faut et il suffit que les conditions suivantes soient satisfaites.*

(7.4.1)
$$\begin{cases} \text{a)} \quad TC \overset{\text{déf}}{=} W \cap \mathrm{Mon} \text{ stable par cochangement de base.} \\ \text{b)} \quad TF \overset{\text{déf}}{=} (\mathrm{Mon})_* = \text{applications de type injectif} \subset W. \end{cases}$$

4°) *Pour que (W, C, F) soit un triple de Quillen clos et propre à gauche* (i.e. $C \subset \mathrm{Cof}_W$), *il faut et il suffit qu'on ait la condition* (7.4.1), (b) (i.e. *W contient les morphismes de type injectif*), *et de plus* [page 99]

$$C \subset \mathrm{Cof}_W, \text{ ou encore : pour tout carré cocartésien}$$

(7.4.2)
$$\begin{array}{ccc} A & \xrightarrow{\ i\ } & B \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\beta} \\ A' & \xrightarrow{\ i'\ } & B' \end{array},$$

avec i un monomorphisme, alors $\alpha \in W \Longrightarrow \beta \in W$.

Commentary · Exposition [ms. 98]

Why the two factorization systems fit together

The remaining issue in Corollary 7.4 is compatibility. Two weak factorization systems on the same category do not by themselves make a model structure. Here the required compatibility is concentrated in the inclusion $TF \subset W$, and the retract argument explains why this one inclusion is enough.

Assume that (C, TF) and (TC, F) are weak factorization systems, that $TC = C \cap W$, that $TF \subset W$, and that W has two-out-of-three and is closed under retracts. Because $TC \subset C$, every map right orthogonal to C is right orthogonal to TC; hence $TF \subset F \cap W$. Conversely, let $p : X \to Y$ lie in $F \cap W$. Factor it using the first system as

$$X \xrightarrow{i} Z \xrightarrow{q} Y, \qquad i \in C, \quad q \in TF.$$

Since $q, p \in W$, two-out-of-three gives $i \in W$, hence $i \in TC$. Lifting i against p gives $r : Z \to X$ with $ri = 1_X$ and $pr = q$. In the arrow category the maps $(i, 1_Y)$ and $(r, 1_Y)$ exhibit p as a retract of q. Right lifting classes are retract-closed, so $p \in TF$. Consequently

$$TF = F \cap W, \qquad TC = C \cap W,$$

and the two factorizations and lifting properties are exactly the model-category axioms. Completeness and cocompleteness are supplied by the ambient hypotheses in the applications. This proves the sufficiency left implicit in the reference to §4.3.

36. **N.B.** Dans les cas 1° et 2°, C, $TC = C \cap W$ sont Q-engendrés à gauche par des *petites* parties.

For $C = \mathrm{Mon}$ the class TF is independent of W. It is already fixed by the ordinary category, and condition (7.2.7) asks the proposed homotopy theory to regard all those maps as equivalences. This is a substantial condition. In Set, for example, $\mathrm{Mon}^{\square}$ is the class of surjections, assuming the usual axiom of choice: testing $\varnothing \to \{*\}$ gives surjectivity, and choices of preimages solve the general lifting problem. If W consists only of bijections, $TF \subset W$ fails. Thus the category of sets with weak equivalences the bijections cannot have all injections as cofibrations and the factorization systems prescribed here.

Left properness has a separate role. It asks that a pushout of any weak equivalence along a cofibration be a weak equivalence. At this stage the source uses its previously established identity $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$, where the superscript denotes universal stability under *cobase* change, to obtain pushout stability of TC. In the presheaf applications, once the model structure is constructed, there is also the general explanation that every object is cofibrant: initial maps are monomorphisms, and these are the cofibrations. Homotopy invariance of pushouts of cofibrant objects then gives left properness. The assertion about initial maps is a property of presheaves, not of arbitrary categories. None of these arguments gives right properness automatically. The symbols W^{univ} and W_{univ} must therefore retain their opposite variances throughout this passage.

p. 55

5°) *Pour que* (W, C, F) *soit un triple de Quillen clos et* propre, *il faut et il suffit que les deux conditions de 4° soient satisfaites, ainsi que l'on ait :*

$$F \subset \mathrm{Fib}_W, \ \textit{ou encore : pour tout carré cartésien}$$

$$\begin{array}{ccc} X & \xrightarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ Y & \xrightarrow[p]{} & Y' \end{array} \qquad (7.4.3)$$

$$\textit{si } f \in F \ (\text{i.e. } f \in (C \cap W)_*) \textit{ et } p \in W, \ \textit{on a } q \in W.$$

Démonstration de 7.4. Les parties 1°, 2°, 3° ne sont qu'un résumé de ce qui a été établi. Pour 4°, il faut voir que les conditions dites impliquent (7.4.1), (a), or on a $C \subset \mathrm{Cof}_W$, donc $C \cap W \subset \mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$ donc $C \cap W = C \cap W^{\mathrm{univ}}$, qui est stable par cochangement de base, puisque C et W^{univ} le sont. Quant à 5°, c'est une tautologie, compte tenu de 4°. [page 100]

Commentary · Examples [ms. 99]

Which vertical map is the fibration

Grothendieck wants the last clause of Corollary 7.4 to record right properness. In the displayed cartesian square the fibration hypothesis belongs to $f' : X' \to Y'$, the arrow *along which* $p : Y \to Y'$ is pulled back. The edition instead prints $f \in F$, referring to its pullback. This is a source slip, not a transcription error. The correction is necessary even in the most familiar proper model category.

In simplicial sets with the Kan–Quillen structure, take $Y' = \Delta[1]$, let $Y = \{0\}$, and let $X' = \{1\}$. Both maps to Y' are the indicated endpoint inclusions. Their pullback is empty, so the square is

$$\begin{array}{ccc} \varnothing & \longrightarrow & \{1\} \\ \downarrow & & \downarrow \\ \{0\} & \longrightarrow & \Delta[1]. \end{array}$$

The bottom map is a weak equivalence. The left map $\varnothing \to \{0\}$ is a Kan fibration: every horn is nonempty, so there are no lifting problems with a map from a horn into its empty domain. The top map is not a weak equivalence, since it changes the set of connected components from empty to a singleton. The right endpoint inclusion is not a Kan fibration; a one-dimensional horn asking for the missing endpoint has no lift. Thus the erroneous condition on the left-hand vertical map does not express right properness. Replacing it by $f' \in F$ restores the intended statement.

8 Application aux catégories de modèles $(A^\wedge, W_A)$

Soit A dans Cat, et considérons dans $A^\wedge$ le localiseur W_A, image inverse par

$$\text{(8.1)} \qquad \begin{cases} i_A : A^\wedge & \longrightarrow & \mathrm{Cat} \\ F & \longmapsto & A/F \end{cases}$$

d'un localiseur fondamental donné W, satisfaisant les conditions

(8.2) $\mathrm{W}(\underbrace{1}_{\text{sat.}}, \underbrace{2}_{\text{loc.}}, \underbrace{3}_{\text{objet fin.}}, \underbrace{5}_{\text{conn. } \pi_0}, \underbrace{6}_{\varinjlim}, \underbrace{7\text{ bis}}_{\substack{\text{carrés coc.} \\ \text{ou "M.V."}}}, \underbrace{8}_{\text{acc.}})$, où $\mathrm{W}(8)$ est l'accessibilité de W (donc W est L-accessible s'il satisfait aussi $\mathrm{W}(6)$).

Pour pouvoir cependant appliquer les développements sur les parties accessibles d'une grosse catégorie du §5, il faut vérifier les conditions (a), (b), (c), (d), (e) du §5, tant dans Cat, que (surtout) dans $A^\wedge$.

a) Stabilité par petites $\varinjlim$ filtrantes, O.K.

b) Filtration cardinale. Bien connu pour $A^\wedge = \underline{\mathrm{Hom}}(A, \mathrm{Ens})$, à partir de celle de Ens par les cardinaux (*cf.* SGA 4 I, 9.24, p. 177). Pour Cat, on définit une filtration cardinale

$$\text{(8.3)} \qquad (\mathrm{Cat}^\pi)_{\pi \geq \pi_0}\ , \qquad \text{où } \pi_0 = \text{cardinal des ensembles dénombrables}\ ,$$

par la condition, pour A dans Cat,

p. 56 [page 101]

$$\text{(8.4)} \qquad A \in \mathrm{Filt}^\pi(\mathrm{Cat}) \ = \ \mathrm{Cat}^\pi \qquad \Longleftrightarrow \qquad \mathrm{card}\,\mathrm{Fl}(A) \ \leq \ \pi\ .$$

Il faut vérifier les conditions (a), (b), (c) de *loc. cit.* 9.12. La condition (a) est évidente, (b) est contenue dans la condition plus forte de stabilité de Cat^π par $\varinjlim_I$, pour I une catégorie telle que $\mathrm{card}\,\mathrm{Fl}(I) \leq \pi$ (c'est la condition (d_0) de ces notes, p. 45-46). Notons que Cat^π est également stable par $\varprojlim$ finies (et si π est de la forme 2^c, il est stable même par limites projectives $\varprojlim_I$, avec $\mathrm{card}\,\mathrm{Fl}(I) \leq c$ ...). La condition (c) se vérifie aisément par la méthode du §5, en notant que pour X dans Cat, l'ensemble

$$\mathrm{Ss}_\pi(X)$$

des sous-catégories de X qui sont dans Cat^π est filtrant croissant et grand devant π, et que X en est la limite inductive. D'autre part, il est clair aussi que si $X \in \mathrm{Cat}^{\pi'}$ avec $\pi' > \pi$, alors

$$\mathrm{card}\,\mathrm{Ss}_\pi(X) \ \leq \ \pi'^\pi\ ,$$

ce qui achève d'établir la condition (c).

De plus, la condition (d) de p. 45 se vérifie immédiatement pour les Cat^π, et aussi pour les $A^{\wedge\pi}$ (pour $\pi \geq \mathrm{card}\,\mathrm{Fl}(A)$).

Aussi que les monomorphismes sont stables par $\varinjlim$ filtrantes (condition (e), page 46).

Passons aux conditions supplémentaires (e'), (f), (g) exigées dans le corollaire 7.4. La condition (e') (commutativité des $\varinjlim$ filtrantes au changement de base) est satisfaite dans $A^\wedge$ et dans Cat. La condition (f) dit que pour deux sous-objets A_1, A_2 d'un objet B, si $A_0 = A_1 \cap A_2$, alors [page 102]

$$A_1 \amalg_{A_0} A_2 \longrightarrow B$$

est un monomorphisme. Je doute que c'est vrai dans Cat, et ce n'est pas grave, car c'est à $A^\wedge$, non à Cat, qu'on voudra appliquer 7.4 – et c'est évidemment vrai dans $A^\wedge$, et dans tout topos, l'étant dans (Ens). Enfin, la stabilité des monomorphismes par cochangement de base est sûrement fausse dans Cat, mais vraie dans $A^\wedge$ – donc c'est O.K.

Comme W est stable par $\varinjlim$ filtrantes (W (6)), et que i_A y commute, W_A est également stable. De même, W_A est L-accessible, en vertu du

Lemme 8.1. *Soient $\mathcal{M}$, $\mathcal{M}'$ deux catégories satisfaisant* (a), (b), (c), (d), (e), *et $\varphi : \mathcal{M} \longrightarrow \mathcal{M}'$ un foncteur commutant aux $\varinjlim$ filtrantes. Alors pour toute partie L-accessible M' de $\mathcal{M}'$, $\varphi^{-1}(M')$ est L-accessible.*

De façon précise, soit π un cardinal tel que M' soit π-accessible et que φ applique $\mathcal{M}^\pi$ dans $\mathcal{M}'^\pi$ (par exemple, pour cette dernière condition, il suffit $\pi = 2^c$ pour c assez grand, cf. loc. cit. 9.14, p. 153). *Alors $M = \varphi^{-1}(M')$ est π-accessible.* [page 103]

Commentary · Development (commentators') [ms. 102]

Two finite categorical obstructions to the exactness hypotheses

Grothendieck separates Cat from a presheaf topos because the generation argument needs effective unions and stable monomorphisms, not only filtered-colimit exactness. His doubts about these two properties in Cat admit very small witnesses. We give them explicitly, so that the restriction to presheaves can be seen in the actual constructions. We checked the model-recognition discussions of Beke (2000, Section 1) and Cisinski (2006a, Sections 1.2 and 4.2); neither is being cited as the source of the particular finite presentations below. The examples establish familiar failures and carry no claim of priority.

Failure of effective unions. [ours] Let B be the four-element diamond poset, with objects $0, 1, 2, 3$ and nonidentity relations

$$0 < 1 < 3, \qquad 0 < 2 < 3.$$

Let A_1 contain all four objects and just the nonidentity arrows $0 \to 1$ and $2 \to 3$, and let A_2 contain all four objects and just $0 \to 2$ and $1 \to 3$. Each is a subcategory of B, and $A_0 = A_1 \cap A_2$ is discrete. Their pushout $P = A_1 \amalg_{A_0} A_2$ is the free category on the directed diamond: a functor from P is exactly the data of functors from A_1 and A_2 agreeing on objects, with no imposed relation between the two length-two paths. Thus P has two distinct arrows $0 \to 3$, whereas B has one. The comparison $P \to B$ is not faithful and therefore is not a monomorphism in Cat. This disproves condition (f) of (7.2.1).

Failure of stability of monomorphisms under pushout. [ours] Let $A = [1]$, with arrow $a : 0 \to 1$, and let B be the category obtained by making a invertible. The functor $A \to B$ is injective on objects and faithful, hence monic. Let C have objects $0, 1, 2$, arrows

$$a : 0 \to 1, \quad b, c : 1 \to 2, \quad d : 0 \to 2, \qquad ba = d = ca,$$

with $b \neq c$ and no further nonidentity arrows or relations. This is a finite category, and $A \to C$ is the evident inclusion. In the pushout $D = B \amalg_A C$, the image of a is invertible. Therefore the equality $ba = ca$ forces $b = c$ in D. The induced functor $C \to D$ is not faithful. It is the pushout of the monomorphism $A \to B$, so condition (g) also fails.

Both failures concern creation and identification of composites. In a presheaf category the corresponding constructions are computed in sets at each object; no new paths have to be composed, and there is no cancellation forced by an inverse newly adjoined in another piece. For the finite-union example the precise defect is an additional relation on two newly composable paths. For the pushout example it is a cancellation relation imposed by a new inverse. These are different obstructions, which is why conditions (f) and (g) were listed separately.

Vérification immédiate.

On a donc le

Lemme 8.2. *Soit A dans* Cat. *Alors $(A^\wedge, W_A)$ satisfait aux conditions préliminaires du corollaire* 7.4, *ainsi qu'aux conditions suivantes.* p. 57

(8.2.1) $$\underbrace{\mathrm{Mon}(A^\wedge)}_{\substack{\text{ensemble des}\\ \text{monomorphismes}\\ \text{dans } A^\wedge}} \quad \subset \ \mathrm{Cof}_{W_A} ,$$

(8.2.2) $$\mathrm{Mon} \cap W_A \qquad \text{stable par cochangement de base} ,$$

en d'autres termes (*compte tenu que* Mon *est stable par cochangement de base*), *pour un carré cocartésien*

$$\begin{array}{ccc} A & \xrightarrow{\ i\ } & B \\ {\scriptstyle\alpha}\searrow & & \searrow{\scriptstyle\beta} \\ & A' \xrightarrow{\ i'\ } & B' \end{array} \tag{8.2.3}$$

avec i un monomorphisme, si $\alpha \in W_A$ (resp. $i \in W_A$), on a $\beta \in W_A$ (resp. $i' \in W_A$). En fait, on a mieux :

$$i \in W_A \iff i' \in W_A\ , \qquad \alpha \in W_A \iff \beta \in W_A\ . \tag{8.2.4}$$

Il reste à vérifier (8.2.4), qui a été vu dans XII … [page 104]

Commentary · Exposition [ms. 103]

The filtration and the inverse-image lemma

Grothendieck needs the class W_A to inherit the smallness properties of W before the generation theorem can be applied. The cardinal bookkeeping is straightforward once the correct presentation is fixed. For an infinite π, a category with at most π arrows has at most π objects. A colimit of a diagram with at most π arrows, whose values have at most π arrows, is a quotient of the free category on a graph of size at most π. Finite strings in such a graph still form a set of size at most π, so the same cardinal bound holds for the colimit. Finite limits are subsets of finite products of object and arrow sets, with composition inherited componentwise. The estimate for larger limits when $\pi = 2^c$ uses $(2^c)^c = 2^c$, for infinite c.

Every set of at most π arrows of an arbitrary category is contained in a subcategory with at most π arrows, obtained by adding identities and finite composites. The poset of these small subcategories is π-directed in the source's cardinal convention, admits the required small directed unions, and has colimit the whole category. If the ambient arrow set has cardinal π', there are at most $(\pi')^\pi$ such subcategories. For presheaves, restriction maps replace finite composites in the same calculation, and the bound $\pi \geq |\operatorname{Mor} A|$ controls the closure under all restrictions.

Lemma 8.1 then amounts to transporting an adapted presentation. Choose π for which M' is π-accessible and $\varphi(\mathcal{M}^\pi) \subset \mathcal{M}'^\pi$. For a π-adapted presentation $X = \varinjlim_i X_i$, preservation of filtered colimits gives an adapted presentation $\varphi X = \varinjlim_i \varphi X_i$. Membership of φX in M' is equivalent to cofinality of the indices with $\varphi X_i \in M'$. This is exactly the criterion for $X \in \varphi^{-1} M'$. Closure of the inverse image under arbitrary filtered colimits follows separately from the same preservation property. The proof establishes the source's L-accessibility; it does not identify this notion merely by terminology with modern accessibility of a full arrow subcategory.

For $i_A : F \mapsto A/F$, the objects are pairs (a, x) and an arrow $(a, x) \to (b, y)$ is an arrow $u : a \to b$ with $x = F(u)(y)$. Filtered colimits of these finite data are computed as expected, so i_A preserves them. Its cardinal bound follows from the number of choices of u and y. On enlarging the initial cardinal, the inverse-image lemma therefore applies to $W_A = i_A^{-1} W$.

On conclut donc de 7.4 1°, 2°, 3° :

Corollaire 8.3. *Posons*

$$\begin{cases} C \ = \ \operatorname{Mon}(A^\wedge)\ , & TC \ = \ C \cap W\ , \\ F \ = \ (TC)_*\ , & TF \ = \ C_*\ . \end{cases} \tag{8.3.1}$$

Alors (C, TF) et (TC, F) sont des couples de Quillen à factorisation fonctorielle. (**N.B.** *C et TC étant de plus Q-engendrés à gauche par des petites parties de* $\operatorname{Fl}(A^\wedge)$.) *Pour que (W_A, C, F) soit un triple de Quillen clos, il faut et il suffit qu'on ait*

$$\underbrace{TF}_{\overset{\text{déf}}{=}(\operatorname{Mon})_*} \ \subset \ W_A\ , \tag{8.3.2}$$

i.e. *que toute flèche* $f : X \longrightarrow Y$ *de type injectif dans* $A^\wedge$ (i.e. *qui fait de* X *un objet injectif de* $A^\wedge/Y$) *soit dans* W_A.

Quand cette condition est satisfaite, le triple de Quillen (W_A, C, F) *est propre à gauche, par* 8.2.1.

Il n'est pas clair qu'il soit forcément propre-tout-court, *i.e.* qu'on ait

$$F \ \subset \mathrm{Fib}_W \qquad (?)\ . \tag{8.3.3}$$

Nous y reviendrons par la suite. Pour l'instant, la chose essentielle, c'est d'examiner la condition (8.3.2) sur A.

Théorème 8.4. *Soit* W *un localiseur fondamental dans* Cat *satisfaisant* W (1, 2, 3, 6, 7, 8), p. 58
notations de XII, (i.e. *tous les axiomes envisagés jusqu'à présent, sauf peut-être celui* W (4) [page 105]
des fibrations `[et celui W(5) de connexité]`), *supposons de plus* W *stable par facteurs directs* (*renforcement* W (1 bis) *de l'axiome de saturation modérée* W (1)).[37] *Soit* A *un objet de* Cat, *et* $W_A = i_A^{-1}(W)$ *le localiseur de* $A^\wedge$ *déduit de* W. *Avec les notations de* 8.3 :

1°) *Les conditions suivantes sont équivalentes.*

a) *On a* (8.3.2),

$$TF \ \subset \ W_A\ ,$$

i.e. *toute flèche de type injectif dans* $A^\wedge$ *est dans* W_A.

b) *Soit*

$$L \ = \ L_A \tag{8.4.1}$$

l'élément de Lawvere dans $A^\wedge$, *donc le préfaisceau*

$$a \quad \longmapsto \quad \begin{array}{l} \text{ensemble des sous-préfaisceaux de } a \\ (\text{i.e. ensemble des ouverts de } A/a, \\ \text{i.e. des cribles de } A/a)\ , \end{array}$$

et considérons la flèche $L \longrightarrow e_A$ *(objet final de* $A^\wedge$*). On veut que cette flèche soit* W_A*-asphérique,* i.e. *soit universellement dans* W_A *– ou ce qui revient au même, que pour tout* $a \in A$, $L_A \times a$ $(= L_{A/a})$ *soit un objet* W_A*-asphérique de* $A^\wedge$ *(ou, ce qui revient au même, de* $(A/a)^\wedge$*).* [page 106]

c) *Il existe un objet* I *de* $A^\wedge$ *tel que* $I \longrightarrow e_A$ *soit* W_A*-asphérique, avec deux sections* δ_0, δ_1 *de* I *sur* e_A, *avec* $\mathrm{Ker}(\delta_0, \delta_1) = \emptyset_A$ *(préfaisceau vide).*

d) *Les catégories localisées* $A/a = B$ *sont des* catégories-test *pour* W (cf. *Pursuing Stacks, §65, notamment pages 172-173), ce qui revient à dire que l'on a ceci, pour chacune des catégories* $B = A/a$ *:*

Les foncteurs

$$\begin{cases} i_B : \ B^\wedge \ \longrightarrow \ \mathrm{Cat} \ \ (\ F \ \longmapsto \ B/F\ ) \\ j_B : \ \mathrm{Cat} \ \longrightarrow \ B^\wedge \ \ (\ C \ \longmapsto \ (b \longmapsto \mathrm{Hom}(B/b, C))\ ) \end{cases} \tag{8.4.2}$$

(*où* j_B *est l'adjoint à droite de* i_B) *sont tous les deux "model preserving"*, i.e.

$$\begin{cases} W_B \ = \ i_B^{-1}(W) \qquad \textit{(par définition de } W_B\textit{, en fait)} \\ W \ = \ j_B^{-1}(W_B)\ , \end{cases} \tag{8.4.3}$$

37. **N.B.** Pour la validité de 1°, 3° on n'a pas besoin de W (6) ($\varinjlim$) ni de W (8) (accessibilité), ni même de W (7) (axiome du carré cocartésien). Ce dernier est nécessaire déjà pour assurer la partie (*a*) du corollaire 8.5. Mais pour la partie 2° du théorème 8.4, on a besoin de *tous* les axiomes du localiseur fondamental W, sauf seulement W (4) `[et W(5)]`.

Commentary · Present state [ms. 104]

The forward gluing theorem and the extra converses

Grothendieck's immediate objective is a model structure, for which the forward implications in (8.2.4) are sufficient: pushouts of weak equivalences along monomorphisms remain weak equivalences, and pushouts of trivial monomorphisms remain trivial. The two converse implications printed in that formula impose a stronger requirement. They belong to the strengthened excision framework invoked here and must not be silently identified with the ordinary gluing theorem for homotopy types.

This distinction has already been analysed in the commentary on Chapter XII, manuscript p. 78 ("A finite counterexample to the asserted reverse excision") and p. 126 ("Why converse excision is an additional axiom"). We refer to those blocks rather than reproduce their examples. In particular, an application to W_∞ must retain the forward statements and use the actual presheaf gluing theorem, rather than assume that the stronger biconditionals hold for ordinary weak homotopy equivalences.

The surviving construction is substantial. Under the forward stability, the two weak factorization systems in Corollary 8.3 exist, and the sole remaining model-recognition condition is that maps right orthogonal to all monomorphisms belong to W_A. Theorem 8.4 turns that apparently large condition into an interval condition. Later, Cisinski (2006a, Corollary 4.2.18) proves the model-structure theorem for every accessible fundamental localizer and every corresponding local test category. This theorem supplies the intended application without the reverse-excision assertion.

p. 59

et les foncteurs localisés

$$\mathrm{Hot}_{B,W} \underset{\overline{j_B}}{\overset{\overline{i_B}}{\rightleftarrows}} \mathrm{Hot}_W$$

sont des équivalences de catégories. De plus, ces équivalences de catégories sont quasi-inverses l'une de l'autre, les morphismes d'adjonction étant déduits des morphismes d'adjonction pour le couple de foncteurs adjoints (i_B, j_B), ces morphismes d'adjonction étant de plus dans W resp. dans W_B.[38]

Commentary · Exposition [ms. 106]

The Lawvere object and the local interval test

Grothendieck is looking for an intrinsic cylinder in $\widehat{A}$. The subobject classifier $\Omega = L_A$ is available before any homotopy theory is chosen, and its two sections classify the empty and the full subobject. They are disjoint because a sieve cannot be both empty and maximal. Thus Ω is always a separated interval as a piece of topos theory; the additional homotopical question is whether its projection to the terminal object is universally a weak equivalence.

Injectivity of Ω has a direct proof. Given a monomorphism $U \hookrightarrow V$ and a map $U \to \Omega$, let $S \hookrightarrow U$ be its classified subobject. The composite $S \hookrightarrow V$ is a subobject of V, so its characteristic map $V \to \Omega$ extends the original map: pulling $S \hookrightarrow V$ back to U recovers $S \hookrightarrow U$. Consequently $\Omega \to 1$ has the right lifting property against all monomorphisms. The same is true after every base change, since right lifting properties are stable under pullback. This proves the implication (a)⇒(b) in 8.4, including its universal quantifier.

Checking universal asphericity on representables is the relevant local criterion. For $a \in A$, the slice topos $\widehat{A}/h_a$ identifies with $\widehat{A/a}$. Under that identification $\Omega \times h_a \to h_a$ is its subobject classifier. More generally, a separated interval I with $I \times h_a \to h_a$ a weak equivalence for every a gives a cylinder after passage to every slice. The localizer's localization axiom then extends the test to arbitrary bases. The equality $L_A \times a = L_{A/a}$ in the source is understood in this slice equivalence; the two objects are not literally presheaves on the same category before that identification.

The category-of-elements functor also explains the right adjoint appearing in (8.4.2). A map $F \to j_A(C)$ assigns to every element $x \in F(a)$ a functor $A/a \to C$, compatibly with restriction along

38. **N.B.** La condition (d), d'apparence très forte, est équivalente à la condition d'apparence plus anodine :
d') le foncteur $j_A : \mathrm{Cat} \longrightarrow A^\wedge$ transforme éléments de W en flèches W_A-asphériques ;
et il suffit même de l'exiger pour $C \longrightarrow e$ dans Cat, où C est un objet de Cat ayant objet final.
[La condition (d') ci-dessus est trop forte et n'est pas équivalente à la condition (d) ; en revanche la condition plus faible envisagée ensuite est bien équivalente à (d)].

arrows of A. This is equivalent to a functor $A/F \to C$: evaluate the assigned functor at 1_a, and use the compatibility to recover its action on arrows. Conversely, restrict a functor $A/F \to C$ along the canonical functor $A/a \to A/F$ attached to x. These constructions are inverse. Hence $i_A \dashv j_A$ is an ordinary adjunction, and the stronger test-category assertion says that its unit and counit become weak equivalences on all relevant slices.

The interval characterization is already present in Grothendieck (1983, §65, Proposition 3 and Corollary 1); in the 2015 transcription the proposition spans printed pages 171–172, corresponding to the manuscript pagination cited here. It is the local condition, followed by the additional asphericity of A, which distinguishes a local test category from a test category.

2°) *Si les conditions équivalentes de* 1° *sont satisfaites, alors le triple*

$$(W_A\,,\ C = \mathrm{Mon}_{A^\wedge}\,,\ F = (C \cap W_A)_*)$$

est un triple de Quillen (clos) propre à gauche.

3°) *Si les conditions équivalentes de* 1° *sont satisfaites, et si de plus A est W-asphérique, alors (et alors seulement) A elle-même est une* catégorie-test *pour W, ce qui revient à dire que les conditions sur la catégorie B dans* (d) *sont satisfaites quand B est* soit *A, soit une catégorie localisée A/a.*

Corollaire 8.5. *Les conditions équivalentes de* 1° *et de* 3° *sont satisfaites dans chacun des cas suivants (et ceci quel que soit W, satisfaisant aux hypothèses dites).*

b) *A est stable par produits finis*[40]*, et contient un objet I tel que I ait deux sections δ_0, δ_1 sur l'objet final, avec δ_0, δ_1 disjointes,* i.e. $\mathrm{Ker}(\delta_0, \delta_1) = \emptyset_{A^\wedge}$ *(sous-préfaisceau vide du préfaisceau final).*

[page 108]

Commentary · Examples [ms. 107]

A terminal category fails and a separated interval succeeds

Theorem 8.4 is not saying that every category with a terminal object is a test category. For $A = e$, presheaves are sets and i_A regards a set as a discrete category. For $W = W_\infty$, the induced class W_A is therefore the bijections. The Lawvere object is the two-element set, whose projection to a singleton is not a weak equivalence. Equivalently, there cannot be a separated interval in sets which is weakly equivalent to a point. The terminal object of A supplies asphericity of the indexing category, but cannot supply the missing interval.

The positive criterion in Corollary 8.5(b) fills exactly this gap. Suppose A has a terminal object and an object I with disjoint endpoint sections, and that $a \times I$ exists for every a. The representable presheaf h_I has disjoint sections, and

$$h_a \times h_I \simeq h_{a \times I}.$$

Its category of elements is $A/(a \times I)$, which has a terminal object. Thus the required local asphericity follows from the terminal-object axiom. Since A itself has a terminal object, the additional global asphericity holds as well. This proves the weakened finite-product hypothesis in footnote 40; no products unrelated to I were used.

For the ordinary simplex category, the interval is $\Delta[1]$. The product $\Delta[n] \times \Delta[1]$ is the nerve of the product poset $[n] \times [1]$, whose largest element contracts its nerve. The two endpoint simplicial subsets are disjoint. This supplies the concrete homotopy behind the local criterion, while the terminal object $[0]$ makes Δ aspherical. The names of the cubical categories in the source require

39. $\square^\sim$ est essentiellement la catégorie A "universelle", stable par produits finis, et contenant un "intervalle séparant" (I, δ_0, δ_1) comme dans (b).

40. En fait, il suffit que $I \longrightarrow e$ soit quarrable, *i.e.* que A ait un objet final, et que les produits $I \times a$ ($a \in \mathrm{Ob}\, A$) existent dans A.

their prescribed choices of maps; one should not transfer the statement to every category called "cubical", since diagonals, symmetries and connections change the indexing category.

Footnote 38 distinguishes a genuinely stronger, false reformulation. In the simplicial case let $u : e \to [1]$ select one endpoint. Both categories have terminal objects, so $u \in W_\infty$. The two endpoint maps $j_A(e) \to j_A([1])$ are disjoint: at every a they are the distinct constant functors $A/a \to [1]$. Pulling one endpoint back along the other gives $\varnothing \to j_A(e) = 1$. For $A = \Delta$ this is not a weak equivalence. Hence $j_A(u)$ is not universally a weak equivalence, although A is a test category. The weaker condition involving only projections $C \to e$ with C terminal-pointed avoids this counterexample, exactly as the editors' bracketed correction says.

Le cas (b) du corollaire est justiciable de la condition (c) dans 1°. (De plus, A ayant un objet final, est W-asphérique, donc on est dans les conditions de 3°.) Les cas $\mathbf{\Delta}$, $\mathbf{\Delta}^\sim$, $\square$ (et $\square^\sim$, qui tombe en fait dans le cas (b)) sont traités dans Pursuing Stacks §34 (p. 47-50) `[voir aussi §36]`.

Démonstration du théorème 8.4. La partie essentielle, techniquement, est bien sûr 1° [41]. On a les implications ± tautologiques

$$(a) \implies (b) \implies (c)\ ,$$

où $(a) \Longrightarrow (b)$ provient du fait que L est évidemment un objet injectif de $A^\wedge$. (L'objet de Lawvere d'un topos quelconque est un objet injectif.) Il reste à établir

$$(c) \implies (d) \implies (a)\ .$$

Que l'on ait $(c) \Longrightarrow (d)$ (et $(c) \Longrightarrow (b)$) est établi dans Pursuing Stacks, voir le résumé des notions W-test dans Pursuing Stacks, §65, p. 168-179; l'énoncé pertinent ici est la proposition 3, page 173. p. 60

Il reste à établir $(d) \Longrightarrow (a)$ – mais à présent on joue sur du velours! Je note ici le lemme suivant, dont la place serait plutôt à la fin du §4 des généralités sur les triples de Quillen : [page 109]

Lemme 8.6. *Soit $\mathcal{M}$ une catégorie, (C, TF) un précouple de Quillen dans $\mathcal{M}$, et $W \subset \mathrm{Fl}(\mathcal{M})$ une partie de $\mathrm{Fl}(\mathcal{M})$ stable par facteurs directs. Conditions équivalentes :*

a) $TF \subset W$.

b) *Toute flèche f dans $\mathcal{M}$ se factorise en $f = pi$, avec $i \in C$, $p \in W$.*

b′) *Comme* (b), *avec f dans TF.*

Démonstration. Les implications $(a) \Longrightarrow (b) \Longrightarrow (b')$ sont tautologiques et ne font pas appel à l'hypothèse de stabilité sur W. Mais pour un $f \in TF$ donné, pour voir qu'il est dans W, si W est stable par facteurs directs, il suffit que cet-f-là se factorise en pi, avec $i \in C$, $p \in W$. En effet, on voit aussitôt qu'alors f est facteur direct de p (car $i \in C$), et comme $p \in W$, on a $i \in W$, *q.e.d.*

Revenons à 8.4, démonstration de $(d) \Longrightarrow (a)$.

Commentary · Exposition [ms. 109]

The retract in Lemma 8.6

Grothendieck isolates a useful recognition principle: to prove that a right lifting class consists of weak equivalences, it can be enough to factor its arrows through weak equivalences. Write $f : X \to Y$ in TF as $f = pi$, where $i : X \to Z$ is in C and $p : Z \to Y$ is in W. The lifting square with top map 1_X, left edge i, bottom map p, and right edge f yields $r : Z \to X$ satisfying

$$ri = 1_X, \qquad fr = p.$$

41. La partie 2° en résulte, grâce au corollaire 8.3.

Therefore $(i, 1_Y) : f \to p$ and $(r, 1_Y) : p \to f$ exhibit f as a retract of p in the arrow category. Retract closure of W gives $f \in W$. The final $i \in W$ printed in the proof is a slip: the assertion proved and needed is $f \in W$.

The other direction uses the factorization already included in the precouple hypothesis: factor any arrow as a C-map followed by a TF-map, and then use $TF \subset W$. Thus one must retain both ingredients of the precouple, factorization and the lifting relation; a bare orthogonality inclusion would not prove (a)⇒(b). No two-out-of-three property is needed for this lemma. Its economy is what makes it attractive here, where the interval construction is intended to provide the weaker factorization C followed by W before the model structure is known.

Finalement, mon projet de démonstration se modifie, car bien que (d) ait l'air très, très fort comme condition, telle quelle je ne vois pas, finalement, comment en déduire (a). Mais en fait on peut considérer que l'équivalence de (b), (c), (d) est mise ici pour mémoire, elle est établie dans *loc. cit.*, donc je n'ai à me préoccuper que de l'implication $(c) \Longrightarrow (a)$, qui va résulter du lemme 8.6, qui nous ramène à prouver que toute flèche $f : X \longrightarrow Y$ dans $A^\wedge$ [page 111] se factorise en pi, avec i monomorphisme et $p \in W_A$. On fait l'argument du mapping-cone `[plutôt mapping-cylinder]`, en partant de

$$\begin{array}{ccc} e_A \amalg e_A & \xrightarrow[\text{mono}]{(\delta_0,\delta_1)} & I \\ & \searrow \quad \swarrow_{(W_A)_{\text{univ}}} & \\ & e_A\ , & \end{array}$$

d'où pour tout X dans $A^\wedge$, en prenant le produit par X,

$$\begin{array}{ccc} X \amalg X & \xrightarrow[\text{mono}]{(\delta_0^X,\delta_1^X)} & X \times I \\ & \searrow_{(\text{id},\text{id})} \quad \swarrow_{\text{pr}_1^X \in W_A} & \\ & X\ , & \end{array}$$

et on construit le mapping-cone `[plutôt mapping-cylinder]` de f par le diagramme cocartésien p. 61

(8.6.1)

$$\begin{array}{ccccc} X & & \xrightarrow{\quad f \quad} & & Y \\ & {\scriptstyle \delta_0^X}\big\uparrow & \text{pr}_1^X \text{ cocart.} & {\scriptstyle \beta}\big\uparrow & \big\uparrow{\scriptstyle p_f} \\ X & \xrightarrow{\delta_1^X} & X \times I & \xrightarrow{\quad f' \quad} & Z(f)\ , \\ & \searrow & & \nearrow & \\ & & {\scriptstyle i_f} & & \end{array}$$

p_f déduit de $\text{pr}_1^X : X \times I \to X$

la factorisation cherchée de f est

$$f \;=\; p_f\, i_f\ , \qquad \text{où} \quad i_f = f' \delta_1^X\ .$$

Ici, comme $\text{pr}_1^X \in W_A$, on en conclut que δ_0^X, δ_1^X (qui en sont des sections) sont dans [page 112] W_A, comme δ_0^X est un monomorphisme, on a donc $\delta_0^X \in TC$, donc (TC étant stable par cochangement de base) $\beta \in W_A$, donc enfin p_f (qui est une rétraction de $Z(f)$ sur Y) est aussi dans W_A. Il reste à voir que i_f est un monomorphisme, ce qui se voit sur le diagramme plus complet (*cf.* XII, p. 230) que j'ai sous les yeux : i_f apparaît comme composé de deux monomorphismes $X \longrightarrow Y \amalg X$ et $Y \amalg X \longrightarrow Z(f)$ … Le théorème 8.4 est démontré.

Je vais quand même isoler l'argument formel sempiternel (que j'ai utilisé surtout sous forme duale) dans un

Lemme 8.7. *Soit $\mathcal{M}$ une catégorie, W un localiseur modérément saturé dans $\mathcal{M}$, C une partie stable par composition et par cochangement de base. On se propose, pour X fixé dans $\mathcal{M}$, de trouver une factorisation fonctorielle de toute flèche $f : X \longrightarrow Y$* (i.e. *du morphisme costructural d'un Y dans $X\backslash\mathcal{M}$) en $p_f i_f$, avec $i_f \in C$, $p_f \in W$. On suppose pour ceci qu'on a une factorisation de ce type pour $X \amalg X \xrightarrow{(\mathrm{id},\mathrm{id})} X$,* i.e. *un objet I_X et une factorisation* [page 113]

$$X \amalg X \xrightarrow{i_X=(\delta_0^X,\delta_1^X)} I_X \xrightarrow{\quad p_X \quad} X \ ,$$
$$\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \searrow \quad \nearrow$$
$$\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (\mathrm{id}_X,\mathrm{id}_X)$$

avec $i_X \in C$, $p_X \in W$. On associe alors à toute f le mapping cone [plutôt cylinder] *$Z(f)$ comme dans le diagramme* (8.6.1) *(où il faut lire I_X au lieu de $X \times I$), et on a alors $p_f \in W$, $i_f \in C$ comme voulu. Mais il faut supposer, pour savoir que $i_f \in C$, que $X \in \mathcal{M}_C$ (objets C-cofibrants),* i.e. *que pour tout Y, $X \longrightarrow Y \amalg X$ est dans C. (De plus, on a supposé tacitement $\mathcal{M}$ stable par $\varinjlim$ finies.)*

Commentary · Exposition [ms. 112]

What the mapping cylinder proves

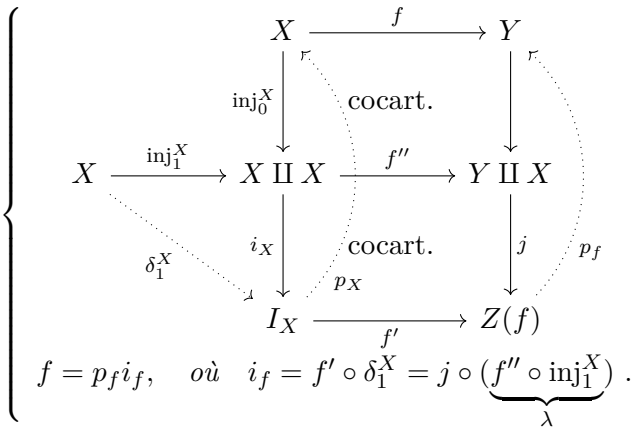
The mapping cylinder converts a homotopy between two copies of the source into a factorization of an arbitrary map. For $f : X \to Y$ in a presheaf category, form

$$Z(f) = Y \amalg_{X,\delta_0} (X \times I), \qquad i_f(x) = [(x, \delta_1)],$$

and let $p_f : Z(f) \to Y$ equal 1_Y on Y and $f\,\mathrm{pr}_X$ on $X \times I$. The compatibility on the identified copy of X makes p_f well defined, and $p_f i_f = f$.

There are two independent verifications. First, the map

$$Y \amalg X \longrightarrow Z(f)$$



is the pushout of the boundary inclusion $X \amalg X \hookrightarrow X \times I$. It is monic, as are coproduct inclusions in a presheaf category. Their composite $i_f : X \to Y \amalg X \to Z(f)$ is therefore monic. This proves the assertion about the left factor and explains why disjoint endpoints are needed.

Second, $\mathrm{pr}_X \in W_A$, and its sections δ_0^X, δ_1^X lie in W_A by two-out-of-three. If trivial monomorphisms are stable under pushout, then the map $\beta : Y \to Z(f)$ is in W_A. Since $p_f\beta = 1_Y$, two-out-of-three gives $p_f \in W_A$. This proves the assertion about the right factor. The two arguments use different hypotheses: ordinary monomorphism stability for the first, and *weak-equivalence* stability for the second.

The construction is functorial in maps $Y \to Y'$ under the fixed source X, because the universal property of the pushout supplies $Z(f) \to Z(f')$ and these maps respect identities and composition. A varying-source functorial factorization additionally requires a functorial choice of the cylinders I_X and their structure maps. In the present application $I_X = X \times I$, so this further functoriality is available. Compare the commentary on Chapter XII, manuscript p. 230 ("The mapping cylinder, with the two endpoints distinguished"); the present discussion addresses the additional issue of which hypotheses remain when the argument is extracted as Lemma 8.7.

Le diagramme complet est

(8.7.1)

Commentary · Development (commentators') [ms. 113] [page 114]

The omitted hypothesis in the abstract cylinder lemma

Grothendieck has established the mapping-cylinder argument in a presheaf category where trivial monomorphisms are stable under pushout. Lemma 8.7 then extracts an abstract statement but retains only stability of C under composition and pushout. That suffices to prove $i_f \in C$ under the stated coproduct condition; it does not suffice to prove $p_f \in W$. The following example separates the two assertions completely. We checked the cylinder criterion of Cisinski (2006a, Lemma 1.4.13) and the model-recognition argument of Beke (2000, Section 1); we did not find this particular counterexample in those sources.

Counterexample to Lemma 8.7 as stated. [ours] Take $\mathcal{M} = \mathrm{Grp}$, let C be all group homomorphisms, and let W consist of the homomorphisms $u : G \to H$ such that

$$\mathrm{Hom}(C_2, G) \longrightarrow \mathrm{Hom}(C_2, H)$$

is a bijection. The class W is the inverse image of the isomorphisms of sets under a functor. It therefore contains all isomorphisms, has two-out-of-three, and is closed under retracts; it also satisfies the usual saturation condition involving two opposite composites. The category has finite colimits, and C satisfies every stability and coproduct condition in the lemma.

Let $X = 1$, the trivial group, and choose $I_X = \mathbb{Z}$. There is a factorization of the fold map

$$X * X = 1 \longrightarrow \mathbb{Z} \longrightarrow 1 = X.$$

Its left factor is in C, and its right factor is in W, since $\mathbb{Z}$ has no nontrivial element of order two. Both endpoint maps are the unique map $1 \to \mathbb{Z}$; the abstract lemma does not require them to be disjoint, and its condition on i_X is satisfied.

For $f : 1 \to C_2$, the prescribed mapping cylinder is the free product

$$Z(f) = C_2 * \mathbb{Z}, \qquad p_f : C_2 * \mathbb{Z} \longrightarrow C_2,$$

where p_f is the identity on C_2 and kills the generator z of $\mathbb{Z}$. If t is the nonidentity element of C_2, both t and ztz^{-1} are involutions in the free product. They are distinct by reduced-word normal form, but p_f maps both to t. Thus the induced map on $\mathrm{Hom}(C_2, -)$ is not injective, and $p_f \notin W$. Every explicit hypothesis of Lemma 8.7 holds, while its right-factor conclusion fails.

The repair can be stated at the exact level used by the proof. Assume that $\delta_0 : X \to I_X$ belongs to W and that its pushout along each map $f : X \to Y$ under consideration belongs to W. Then $\beta : Y \to Z(f)$ is in W, and $p_f \beta = 1_Y$ gives $p_f \in W$. A uniform sufficient condition is $C \cap W$ stable under pushout, together with $\delta_0 \in C$. The latter follows if $X \to X \amalg X$ and $i_X : X \amalg X \to I_X$ are in C. For the left factor one also needs $X \to Y \amalg X$ in C, precisely the explicit condition used in the printed proof. In the usual convention this is automatic when Y is cofibrant, and it holds for every X, Y in a presheaf category with $C = \mathrm{Mon}$. Calling it simply "X cofibrant" reverses which added summand supplies the condition.

With these hypotheses the proof on the preceding page is complete: $j : Y \amalg X \to Z(f)$ is a pushout of i_X, so $i_f = j \circ (X \to Y \amalg X)$ lies in C; the separate argument with β proves $p_f \in W$. The failure of the abstract lemma therefore does not invalidate the presheaf application under its original gluing assumptions.

On a $i_X \in C$ par hypothèse, donc $j \in C$ (stabilité de C par cochangement de base), on a $\lambda : X \longrightarrow Y \amalg X$ dans C car X dans $\mathcal{M}_C$, donc le composé $i_f = j \circ \lambda$ est dans C (stabilité de C par composition) – on gagne!

Commentaires. Pour l'équivalence de (a), (b), (c) dans le théorème 8.4, 1°, on n'a donc pas eu à faire appel aux développements de Pursuing Stacks, qui servent seulement à établir l'équivalence des trois conditions en question avec la condition "modélisante" (d). Pour résumer :

1°) Les implications

$$(a) \implies ((b) \iff (c) \iff (d))$$

sont valables sous les seules conditions

$$\mathrm{W}\,(1,\ 2\,\text{bis},\ 3)\ ,$$

et pour l'équivalence de (a) aux autres conditions, il suffit de

$$\mathrm{W}\,(1\,\text{bis},\ 2\,\text{bis},\ 3)$$

(où W (1 bis) renforce W (1) par la condition des facteurs directs, tandis que W (2 bis) affaiblit W (2), en exigeant seulement que les morphismes W-asphériques soient dans W). Les conclusions de 8.4, 3°, relatives au cas où A est W-asphérique, sont valables également sous les conditions W (1, 2 bis, 3) sans plus.

[page 115]

Commentary · Exposition [ms. 114]

The interval proof that avoids pushouts

Grothendieck's final reduction of the hypotheses in 8.4 asks for an argument that no longer uses the pushout axiom. Such an argument exists: the map under examination already has a lifting property, so the interval can be used to construct a homotopy directly. This is the proof later given in Cisinski (2006a, Lemma 1.4.13, printed pp. 56–57). We spell it out with the hypotheses of the present text.

Suppose $\widehat{A}$ has a separated interval I such that $X \times I \to X$ belongs to W_A for every X, and suppose W_A has two-out-of-three and is closed under retracts. Let $p : X \to Y$ have the right lifting property against all monomorphisms. Lifting against $\varnothing \hookrightarrow Y$ gives a section $s : Y \to X$, with $ps = 1_Y$. The endpoint inclusion

$$X \amalg X \hookrightarrow X \times I$$

is monic. Map its two summands to X by 1_X and sp, and map $X \times I$ to Y by $p\,\mathrm{pr}_X$. The equalities $p1_X = p$ and $psp = p$ make this a commutative lifting square. A lift $H : X \times I \to X$ therefore satisfies

$$H\delta_0 = 1_X, \qquad H\delta_1 = sp.$$

Both endpoint maps are in W_A, because they are sections of $\mathrm{pr}_X \in W_A$. From $H\delta_0 = 1_X$, two-out-of-three gives $H \in W_A$, and hence $sp = H\delta_1 \in W_A$.

Finally p is a retract of sp as an arrow: the maps are $(1_X, s) : p \to sp$ and $(1_X, p) : sp \to p$, and their composite on p is $(1_X, ps) = 1_p$. Retract closure gives $p \in W_A$. This proves (c)⇒(a) without a single pushout, without accessibility, and without a model structure. If one uses the weak-saturation axiom saying that ps and sp in W_A force $p, s \in W_A$, the final retract step may be replaced by that axiom.

The reverse implications remain the elementary ones: the subobject classifier is injective, and its empty/full sections form a separated interval. Thus the equivalence of (a), (b) and (c) really has the weaker character claimed at the end of §8. The argument corrects a proof dependency, not the theorem's conclusion. Accessibility is needed later to produce factorizations; it is not needed to decide whether this interval test recognizes the intended weak equivalences.

2°) Le corollaire 8.5, se référant aux conditions (b), (c), (d) de 1° (à l'exclusion de (a), qui suppose W stable par facteurs directs), est valable pour un W satisfaisant

$$\mathrm{W}\,(1,\ 2\,\mathrm{bis},\ 3,\ \underbrace{7\,\mathrm{bis}}_{\substack{\text{carré}\\ \text{cocartésien}}}\ )\ .$$

p. 63

3°) Pour la validité de 8.4, 2°, *i.e.* pour avoir un triple de Quillen (W_A, C, F), il nous faut (presque) tout l'éventail des conditions sur W,

$$\mathrm{W}\,(1\,\mathrm{bis},\ 2\,\mathrm{bis},\ 3,\ \underbrace{6}_{\text{limites}},\ \underbrace{7\,\mathrm{bis}}_{\substack{\text{carré}\\ \text{cocartésien}}},\ \underbrace{8}_{\text{accessibilité}}\ )\ ^{42},$$

à l'exclusion de $\mathrm{W}\,(4)$, et en se contentant pour $\mathrm{W}\,(2)$ de la forme affaiblie $\mathrm{W}\,(2\,\mathrm{bis})$ sans plus. (Même l'axiome de connexité $\mathrm{W}\,(5)$ n'a pas servi, mais je l'avais d'abord inclus, car il y a peu de chances qu'on aura jamais à travailler avec des W qui n'y satisfont pas! Il se pourrait d'ailleurs, en présence des autres axiomes, ou seulement de $\mathrm{W}\,(1\,\mathrm{bis}, 2\,\mathrm{bis}, 3, 7\,\mathrm{bis})$, que si $\mathrm{W}\,(5)$ n'est *pas* satisfait, on ait $W = \mathrm{Fl}\,\mathrm{Cat}$ tout entier, donc $W_A = \mathrm{Fl}\,A^{\wedge}$!)

[page 116]

Commentary · Later developments [ms. 115]

What later model recognition establishes

The construction sought here became a theorem with fewer auxiliary hypotheses. For a fundamental localizer W generated by a set and a W-local test category A, Cisinski (2006a, Corollary 4.2.18) constructs the cofibrantly generated model structure with weak equivalences W_A and cofibrations all monomorphisms. The interval characterization is Theorem 4.1.19. The source's question about right properness is a separate question: Cisinski's Theorem 4.3.24 makes properness of the fundamental localizer independent of the chosen test category, and the minimal localizer is proper (Example 4.3.22).

There are three smallness statements to keep distinct. Grothendieck's L-accessibility includes closure under *every* filtered colimit together with his adapted-presentation criterion. Modern accessibility of a full subcategory of the arrow category concerns a sufficiently large regular cardinal and an accessible inclusion. Cisinski calls a localizer accessible when it is generated by a *set as a localizer*; for presheaf localizers, his Scholie 1.4.6 compares this with accessibility of the arrow class. These comparisons are theorems, not interchangeable definitions. In particular, the model-recognition theorem for a general accessible presheaf localizer should not be reported as assuming closure under all filtered colimits merely because the present chapter does so.

The logical order of the achievement also matters. A separated interval first proves that injective-type maps are weak equivalences; a bounded generation argument then supplies the weak factorization systems; their compatibility yields the model structure. The associated derivator can subsequently be formed from diagram categories and their weak equivalences. This order explains why the elementary topos-theoretic object L_A is central to a chapter whose ultimate purpose is the construction of homotopy theories.

9 Révision des notations, pour les axiomes d'un localiseur fondamental [43]

Loc (1) (Saturation).

a) Les isomorphismes sont dans W.

b) Si f, g sont composables, et deux parmi f, g, gf sont dans W, le troisième aussi.

42. **N.B.** On devrait renuméroter les axiomes $\mathrm{W}\,(\ldots)$.

43. *Cf.* XVII `[plutôt XVI]` pour une version définitive (?).

c) Si $X \underset{g}{\overset{f}{\rightleftarrows}} Y$, si gf et fg sont dans W, alors f et g aussi.

Variante renforcée :

Loc (1 bis) Loc (1) plus

d) W est stable par facteurs directs.

Loc (2) (Axiome de l'objet final). Si X dans Cat a un objet final, alors X est W-asphérique, *i.e.* $X \longrightarrow e$ est dans W.

Loc (3) (Axiome de localisation, forme faible). Soit $f : X \longrightarrow Y$ tel que pour tout $y \in Y$, X/y soit W-asphérique (*i.e.* le morphisme $f/y : X/y \longrightarrow Y/y$ déduit de f par changement de base $Y/y \longrightarrow Y$ est dans W). Alors $f \in W$.

Variante renforcée de Loc (3) :

Loc (3 bis) (Axiome de localisation, forme forte). Soit $f : X \longrightarrow Y$ un morphisme dans Cat/S, tel que $\forall\ s \in S$, $f/s : X/s \longrightarrow Y/s$ (déduit de f par changement de base $S/s \longrightarrow S$) soit dans W. Alors $f \in W$. (**N.B.** Sauf erreur, il suffit le l'exiger si X, Y sont Cat-fibrés scindés sur S, et f S-cartésien compatible avec le scindage – en supposant Loc (1, 2)).

Commentary · Exposition [ms. 116]

The catalogue distinguishes several notions of localizer

Grothendieck is reorganizing the hypotheses so that each construction can carry only the assumptions it needs. The list is a catalogue of possible conditions, not a declaration that all of them are in force. This matters particularly for localization: in these pages a "localiseur fondamental" without qualification satisfies Loc (1,2,3), whereas the subsequent standard definition uses the relative condition Loc (3 bis).

The distinction can be expressed without terminology. The weak condition recognizes a functor $u : A \longrightarrow B$ when every comma category A/b has the homotopy type of a point, relative to W. The relative condition starts with a map of diagrams over a third category S and recognizes u from the maps $A/s \longrightarrow B/s$. Here A/s has objects $(a, p(a) \longrightarrow s)$; it is not generally the strict fibre of $p : A \longrightarrow S$. The equivalence between the two formulations of Loc (3) uses the terminal object $(b, 1_b)$ of B/b and two-out-of-three. It does not make the relative condition redundant.

There is a similarly necessary distinction within "saturation". Loc (1 c) is the two-sided inverse test: if gf and fg belong to W, then so do f and g. Loc (1 bis) adds closure under retracts in the arrow category. Strong saturation, later called Loc (1 ter), says that an arrow belongs to W precisely when its image in Cat$[W^{-1}]$ is invertible. The last condition implies the preceding ones, but its proof requires work; it is not part of the three displayed clauses of Loc (1).

The modern vocabulary records these distinctions. The definitions of weak and ordinary fundamental localizers in Maltsiniotis (2020, §§1.1 and 2.1) use respectively the absolute and relative forms of Theorem A. The theorem that every weak fundamental localizer contains the nerve weak equivalences is Cisinski (2006a, Theorem 6.1.18). Containment of the usual weak equivalences does not, by itself, supply every stability assertion concerning the additional arrows of W.

We should also keep the strength of Loc (4) visible. Its reverse implication is an extra excision condition, not a general property of homotopy pushouts. The commentary on Chapter XII already gives the relevant warnings: manuscript p. 126 ("Why converse excision is an additional axiom") and, in the appendix, manuscript p. 17 ("Acyclic links and a false converse"). Those examples are not repeated here. In this chapter Loc (4) may legitimately be assumed; it should not be silently assigned to every localizer obtained from a familiar homotopy theory. Finally, the parenthetical reduction of Loc (3 bis) to split fibred categories is proposed rather than demonstrated. A proof must specify its fibration convention and compare the comma resolutions with the original categories; replacing comma categories by strict fibres without that comparison would lose the hypothesis being tested.

Loc (4) (Axiome du carré cocartésien). Soit X dans Cat, X_1, X_2 deux ouverts de réunion X, $X_0 = X_1 \cap X_2$, d'où un diagramme cocartésien dans Cat,

$$\begin{array}{ccc} X_0 & \xrightarrow{i_1} & X_1 \\ {\scriptstyle i_2}\downarrow & & \downarrow{\scriptstyle j_2} \\ X_2 & \xrightarrow{j_1} & X\ . \end{array}$$

On a alors $i_1 \in W \iff j_1 \in W$ (et symétriquement $i_2 \in W \iff j_2 \in W$).

Loc (6) [44] (Axiome des W-fibrations). Il y a des variantes ⓐ, (a′), ⓑ, (b′), (b″), (c), (c′), *cf.* XII, p. 53-59. La forme la plus forte ⓐ est celle-ci :
Soit $f : X \longrightarrow Y$ dans Cat une W-fibration au sens ancien, *i.e.* telle que pour toute $Y'' \longrightarrow Y'$ dans Cat$/Y$, avec Y', Y'' contractiles, la flèche $X'' \longrightarrow X'$ déduite par le changement de base $X \longrightarrow Y$ soit dans W. Alors f est dans Fib$_W$, *i.e.* le foncteur de changement de base par f, Cat$/Y \longrightarrow$ Cat$/X$, transforme flèches dans W en flèches dans W.

Loc (7) (Axiome des limites inductives). W est stable par limites inductives filtrantes.

Forme renforcée de Loc (7) :

Loc (7 bis) (L-accessibilité). W est stable par $\varinjlim$ filtrantes *et* accessible, *i.e.* il existe une petite partie W_π de Fl(Cat), telle que W soit la plus petite partie de Fl(Cat) stable par $\varinjlim$ filtrantes, contenant W_π.

[page 118]

Commentary · Context [ms. 117]

Which fibration hypothesis is being invoked

The variants imported from chapter XII concern the old notion of W-fibration. Write F_{old} for that class, reserving Fib$_W$ for the intrinsic condition that pullback preserves every W-map. The reference is Grothendieck (1990–1991f, ms. 53); after the renumbering, its W (4) becomes Loc (6). The seven tests are as follows.

a	$F_{\text{old}} \subseteq \text{Fib}_W$;
a'	the same test restricted to Parf$_\omega$;
b	$f : X \to Y$ over S, $p, q \in F_{\text{old}}$, $f \in W \implies f_s \in W$ for all s;
b'	the preceding test for split fibred objects and split cartesian f;
b''	the preceding test with p, q both W-perfect;
c	$p \in F_{\text{old}} \cap W \implies p^{-1}(s)$ is W-aspherical;
c'	the preceding test restricted to Parf$_\omega \cap W$.

Here $p : X \to S$, $q : Y \to S$, and Parf$_\omega$ refers to the least weak fundamental localizer. The restricted classes are part of the hypotheses. In particular, the proof on ms. 121 invokes c' after writing only $p \in \text{Parf}_W$. It needs a replacement in the restricted perfect class, together with componentwise weak equivalences for its first factor. These are dependencies of that short argument. The modern theorem identifying the least weak fundamental localizer with W_∞ clarifies the subscript, but does not supply an unmentioned replacement construction merely by changing the notation.

Loc (8) [45] (Axiome de connexité). $f \in W \Longrightarrow \pi_0(f)$ bijectif.

N.B. Tous les axiomes, sauf le dernier (et un chouïa de l'avant dernier) sont des axiomes de stabilité – ils disent tous que W est "grand" : il contient certaines flèches, et s'il contient telles flèches, il contient telles autres. Loc (8), et dans une certaine mesure Loc (7 bis), sont des axiomes "limitatifs" sur la taille de W : Loc (7) nous dit que $W \subset \mathbf{W}_0$ (= ensemble des

44. Il y aura un Loc (5) plus "basique" plus bas.

45. J'ai changé la numérotation, pour tenir compte d'un Loc (5) plus bas, qui est encore un axiome de stabilité [initialement les axiomes Loc (6) à Loc (8) étaient notés Loc (5) à Loc (7)].

$f \in \mathrm{Fl}\,\mathrm{Cat}$ telles que $\pi_0(f)$ soit bijectif), Loc (7 bis) nous dit l'existence d'un cardinal tel que W soit égal à la L-enveloppe de W^π (donc $W \subset \text{L-env}(W^\pi)$).

J'ai essayé de ranger les axiomes par ordre d'importance pratique. J'ai fini par rajouter l'axiome de connexité à la fin, car dans les développements théorique sur les localiseurs généraux, il n'intervient pratiquement jamais. Mais je rappelle (XII, p. 20, th. 2) que si W satisfait Loc (1, 2, 3, 6), et si Loc (8) n'est *pas* satisfait, alors $W = \mathrm{Fl}(\mathrm{Cat})$; donc en présence de Loc (1, 2, 3, 6), Loc (8) *équivaut* à $W \neq \mathrm{Fl}(\mathrm{Cat})$ tout entier.

[page 119]

Commentary · Context [ms. 118]

A size condition with a particular closure operation

The accessibility hypothesis is doing a different job from the homotopical axioms. It is intended to turn a proper class of potential attachments into a set from which a factorization can be constructed. In Loc (7 bis), the closure operation is specifically closure under all small filtered colimits in the arrow category of Cat. Its relationship with the cardinal filtration was developed in §5. Thus "L-accessible" contains both a bounded generation assertion and a closure assertion.

Later authors also call a fundamental localizer accessible when a set generates it *as a fundamental localizer*; this is Cisinski (2006a, Definition 4.2.10). The latter closure includes the localizer axioms. These two formulations must not be identified simply because they share the word "accessible". A comparison requires a theorem connecting the two closure operations. The theorem on filtered colimits in the mature theory is recorded separately in Maltsiniotis (2020, Proposition 2.4.12 and Corollary 2.4.14). The size and closure requirements in Grothendieck's stated theorems are retained in the audit rather than replaced by an unqualified modern accessibility assumption.

Les axiomes qui ont servi pour 8.4, 1°, 3° et 8.5, (b) sont

$$\mathrm{Loc}\,(1\,\mathrm{bis},\ 2,\ 3)\ .$$

Ceux qui sont nécessaires pour 8.5, (a) sont p. 65

$$\mathrm{Loc}\,(1\,\mathrm{bis},\ 2,\ 3,\ 4)\ .$$

Enfin, ceux nécessaires pour 8.4, 2° sont

$$\mathrm{Loc}\,(1\,\mathrm{bis},\ 2,\ 3,\ 4,\ 7\,\mathrm{bis})\ ,$$

et ils impliquent la *saturation forte de* W (*cf.* paragraphe suivant).

Il me faut réparer un oubli, ayant traité un peu par le mépris (!) les questions de composantes connexes, jusqu'à présent.

Proposition 9.1. *Supposons que* W *satisfait* Loc (1, 2, 3, 4) *sans plus. Soit* $f_i : X_i \longrightarrow Y_i$ $(i \in I)$ *une famille* finie *de flèches de* Cat. *Pour que* $f = \coprod f_i : \coprod X_i \longrightarrow \coprod Y_i$ *soit dans* W, *il suffit que* $\forall\ i \in I$, *on ait* $f_i \in W$. *Si* W *satisfait de plus à* Loc (7) (*axiome des limites inductives*), *alors cette conclusion reste valable sans condition de finitude sur* I.

Démonstration. Le cas I fini se traite par récurrence sur $n = \mathrm{card}\, I$, on est ramené aussitôt au cas où $n = 2$ [46]. On voit d'abord le

Corollaire 9.2. *Sous l'hypothèse* Loc (1, 4), *soit* $f : X \longrightarrow Y$ *une flèche de* Cat, *et* Z *un objet de* Cat. *Alors* $f \in W$ *si et seulement si* $f \amalg \mathrm{id}_Z : X \amalg Z \longrightarrow Y \amalg Z$ *est dans* W. [page 120]

Immédiat sur le carré cocartésien, où inj_0^X est une immersion ouverte de Dwyer,

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ {\scriptstyle \mathrm{inj}_0^X}\downarrow & & \downarrow{\scriptstyle \mathrm{inj}_0^Y} \\ X \amalg Z & \xrightarrow[f' = f \amalg \mathrm{id}_Z]{} & Y \amalg Z\ , \end{array}$$

46. Le cas infini s'y ramène sous l'hypothèse Loc (7), par passage à la limite.

qui montre que $f \in W \iff f' \in W$.

En itérant ce résultat, on trouve, si

$$f_1 \ : \ X_1 \longrightarrow Y_1 \ , \qquad f_2 \ : \ X_2 \longrightarrow Y_2$$

sont donnés, que

$$f_1 \ \in \ W \ , \ f_2 \ \in \ W \quad \Longrightarrow \quad f_1 \amalg f_2 \ \in \ W \ ,$$

en regardant le diagramme de deux carrés cocartésiens :

$$\begin{array}{ccc} X_1 & \xrightarrow{\quad f \quad} & Y_1 \\ \downarrow & & \downarrow \\ X_1 \amalg X_2 & \xrightarrow[f_1'=f_1 \amalg \mathrm{id}_{X_2}]{} & Y_1 \amalg X_2 \\ {\scriptstyle f_2'=\mathrm{id}_{X_1} \amalg f_2}\downarrow & & \downarrow{\scriptstyle g_2=\mathrm{id}_{Y_1} \amalg f_2} \\ X_1 \amalg Y_2 & \xrightarrow[g_1=f_1 \amalg \mathrm{id}_{Y_2}]{} & Y_1 \amalg Y_2 \ . \end{array}$$

Si f_1 et f_2 sont dans W, il en est de même de f_1', f_2', g_1, g_2, par 9.2, donc aussi de $f_1 \amalg f_2 = g_2 f_1'$.

p. 66

Commentary · Exposition [ms. 120] [page 121]

Adding a summand and recovering a summand

The point of this discussion is to make weak equivalence compatible with the decomposition of a category into connected components. There are two operations to control. One adds an unrelated component to an equivalence. The other extracts a component from an equivalence already given. Proposition 9.4 separates them cleanly, and its proof is entirely formal once those operations are stated.

Write P for the condition that $f \in W$ implies $f \amalg 1_Z \in W$, and R for the condition that restriction to a summand of the target preserves W. Assuming identities and composition belong to the saturation rules, P implies closure under binary sums because

$$f_1 \amalg f_2 = (1_{Y_1} \amalg f_2)(f_1 \amalg 1_{X_2}).$$

Conversely, binary closure implies P. If $f_1 \amalg f_2 \in W$, condition R, applied to each of the two target summands, recovers f_1 and f_2. If binary sums are both preserved and reflected, any $f : X \longrightarrow Y_0 \amalg Y_1$ decomposes canonically as $f_0 \amalg f_1$, since a functor cannot carry an arrow between two different components of the target. Reflection then proves R.

The same argument works for an arrow $X \longrightarrow X'$ over a category Y and a summand $Y_0 \subset Y$: decompose X and X' by inverse image of Y_0 and its complement. This proves that R is exactly the assertion that the inclusion $Y_0 \hookrightarrow Y$ belongs to Fib_W. The target of the restricted arrow in Corollary 9.3 must therefore be X_0', not Y_0. The latter is the base of the restricted diagram, not its target.

Reflection for an arbitrary family already follows from binary reflection. For a fixed index i, group all other indices into one summand. No limiting argument is needed for this direction. Preservation for an infinite family requires an additional step: the coproduct arrow is the filtered colimit of its finite subcoproducts, indexed by the finite subsets of the index set. Thus Loc (7) upgrades finite preservation to arbitrary preservation. This explains why Loc (5 bis) only adds the infinite version of the forward implication. It also proves the two equivalent componentwise formulations of Corollary 9.5.

The proof of Corollary 9.2 deserves a small qualification. Its displayed square is a pushout along a summand inclusion, but the horizontal arrow f is arbitrary. Literally, Loc (4) on ms. 117 is phrased for a union of two open subcategories. To apply an excision theorem to this square one must use the corresponding extension to pushouts along Dwyer inclusions, or first perform the mapping-cylinder reduction established in the preceding discussion. The word “immédiat” suppresses that extension. Under the stronger pushout formulation the claimed equivalence is immediate; the displayed square alone is not an instance of the literal two-open-cover formulation. We do not infer a counterexample to the conclusion from this mismatch of formulations.

Mais je ne vois aucun moyen de prouver la réciproque, que $f_1 \amalg f_2 \in W \Longrightarrow f_1, f_2 \in W$. Grâce à ce qui a été prouvé, on est ramené au cas où f_1, f_2 sont des immersions ouvertes de Dwyer, mais il ne semble pas que cela nous avance d'un cheveu ! En somme, il faut savoir que les applications canoniques $Y_i \hookrightarrow \coprod Y_i$ sont dans Fib_W. Comme Y_i est un sommand direct, on est ramené au cas d'une immersion canonique $Y_1 \hookrightarrow Y_1 \amalg Y_2 = Y$: si $f : X \longrightarrow Y$ est dans W, en est-il de même de $X_1 = X \times_Y Y_1 \longrightarrow Y_1$? C'est une propriété qui, bien sûr, serait conséquence de l'ancien W (4 a) (XII, p. 53), ou seulement W (4 a′), donc de l'actuel Loc (6 a′). Il suffit même de la forme W (4 c′) = Loc (6 c′) la plus faible de toutes, comme on voit en décomposant $X_1 \longrightarrow Y$ en $X \xrightarrow{i} X' \xrightarrow{p} Y$, avec $i \in W$ (plus précisément, $i_1 : X_1 \longrightarrow X'_1$ et $i_2 : X_2 \longrightarrow X'_2$ dans W !), et $p \in \mathrm{Parf}_W$. Par Loc (6 c′), $f \in W$, donc $p \in W$ implique que les fibres de p sont W-asphériques, ce qui implique que p est dans W_{univ}, donc $p_1 : X'_1 \longrightarrow Y_1$ est dans W.

[page 122]

Donc notons par acquis de conscience :

Corollaire 9.3. *Si W satisfait* Loc (1, 2, 3, 6 c′) (*où* Loc (6 c′) *est la variante la plus faible de toutes de l'axiome des fibrations*), *alors pour toute famille $(f_i : X_i \longrightarrow Y_i)_{i\in I}$ de flèches dans* Cat, $f = \coprod f_i \in W \Longrightarrow$ *les f_i sont dans W $\forall\, i \in I$* [47]. *Et si $i : Y_0 \hookrightarrow Y$ est une flèche qui est à la fois immersion ouverte et immersion fermée* (i.e. *un isomorphisme avec un sommand direct de Y*), *alors i est dans* Fib_W, i.e. *si $f : X \longrightarrow X'$ est une flèche dans* Cat$/Y$, *alors $f \in W$ implique $(f_0 : X_0 \longrightarrow Y_0) \in W$, où $X_0 = X|Y_0$, $X'_0 = X'|Y_0$.*

Mais il est assez scandaleux d'avoir à utiliser un axiome aussi fort, pour en conclure un résultat aussi anodin ! Je note ceci :

Proposition 9.4. *Soit $W \subset$* Fl(Cat), *satisfaisant* Loc (1) *sans plus. Les conditions suivantes sont équivalentes* (*et impliquées par* Loc (1, 2, 3, 4, 6 c′)).

a) *Si $f_1 : X_1 \longrightarrow Y_1$, $f_2 : X_2 \longrightarrow Y_2$ sont deux flèches de* Cat, *alors*

$$f_1 \amalg f_2 \in W \iff f_1 \in W,\ f_2 \in W\,.$$

b) *Les deux conditions suivantes sur W sont satisfaites :*

[page 123]

1°) *Si $f : X \longrightarrow Y$ est dans W, alors il l'est coüniversellement sous $\emptyset$,* i.e. *pour tout Z dans* Cat, $f \amalg \mathrm{id}_Z : X \amalg Z \longrightarrow Y \amalg Z$ *est dans W.* (**N.B.** *Ceci équivaut à : toute somme finie de flèches $f_i \in W$ est dans W – et itou même pour sommes infinies, si* Loc (7), *axiome des limites, est satisfait.*)

2°) *Soit $Y_0 \hookrightarrow Y$ une inclusion d'un sommand direct d'un objet de* Cat. *Alors si $X \xrightarrow{f} Y$ est dans W, de même $X_0 = X|Y_0 \longrightarrow Y_0$.* (**N.B.** *Ceci équivaut à la condition que l'inclusion d'un sommand direct est toujours une W-fibration.*)

De plus, si $\pi_0(Y)$ est fini, ou si W satisfait l'axiome des limites Loc (7), *il suffit d'exiger 2° pour Y_0 une composante connexe de Y.*

p. 67

c) *Pour toute famille* finie $(f_i)_{i\in I}$ *de flèches $f_i : X_i \longrightarrow Y_i$ dans* Cat,

$$\coprod f_i \in W \iff f_i \in W \quad \textit{pour tout } i \in I.$$

De plus, si W satisfait Loc (7), *alors il est inutile dans* (c) *de se borner à I fini.* (*Et en tous cas, les conditions équivalentes* (a), (b), (c) *impliquent pour* toute *famille de flèches $(f_i)_{i\in I}$, $\coprod f_i \in W \Longrightarrow f_i \in W\ \forall\, i \in I$.*)

[page 124]

D'après 9.3, ces conditions sont satisfaites moyennant Loc (1, 2, 3, 4, 6 c′), mais Loc (6 c′) est un marteau-pilon pour une mouche ! On aurait envie plutôt d'ajouter un axiome aux axiomes Loc (1) à Loc (4) et Loc (6) à Loc (8), qui avec Loc (8) serait l'axiome le plus anodin de tous.

47. En fait, je ne sais prouver l'implication en sens inverse, moyennant seulement Loc (1, 2, 3, 6 c′).

Loc (5) (Axiome de décomposition, forme faible). Si $(f_i)_{i\in I}$ est une famille finie de flèches de Cat, alors $f = \coprod f_i$ est dans W si et seulement si les f_i le sont. (Ce sont les conditions équivalentes de 9.4.) [48]

Loc (5 bis) (Axiome de décomposition, forme forte). Comme Loc (5), mais sans supposer I finie. [49]

Ainsi, moyennant l'axiome des limites Loc (7), les deux axiomes précédents sont équivalents. De plus, notons ceci :

Corollaire 9.5 (de la proposition 9.4). *L'axiome* Loc (5 bis) *équivaut à chacune des propriétés suivantes :*

ⓐ *Pour tout Y de* Cat, *décomposé en ses composantes connexes Y_i ($i \in I = \pi_0(Y)$), et pour toute flèche $f : X \longrightarrow Y$ dans* Cat, *on a $f \in W$ si et seulement si les $f_i : X_i = X|Y_i \longrightarrow Y_i$ sont dans W.*

ⓑ *Pour Y, Y_i comme dans* ⓐ, *pour toute flèche $f : X \longrightarrow X'$ dans* Cat$/Y$, *on a $f \in W$ si et seulement si $\forall\ i \in I$, le morphisme $f_i : X_i \longrightarrow X'_i$ au-dessus de Y_i est dans W.* [page 125]

Corollaire 9.6. *Si l'axiome* Loc (5) *est satisfait, alors l'axiome de connexité* Loc (8) *équivaut à ceci : pour toute flèche $f : X \longrightarrow Y$ dans W, avec Y 0-connexe, X est 0-connexe.*

N.B. Les axiomes Loc (8) (connexité) et Loc (5 bis) (de décomposition) ont l'air de nature voisine, étant liés l'un et l'autre à la décomposition des objets de Cat en composantes connexes. (Néanmoins, je pense qu'ils sont indépendants.) Je présume qu'on n'aura jamais à travailler vraiment avec des W qui ne satisfont à ces deux axiomes ! (En plus de Loc (1, 2, 3), qui eux constituent le "minimum vital".) Mais apparemment il n'y en a pas besoin dans les développements théoriques généraux jusqu'ici. (Mais l'axiome de connexité Loc (8) pourrait jouer un rôle, quand on parle de la détermination réciproque des structures de contractibilité, et de W-asphéricité, *cf.* Pursuing Stacks. p. 68

[page 126]

Commentary · Development (commentators') [ms. 125]

Connectivity supplies the missing retraction

Grothendieck asks whether the decomposition axiom and the component axiom are independent. The question changes once closure under retracts is available. The following elementary observation makes the relation precise, and accounts for why the modern situation is more rigid than the tentative list suggests. We checked the localizer discussions in Maltsiniotis (2020, §2.1 and §2.4) and Cisinski (2006a, §9.3); the particular retract argument below is supplied here, without a claim of priority.

Summand reflection from connectivity. [ours] Let W be a class of functors containing the identities and closed under retracts in $\underline{\mathrm{Fl}}(\mathrm{Cat})$. Suppose every W-map induces a bijection on connected components. Then, for every small family $(f_i : X_i \longrightarrow Y_i)_{i\in I}$,

$$\coprod_{i\in I} f_i \in W \quad \Longrightarrow \quad f_i \in W \quad \text{for every } i.$$

Consequently, if W is also closed under arbitrary coproducts, it satisfies Loc (5 bis).

Proof. Fix i. If X_i is empty, then Y_i is empty: otherwise the component of any object of Y_i would not be in the image of $\pi_0(\coprod f_j)$, since all the other source summands map into the other target

48. Il peut être commode aussi d'introduire la condition encore plus faible :
Loc (5 a) Si f_1, f_2 sont dans W, alors $f_1 \amalg f_2 \in W$.
C'est aussi la condition (b), 1° de la proposition 9.4.
Loc (5 b) Si $f_1 \amalg f_2$ est dans W, alors f_1 et f_2 aussi.
$\iff$ Si $Y_0 \subset Y$ est un sommand direct, alors $Y_0 \hookrightarrow Y$ est dans Fib_W.

49. `[Réécrivons :]`
Loc (5) a) Si $f_1, f_2 \in W$, alors $f_1 \amalg f_2 \in W$.
b) Si $f_1 \amalg f_2 \in W$, alors $f_1, f_2 \in W$
($\iff b'$) tout $Y_0 \hookrightarrow Y$ sommand direct est dans Fib_W).
Loc (5 bis) Comme Loc (5), mais (a) remplacé par (a bis) une famille (pas nécessairement finie).

summands. In this case f_i is an identity. If X_i is nonempty, choose an object x_i. The inclusion of f_i into $\coprod f_j$ is an arrow-category map. Define a retraction on sources to be the identity on X_i and, on each X_j with $j \neq i$, the constant functor at x_i. Define the retraction on targets to be the identity on Y_i and constant at $f_i(x_i)$ on the other Y_j. These two functors form a commutative square: on the selected summand this is tautological, and on each other summand both composites are the same constant functor. Their composite with the inclusion is the identity of f_i. Thus f_i is a retract of $\coprod f_j$ and belongs to W. □

This proves a sharper statement than the finite reflection needed in Proposition 9.4. It uses no lifting property and no properness theorem. The empty-source case is the only point where preservation of components is needed; the chosen point supplies the retraction in every other case.

Corollary 9.6 can now be read directly at the level of components, even without this retract argument. Under Loc (5), an arrow in W restricts to an arrow in W over each connected component of its target. If every such arrow with connected nonempty target has connected nonempty source, these restrictions each have exactly one source component; therefore the original map induces a bijection on components. The converse follows by applying a component-preserving map to a target having one component. Likewise, the equivalence between (a) and (c) of Proposition 9.11 is formal: a component bijection identifies the coproduct decompositions, and Loc (5 bis) applies to that coproduct. Conversely, criterion (c) implies component preservation and reconstructs both preservation and reflection of arbitrary coproducts by inspecting their component maps. Only the comparison with nondegeneracy in (b) invokes the collapse theorem discussed below.

For a fundamental localizer in the modern, relative sense, coproduct closure and retract closure are available. Hence Loc (8) implies Loc (5 bis) in that setting. The reverse implication fails: the class of all functors satisfies decomposition and does not preserve components. Thus the proposed mutual independence does not survive in the modern setting. For the literal weaker assumptions Loc (1,2,3) of the present manuscript, the cited modern theorems do not eliminate the distinction between weak and relative localization; we do not claim that they settle that separate implication.

There is also a direct explanation of footnote 57. In any category with sequential colimits, a retract a of an object b, with inclusion i and retraction r, is the colimit of the constant-object sequence

$$b \xrightarrow{ir} b \xrightarrow{ir} b \xrightarrow{ir} \cdots .$$

Indeed, a compatible cocone is one arrow $h : b \longrightarrow z$ satisfying $h = hir$, and it factors uniquely through r as $(hi)r$. Apply this observation in the arrow category. A class closed under filtered colimits and isomorphism is therefore closed under retracts. Loc (7) supplies the extra saturation condition Loc (1 bis); it does not by this argument alone establish strong saturation.

Notons ceci :

Proposition 9.7.[50] *Supposons que W satisfait* Loc (1, 2, 3, 5), i.e. *c'est un localiseur fondamental satisfaisant la condition de décomposition* (*forme faible*). *Si l'axiome* Loc (8) *de connexité n'est* pas *satisfait, alors la sous-catégorie* Hot_W^* *des* $X \in \mathrm{Cat}$ *non vides est équivalente à la catégorie ponctuelle* (*donc* Hot_W *est équivalente soit à la catégorie ponctuelle, si* $\emptyset \longrightarrow e$ *est un isomorphisme dans* Hot_W, *soit à* $\mathbf{\Delta}_1$ *dans le cas contraire*[51].)

Ceci est une variante du th. 2 de XII (p. 20), où on faisait l'hypothèse Loc (6 c′), plus forte que Loc (5) et même que Loc (5 bis), mais avec la conclusion plus forte que $W = \mathrm{Fl}(\mathrm{Cat})$.

Démonstration. Soit

$$f \ : \ X \longrightarrow Y \ , \qquad f \ \in \ W \ ,$$

telle que $\pi_0(f)$ ne soit pas *surjective.* Si Y_0 est une composante connexe qui n'est pas dans $\mathrm{Im}\pi_0(f)$, alors $X_0 = X|Y_0$ est vide, et par Loc (7), $\emptyset \longrightarrow Y_0$ est dans W. Donc $\forall\ Z$ dans Cat, $\underbrace{\emptyset \times Z}_{=\emptyset} \longrightarrow Y_0 \times Z$ est dans W, et pour toute flèche $g : Z \longrightarrow Z'$, $\mathrm{id}_{Y_0} \times g : Y_0 \times Z \longrightarrow Y_0 \times Z'$ est dans W. Prenant g telle que $\pi_0(g)$ ne soit pas injective, p. ex. $e \amalg e \longrightarrow e$, on trouve une flèche $\varphi = \mathrm{id}_{Y_0} \times g$ dans W telle que $\pi_0(\varphi)$ ne soit pas injective.

50. *Cf.* version plus forte dans 9.9 plus bas (débarrassée de l'hypothèse Loc (5).) [page 127]

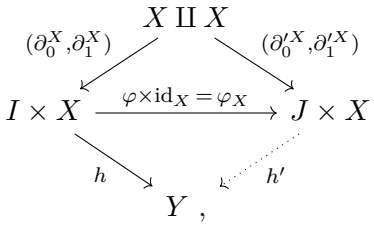
51. Le premier cas est aussi celui où $\exists\ f \in W$ avec $\pi_0(f)$ *non surjectif,* ou encore $\emptyset \longrightarrow X$ dans W, avec X non vide.

Soit donc $\varphi : I \longrightarrow J$ dans W, avec $\pi_0(\varphi)$ non injective. Procédant comme tantôt en utilisant Loc (5), on est ramené au cas où de plus J est 0-connexe. (**N.B.** Dans les deux cas, on aurait pu aussi invoquer 9.6.) Choisissons deux éléments i_0, i_1 dans I dans deux composantes connexes distinctes, soient j_0, j_1 leurs images dans J. On va traiter (I, i_0, i_1) et (J, j_0, j_1) comme des "intervalles homotopiques". Le fait que i_0, i_1 appartiennent à des composantes distinctes de I implique que deux flèches $f_0, f_1 : X \rightrightarrows Y$ sont "homotopes par rapport à (I, i_0, i_1)", *i.e.* il existe $h : X \times I \longrightarrow Y$ dans Cat telle que $f_0 = h\partial_0^X$, $f_1 = h\partial_1^X$, où

$$\partial_0^X \ , \ \partial_1^X \ : \ X \ \longrightarrow \ I \times X$$

sont données par $x \longmapsto (i_\alpha, x)$ $(\alpha \in \{0,1\})$. Pour trouver h, on décompose I en

$$I \ = \ I_0 \amalg I_1 \ , \qquad \text{avec} \quad i_0 \in I_0, \ i_1 \in I_1 \ ,$$



d'où $I \times X \ \simeq \ (I_0 \times X) \amalg (I_1 \times X)$, et on définit h par ses restrictions h_0, h_1 aux deux morceaux $I_0 \times X$, $I_1 \times X$, savoir

$$h_0 \ = \ f_0 \circ \mathrm{pr}_2^{I_0} \ , \qquad h_1 \ = \ f_1 \circ \mathrm{pr}_2^{I_1} \ ,$$

où p. 69

$$\mathrm{pr}_2^{I_\alpha} \ : \ I_\alpha \times X \longrightarrow X \ .$$

Considérons maintenant le diagramme (traits pleins) [page 128]

où $\partial_0'^X$, $\partial_1'^X$ sont définis comme ∂_0^X, ∂_1^X, mais utilisant $j_0, j_1 \in \mathrm{Ob}J$ au lieu de $i_0, i_1 \in \mathrm{Ob}I$. S'il existait dans Cat une flèche h' (pointillée) telle que $h' \circ \varphi_X = h$, il s'ensuivrait que h' est une homotopie de f_0 et f_1 suivant (J, j_0, j_1). Comme J est 0-connexe, il s'ensuivrait aussitôt que f_0, f_1 sont homotopes au sens habituel dans Cat, donc que f_0 et f_1 ont même image dans Hot_W. Mais si on ne peut trouver une flèche h' dans Cat, du moins peut-on la trouver dans Hot_W, puisque $\varphi_X \in W$, donc un isomorphisme dans Hot_W (et h' dans $\mathrm{Hom}_W(J \times X, Y)$ sera même uniquement déterminé). Donc dans Hot_W, on a

$$f_0 \ = \ h'\partial_0'^X \ , \qquad f_1 \ = \ h'\partial_1'^X \ .$$

Pour prouver que [page 129]

$$f_0 \ = \ f_1 \qquad \text{dans} \quad \mathrm{Hom}_W(X, Y) \ ,$$

il suffit de voir que

$$\partial_0'^X \ = \ \partial_1'^X \qquad \text{dans} \quad \mathrm{Hom}_W(X, J \times X) \ .$$

Or en fait $\partial_0'^X$ et $\partial_1'^X$ sont homotopes, car $e \overset{j_0}{\underset{j_1}{\rightrightarrows}} J$ sont homotopes (j_0 et j_1 appartenant à la même composante connexe de J), donc aussi leur produit par id_X.

On voit donc que pour deux objets quelconques X, Y de Cat, toutes les flèches de X dans Y sont égales dans Hot. L'argument fait prouve même que toutes les flèches *dans* Hot_W de X dans Y sont égales. Cela signifie que la catégorie Hot_W^* (où pour deux objets quelconques X, Y, $\mathrm{Hom}_{\mathrm{Cat}}(X, Y)$, et a fortiori $\mathrm{Hom}_W(X, Y)$ est $\neq \emptyset$) est équivalente à la catégorie ponctuelle. Quant à Hot_W elle-même, dont l'ensemble des objets est $\{\emptyset\} \amalg \mathrm{Ob}\mathrm{Hot}_W^*$, avec $\emptyset$ objet initial, [page 130]

elle sera donc équivalente à la catégorie ponctuelle, ou bien à $\mathbf{\Delta}_1$, selon que $\emptyset \longrightarrow e$ est un isomorphisme dans Hot_W, ou non.

Commentaire 9.8. Si les axiomes Loc (1, 2, 3, 5) [52] sont satisfaits, alors l'axiome de connexité Loc (8) *équivaut* à chacun des suivants :

Commentary · Examples [ms. 129]

The two degenerate homotopy categories

Grothendieck's conclusion allows two outcomes because the empty category can retain information after every nonempty category has become indistinguishable. Both outcomes occur, and computing them helps separate a statement about a localization from a statement about its specified class of denominators.

Let W_{-1} consist of all functors whose source and target are both nonempty, together with the identity of the empty category. Equivalently, these are precisely the functors which preserve and reflect emptiness. This class satisfies two-out-of-three and the inverse test by applying the functor

$$E : \mathrm{Cat} \longrightarrow [1], \qquad E(A) = \begin{cases} 0 & A = \emptyset, \\ 1 & A \neq \emptyset. \end{cases}$$

It satisfies the terminal-object axiom. It even satisfies the relative Theorem A: if $A/s \longrightarrow B/s$ preserves emptiness for every $s \in S$ and B is nonempty, choose $b \in B$ and $s = p(b)$. Then B/s contains $(b, 1_s)$, so A/s is nonempty and therefore A is nonempty. The reverse nonemptiness implication is automatic for a functor. Thus the comparison itself lies in W_{-1}.

The localization at W_{-1} is [1]. To check the universal property, let $F : \mathrm{Cat} \longrightarrow \mathcal{H}$ invert W_{-1}. For nonempty A, the arrow $A \longrightarrow e$ becomes invertible. For any $u : A \longrightarrow B$ between nonempty categories, the equation $p_B u = p_A$ forces

$$F(u) = F(p_B)^{-1} F(p_A).$$

Consequently every arrow between nonempty categories has a uniquely prescribed image, and the unique arrow $\emptyset \longrightarrow e$ supplies the remaining arrow of [1]. This is exactly the required factorization, with its natural-isomorphism version as well. Localizing at all functors additionally makes $\emptyset \longrightarrow e$ invertible and gives the terminal category.

The class W_{-1} fails component preservation: the fold $e \amalg e \longrightarrow e$ belongs to it. It also fails summand reflection, since

$$(\emptyset \longrightarrow e) \amalg (1_e : e \longrightarrow e)$$

has nonempty source and target, while its first summand is not in W_{-1}. This is the precise obstruction behind the concern on ms. 121. A weak equivalence of a disjoint union need not restrict to a weak equivalence merely because both unions are nonempty.

By contrast, for $W_0 = \{u \mid \pi_0(u) \text{ is bijective}\}$, the localization is Set. The component functor has a section sending a set to its discrete category, and the canonical functor $A \longrightarrow \pi_0(A)$ belongs to W_0. Its universal property identifies the localization with Set. This supplies infinitely many isomorphism classes, including the finite discrete categories of every cardinality. Thus the alternatives of Proposition 9.12 already occur in these elementary examples; the point of its argument is to show that loss of components leaves no intermediate nonempty homotopy theory under the necessary tensor hypothesis.

p. 70

a) Hot_W n'est équivalente ni à e, ni à $\mathbf{\Delta}_1$.

b) Hot_W a une infinité de classes d'isomorphie.

c) $f_0 : X_0 \longrightarrow Y_0$ (flèche donnée d'avance dans Cat, telle que $\pi_0(f_0)$ n'est pas un isomorphisme, et $X_0 \neq \emptyset$) n'est *pas* un isomorphisme de Hot_W.

d) X_0 et Y_0 ne sont pas isomorphes dans Hot_W (où X_0, Y_0 sont deux objets donnés d'avance dans Cat, avec X_0, Y_0 non vides et $\mathrm{card}\,\pi_0(X_0) \neq \mathrm{card}\,\pi_0(Y_0)$).

52. En fait, ce commentaire vaut même en l'absence de l'hypothèse Loc (5), *cf.* 9.9 ci-dessous.

On peut donc dire que l'axiome de connexité joue le rôle d'un *axiome de non trivialité* pour la catégorie Hot_W localisée de Cat. Il sera satisfait automatiquement pour tous les localiseurs fondamentaux W qu'on sera amené à construire ou à introduire. Mais on n'aura pratiquement jamais à l'invoquer comme une hypothèse, en vue de certaines conclusions.

Je m'aperçois finalement que dans la proposition 9.7 l'hypothèse Loc (5) est inutile :

Proposition 9.9.[53] *Soit W un localiseur fondamental dans* Cat (i.e. *on a* Loc (1, 2, 3) *sans plus*), *plus la condition que la* somme *de $f_1, f_2 \in W$ est dans W*[54]. *Si l'axiome de connexité n'est pas satisfait, alors* Hot_W *est équivalente à la catégorie ponctuelle* (*si $\emptyset \longrightarrow e$ est un isomorphisme dans* Hot_W[55]) *ou à $\mathbf{\Delta}_1$* (*dans le cas contraire*), *et* Hot_W^* ($\overset{\text{déf}}{=} \mathrm{Hot}_W \backslash \{\emptyset\}$) *est équivalente à la catégorie ponctuelle.*

La condition sur les sommes assure que dans Hot_W la somme de deux objets existe, et [page 131] que $\mathrm{Cat} \longrightarrow \mathrm{Hot}_W$ commute aux sommes de deux objets. Ceci dit, soit

$$(*) \qquad f \ : \ X \longrightarrow Y$$

une flèche telle que $f \in W$, mais $\pi_0(f)$ non surjectif. Supposons d'abord $X \neq \emptyset$ (cas le moins évident). Si Y_0 est un sommand non vide de Y tel que f se factorise par $Y_1 = Y \backslash Y_0$, alors f est somme de

$$f_1 \ : \ X \ = \ X_1 \longrightarrow Y_1 \qquad \text{et} \qquad f_0 \ : \ X_0 \ = \ \emptyset \longrightarrow Y_0$$

dans Cat, donc aussi dans Hot_W. Donc on a une somme $f \ = \ f_0 \amalg f_1$ dans Hot_W qui est un isomorphisme, donc pour tout Z dans Hot_W,

$$\mathrm{Hom}_W(Y_0, Z) \times \mathrm{Hom}_W(Y_1, Z) \ \xrightarrow{\sim} \ \underbrace{\mathrm{Hom}_W(X_0, Z)}_{=e} \times \mathrm{Hom}_W(X_1, Z)$$

(**N.B.** $\emptyset$ est objet initial de Hot_W, l'étant de Cat), *i.e.* le composé

$$Z(Y_0) \times Z(Y_1) \ \xrightarrow{\mathrm{pr}_2} \ Z(Y_1) \ \xrightarrow{Z(f_1)} \ Z(X_1)$$

est bijectif. Comme $X \ = \ X_1 \neq \emptyset$, donc aussi $Y_1 \neq \emptyset$, et $Y_0 \neq \emptyset$, les ensembles $Z(Y_0)$, $Z(Y_1)$, $Z(X_1)$ sont $\neq \emptyset$ si $Z \neq \emptyset_{\mathrm{Cat}}$. Le composé étant bijectif, la première flèche pr_2 est injective, ce qui implique que $Z(Y_0)$ est réduit à un point (les deux facteurs $Z(Y_0)$, $Z(Y_1)$ étant $\neq \emptyset$). Cela p. 71 signifie que Y_0 est un objet initial dans Hot_W^*. Il s'ensuit notamment que $Y_0 \amalg Y_0$ est aussi un [page 132] objet initial, et l'application canonique $Y_0 \amalg Y_0 \longrightarrow Y_0$ est donc un isomorphisme dans Hot_W, alors que l'application induite sur les π_0 n'est pas injective. (C'est $\pi_0(Y_0) \amalg \pi_0(Y_0) \longrightarrow \pi_0(Y_0)$, avec $\pi_0(Y_0)$ non vide.) Ce cas va être traité ci-dessous.

Si dans $(*)$ X est vide, Y non vide (puisque $\pi_0(f)$ non surjectif), alors Y est objet initial de Hot_W, et on voit encore que $Y \amalg Y \longrightarrow Y$ est un isomorphisme dans Hot_W, bien que n'induisant pas un isomorphisme des π_0. La proposition 9.9 va donc résulter du

Lemme 9.10. *Soit W localiseur fondamental sans plus* (*axiomes* Loc (1, 2, 3)). *Supposons qu'il existe $f : I \longrightarrow J$ dans* Cat *tel que* $\mathrm{hot}_W(f)$ *soit un isomorphisme, mais que $\pi_0(f)$* ne soit pas injectif[56]. *Alors* Hot_W^* *est équivalente à la catégorie ponctuelle e, et* Hot_W *est équivalente à e* (*si $\emptyset \longrightarrow e$ est un isomorphisme dans* Hot_W) *ou à $\mathbf{\Delta}_1$* (*dans le cas contraire*).

La démonstration est celle donnée pour 9.7 : on prouve que si X, Y sont deux objets de [page 133] Cat, *non vides*, alors deux flèches $f_0, f_1 : X \rightrightarrows Y$ sont égales dans Hot_W, par un argument

53. *Cf.* meilleur énoncé 9.12 (p. 133 bis).

54. Cette condition Loc (5 a) est vérifiée notamment si W satisfait de plus l'un des deux axiomes Loc (4) (*cf.* 9.1), ou Loc (6 c′) (*cf.* 9.3).

55. Cela signifie aussi qu'il existe $Z \neq \emptyset$ dans Cat, tel que $\emptyset \longrightarrow Z$ soit un isomorphisme dans Hot_W.

56. Ou bien tel que I soit 0-connexe, et J non 0-connexe (*i.e.* $\mathrm{card}\, \pi_0(I) \ = \ 1$, $\mathrm{card}\, \pi_0(J) \ \geq \ 2$). Ce deuxième cas se traite par la même méthode essentiellement.

d'homotopie, en choisissant deux points i_0, i_1 de I qui sont dans deux composantes connexes distinctes, et tels que leurs images j_0, j_1 dans J soient dans la même composante.

Proposition 9.11. *Soit W un localiseur fondamental* (i.e. *on a* Loc (1, 2, 3)). *Alors les conditions suivantes sont équivalentes.*

a) *On a* Loc (5 bis) (*axiome de décomposition, forme forte*) *et* Loc (8) (*axiome de connexité*).

b) *On a* Loc (5 bis), *et* Hot_W *n'est pas équivalente à e ou à* $\mathbf{\Delta}_1$ (cf. *commentaire* 9.8).

c) *Pour toute $f : X \longrightarrow Y$, on a $f \in W$ si et seulement si $\pi_0(f)$ est un isomorphisme, et pour toute composante connexe X_i de X, si Y_i désigne la composante connexe correspondante de Y, la flèche induite $f_i : X_i \longrightarrow Y_i$ est dans W.*

La raison pour laquelle je n'isole pas cette propriété en un des axiomes Loc (…), c'est que ce n'est *pas* un axiome de stabilité, mais un axiome de nature mixte.

Proposition 9.12. *Soit W un localiseur fondamental* (*sans plus*), i.e. *satisfaisant* Loc (1, 2, 3). *Les conditions suivantes sont équivalentes.* [page 133 bis]

a) *W satisfait l'axiome de connexité* Loc (8), i.e. *$f \in W \Longrightarrow \pi_0(f)$ bijectif.*

b) *Si $f, g : X \rightrightarrows Y$ dans* Cat *sont telles que* $\mathrm{hot}_W(f) = \mathrm{hot}_W(g)$, *alors* $\pi_0(f) = \pi_0(g)$.

c) *Il existe X, Y dans* Cat *tel que l'application* $\mathrm{hot}_W^{X,Y} : \mathrm{Hom}_{\mathrm{Cat}}(X, Y) \longrightarrow \mathrm{Hom}_W(X, Y)$ *ne soit pas constante.*

c′) *La sous-catégorie* Hot_W^* *de* Hot_W, *formée des objets non vides, n'est pas équivalente à la catégorie ponctuelle.*

c″) *La catégorie* Hot_W *n'est pas équivalente à la catégorie e ni à la catégorie* $\mathbf{\Delta}_1$.

d) *L'ensemble des classes d'isomorphie d'objets de* Hot_W *est infini.*

Démonstration. On a $(a) \Longrightarrow (b)$, puisque (a) équivaut à dire que le foncteur $\pi_0 :$ Cat $\longrightarrow$ Ens se factorise par Hot_W. D'ailleurs le foncteur correspondant [p. 72]

$$\mathrm{Hot}_W \longrightarrow (\mathrm{Ens})$$

est essentiellement surjectif – il y a un inverse à isomorphisme près, $I \longmapsto \mathrm{hot}_W(I)$. Cela prouve que (a) implique (d), et on a $(d) \Longrightarrow (c')$, $(d) \Longrightarrow (c'')$ tautologiquement. Un argument plus ou moins tautologique montre d'ailleurs que si Hot_W^* est équivalente à e, alors Hot_W est équivalente à e ou à $\mathbf{\Delta}_1$ (car $\emptyset$ est objet initial de Hot_W) – donc $(c'') \Longrightarrow (c')$. Donc on a plus ou moins tautologiquement

$$\begin{array}{ccccccc} (\mathrm{a}) & \Longrightarrow & (\mathrm{d}) & \Longrightarrow & (\mathrm{c}'') & \Longrightarrow & (\mathrm{c}') \\ \Downarrow & & & & & \nearrow\!\nearrow & \\ (\mathrm{b}) & & \Longrightarrow & & (\mathrm{c}) & & \end{array}$$

où les implications $(b) \Longrightarrow (c) \Longrightarrow (c')$ sont elles aussi triviales [c'est plutôt l'implication (c′) ⟹ (c) qui est triviale ; l'implication (c) ⟹ (c′) est démontrée après l'énoncé du corollaire 9.13, avant la preuve de ce dernier]. Donc tout revient à prouver que $(c) \Longrightarrow (a)$, ou encore : [page 133 ter]

Corollaire 9.13. *Si l'axiome de connexité n'est pas satisfait, alors si X, Y sont deux objets de* Cat, *toutes les flèches $X \longrightarrow Y$ dans* Cat *sont égales dans* Hot_W, i.e. *l'application* $\mathrm{Hom}_{\mathrm{Cat}}(X, Y) \longrightarrow \mathrm{Hom}_W(X, Y)$ *est constante.*

Cela implique donc que tous les objets de Cat*, *i.e.* tous les objets non vides de Cat, sont isomorphes dans Hot_W, et on trouve un isomorphisme canonique entre elles, avec transitivité. Soit alors $\mathcal{H}$ la catégorie quotient de Cat, ayant mêmes objets que Cat, et ayant exactement une flèche entre deux objets non vides de Cat et exactement une flèche de $\emptyset$ dans tout autre

objet de Cat (et pas de flèche d'un objet non vide de Cat dans $\emptyset$). C'est donc une catégorie équivalente à $\mathbf{\Delta}_1$. On a vu que $\mathrm{Cat} \longrightarrow \mathrm{Hot}_W$ se factorise en

$$\mathrm{Cat} \xrightarrow{\text{can.}} \mathcal{H} \longrightarrow \mathrm{Hot}_W \ .$$

Si $\mathrm{Cat} \longrightarrow \mathcal{H}$ transforme toute flèche appartenant à W en isomorphisme, alors il est immédiat que $\mathcal{H}$ est solution au problème universel définissant Hot_W, donc que $\mathcal{H} \longrightarrow \mathrm{Hot}_W$ est un isomorphisme. Cela signifie aussi que W ne contient pas de flèche $\emptyset \longrightarrow X$ avec X non vide (auquel cas W contient toutes les flèches). Donc dans ce cas $\mathrm{Hot}_W \simeq \mathbf{\Delta}_1$. Dans le cas contraire, soit $\mathcal{H}'$ la catégorie déduite de $\mathcal{H}$ en inversant les flèches $\emptyset \longrightarrow X$, *i.e.* le groupoïde 1-connexe sur l'ensemble d'objets ObCat. Ce n'est plus une catégorie quotient de Cat, mais on a encore une factorisation

$$\mathrm{Cat} \xrightarrow{\text{épi}} \mathcal{H} \xrightarrow{\text{loc.}} \mathcal{H}' \longrightarrow \mathrm{Hot}_W \ ,$$

et cette fois c'est $\mathcal{H}'$ qui est solution du problème universel ($\mathrm{Cat} \longrightarrow \mathcal{H}'$ transformant flèches de W en isomorphismes). Donc dans ce cas, $\mathcal{H}' \longrightarrow \mathrm{Hot}_W$ est un isomorphisme, et Hot_W est équivalente à e. Dans les deux cas, Hot_W^* est équivalente à e. p. 73 [page 133 quater]

Donc, la proposition 9.12 résulte du corollaire 9.13, qu'il s'agit à présent de démontrer.

Commentary · Exposition [ms. 133]

The precise hypothesis behind the collapse argument

Grothendieck has found a remarkably economical way to detect nontriviality: two points must remain distinguishable. The argument is correct once product with a category carries weak equivalences to weak equivalences. This is exactly the operation used when an equality of two points is promoted to an equality of two maps with arbitrary source. We give the full argument with that hypothesis visible, rather than silently proving a statement under stronger axioms than those printed.

Assume Loc (1,2,3), and in addition

(T) $$u \in W \quad \Longrightarrow \quad u \times 1_X \in W \quad \text{for every small category } X.$$

Write $L : \mathrm{Cat} \longrightarrow \mathcal{H} = \mathrm{Cat}[W^{-1}]$. Natural transformations already identify functors in $\mathcal{H}$ under the weak axioms. To see this directly, the projection $[1] \times X \longrightarrow X$ has comma category $[1] \times (X/x)$ over x, which has a terminal object. Loc (2,3) therefore puts the projection in W. Its two sections have the same image, being inverses to the same isomorphism. A natural transformation $F \Rightarrow G$ is a functor $[1] \times X \longrightarrow Y$, and composition with the sections gives $L(F) = L(G)$. A finite zigzag of natural transformations gives the same conclusion.

Suppose first that $u : I \longrightarrow J$ belongs to W and identifies two different components of I. Choose i_0, i_1 in those components, with images j_0, j_1 in the same component of J. Given $f_0, f_1 : X \longrightarrow Y$, split $I = I_0 \amalg I_1$ with the chosen objects in different summands, and define $h : I \times X \longrightarrow Y$ by f_0 on the first summand and f_1 on the second. By (T), $L(u \times 1_X)$ is invertible. The two inclusions $X \longrightarrow J \times X$ at j_0, j_1 are joined by a zigzag of natural transformations, hence equal in $\mathcal{H}$. Their inverse images through $L(u \times 1_X)$ are equal, and composing with $L(h)$ proves $L(f_0) = L(f_1)$.

Suppose instead that u misses a component of J. Let ε be the discrete category $\{0, 1\}$. Define $g_0 : J \longrightarrow \varepsilon$ to be constantly zero, and g_1 to be zero on every component met by u and one on a chosen complementary nonempty union. The equation $g_0 u = g_1 u$ and invertibility of $L(u)$ imply $L(g_0) = L(g_1)$. Evaluation at an object of the complementary part gives equality of the two arrows $e \longrightarrow \varepsilon$ in $\mathcal{H}$. By (T), product with X induces an endofunctor of $\mathcal{H}$, so the two coproduct inclusions $X \longrightarrow X \amalg X$ have equal images. Composing with $(f_0, f_1) : X \amalg X \longrightarrow Y$ again gives $L(f_0) = L(f_1)$. Notice the target Y: the printed X in the final display is a slip.

It remains to justify why equality of ordinary functors determines all arrows of the localization. Let $\mathcal{Q}$ have the objects of Cat, one arrow between any two nonempty objects, one arrow from the empty object to every object, and no arrow from a nonempty object to the empty one. Equality of all parallel ordinary functors gives a factorization of L through $\mathcal{Q}$. If W contains no arrow with empty source and nonempty target, the functor $\mathrm{Cat} \longrightarrow \mathcal{Q}$ inverts W and has the same universal property as L. Thus $\mathcal{H} \simeq [1]$. Otherwise invert the unique missing type of arrow in $\mathcal{Q}$; the resulting category is equivalent to e and has the universal property. In either case the full subcategory on

the nonempty categories is equivalent to e. This argument includes arbitrary zigzags and does not assume a calculus of fractions.

If, on the other hand, every element of W preserves components, π_0 factors through $\mathcal{H}$. The discrete finite categories then remain pairwise nonisomorphic, and the two points of ε remain distinct. These observations prove all six equivalences of Proposition 9.12 under (T). In particular, (c)⇒(c′) is immediate: a nonconstant map on a hom-set exhibits two distinct arrows between nonempty objects. The argument through $\mathcal{Q}$ proves the contrapositive of (c′)⇒(c). The editorial bracket on ms. 133 bis interchanges these two roles; the original direction called trivial there was correct.

The additional hypothesis is available for relative fundamental localizers; see Maltsiniotis (2020, Propositions 2.1.3 and 2.1.9). The modern classification of the two exceptional localizers is Cisinski (2006a, Proposition 9.3.2). Under the manuscript's literal weak hypotheses, the displayed proof has a gap, already flagged by the edition on ms. 133 quinquies. We found no proof in the checked sources that removes it. Finally, the conclusion $\mathcal{H} \simeq e$ should not be substituted for $W = \mathrm{Fl}(\mathrm{Cat})$ without a saturation argument. The ambiguous parenthesis on ms. 133 ter is read with this distinction maintained.

Soit $f : I \longrightarrow J$ dans Cat telle que $\pi_0(f)$ ne soit pas injective. On a vu dans la démonstration de 9.7 comment on en déduit (en choisissant deux éléments i_0, i_1 dans deux composantes connexes distinctes de I, telles que $j_0 = f(i_0)$ et $j_1 = f(i_1)$ soient dans une même composante connexe de J) que pour X, Y dans Cat, deux flèches $f_0, f_1 : X \rightrightarrows Y$ sont toujours égales dans Hot_W (*cf.* lemme 9.10).

Soit maintenant

$$f \ : \ I \longrightarrow J$$

dans Cat telle que $\pi_0(f)$ ne soit pas surjective, donc $J = J_0 \amalg J_1$, avec f se factorisant par J_0, et $J_1 \neq \emptyset$. Considérons alors la catégorie discrète à deux objets,

$$\varepsilon \ = \ \{0, 1\} \ ,$$

et deux flèches

$$g_0, \ g_1 \ : \ J \ \rightrightarrows \ \varepsilon \ ,$$

g_0 étant constante de valeur 0, et g_1 étant égale à 0 sur J_0, à 1 sur J_1. On a

$$g_0 f \ = \ g_1 f \ ,$$

donc, comme $f \in W$,

$$g_0 \ = \ g_1 \qquad \text{dans} \quad \mathrm{Hot}_W \ .$$

On en conclut, en prenant un point j_1 dans J_1, et l'inclusion $\alpha_{j_1} : e \longrightarrow J$ correspondante, que

$$g_0 \alpha_{j_1} \ = \ g_1 \alpha_{j_1} \ ,$$

i.e. les deux sections de ε sur e sont égales dans Hot_W. Comme le foncteur Cat $\longrightarrow \mathrm{Hot}_W$ commute aux produits finis [cette propriété n'est pas établie sous les seules conditions Loc(1,2,3) ; elle est démontrée dans Pursuing Stacks, section 64, en remplaçant Loc(3) par l'axiome plus fort Loc(3bis)], il s'ensuit que pour X dans Cat, les deux flèches [page 133 quinquies]

$$X \ \overset{\partial_0^X}{\underset{\partial_1^X}{\rightrightarrows}} \ X \times \varepsilon \ = \ X \amalg X$$

sont égales dans Hot_W. Si alors

$$f_0, \ f_1 \ : \ X \ \rightrightarrows \ Y$$

sont deux flèches dans Cat, elles sont de la forme

$$f_0 \ = \ h\partial_0^X \ , \qquad f_1 \ = \ h\partial_1^X \ ,$$

avec

$$h \ = \ (f_0, f_1) \ : \ X \amalg X \ \longrightarrow \ X \ ,$$

et comme $\partial_0^X = \partial_1^X$ dans Hot_W, on en conclut $f_0 = f_1$ dans Hot_W, *q.e.d.* p. 74 [page 134]

10 Application au dérivateur HOT_W

Théorème 10.1. *Soit W un localiseur dans* Cat *satisfaisant les conditions* Loc (1, 2, 3, 4, 7 bis) (*axiomes de saturation forme forte* (*facteurs directs*), *de l'objet final, de localisation forme faible, du carré cocartésien, de la L-accessibilité* [57]). *Soit* HOT_W *le prédérivateur sur* (Cat) *associé à* (Cat, W) *de la façon habituelle,*

$$I \longmapsto \mathrm{Cat}(I)\, W(I)^{-1} \;=\; \underline{\mathrm{Hom}}(I^\circ, \mathrm{Cat})\, W(I)^{-1}\,. \tag{10.1.1}$$

On a alors ce qui suit.

1 °) *Pour toute flèche $u : I \longrightarrow J$ dans* Cat, *le foncteur $u_!$* (*adjoint à gauche de u^**) *existe* (**N.B.** On n'a pas besoin pour ceci de Loc (4) ni de Loc (7 bis), il suffit que W soit un localiseur fondamental `[on a néanmoins besoin de l'axiome de localisation forme forte Loc (3 bis)]`), *et il se calcule de la façon standard* (*axiomes* Der 4 bis *et* Der 5 bis). *Le foncteur u_*, adjoint à droite de u^*, existe* [58] [*si u est de la forme $v \times \mathrm{id}_S$, où $v : I_0 \longrightarrow J_0$ est une flèche entre catégories ordonnées finies, et S un objet quelconque de* Cat], *et ce foncteur u_* se calcule de façon standard* (*axiomes* Der 4 *et* Der 5). *Donc on a une théorie des carrés W-cartésiens et des carrés W-cocartésiens dans les catégories* $\mathrm{HOT}_W(S)$, *et des suites longues* [page 135] *de suspension et de cosuspension dans les catégories* $\mathrm{HOT}^\bullet_W(S)$. (*Plus exactement, ce sont des théories relatives aux dérivateurs induits* $\mathrm{HOT}_{W,S}$, $\mathrm{HOT}^\bullet_{W,S}$ *sur S, $I \longmapsto \mathrm{HOT}_W(S \times I)$ resp. $I \longmapsto \mathrm{HOT}^\bullet_W(S \times I)$ …*). *De plus, les carrés cocartésiens et les carrés cartésiens relatifs aux dérivateurs induits* $\mathrm{HOT}_{W,S}$ *sont* exacts, i.e. *les suites longues de suspension et de cosuspension sont exactes* (*axiomes d'exactitude à droite et à gauche* Der 6 bis *et* Der 6).

Commentary · Exposition [ms. 134]

What the model structure supplies to the derivator

Grothendieck is returning to the purpose of the factorization theorems: they should make homotopy Kan extensions available for diagrams of every shape. The final paragraph says that the proof will be given next, but the announced paragraph is absent. The theorem must therefore be read as a collected statement with several recalled ingredients, not as a theorem proved in these pages.

There is now a convenient independent route to its main structural conclusions. For an accessible fundamental localizer in the relative modern sense, Cisinski (2006a, Theorem 5.2.15) constructs a combinatorial model structure on Cat with weak equivalences W. The associated diagram theory is a strong derivator by Groth (2013, Proposition 1.30). These are sufficient modern hypotheses, not a verbatim replacement of the manuscript's L-accessibility condition or a proof that weak Loc (3) implies relative Loc (3 bis).

Here is how this route accounts for the assertions. The projective and injective model structures on diagram categories have the same objectwise weak equivalences. Projective cofibrant replacements compute left derived Kan extensions; injective fibrant replacements compute right derived Kan extensions. Derived adjunctions give both adjoints to restriction. The pointwise formulas retain the variance in (10.1.1). If $X : I^{\mathrm{op}} \longrightarrow \mathrm{Cat}$ and $u : I \longrightarrow J$, they have the form

$$(u_! X)_j \simeq \mathrm{hocolim}_{(j/u)^{\mathrm{op}}} X_i, \qquad (u_* X)_j \simeq \mathrm{holim}_{(u/j)^{\mathrm{op}}} X_i.$$

In the first comma category an object is $j \longrightarrow u(i)$, and in the second it is $u(i) \longrightarrow j$. The opposite categories occur because the coefficient diagrams are contravariant. They should not be omitted by importing a formula written for covariant diagrams.

The model of a diagram also explains evaluation conservativity. Represent a morphism of the diagram homotopy category by a map from a cofibrant replacement to a fibrant replacement. If every evaluated morphism is invertible in the underlying homotopy category, every component of this representing map is a weak equivalence. Hence the map is an objectwise weak equivalence and is invertible in the diagram homotopy category. This is the content needed for Der 2; it is not a formal

57. **N.B.** Loc (1 bis), *i.e.* $W = W^\natural$, est déjà impliqué par la condition que W soit stable par $\varinjlim$ filtrantes.
58. *Toujours ! Cf.* XIX, p. 29.

consequence of strong saturation of W alone. Compare the commentary on Chapter VI, manuscript p. 130.

Finite decomposition requires much less. A diagram on $I \amalg J$ is a pair of diagrams, and localization at the corresponding product class gives the product of the two localizations when identities belong to that class. This is the finite-product localization argument already discussed in the commentary on Chapter X, manuscript p. 5 ("Finite products and sums already descend"). It does not require the coproduct axiom Loc (5) for functors in Cat: a coproduct of *index categories* and a coproduct of *coefficient objects* are different operations.

Finally, shifts $I \mapsto \mathbf{D}(S \times I)$ are derivators, by Groth (2013, Theorem 1.25). Pointed versions therefore have the coherent fibre, cofibre, loop and suspension constructions needed for the sequences mentioned here. No assertion of stability is involved: for spaces, suspension and looping are not inverse equivalences, and cocartesian squares need not be cartesian. The older exactness axioms should be read in their pointed, unstable sense. The limitation to certain finite shapes for u_* is superseded under the modern model hypotheses; footnote 58 itself records that Grothendieck later removed it.

Commentary · Examples [ms. 135]

Constant objects retain coherent maps

The detection statement in 10.1(3a) becomes natural when we ask what the morphisms between constant diagrams actually are. The full subcategory of constant objects has all the morphisms inherited from the homotopy category of diagrams. These morphisms remember the indexing homotopy type, even though the displayed objects are constant. This is the same issue introduced in the commentary on Chapter I, manuscript pp. 61–62 ("Equivalence measured by constant coefficients" and "How much constant coefficients can detect"); the following computation makes its role in the present theorem explicit.

For the ordinary homotopy theory of spaces, write $BS = |N(S)|$ and let K, L be spaces. The derived space of maps between their constant diagrams on S is the homotopy limit of the constant mapping-space diagram, hence

$$\mathrm{Map}_{\mathrm{Fun}(S^{\mathrm{op}},\mathcal{S})}(\mathrm{const}\, K, \mathrm{const}\, L) \simeq \mathrm{Map}(BS, \mathrm{Map}(K, L)).$$

On connected components this gives

$$(*) \qquad \mathrm{Hom}_{\mathbf{D}(S)}(K_S, L_S) \cong [BS \times K, L].$$

One can obtain the same formula by the adjunction between homotopy colimit and the constant diagram functor: the homotopy colimit of the constant diagram K is $BS \times K$. This derivation also shows that restriction along $f : S' \longrightarrow S$ corresponds to precomposition with $Bf \times 1_K$.

If Bf is a weak equivalence, every such map of hom-sets is a bijection. Conversely, take $K = *$ and let L vary. Full faithfulness on constant objects says that

$$[BS, L] \longrightarrow [BS', L]$$

59. Sans aucun axiome sur W ! `[On a besoin simplement que les identités soient dans` W`.]`

60. On n'a besoin ici que de Loc (1 ter, 2, 3) (Loc (1 ter) est la saturation forte, *i.e.* $f \in W \iff \mathrm{hot}_W(f)$ isomorphisme).

is a bijection for every space L. The contravariant Yoneda lemma in the homotopy category then says that Bf is invertible there, hence is a weak equivalence. Essential surjectivity on the full constant subcategories is automatic: the constant object with value L on S' is the restriction of the constant object with value L on S. Thus full faithfulness and equivalence give the same test here.

For a concrete calculation let $S = B\mathbb{Z}$, the one-object category of the group $\mathbb{Z}$, and let $K = *$, $L = S^1$. Its classifying space is S^1. Formula $(*)$ gives

$$\mathrm{Hom}_{\mathbf{D}(B\mathbb{Z})}(*_{B\mathbb{Z}}, (S^1)_{B\mathbb{Z}}) \cong [S^1, S^1] \cong \mathbb{Z}.$$

The integer is the degree of the corresponding map. On restriction along the object $e \longrightarrow B\mathbb{Z}$, all these morphisms map to the unique element of $[*, S^1]$. The distinction between degrees has been forgotten. Consequently this restriction is not fully faithful on constant objects, exactly as the theorem predicts. Looking only at strict natural transformations between the original constant diagrams would miss these derived morphisms.

For a general W, the analogous proof uses the homotopy-colimit formula for constant families, product stability, invariance under passage to opposite categories, and strong saturation. These ingredients are available in the relative accessible setting of the preceding block. The smaller hypothesis list in footnote 60 should be read with the earlier construction it invokes, not as a new proof of those ingredients under weak Loc (3). In particular, strong saturation is what changes "the comparison is invertible in Hot_W" into "$f \in W$".

b) *Supposons que W satisfasse* Loc (1 ter, 2, 3, 5 b) (*donc l'axiome* Loc (5 b) *des W-fibrations, variante* b). *Alors pour toute $f : S' \longrightarrow S$ dans W,* $\mathrm{HOT}^{\mathrm{lc}}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_W(S')$ *est une* équivalence de catégories (*la réciproque étant clair par* (a)). *Itou pour*

$$\mathrm{HOT}^{\mathrm{lc}}_{W,I}(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_{W,I}(S') \qquad (\text{i.e. } \textit{pour } \mathrm{HOT}^{\mathrm{lc}/I}_W(S \times I) \longrightarrow \mathrm{HOT}^{\mathrm{lc}/I}_W(S' \times I)\ ).$$

En d'autres termes, pour le dérivateur HOT_W *et pour tous les* $\mathrm{HOT}_{W,I}$ (**D** *étant un des ces dérivateurs*) [61], *toute* **D***-équivalence est une* **D***-équivalence* 2*-complète,* i.e. *pour $f : S' \longrightarrow S$, pour que $f^* : \mathbf{D}(S) \longrightarrow \mathbf{D}(S')$ induise une équivalence entre les sous-catégories $\mathbf{D}^{\mathrm{lc}}(S) \longrightarrow \mathbf{D}^{\mathrm{lc}}(S')$, il suffit déjà qu'elle induise un foncteur pleinement fidèle sur les sous-catégories pleines formées des objets constants, et ceci équivaut (si $I \neq \emptyset$) à la condition que $f \in W$.*

Commentary · Development (commentators') [ms. 136] [page 137]

A finite monodromy test for the displayed hypotheses

The extra hypothesis in 10.1(3b) is meant to control locally constant families, whose fibres may be transported nontrivially around loops. There is a consequential numbering slip: the printed Loc (5 b) is described as the fibration axiom, but in the new list Loc (5 b) means reflection of coproducts. The intended reference is Loc (6 b), corresponding to W (4 b) in chapter XII. The distinction can be tested by a finite group.

Failure under the literal reduced list. [ours] Let $W_{\mathbb{Q}}$ be the functors inducing isomorphisms on rational homology of nerves. It satisfies strong saturation, the terminal-object axiom, relative Theorem A and coproduct reflection. Nevertheless there is $f \in W_{\mathbb{Q}}$ for which restriction on locally constant objects is not essentially surjective.

Proof. Strong saturation follows directly from the definition: rational homology factors through the localization, so an arrow made invertible by localization must induce an isomorphism on rational homology. The terminal-object assertion follows from contractibility of the nerve. Rational homology of a coproduct is the direct sum of the homologies of its summands. A block-diagonal direct sum map is invertible precisely when each component map is invertible, which proves coproduct preservation and reflection. That $W_{\mathbb{Q}}$ is a relative fundamental localizer follows from Cisinski (2006a, Corollary 9.4.3 and §9.4.4); equivalently, it is the nerve pullback of the homological localization of simplicial sets.

Choose a nontrivial finite group G, for example C_2. The map $p : BG \longrightarrow e$ belongs to $W_{\mathbb{Q}}$. Indeed, the augmentation $\mathbb{Q}[G] \longrightarrow \mathbb{Q}$ splits as a map of $\mathbb{Q}[G]$-modules by

$$1 \longmapsto \frac{1}{|G|} \sum_{g \in G} g.$$

61. À vérifier avec soin dans le cas $\mathbf{D} = \mathrm{HOT}_{W,I}$.

Thus the trivial module $\mathbb{Q}$ is projective, and

$$H_n(BG;\mathbb{Q}) = \operatorname{Tor}_n^{\mathbb{Q}[G]}(\mathbb{Q},\mathbb{Q}) = 0 \quad (n>0), \qquad H_0(BG;\mathbb{Q}) = \mathbb{Q}.$$

Let $A : (BG)^{\mathrm{op}} \longrightarrow \mathrm{Cat}$ be the discrete category on the regular right G-set, with its action. Every structure map is an isomorphism, so A is locally constant.

The component functor sends every $W_{\mathbb{Q}}$-map to a bijection. To verify this last point without a finiteness assumption, $H_0(NC;\mathbb{Q})$ is the vector space with basis $\pi_0(C)$, and a map induced by a function on those bases is invertible only when that function is bijective: two identified basis vectors give a nonzero kernel element, while an omitted basis vector cannot lie in the image. Applied objectwise, π_0 therefore descends to a functor

$$\mathrm{Cat}^{(BG)^{\mathrm{op}}}[W_{\mathbb{Q}}(BG)^{-1}] \longrightarrow \mathrm{Set}^{(BG)^{\mathrm{op}}}.$$

An object in the image of p^* has trivial G-action after this functor is applied. The regular G-set is nonempty and has no point fixed by all of G, so it is not equivariantly isomorphic to any nonempty trivial G-set. Hence A cannot be isomorphic to a constant object in the localized diagram category. This proves the failure of essential surjectivity. □

The example also satisfies the opening excision and size hypotheses of 10.1. For Loc (4), a simplex in the nerve of a category covered by two open subcategories lies in one of the two subcategories: for sieves, its last vertex determines this, and for the opposite convention its first vertex does. Consequently

$$C_*(NX, NX_2;\mathbb{Q}) \cong C_*(NX_1, NX_0;\mathbb{Q}).$$

The two inclusions $X_0 \longrightarrow X_1$ and $X_2 \longrightarrow X$ are rational homology equivalences precisely when these isomorphic relative chain complexes are acyclic. This proves both directions of Loc (4). Unlike the corresponding assertion for ordinary weak homotopy equivalences, this reverse implication is valid for the homological invariant used here.

For completeness, L-accessibility can be checked in the manuscript's own sense. Fix an infinite cardinal π and a rational homology equivalence $f : X \longrightarrow Y$. Start with a subarrow $f_0 : X_0 \longrightarrow Y_0$ having at most π arrows in total. The rational mapping cone $C_*(Nf_0;\mathbb{Q})$ has at most π elements. For every cycle in it choose a bounding chain in the acyclic cone $C_*(Nf;\mathbb{Q})$. Each bounding chain uses finitely many simplices. Adjoin all their objects and arrows, their images under f, and all necessary composites. This gives a subarrow f_1 still of size at most π. Repeat countably often. In the union $\bar{f}$, every cycle has finite support and therefore occurs at one stage; its chosen bounding chain occurs at the next. Thus $\bar{f} \in W_{\mathbb{Q}}$ and has size at most π.

It follows that the $W_{\mathbb{Q}}$-subarrows of size at most π are cofinal among all subarrows of that size and form a filtered family whose union is f. Rational chain complexes of nerves commute with filtered colimits, and filtered colimits of vector spaces preserve exactness, so $W_{\mathbb{Q}}$ is closed under all filtered colimits. There is a set of representatives of the arrows of size at most π. They generate $W_{\mathbb{Q}}$ under this closure. This is precisely the condition displayed in Loc (7 bis). It also gives the stronger bounded-subobject criterion used in the second Proposition 5.7: categories and functors of size at most π have presentations with at most π generators and relations, hence maps out of them factor through a stage of a π^+-filtered diagram, with equalities detected at a later stage. Thus the comparison with manuscript L-accessibility is explicit here; it is not inferred from the modern terminology.

The example therefore refutes the assertion with current Loc (5 b) read literally, even together with the opening assumptions. It does not refute the corrected assertion with the intended fibration axiom. The exact issue is that a test which preserves components of disjoint unions need not eliminate monodromy.

The regular action makes the missing fibration hypothesis visible as well. Its translation groupoid EG has one arrow between any two objects and is contractible. The projection $EG \longrightarrow BG$ has discrete fibre G. It is an old-style W-fibration: on a contractible base the discrete covering is trivializable, and a map between two such bases induces weak equivalences on the corresponding sheets. Compare it over BG with the identity fibration $BG \longrightarrow BG$. The map of total categories $EG \longrightarrow BG$ is a rational homology equivalence, while its fibre map $G \longrightarrow e$ is not. This directly violates Loc (6 b). Pullback along $e \longrightarrow BG$ also gives $G \longrightarrow EG$, which is not a rational homology equivalence because $|G| > 1$, illustrating failure of the base-change condition Loc (6 a). We checked the manuscript's earlier fibration variants at Grothendieck (1990–1991f, chapter XII, ms. 53–56) and the rational-localizer example in Cisinski's §9.4; we did not find this precise diagnostic of the

renumbered assertion stated there. The proof is offered as a check of the manuscript, not as a new claim about homological localization.

Commentary · Development (commentators') [ms. 136]

Why a nonempty shift still detects the base test

Footnote 61 asks that the shifted assertion be checked with care. One half is formal and explains exactly why the exclusion of the empty category is necessary. The other half needs a theorem about coherent diagrams with the shifted coefficient category; checking each value separately does not by itself prove full faithfulness of the whole diagram functor.

Reflection by a nonempty shift. [ours] Let $\mathbf{D}$ be a prederivator, let I have an object i, and put $\mathbf{D}^I(S) = \mathbf{D}(I \times S)$. If restriction along $f : S' \longrightarrow S$ is fully faithful on the full subcategories of constant objects for $\mathbf{D}^I$, then it is fully faithful on the corresponding full subcategories for $\mathbf{D}$.

Proof. The projection $I \times S \longrightarrow S$ and the inclusion $s \mapsto (i, s)$ induce functors

$$c_S : \mathbf{D}(S) \longrightarrow \mathbf{D}(I \times S), \qquad e_S : \mathbf{D}(I \times S) \longrightarrow \mathbf{D}(S)$$

with $e_S c_S = 1$, up to the canonical coherence isomorphism if pseudofunctors are used. These functors commute with restriction along f. If $A, B \in \mathbf{D}(e)$, the objects $c_S(A_S), c_S(B_S)$ are constant in the S-direction, with values $c_e(A), c_e(B) \in \mathbf{D}(I)$. Therefore the map

$$\mathrm{Hom}_{\mathbf{D}(S)}(A_S, B_S) \longrightarrow \mathrm{Hom}_{\mathbf{D}(S')}(A_{S'}, B_{S'})$$

is a retract, in the arrow category of sets, of the corresponding map between the hom-sets of the shifted constant objects. The latter is bijective by hypothesis. A retract of a bijection is bijective: if q is the large bijection, its inverse on the retract is obtained by inclusion, then q^{-1}, then retraction. The two commutative squares and the retraction identities verify both inverse equations. This proves full faithfulness. □

Every constant object on S' is the restriction of the constant object with the same coefficient on S, so the test is also reflection of equivalence between the full constant subcategories. The argument uses an object of I, not an initial or terminal object, and it does not require I to be connected. If $I = \emptyset$ and $\mathbf{D}$ satisfies the usual empty-index axiom, every category $\mathbf{D}^I(S)$ is terminal; every f then passes the test, so detection of W is impossible.

For the ordinary localizer W_∞, the forward statement and its locally constant refinement hold for every shift: apply Cisinski (2009, Theorem 1.3) to a model category of I-diagrams. This coefficient category retains coherent diagrams; it is not merely the ordinary functor category with values in Hot. The theorem just cited concerns nerve weak equivalences. It is not a theorem that every element of an arbitrary larger localizer preserves all locally constant coefficients; the preceding finite-group example explains why such a reformulation would be false. We checked this formal shifted argument against Groth (2013, Theorem 1.25) and the derivator discussion in Cisinski's §3, and supply the retract proof to settle the specific reflection point left implicit here.

Commentaire. Dans cet énoncé récapitulatif de ce que je sais prouver à présent pour HOT_W, j'ai un peu mélangé les provenances diverses – ce qui est mis "pour mémoire" de VI (et qui ne dépend pas de Loc (4, 7 ou 7 bis)), *i.e.* ce qui dépend pour l'essentiel de la construction de $u_!$ donnée dans VI (donc ce qui concerne $u_!$ dans 1°, *moins* l'exactitude à droite, et tout ce qui concerne 3°, (a), (b)).

La démonstration de 10.1 résultera des développements du paragraphe suivant `[qui n'existe pas]`, compte tenu du résultat principal du paragraphe 8 (th. 8.4), et du paragraphe 7 (cor. 7.4), qui sont les ingrédients "durs" du théorème 10.1.

Commentary · Later developments [ms. 137]

The later theorem and the scope of the unfinished proof

The principal construction announced here has a full modern realization through model categories and their diagram homotopy theories. Locally constant coefficients likewise have a precise invariant formulation: Cisinski (2009, Theorem 1.3 and Corollaries 1.28 and 3.8) proves invariance under nerve

weak equivalences, and conversely characterizes those equivalences by testing all model-category or derivator coefficients. In the published paper these are the numbers; the shorter preprint has different numbering. In higher-category language the underlying object is the functor category out of the groupoid completion of the indexing category, which is the perspective described in that paper's introduction.

The unresolved matters in these pages are therefore specific. The missing next paragraph does not provide a proof of 10.1 under each of its reduced hypothesis lists. The weak-versus-relative localization issue remains visible in 9.12 and in the claimed construction of $u_!$. The fibration reference in 10.1(3b) must be read after correcting its old numbering. None of these points is a reason to withhold the established constructions under their verified hypotheses, and none is repaired simply by citing a theorem about the ordinary localizer while leaving an arbitrary W in the statement.

Overview · XV-b

The end of Chapter XV asks how a homotopy theory can be constructed from a class of weak equivalences and a supply of small pieces. Grothendieck approaches that question in three stages. He first develops a calculus for classes recognized on bounded approximations. He then tries to turn that calculus into a general factorization theorem, discovers that the proof has lost its cardinal bound, and recovers a more structured theorem for monomorphisms. Finally, he applies the result to presheaves and returns to the axioms for a fundamental localizer and its associated derivator. The progression is mathematically instructive because the abandoned argument and the successful one use nearly the same constructions. What distinguishes them is control of the morphism left over after an attachment (Grothendieck, 1990–1991k).

The accessibility language must be read with its original conventions. A cardinal π is an infinite bound on sizes, and a filtered indexing category "large with respect to π" has the directedness now associated with the regular cardinal π^+. At a good cardinal, an object called π-accessible is therefore π^+-presentable in current terminology. The accessibility of a *class*, however, is not merely accessibility of its full subcategory. It is the embedded recognition condition b_π: in every continuous, suitably directed presentation by objects of the chosen bounded filtration, the colimit belongs to the class if and only if cofinally many stages do. The letter L adds closure under all small filtered colimits. These distinctions are essential both to the positive results of §5 and to the defect found in §6.

Under the standing subobject, image, and exactness assumptions, an object has a canonical presentation by its small subobjects. Proposition 5.7, its corollary, and the ensuing lemmas explain when a class can be recovered from its bounded part. The basic index is a directed poset closed under bounded directed suprema. A subset that is both cofinal and closed under those suprema can be intersected with another such subset without losing cofinality: alternately enlarge an approximation into each subset and take a countable supremum. A transfinite version gives intersections of at most π such subsets. The same idea proves closure of L-π-accessible classes under suitably bounded intersections. Finite unions use a different fact: among finitely many subsets covering a directed set, one is cofinal. Thus finite unions and arbitrary small intersections are available for the absolute L-accessibility notion, after increasing the witness cardinal when necessary.

The flattening argument in Proposition 5.9 deserves to be read alongside these cofinality calculations. A filtered family of objects, each described by bounded pieces, is replaced by the category of all those pieces mapping into the various stages. This category is an opfibration over the original index, with filtered fibres. Its total category is filtered, and the tautological source functor has the desired colimit. Regrouping the resulting diagram by its directed subdiagrams of cardinal at most π produces an adapted presentation. The commentary supplies the intervening finality and continuity arguments. It also records the precise limit of the written proof: the proposition advertises the weakened assumption (d_0), but its subobject proof uses stronger hypotheses. A complete proof is given under the full standing assumptions, and another under (d_0) at a good cardinal. We do not identify the remaining weakening with a disproved assertion.

The passage from objects to arrows comes from the theory of categories of sections in SGA 4, Exposé I, 9.22–9.24 (Artin et al., 1972). It requires a common cardinal bound large enough to accommodate the diagram's objects, structure maps, and equations. In the arrow category a bounded object has *both* bounded source and bounded target. Theorem 6.1 attempts to show that any L-accessible class of monomorphisms containing the isomorphisms is generated, in the lifting sense, by a small subcollection. Grothendieck builds a transfinite succession of attachments inside a fixed target. At the crucial step he invokes accessibility on a continuous family whose targets remain that fixed, possibly large object. His footnotes correctly withdraw the inference: this is no longer a presentation by bounded arrows.

The distinction can be seen without homotopy theory. For a set B larger than π, the arrows $S \hookrightarrow B$, indexed by the subsets S of size at most π, form a continuous, highly directed diagram with colimit id_B. None of its stages is an isomorphism, although the isomorphisms form an L-π-accessible class. This diagnoses the failed inference. To decide the proposed theorem itself requires more. A recent classification provides that decision: pure monomorphisms in the category of spans of sets are not cofibrantly generated (Cox et al., 2026b, Theorem 5.1). The development at manuscript page 84 proves that this class satisfies the manuscript's stronger recognition condition, as well as closure under pushouts, transfinite composition, and retracts. It is therefore an actual presheaf counterexample to Theorem 6.1. The cited authors prove the non-generation theorem; the commentary supplies its comparison with Grothendieck's cardinal filtration.

Section 7 succeeds by imposing structure which an arbitrary class does not have. In a presheaf category, two subobjects glued over their intersection form their union, still a subobject of the ambient object. Monomorphisms are stable under pushout and filtered colimits. Small quotient images of representables supply enough bounded pieces. If the class being constructed is $\mathrm{Mon} \cap W$, pushing out a bounded trivial monomorphism gives another weak equivalence, and cancellation in W proves that the residual inclusion is again a weak equivalence. The induction can therefore continue. Well-poweredness makes it terminate, by preventing a strictly increasing chain of subobjects from having arbitrarily large length.

Once a set of generators has been obtained, the small object argument gives two weak factorization systems. The remaining recognition condition is that every map right orthogonal to all monomorphisms belongs to W. A retract argument then identifies these maps with the trivial fibrations, and the two factorizations fit together into a model structure. The general recognition theorem later associated with Smith, in the form proved by Beke (2000, Theorem 1.7), places this reasoning in locally presentable categories. Its closure and solution-set hypotheses explain what survives of the question on manuscript page 85. They do not validate the unrestricted theorem of §6.

Section 8 turns the remaining recognition condition into geometry. For a small category A, the category-of-elements functor $i_A : \widehat{A} \to \mathrm{Cat}$ transports a fundamental localizer to a class W_A of presheaf maps. The subobject classifier, called the Lawvere object here, is injective with respect to monomorphisms. Its two disjoint sections provide the universal candidate for an interval. Theorem 8.4 relates universal asphericity of such an interval, triviality of maps right orthogonal to all monomorphisms, and the test-category property of every slice A/a. An additional asphericity condition on A itself gives the global test-category conclusion. These are statements about modelling homotopy types, not automatically about preserving their cartesian products.

The mapping-cylinder proof makes the interval criterion concrete. In its presheaf application, the endpoint inclusion is a trivial monomorphism and remains so after pushout. The resulting projection is a weak equivalence by two-out-of-three. The abstract Lemma 8.7 omits that pushout condition. The commentary gives an explicit counterexample in groups, then restores the needed hypothesis. It also presents the direct interval-lifting proof, available when the morphism being tested has the right lifting property against every monomorphism; this proof validates the reduced hypothesis formulation of the interval criterion without invoking the faulty abstract lemma. The corresponding later argument is Cisinski's Lemma 1.4.13 (Cisinski, 2006a).

Two other distinctions govern the application. First, the right properness criterion in (7.4.3) puts the fibration condition on the wrong vertical side of the pullback square; a small simplicial example detects the error. Second, the two converses in (8.2.4) belong to the manuscript's stronger excision axiom. They are not consequences of ordinary left properness and do not hold for arbitrary weak homotopy equivalences. Earlier commentary blocks indexed in DER XIIb discuss that obstruction; they are referred to here without reproducing them.

Cisinski's later model theorem for accessible fundamental localizers and local test categories supplies the intended presheaf construction using the appropriate gluing results (Cisinski, 2006a, Corollary 4.2.18). His term "accessible localizer" means generation by a set *as a localizer*; its relationship with accessibility of an arrow class is a theorem, rather than a change of spelling for L-accessibility.

The final two sections return from models to the intrinsic theory. Section 9 reorganizes the localizer axioms and studies how coproducts and connected components behave after localization. The distinction between weak Theorem A, Loc(3), and its relative version over an arbitrary base, Loc(3 bis), remains significant. The argument that a failure to preserve connected components collapses the localization to a point or to the walking arrow uses compatibility with products. The editors explicitly observe that this compatibility has not been obtained from the weak axiom alone. The commentary retains that qualification and proves the degeneration mechanism under the needed product hypothesis. Later treatments make the relative hypothesis and its consequences systematic; they should not be silently substituted for the weaker definition printed on these pages.

The decomposition problem also admits a useful direct argument. If a retract-closed class preserves connected components and a coproduct of maps belongs to it, each nonempty summand is an arrow-category retract of the whole map, by collapsing the other summands to a chosen point. An empty source summand has empty target because the total map preserves components. Thus reflection of weak equivalences by summands follows under these hypotheses. This specifies one setting in which the proposed independence of decomposition and connectivity cannot hold, while keeping the manuscript's weaker axiom system separate.

Theorem 10.1 gathers the desired conclusions for HOT_W: homotopy Kan extensions, pointwise detection of isomorphisms, strong saturation, and invariance of locally constant diagrams. Its promised next section is absent. Modern model-category and derivator results provide the appropriate existence statements under their stated hypotheses; the commentary identifies those hypotheses and the exact published references. Locally constant diagrams require particular care, because they retain monodromy. The printed reference to Loc(5 b) in part 3(b) is stale: the prose means the fibration axiom, now numbered Loc(6 b). A rational-homology equivalence $BC_2 \to e$, together with the nontrivial action of C_2 on a two-element set, shows why summand reflection alone cannot replace that fibration condition. The shifted statement likewise requires the nonempty indexing category indicated in the manuscript; an empty shift cannot detect a weak equivalence.

1 Axiomes Loc(1) à Loc(3) (et variantes) : localiseurs fondamentaux

p. 1
[page 1]

J'ai envie de reprendre l'exposé des axiomes utiles pour un localiseur fondamental

$$W \subset \mathrm{Fl}(\mathrm{Cat}),$$

en me guidant cette fois plus sur la signification géométrique des axiomes, que sur les alias ± techniques qu'on rencontre (ou ne rencontre pas) pour les vérifier. Je révise donc dans cet esprit la présentation de XV §9.

Loc (1) (*saturation*).

a) Iso $\subset W$.

b) Si deux parmi f, g, gf sont dans W, aussi le troisième.

c) Si gf et fg sont dans W, f et g aussi.

Les conditions (*a*) et (*b*) toutes seules, je vais les appeler (pour un $W \subset \mathrm{Fl}\,\mathcal{M}$ général) *saturation faible* du localiseur. Les conditions (*a*), (*b*), (*c*), *saturation modérée* ("mild saturation"). Autres variantes :

Loc (1 bis) Les conditions (*a*), (*b*), (*c*) du haut, plus

d) W stable par facteurs directs.

C'est bien sûr impliqué par :

Loc (1 ter) W est *fortement saturé, i.e.* si $f \in \mathrm{Cat}$ est telle que $\mathrm{hot}_W(f)$ est un isomorphisme, alors $f \in W$.

Loc (2) (*Objet final*). Si X dans Cat a un objet final, alors X est W-asphérique, *i.e.* $X \longrightarrow e$ est dans W.

Parfois, cet axiome est conséquence de la variante affaiblie suivante.

Loc (2_0) (Axiome du segment). $\mathbf{\Delta}^1$ est W-asphérique.

Loc (3) (*localisation,* forme faible). Soit $f : X \longrightarrow S$ une flèche dans Cat *W-asphérique, i.e.* telle que $\forall\ s \in \mathrm{Ob}\,S$, la catégorie localisée X/s sur S en s, $X/s = X \times_S S/s$, soit W-asphérique. Alors $f \in W$. [1]

[page 2]

Rappel 1. Loc (1, 2, 3) impliquent que l'on a

$$W = W^\circ \qquad \textit{i.e. } f \in W \iff f^\circ \in W,$$

où on dénote par $X \longmapsto X^\circ$, $f \longmapsto f^\circ$ le foncteur de passage à la catégorie opposée, foncteur

$$X \longmapsto X^\circ : \mathrm{Cat} \xrightarrow{\sim} \mathrm{Cat}$$

p. 2

qui est un *automorphisme* de Cat (donc commute à toutes $\varinjlim$ et $\varprojlim$). Il s'ensuit que l'ensemble d'axiomes Loc (1, 2, 3) équivaut à Loc (1, 2^{opp}, 3^{opp}), où Loc (2^{opp}) est l'axiome "dual" de Loc (2), savoir que tout objet de Cat ayant un objet initial est W-asphérique, et de même Loc (3^{opp}) l'axiome que toute $f : X \longrightarrow S$ *W-coasphérique, i.e.* telle que les catégories colocalisées $s\backslash X$ de X sur S soient W-asphériques, est dans W.

Définition 1.1. On appelle *localiseur fondamental* une partie W de Fl(Cat) satisfaisant les axiomes Loc (1, 2, 3) (*i.e.* saturation modérée, axiome de l'objet final, axiome de localisation).

1. Dans une version finale, il faudrait intervertir les notations pour Loc (3) et pour Loc (3 bis), car ce dernier m'apparaît comme le plus important des deux - il est satisfait pour tous les localiseurs qui ont été utilisées (à ma connaissance), et est valable pour tout localiseur de la forme $W_{\mathbf{D}}$, où $\mathbf{D}$ est un dérivateur (ou seulement un prédérivateur satisfaisant Der (4,5) `[il faut aussi Der (2) ; la numérotation des axiomes est celle du chapitre I, p. 68]`).

[page 3]

Commentary · Context [ms. 2]

Axioms for equivalences before a choice of model

Commentary and mathematical audit AI-produced by GPT-6 Astra (OpenAI, ChatGPT Pro mode), checked and integrated by Claude (Anthropic).

Grothendieck starts with a class of functors, rather than with cofibrations and fibrations. The distinction matters throughout this chapter: the latter classes are to be recovered, when possible, from stability properties of the former. His letter to Thomason of 2 April 1991, §1, describes precisely this separation between the equivalences carrying the homotopy theory and the auxiliary devices used to calculate it (Grothendieck, 1991a). Here the basic datum is a class W in Cat; the localization $L : \mathrm{Cat} \to \mathrm{Hot}_W$ exists in the chosen larger universe and need not come with a calculus of single fractions.

Three meanings of saturation must consequently remain distinct. The two-out-of-three property controls a composable pair. The extra condition (1c) controls a pair $f : A \to B$, $g : B \to A$ when both composites are already equivalences. It is just what is needed to recognize a homotopy inverse before one knows that every arrow inverted by L belongs to W. Closure under retracts is an additional requirement here. Strong saturation means $W = L^{-1}(\mathrm{Iso})$; it implies retract closure because an arrow which is a retract of an isomorphism is an isomorphism. One cannot substitute strong saturation silently in arguments made under (1).

There is also a consequential change of terminology in the later literature. Definition 1.1 calls the class satisfying (1,2,3) a fundamental localizer. Later authors generally call this a *weak* fundamental localizer and reserve the unqualified name for the relative axiom (3 bis). The distinction concerns the hypothesis of Theorem A, not merely a word. In (3), the comma categories X/s are individually aspherical. In (3 bis), the two comma categories may each have substantial homotopy, provided that the comparison between them is an equivalence. The latter implication does not follow by applying the former separately to $X \to S$ and $Y \to S$.

The editor's addition of Der (2) in footnote 1 is therefore mathematically substantive. A pointwise comparison of diagram objects gives an isomorphism only when the evaluations detect isomorphisms. The derivator axioms numbered here are those of Chapter I; importing a modern numbering without translating it would conceal the missing conservativity assumption. This is the same point already isolated in the commentary to XIIa on constructing localizers from derivators.

Rappel 1.2. Si W est un localiseur fondamental, alors tout *homotopisme* $f : X \longrightarrow Y$ de Cat est dans W (c'est pour cela essentiellement que l'on a imposé (c) dans la saturation modérée Loc (1)). Si $f, g : X \rightrightarrows Y$ sont homotopes (*i.e.* appartiennent à une même composante connexe de $\underline{\mathrm{Hom}}(X, Y)$), alors $\mathrm{hot}_W(f) = \mathrm{hot}_W(g)$ et $f \in W \iff g \in W$.

Voici la forme forte de Loc (3).

Loc (3 bis) (*Localisation,* forme forte). Soit S dans Cat et $f : X \longrightarrow Y$ un morphisme dans Cat/S tel que "f soit une W-équivalence localement sur S", *i.e.* pour tout $s \in \mathrm{Ob}\, S$, le morphisme induit

$$f/s : X/s \longrightarrow Y/s$$

pour les catégories localisées de X, Y sur S en s, soit dans W. Alors $f \in W$.

L'axiome Loc (3) n'est autre que le cas particulier de Loc (3 bis) relatif au cas où $Y = S$.

Proposition 1.3. *Soit $W \subset \mathrm{Fl}(\mathcal{M})$. Alors on a les équivalences suivantes*

$$\mathrm{Loc}\ (1,\ 2,\ 3) \iff \mathrm{Loc}\ (1,\ 2_0,\ 3')$$
$$\mathrm{Loc}\ (1,\ 2,\ 3\ \mathrm{bis}) \iff \mathrm{Loc}\ (1,\ 2_0,\ 3'\ \mathrm{bis}),$$

où les axiomes Loc $(3')$ *et* Loc $(3'$ bis$)$ *se formulent ainsi :*

Loc (3′) ⓐ (Axiome des Cat-fibrations, forme directe faible). Soient S dans Cat, X une catégorie fibrée scindée sur S, telle que les fibres X_s $(s \in \mathrm{Ob}\, S)$ soient W-asphériques. Alors $X \longrightarrow S$ est dans W. [page 4]

ⓑ Soit X dans Cat/S, alors $i_X : X \longrightarrow \Phi_S(X)$ est dans W [2].

2. (b) concerne la *comparaison* d'une X quelconque sur S, avec la catégorie fibrée scindée $\Phi_S(X)$ sur S.

Loc (3′ bis) ⓐ (Axiome des Cat-fibrations, forme directe forte). Soient S dans Cat, X, Y deux catégories fibrées scindées sur S, $f : X \longrightarrow Y$ un S-foncteur cartésien compatible aux scindages, tel que $\forall\ s \in \mathrm{Ob}\, S$, le foncteur induit sur les fibres p. 3

$$f_s : X_s \longrightarrow Y_s$$

soit dans W. Alors $f \in W$.

ⓑ Comme Loc (3′) (b).

N.B. En fait, moyennant Loc (1, 2), les énoncés Loc (3′), Loc (3′ bis) impliquent les énoncés similaires sans scindages, et sans même supposer f cartésien dans Loc (3′ bis), *cf.* démonstration ci-dessous.

Démonstration. a) Loc (1, 2, 3) $\Longrightarrow$ Loc (1, 2_0, 3′). Il suffit de prouver Loc (3′). Prouvons Loc (3′ a). Pour ceci, sous les conditions de Loc (3′ a), prouvons que $X \longrightarrow S$ est W-coasphérique, *i.e.* que les catégories

$$s\backslash X = X \times_S s\backslash S$$

sont W-asphériques. Il en résultera bien que $f \in W$ en vertu de Loc (3) appliqué à f° et de $W = W^\circ$. Mais considérons l'inclusion canonique [page 5]

$$i_s : X_s \hookrightarrow s\backslash X,$$

il résulte du fait que $p : X \longrightarrow S$ est Cat-fibrant que ce foncteur est W-asphérique (il a même un adjoint à droite, *i.e.* les catégories X_s/u, où $u \in \mathrm{Ob}\,(s\backslash X)$, ont un objet final). Donc par Loc (3) on a $i_s \in W$, et comme X_s est W-asphérique par hypothèse, de même $s\backslash X$, q.e.d.

Commentary · Exposition [ms. 4]

Comma categories replace a map by a fibration

The construction $\Phi_S(X)$ makes Proposition 1.3 transparent. For $p : X \to S$, its objects can be written

$$(s, x, \alpha : s \longrightarrow p(x)).$$

A morphism to (t, y, β) is a pair $(h : s \to t, k : x \to y)$ satisfying $p(k)\alpha = \beta h$. Projection to s is a split Grothendieck fibration; reindexing along $h : s \to t$ replaces (t, y, β) by $(s, y, \beta h)$. Thus its fibre over s is $s\backslash X$. The inclusion

$$i_X(x) = (p(x), x, \mathrm{id}_{p(x)})$$

has left adjoint $q(s, x, \alpha) = x$: a map from (s, x, α) to $i_X(y)$ is determined uniquely by $k : x \to y$. In particular, $qi_X = \mathrm{id}_X$, and the unit supplies the other homotopy. This explains the comparison axiom (3′b), including the direction of its adjoint.

If $p : X \to S$ is itself a fibration, the inclusion $X_s \to s\backslash X$ has a right adjoint: choose the cartesian pullback $\alpha^* x$ of x along $\alpha : s \to p(x)$. The adjunction follows from the defining universal property of a cartesian arrow. Its comma categories have terminal objects, so (2) and (3) put the inclusion in W. Consequently the fibrewise hypothesis can be transferred to the comma categories. This is the sole place where the fibration condition is doing work; a general functor's strict fibres need not compute the comma categories.

For example, take $S = (0 \to 1)$ and let $X = e$ map to 1. The strict fibre over 0 is empty, although $0\backslash X = e$. Replacing X by $\Phi_S(X)$ produces S itself. A condition on strict fibres of an arbitrary map would incorrectly reject this contractible example; the replacement repairs exactly that defect.

The reverse implication in the proposition first gets $\Delta^1 \times X \to X$ from the fibre axiom and the segment axiom. The two endpoint inclusions become equal inverses after localization. A natural transformation therefore makes its endpoint functors equal in Hot_W, and two-out-of-three gives the corresponding equivalence of membership in W. For a homotopy equivalence, (1c) then recognizes the two inverse functors as members of W. A category with a final or initial object is contractible by these natural transformations, which recovers (2). Finally the displayed square involving $\Phi_S(f)$ transfers the relative fibre condition back to f. This proof also explains why a chosen splitting and

preservation of its cartesian arrows are unnecessary in the final fibrewise criterion: the comparison with the comma categories works for every functor over S between fibrations. For the later systematic separation of fibrations and asphericity structures, see Maltsiniotis (2005, §1).

Two slips in the printed proof should not change the argument. The last conclusion on ms. 5 is $i_X \in W$, rather than its printed repetition $i_X^\circ \in W^\circ$. On ms. 7 the fibres $s\backslash X$ are *aspherical categories*; coasphericity properly describes the original map $X \to S$.

Prouvons Loc (3′ *b*) : On note que $i_X : X \longrightarrow \Phi_S(X)$ est W-*coasphérique* (il a même un adjoint à gauche), donc i_X° est W-asphérique, donc dans W, donc $i_X^\circ \in W^\circ$ car $W = W^\circ$.

a bis) Loc (1, 2, 3 bis) $\Longrightarrow$ Loc (1, 2_0, 3′ bis). Cette fois il faut prouver seulement Loc (3′ bis). Pour (*b*), c'est déjà fait. Reste à prouver (*a*). Si f est comme dans l'énoncé Loc (3′ bis *a*), prouvons que pour tout s dans S, le morphisme induit

$$s\backslash f : s\backslash X \longrightarrow s\backslash Y$$

est dans W. Comme $W = W^\circ$, on aura donc $(s\backslash f)^\circ \in W$, et appliquant Loc (3 bis) à f°, on trouve $f^\circ \in W$, donc $f \in W$, et on aura fini. Mais $s\backslash f$ s'insère dans le carré commutatif [page 6]

$$\begin{array}{ccc} X_s & \xrightarrow{f_s} & Y_s \\ {\scriptstyle i_s^X}\downarrow & & \downarrow{\scriptstyle i_s^Y} \\ s\backslash X & \xrightarrow{s\backslash f} & s\backslash Y, \end{array}$$

où, on l'a vu dans (*a*), i_s^X et i_s^Y sont dans W. Par hypothèse on a $f_s \in W$, donc $s\backslash f \in W$, p. 4
q.e.d.

b) Loc (1, 2_0, 3′) $\Longrightarrow$ Loc (1, 2, 3). Prouvons d'abord Loc (2). Appliquant Loc (3′ *a*) à la projection

$$\mathbf{\Delta}^1 \times X \longrightarrow X \qquad (\text{où } X \in \mathrm{Ob}\,\mathrm{Cat}),$$

qui est fibrée scindée à fibres isomorphes à $\mathbf{\Delta}^1$, donc W-asphériques par Loc (2_0), on voit que cette projection est dans W. Cela permet d'appliquer les arguments standard d'homotopie (*cf.* XII, p. 1 …) pour conclure qu'un homotopisme est dans W, donc une catégorie contractile est W-asphérique, a fortiori une catégorie avec objet final (ou avec objet initial) est W-asphérique, *i.e.* on a Loc (2).

Prouvons Loc (3). Comme Loc (1, 2, 3) $\Longleftrightarrow$ Loc (1, 2°, 3°), il suffit de prouver Loc (3°), vu qu'on a prouvé Loc (2°). Soit

$$f : X \longrightarrow S \qquad W\text{-}co\text{asphérique},$$

prouvons $f \in W$. Introduisons la catégorie *fibrée* sur S dont les fibres sont les $s\backslash X$, soit $\Phi_S(X)$, et considérons l'inclusion canonique

$$i_X : X \longrightarrow \Phi_S(X).$$

Par Loc (3′ *b*) elle est dans W. D'autre part, les fibres $s\backslash X$ de $\Phi_S(X)$ sont W-coasphériques [page 7]
par hypothèse, donc par Loc (3′ *a*) $\Phi_S(X) \longrightarrow S$ est dans W. Comme $i_X \in W$, il s'ensuit $(f : X \longrightarrow S) \in W$, q.e.d.

b bis) Loc (1, 2_0, 3′ bis) $\Longrightarrow$ Loc (1, 2, 3 bis). On a déjà prouvé Loc (1, 2, 3) (vu que Loc (3′ bis) contient Loc (3′) comme cas particulier). Prouvons donc Loc (3 bis) en admettant déjà tout ça. Il suffira encore de le prouver sous forme duale, puisque

$$\text{Loc (1, 2, 3 bis)} \iff \text{Loc(1, 2°, 3 bis°)},$$

et que Loc (2°) est connu par Loc (1, 2, 3) $\Longleftrightarrow$ Loc (1, 2°, 3°). Il reste donc à prouver que si [page 8]

$$f : X \longrightarrow Y \qquad \text{dans } \mathrm{Cat}/S$$

est telle que

$$s\backslash f : s\backslash X \longrightarrow s\backslash Y$$

est dans W pour tout $s \in \mathrm{Ob}\, S$, alors $f \in W$. Considérons alors le carré commutatif

$$\begin{array}{ccc} X & \xrightarrow{i_X} & \Phi_S(X) \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle \Phi_S(f)} \\ Y & \xrightarrow{i_Y} & \Phi_S(Y), \end{array}$$

où $i_X, i_Y \in W$ par Loc (3′ bis b). L'hypothèse sur f signifie que $\Phi_S(f)$ induit des W-équivalences sur les fibres, donc par Loc (3′ bis) $\Phi_S(f) \in W$, donc $f \in W$ par Loc (1), q.e.d.

p. 5

2 Axiomes Loc (4) et Loc (5) (des sommes directes, de connexité) [3]

Loc (4) (Axiome des *sommes directes*). Pour une famille $(f_i)_{i\in I}$ de flèches dans Cat, si $f = \coprod f_i$, on a $f \in W$ si et seulement si $f_i \in W$ pour tout $i \in I$.

Cet axiome se décompose en deux, en le "si" et le "seulement si", que je vais formuler sous la forme la plus économique :

Proposition 2.1. *L'axiome* Loc (4) *des sommes équivaut à la conjonction des deux axiomes suivants :*

[page 9]

Loc (4 a) Soit $(f_i)_{i\in I}$ une famille de flèches dans Cat, si les $f_i \in W$, alors $f = \coprod f_i \in W$.

Loc (4 b) Soit S dans Cat, et $S_0 \hookrightarrow S$ un sommand direct (sous-catégorie à la fois ouverte et fermée). Soit X dans Cat/S. Si $X \longrightarrow S$ est dans W, alors $X_0 = X|S_0 \longrightarrow S_0$ aussi. (En d'autres termes, l'inclusion $S_0 \hookrightarrow S$ est une "W-fibration", *i.e.* est dans Fib_W.)

Commentary · Later developments [ms. 8]

The weak minimum and the stronger axiom

There is a definitive later answer to one foundational issue that must be distinguished from the stronger-axiom problem. Let

$$W_\infty = \{f \mid |Nf| \text{ is a weak homotopy equivalence}\}.$$

Theorem 6.1.18 of Cisinski (2006a, pp. 242–243) proves that W_∞ is the *smallest weak fundamental localizer*. The cited pagination is that of the published Astérisque volume; an earlier author version places the same theorem at pp. 213–214. Definition 6.1.12 and Proposition 6.1.16, pp. 240–241, are indispensable for checking that this theorem really concerns the weak axiom used here. His split-retraction saturation condition follows from (1c), while W_∞ itself satisfies (1c), so the minimum comparison applies to the precise class of localizers in this manuscript. Thus every W of Definition 1.1 contains W_∞, and the intersection of all such W equals W_∞. It is not necessary to assume (3 bis) for this conclusion.

This does not prove that every weak localizer satisfies (3 bis). A theorem identifying the least objects in two partially ordered classes does not identify the two classes. Chiche explicitly records the latter problem as open in his 2014 thesis, Remark 2.1.15, and Cisinski still reported no example distinguishing the classes in his dated 2019 discussion (Chiche, 2014; Cisinski, 2019b). We found no

3. Il s'agit ici d'axiomes qu'on peut considérer comme étant de nature plus ou moins "triviale". Dans tous les cas à ma connaissance, ils sont bel et bien trivialement vérifiés.

resolution in the targeted literature search for this commentary. These are dated statements of the problem's documented status, not a claim that a search can certify the absence of every subsequent result.

There is a further useful distinction. Strong fundamental localizers in the later sense are strongly saturated, by Cisinski (2006a, Proposition 4.2.4). That theorem may be used after (3 bis) has been obtained. It cannot supply strong saturation for an arbitrary W satisfying just Definition 1.1. In particular, neither the finite-product arguments below nor the speculative reverse-excision axioms should acquire extra hypotheses invisibly through a change in terminology.

Corollaire 2.2. *Considérons la variante de* Loc (4 a) *obtenue en se bornant aux familles finies.* (*Elle équivaut à* Loc (4) *lorsque W est stable par* $\varinjlim$ *filtrantes,* cf. *axiome* Loc (8) *plus bas*). *Cette variante équivaut à*

Loc (4 a$_0$) Tout objet X de Cat est "W-cofibrant", *i.e.* $\emptyset \longrightarrow X$ est dans Cof_W, *i.e.* pour toute $f : Y \longrightarrow Y'$ qui est dans W, le morphisme correspondant $\mathrm{id}_X \amalg f : X \amalg Y \longrightarrow X \amalg Y'$ est dans W.

Rappel 2.3. De toutes façons, si W est un localiseur fondamental (ce que nous supposerons désormais, sauf mention du contraire), l'analogue *fini* de Loc (4 a) pour les produits est vrai, *i.e.* si on a une famille *finie* de flèches $(f_i)_{i\in I}$ dans Cat, si les f_i sont dans W, alors $f = \prod f_i \in W$. `[Pour cela, il faut supposer que` W `satisfait à l'axiome de localisation, forme` *`forte`*`, Loc 3 bis.]` L'analogue pour une famille infinie n'est vérifié pratiquement pour aucun localiseur fondamental.

Proposition 2.4. *Soit W un localiseur fondamental. Alors les produits finis existent dans* Hot_W*, et le foncteur* $\mathrm{hot}_W : \mathrm{Cat} \longrightarrow \mathrm{Hot}_W \overset{déf}{=} (\mathrm{Cat})W^{-1}$ *y commute. Si W satisfait à* Loc (4 a) (resp. Loc (4 a$_0$)), *alors les sommes quelconques* (resp. *finies*) *existent dans* Hot_W*, et le foncteur* hot_W *y commute. De plus, dans ce cas les sommes sont distributives par rapport aux produits (vu qu'il en est ainsi dans* Cat). [page 10]

Commentary · Exposition [ms. 9]

Sums and products require different hypotheses

The two halves of the sum axiom do different jobs. Closure under sums builds a global equivalence from component equivalences. Pullback along a summand recovers the component equivalences from the global one. Indeed, in a coproduct map $\coprod X_i \to \coprod Y_i$, the inverse image of the summand Y_i is exactly X_i. This proves Proposition 2.1. For finite sums, the factorization

$$f \amalg g = (\mathrm{id} \amalg g)(f \amalg \mathrm{id})$$

proves that closure is equivalent to the condition that each $\emptyset \to X$ is an intrinsic W-cofibration. Empty and one-term sums cause no problem because identities belong to W.

The parenthesis in Corollary 2.2 should say Loc (4*a*), rather than Loc (4). A coproduct is the filtered colimit of its finite partial coproducts, so filtered-colimit stability promotes finite *closure* to arbitrary closure. This argument gives no summand-reflection statement (4b). The later summary on ms. 15′ correctly supplies a separate fibration axiom for that half. For an explicit counterexample, let W_{ne} consist of all functors between nonempty categories, together with $\mathrm{id}_\emptyset$. This is even a strong localizer: a relative comma comparison cannot belong to it when its source is empty and its target has a chosen object. It is closed under arbitrary coproducts and filtered colimits, since both constructions preserve the test of nonemptiness. However, $e \to e \amalg e$ is in W_{ne}, while its pullback over the other summand is $\emptyset \to e$, which is not. Thus (4b) really fails. The printed parenthesis is retained as an edition slip.

For products the editors' qualification is equally necessary. With (3 bis), consider $f \times \mathrm{id}_C : A \times C \to B \times C$ over C. Over c the comparison is $f \times \mathrm{id}_{C/c}$. Since C/c has a final object, the projection $A \times (C/c) \to A$ has a right adjoint and belongs to W, and likewise for B. Two-out-of-three makes the local comparison a member of W; relative Theorem A then gives $f \times \mathrm{id}_C \in W$. Factoring a finite product into maps changing one coordinate proves finite-product stability. This proof specifically uses the relative axiom at its last step.

The source's phrase that infinite stability holds for practically no localizer should be read as an informal warning, not a quantified theorem. There are immediate degenerate exceptions, such as the class of all functors. Ordinary weak equivalences do not in general enjoy the asserted strict-product stability for arbitrary families of categories: Thomason (1980, pp. 306–308) exhibits the discrepancy using products of a category with two parallel arrows. The lesson needed here is simply that the finite argument must not be extended to infinitely many coordinate changes.

La démonstration résulte simplement du résultat général :

Lemme 2.5. *Soit* $(\mathcal{M}, W)$ *une catégorie de modèles (*W *partie quelconque de* $\mathrm{Fl}\,\mathcal{M}$*). Supposons que les produits* (resp. *les produits finis,* resp. *les produits binaires*) *existent dans* $\mathcal{M}$*, et que de plus pour toute famille* $(f_i)_{i\in I}$ *de flèches de* $\mathcal{M}$ (resp. *toute famille finie,* resp. *famille binaire*) $f_i \in W$ *pour tout* $i \in I$ *implique* $f = \prod f_i \in W$*. Alors les produits du type envisagé existent dans* $\mathrm{Ho}_W = \mathcal{M}W^{-1}$*, et le foncteur* $\mathrm{ho}_W : \mathcal{M} \longrightarrow \mathcal{M}W^{-1}$ *y commute. Enfin, si* $\mathcal{M}$ *admet un objet final* e*, alors* e *est aussi objet final de* Ho_W*.* p. 6

[Il n'est pas clair que l'assertion soit vraie dans cette généralité pour les produits *infinis* ; elle est vraie si W est la classe des équivalences faibles d'une *catégorie de modèles de Quillen.*]

On en conclut les énoncés duaux concernant les sommes directes et les objets initiaux. [page 11]

Commentary · Development (commentators') [ms. 10]

A missing hypothesis in the product lemma

A finite counterexample to the literal generality of Lemma 2.5. [ours] The qualification "W an arbitrary subset" already causes a problem for binary products, independently of the editors' infinite-product warning. Let $\mathcal{M}$ be the four-element Boolean lattice

$$0 < a < 1, \qquad 0 < b < 1,$$

with a and b incomparable, regarded as a category, and put

$$W = \{\mathrm{id}_1,\ a \longrightarrow 1\}.$$

All small products exist and are meets. A product of arrows in W is id_1 if all factors are identities, and is $a \to 1$ otherwise; this includes the empty product. Thus even the strongest product-closure hypothesis printed in the lemma holds.

After localization a and 1 are isomorphic, but 0 and b are not. To verify the latter assertion without guessing the localized category, use the functor to the chain $0 < b < 1$ sending a to 1 and fixing $0, b, 1$. It inverts W, hence factors through the localization, and distinguishes 0 from b. Since $a \times b = 0$ in $\mathcal{M}$, preservation of binary products would make the image of 0 a product of the images of 1 and b. The image of 1 remains terminal, so this product is the image of b, a contradiction. This elementary counterexample is included to repair the wording, with no claim of historical priority.

The appropriate finite version assumes that W contains all identities, as explicitly in Maltsiniotis (2020, Lemma 2.1.7 and Proposition 2.1.8, pp. 114–115). For finite I, localization then commutes with the product of relative categories:

$$(\mathcal{M}^I)[(W^I)^{-1}] \simeq (\mathcal{M}[W^{-1}])^I.$$

One can prove this by changing one coordinate at a time. Every formal inverse in one coordinate lifts to an inverse of a tuple with identities in the other coordinates; coordinate changes commute, and finitely many finite words combine into one finite word. If products preserve W, the diagonal/product adjunction therefore descends and proves the corrected finite lemma. The same reasoning applies to coproducts. Every localizer under consideration in the chapter contains identities, so the counterexample does not affect those finite applications.

For infinite I, coordinatewise finite words need not have a common finite length; the displayed comparison is no longer a formal consequence of the localization universal property. We do not claim a general resolution of the infinite variant under just its printed assumptions. In a Quillen model category the editors' repair works: the product of fibrant replacements computes the derived product, and assumed closure of W under these products identifies it with the ordinary product. Proposition 2.4 should accordingly be read with the editors' strong-localization hypothesis for finite products and with a separate justification whenever arbitrary coproducts are asserted; the finite adjunction argument alone is insufficient for an infinite family.

La démonstration est un cas particulier du résultat bien utile suivant, appliqué au couple de foncteurs adjoints

$$\mathcal{M} \underset{\text{produits dans } \mathcal{M} \text{ indexés par } I}{\overset{\text{diag}}{\rightleftarrows}} \mathcal{M}^I \qquad :$$

Lemme 2.6 [4]. *Soient $(\mathcal{M}, W)$, $(\mathcal{M}', W')$ deux catégories de modèles, et*

$$\mathcal{M} \underset{\psi}{\overset{\varphi}{\rightleftarrows}} \mathcal{M}'$$

un couple de foncteurs adjoints compatibles aux localiseurs, i.e. *tels que*

$$\varphi(W) \subset W', \qquad \psi(W') \subset W.$$

Alors les foncteurs localisés

$$\mathcal{M}W^{-1} \underset{\bar{\psi}}{\overset{\bar{\varphi}}{\rightleftarrows}} \mathcal{M}'W'^{-1}$$

sont également adjoints, les flèches d'adjonction pour $\bar{\varphi}\bar{\psi}$ et $\bar{\psi}\bar{\varphi}$ étant déduites de celles pour $\varphi\psi$ et $\psi\varphi$ par composition avec les foncteurs de localisation $\mathcal{M} \longrightarrow \mathcal{M}W^{-1}$, $\mathcal{M}' \longrightarrow \mathcal{M}'W'^{-1}$.

Loc (5) (Axiome de *connexité* ou de *non-trivialité*).

[page 12]

Commentary · Exposition [ms. 11]

What descends from an adjunction

Lemma 2.6 itself has no product-size defect. Suppose $F : \mathcal{M} \rightleftarrows \mathcal{N} : G$ is an adjunction and both functors send the designated equivalences into equivalences. Its unit and counit give natural transformations after localization. To check naturality on a formally inverted arrow, invert the corresponding naturality square; thus naturality on ordinary arrows suffices. The two triangle identities remain identities after applying the localization functors. They prove $\overline{F} \dashv \overline{G}$ directly, without a calculus of fractions or any claim that localization commutes with an infinite product of categories.

This also proves the final assertion of Lemma 2.5 for an arbitrary class W: a terminal object remains terminal. Use the adjunction between the unique functor $\mathcal{M} \to e$ and the selection of its terminal object, allowing the image of designated arrows to be merely inverted, as the universal property permits. Dually an initial object remains initial. Strictness is another matter; localization may create arrows into an initial object by reversing arrows out of it. The hypotheses of Lemma 2.14 are designed precisely to prevent that phenomenon. Keeping existence, strictness, and preservation of an entire family of products separate prevents several otherwise tempting shortcuts in the next pages.

Soit $f \in W$, alors $\pi_0(f)$ est bijectif.

Cette propriété de W est d'une utilisation constante en pratique, quand on travaille avec W au lieu de se borner à construire des W et faire joujou avec les axiomes et leur stabilité par passage à des $\underline{\mathrm{Hom}}(I, M)$ (où ici $\mathcal{M} = \mathrm{Cat}$). D'autre part, on peut aussi le regarder comme un axiome de *non-trivialité* pour Hot_W. Je rappelle à ce sujet :

Proposition 2.7. *Soit W un localiseur fondamental. Conditions équivalentes :*

a) *W satisfait l'axiome de connexité* Loc (5).

b) *Le foncteur $\pi_0 : \mathrm{Cat} \longrightarrow \mathrm{Ens}$ se factorise par un foncteur*

$$\mathrm{Cat} \dashrightarrow \mathrm{Hot}_W \xrightarrow{\pi_0} \mathrm{Ens}. \qquad \text{(} \pi_0 \text{ : Hot}_W \to \text{Ens)}$$

p. 7

4. *cf.* XII, lemme page 248.

c) *La catégorie* $\mathrm{Hot}_W^* = \mathrm{Hot}_W \backslash \{\emptyset\}$ *n'est pas équivalente à la catégorie ponctuelle.*

c′) *La catégorie* Hot_W *n'est pas équivalente à e ni à* $\mathbf{\Delta}^1$.[5]

Pour la démonstration, et pour d'autres formes équivalentes de l'axiome de connexité, je renvoie à XV 9.12 (p. 133 bis). Pour le nom "axiome de connexité", je peux offrir l'explication suivante 2.8 et 2.9. [page 13]

Commentary · Present state [ms. 13]

Connectivity and a hypothesis hidden in the recalled proof

The equivalence of (2.7a) and (2.7b) is exactly the universal property of localization: π_0 factors if and only if it inverts W. The remaining equivalences require more care than the reference to XV might suggest. In the proof of XV, Proposition 9.12, ms. 133 quinquies, the editors explicitly flag the use of finite-product preservation as unproved under the weak axioms (1,2,3); it is available under (3 bis) (Grothendieck, 1990–1991k). Thus XVI, Proposition 2.7 inherits a missing hypothesis in the cited proof. We do not turn this gap into either a counterexample or an assertion that the weak formulation is an established theorem.

Here is the complete argument once finite-product preservation is supplied, in particular under (3 bis). Suppose $f : A \to B$ belongs to W but does not induce a bijection on components. If two different components of A are identified, choose points in them and a map $A \to \{0, 1\}$ separating them. Their images in B are connected, hence equal as points after localization, so invertibility of f makes the two sections of $\{0, 1\} \to e$ equal in Hot_W. If a component of B is missed, compare the constant map $B \to \{0, 1\}$ with a map which is 1 on that component and 0 on the image of A. Their composites with f agree. Inverting f and evaluating at a point in the missed component gives the same equality of sections.

Product preservation now makes the two inclusions $X \to X \amalg X$ equal for every X. Composing with a map specified by any two functors $X \rightrightarrows Y$ shows that their localized images are equal. For nonempty X, a chosen point $e \to X$ is therefore inverse to $X \to e$. The localization is equivalent to Δ^1 if no arrow from the empty category to a nonempty category is inverted, and to e otherwise. Conversely, if π_0 factors, the discrete categories with different numbers of objects remain distinguishable, so neither degeneration occurs.

Corollary 2.8's forward implication has no such gap: $X \to e$ in W immediately gives $\pi_0 X = \{*\}$. Its converse, as argued through the recalled classification and strong saturation, needs the same repair to that classification. The test of Corollary 2.9 has a direct proof independent of it. Pull a W-map back to each component of its target using (4b); the stated connected-target condition says that every inverse image is nonempty and connected, exactly the bijectivity of π_0. The rest of this section explicitly assumes (5), so the concrete description of points below does not depend on the unresolved weak-hypothesis step.

Corollaire 2.8. *Si l'axiome de connexité* Loc (5) *est satisfait, alors les objets W-asphériques sont* 0*-connexes* (*tautologie*), *et la réciproque est vraie si W est fortement saturé.* (*Ou aussi, si W satisfait l'axiome des fibrations* Loc (7) *ci-dessous, puisque par* XII, th. 2, p. 20, *dans ce cas,* Loc (5) *équivaut à* $W \neq \mathrm{Fl}(\mathcal{M})$ …).

Car si l'axiome de connexité n'est pas satisfait, alors pour toute X non vide dans Cat, $X \longrightarrow e$ est un isomorphisme, donc (W étant fortement saturé) $X \longrightarrow e$ est dans W, *i.e.* X est W-asphérique, donc il y a des objets W-asphériques non 0-connexe. Notons aussi :

Corollaire 2.9. *Supposons que W satisfait à l'axiome* Loc (4) *des sommes directes* (*ou seulement à* Loc (4 b)). *Pour que W satisfasse l'axiome de connexité, il faut et il suffit que pour toute flèche* $f : X \longrightarrow Y$ *avec Y* 0*-connexe, si f est dans W, alors X est* 0*-connexe.* (*C'est nécessaire bien sûr sans supposer* Loc (4 b) *ni rien du tout.*)

`[Les numéros 2.7, 2.8 et 2.9 apparaissent deux fois.]` [page 14]

5. **NB** Si W est fortement saturée (condition Loc (1 ter), alors les conditions ci-contre (*i.e.* Loc (5)) équivalent à ceci :

d) *W n'est égal ni à Fl*(Cat) *tout entier, ni à Fl*(Cat^*) $\cup$ $\{\mathrm{id}_\emptyset\}$ (i.e. *Fl*(Cat)$\backslash W$ *n'est ni vide, ni égal à l'ensemble des flèches* $\emptyset \longrightarrow X$ *avec* $X \neq \emptyset$).

Si W satisfait Loc (7 D_{W_ω}), alors W satisfait Loc (5) si et seulement si $W \neq \mathrm{Fl}(\mathrm{Cat})$ (*cf.* XII, th. 2, p. 20).

2.7. Considérons maintenant le foncteur composé

$$\text{(2.7.1)} \qquad \text{Ens} \xrightarrow{I \longmapsto I_{\text{Cat}}} \text{Cat} \xrightarrow{\text{hot}_W} \text{Hot}_W, \qquad I \longmapsto I_{\text{Hot}_W} \text{ ou } I_W,$$

où le premier foncteur est celui qui associe à l'ensemble I la catégorie discrète I_{Cat} ayant I comme ensemble d'objets. (Le plus souvent, on identifiera I_{Cat} avec I dans les notations, tout comme pour un ensemble ordonné J, on identifie J et la "catégorie ordonné" définie par J. Ici I peut être considéré comme muni de l'ordre discret.) On a d'ailleurs

$$\text{(2.7.2)} \qquad I_{\text{Cat}} \simeq I \times e \quad (\overset{\text{déf}}{=} \text{somme de } I \text{ copies de } e),$$

donc quand Loc (4 a) est satisfait, donc hot_W commute aux sommes directes, on aura un isomorphisme canonique

$$\text{(2.7.3)} \qquad I_W \simeq I \times e_W \quad \begin{array}{l}(\text{où } e_W \text{ est l'objet final de Hot}_W,\\ \textit{i.e. } e \text{ considéré comme objet de Hot}_W).\end{array}$$

Proposition 2.8. *Supposons l'axiome de connexité* Loc (5) *satisfait, d'où un foncteur* p. 8

$$\text{(2.8.1)} \qquad \pi_0 : \text{Hot}_W \longrightarrow \text{Ens}.$$

Ce foncteur est adjoint à gauche *du foncteur* $I \longmapsto I_W$ (2.7.1), i.e. *on a une bijection fonctorielle en* (X, I) *dans* $\text{Hot}_W \times \text{Ens}$:

[page 15]

$$\text{(2.8.2)} \qquad \text{Hom}_{\text{Ens}}(\pi_0(X), I) \simeq \text{Hom}_W(X, I_W).$$

Le foncteur π_0 *est également* adjoint à droite *du* même *foncteur* $I \longmapsto I_W$, i.e. *on a un bijection fonctorielle*

$$\text{(2.8.3)} \qquad \text{Hom}_{\text{Ens}}(I, \pi_0(X)) \simeq \text{Hom}_W(I_W, X).$$

Prenant $I = e$ (ensemble ponctuel), on trouve le :

Corollaire 2.9. *On a l'isomorphisme fonctoriel en* X *dans* Hot_W

$$\text{(2.8.4)} \qquad \boxed{\text{Hom}_W(e_W, X) \simeq \pi_0(X).}$$

Commentaire 2.10. La formule d'adjonction (2.8.2) est d'ailleurs familière, chaque fois qu'on a une catégorie $\mathcal{H}$ (telle Cat, où Hot_W *etc.*) munie d'un foncteur π_0, $\pi_0(X)$ correspondant à l'intuition d'une décomposition d'un objet en "composantes connexes". (Je ne vais pas expliciter ici les conditions générales sous lesquelles on définit un tel foncteur.) Par contre, l'adjonction en sens inverse de ces deux mêmes foncteurs est un phénomène tout à fait spécial à des catégories du type Hot_W. Si on tient compte de la description de I_W comme $I \times e_W$, la formule d'adjonction inhabituelle (2.8.3) équivaut, bien sûr, à la formule (2.8.4) [page 16]
- elle s'en déduit en "élevant à la puissance I". On peut renverser la vapeur, et dans une catégorie générale $\mathcal{H}$, *définir* un foncteur $\pi_0 : \mathcal{H} \longrightarrow \text{Ens}$ par le formule (2.8.4),

$$\pi_0(X) \overset{\text{déf}}{=} \text{Hom}(e_{\mathcal{H}}, X) \qquad (= \Gamma_{\mathcal{H}}(X), \text{ avec une notation familière}),$$

où $e_{\mathcal{H}}$ est un objet final de $\mathcal{H}$. On aura donc, en posant $I_{\mathcal{H}} = I \times e_{\mathcal{H}}$, la formule

$$\text{Hom}(I_{\mathcal{H}}, X) \xrightarrow{\sim} \text{Hom}(I, \pi_0(X))$$

(*i.e.* la formule (2.8.3)), disant que l'on a un couple $(I_{\mathcal{H}}, \pi_0)$ de foncteurs adjoints. Supposons d'autre part que pour tout ensemble I, l'application canonique d'adjonction

$$I \longrightarrow \pi_0(I_{\mathcal{H}}) = \text{Hom}_{\mathcal{H}}(e_{\mathcal{H}}, e_{\mathcal{H}} \times I)$$

soit *bijective*[6], *i.e.* que $I \longmapsto I_{\mathcal{H}}$ soit *pleinement fidèle.* On définit alors, pour tout I, une application canonique

Commentary · Exposition [ms. 15]

The double adjunction without an infinite-coproduct shortcut

Write $d(I) = I_W$ for the image of the discrete category on a set I. The first adjunction $\pi_0 \dashv d$ follows by localizing the familiar adjunction on Cat: every functor to a discrete category is constant on components. The second,

$$d \dashv \pi_0, \qquad \mathrm{Hom}_{\mathrm{Hot}_W}(dI, X) = \mathrm{Set}(I, \pi_0 X),$$

is special to the localized situation. In the printed proof it is reduced to $I = e$ by treating dI as the coproduct of I copies of e. For arbitrary I that reduction calls on the earlier infinite-coproduct assertion. The following direct proof avoids it and works with just (1,2,3,5).

First suppose two functors $u, v : I \to X$ choose points in the same component for every i. For each i choose a finite zigzag joining $u(i)$ to $v(i)$, and let J_i be its walking zigzag category. Its nerve is contractible, so $J_i \to e$ is in $W_\infty \subset W$; alternatively this follows by successive elementary contractions. Put $J = \coprod_i J_i$. The projection $J \to I$ has comma category J_i over i, and (3) therefore puts it in W directly, without (4). Its two endpoint sections are both inverse to it in the localization. Composing with the chosen functor $J \to X$ proves $L(u) = L(v)$. The lengths of the individual zigzags need not be bounded.

Next let $w : X \to Y$ belong to W and let $u : I \to Y$. Surjectivity of $\pi_0(w)$ allows a choice $s : I \to X$ such that ws and u lie in the same component pointwise. The previous paragraph gives $L(w)L(s) = L(u)$. Any localization morphism from dI is represented by a finite word of ordinary arrows and inverses of arrows in W. Whenever its first reversed arrow occurs, this lifting replaces the preceding part of the word by an ordinary map from I. Induction eliminates all reversed arrows. Thus every morphism $dI \to X$ is represented by an actual functor $I \to X$; two representatives agree exactly when their component functions agree, since the descended π_0 detects that distinction. This proves the desired natural bijection, including $I = \emptyset$.

Taking $I = e$ proves Corollaries 2.9 and 2.12. Taking $X = dJ$ shows that d is fully faithful. It also proves, rather than assumes, that dI is the coproduct of I copies of e in Hot_W, since its maps to X are the I-indexed families of points of X. Here $I \times e$ denotes a *copower*, as the source says; it is not an assertion that an external set is already an object participating in a categorical product.

p. 9

$$\begin{array}{ccc} \mathrm{Hom}(X, I_{\mathcal{H}}) & \longrightarrow & \mathrm{Hom}(\pi_0(X), I) \\ & {\scriptstyle \pi_0^{X, I_{\mathcal{H}}}} \searrow \quad \nearrow {\scriptstyle \sim} & \\ & \mathrm{Hom}(\pi_0(X), \pi_0(I_{\mathcal{H}})). & \end{array}$$

La "bi-adjonction" des foncteurs π_0 et $I \longmapsto I_{\mathcal{H}}$ revient à dire que cette flèche est bijective, ou encore, que la flèche $\pi_0^{X, I_{\mathcal{H}}}$: [17]

$$\mathrm{Hom}(X, I_{\mathcal{H}}) \longrightarrow \mathrm{Hom}(\Gamma_{\mathcal{H}}(X), \Gamma_{\mathcal{H}}(I_{\mathcal{H}}) \simeq I)$$

soit bijective.

Corollaire 2.11. *Le foncteur $I \longmapsto I_W$ de* Ens *dans* Hot_W *est pleinement fidèle,* i.e. *l'homomorphisme d'adjonction*

$$\pi_0(I_W) \longrightarrow I$$

est bijectif. (*Où encore, π_0 est un foncteur le localisation.*)

En effet, cette bijectivité est évidente quand on travaille dans Cat, et s'en déduit aussitôt dans Hot_W.

6. ça a tendance à être ultrafaux si $\mathcal{H}$ est additive. Par contre, vrai si $\mathcal{H}$ est une catégorie à sommes distributives par rapport aux produits (voire universelles), dont l'objet final est *connexe* …

Commentary · Examples [ms. 17]

Why the two adjunctions are exceptional

For a category $\mathcal{H}$ with terminal object e and the required coproducts, the copower functor $dI = \coprod_I e$ is automatically left adjoint to $\Gamma = \mathrm{Hom}(e, -)$. The unit $I \to \Gamma(dI)$ is bijective precisely when d is fully faithful. Neither this condition nor the existence of coproducts automatically supplies the other adjunction: that further assertion is that every function $\Gamma(X) \to I$ comes from exactly one morphism $X \to dI$.

The examples distinguish the conditions. In sets both adjunctions hold with $d = \Gamma = \mathrm{id}$. In Cat, d is fully faithful and $\pi_0 \dashv d$, but $\Gamma(X) = \mathrm{Ob}\,(X)$ is usually different from $\pi_0 X$; two objects joined by an arrow still define different functors $e \to X$. Localization makes those two functors equal. In an additive category the terminal object is the zero object, so every copower of it is again zero and $\Gamma(X)$ is a singleton. Consequently $I \to \Gamma(dI)$ is bijective only for singleton I. This explains the warning in footnote 6 without treating additivity as a mild exceptional case of the asserted unit condition.

In the triangular display the edition prints the horizontal top arrow as well as the two dotted downward arrows, the right one labelled $\sim$; the transcription keeps all three. The top arrow is the composite of the left arrow with the inverse of the right arrow, exactly as the surrounding prose requires.

Démonstration de 2.8. La formule d'adjonction (2.8.2) résulte de la formule correspondante pour Cat, évidente, et du lemme 2.6 sur les foncteurs adjoints entre catégories de modèles. L'adjonction dans l'autre sens se réduit à la formule (2.8.4). On a des flèches canoniques

$$\mathrm{Hom}_W(e_W, X) \underset{\beta}{\overset{\alpha}{\rightleftarrows}} \pi_0(X),$$

où α est $\pi_0^{e_W, X}$, compte tenu que $\pi_0(e_W) = \pi_0(e_{\mathrm{Cat}}) = e_{\mathrm{Ens}}$, et $\mathrm{Hom}(e_{\mathrm{Ens}}, \pi_0(X)) \simeq \pi_0(X)$. La flèche β est la flèche composée

$$\mathrm{Ob}\, X \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{Cat}}(e_{\mathrm{Cat}}, X) \xrightarrow{\mathrm{hot}_W} \mathrm{Hom}_W(e_W, X)$$

en notant que cette flèche passe au quotient en $\pi_0(X) \longrightarrow \mathrm{Hom}_W(e_W, X)$, vu que deux [18]
applications homotopes de e_{Cat} dans X sont égales dans Hot_W. Je dis que

$$\beta\alpha = \mathrm{id}\ , \qquad \alpha\beta = \mathrm{id}\ .$$

La relation $\alpha\beta = \mathrm{id}$ revient à dire que la flèche $i_x : e_{\mathrm{Cat}} \longrightarrow X$ définie par $x \in \mathrm{Ob}\, X$, donne $\pi_0(i_x) : e_{\mathrm{Ens}} \longrightarrow \pi_0(X)$ dont la valeur est la classe de x dans $\pi_0(X)$, c'est tautologique. Pour prouver que $\beta\alpha = \mathrm{id}$, il suffit alors de prouver que β est surjective, *i.e.* le

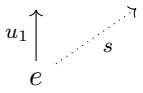
Corollaire 2.12. *Pour tout X dans* Cat, *l'application*

$$\underbrace{\mathrm{Hom}_{\mathrm{Cat}}(e_{\mathrm{Cat}}, X)}_{\simeq \mathrm{Ob}\, X} \longrightarrow \mathrm{Hom}_W(e_W, X)$$

est surjective (*moyennant l'axiome de connexité* Loc (5)). p. 10

Démonstration de 2.12. Si $X = \emptyset$, l'assertion revient à dire que $\mathrm{Hom}_W(e_W, \emptyset) = \emptyset$, mais plus généralement, on a le

Corollaire 2.13. (Moyennant Loc (5).) *Soit X non vide dans* Cat, *alors* $\mathrm{Hom}_W(X, \emptyset) = \emptyset$. (*Donc $\emptyset$ est un objet initial* strict *de* Hot_W.)



En effet, si on avait $X \longrightarrow \emptyset$ dans Hot_W, `[il y a un décalage dans la numérotation]` [page 13']
on en déduirait $\pi_0(X) \longrightarrow \emptyset$, ou $\pi_0(X) = \emptyset$, absurde !

Reste le cas où X est non vide. Cela résulte du fait général :

Lemme 2.14. *Soit $\mathcal{M}$ une catégorie ayant un objet initial* strict (*si* $\mathrm{Hom}_{\mathcal{M}}(X, \emptyset_{\mathcal{M}}) \neq \emptyset$, *on a* $X = \emptyset_{\mathcal{M}}$), *un objet final e, et telle que pour tout $X \neq \emptyset_{\mathcal{M}}$, $X \longrightarrow e$ ait une section,* i.e. $\mathrm{Hom}(e, X) \neq \emptyset$. *Soit* $W \subset \mathrm{Fl}\, \mathcal{M}$

1°) *ne contenant pas de flèches* $\emptyset_{\mathcal{M}} \longrightarrow X$ *avec* $X \neq \emptyset_{\mathcal{M}}$, *et*

2°) *tel que pour tout diagramme* $X_1 \xleftarrow{u_2} X_2$ *avec* $u_2 \in W$ $\exists$ s dans $\mathcal{M}$ *tel que* $u_2 s = u_1$

dans $\mathcal{M}W^{-1}$.

Alors

a) $\emptyset_{\mathcal{M}}$ *est un objet initial* strict *de* $\mathcal{M}W^{-1}$.

b) *Pour tout* $X \neq \emptyset_{\mathcal{M}}$, $\mathrm{Hom}_{\mathcal{M}}(e, X) \longrightarrow \mathrm{Hom}_W(e, X)$ *est surjectif.*

Démonstration. Que $\emptyset_{\mathcal{M}}$ soit objet initial de $\mathcal{M}W^{-1}$ a été vu (dernière assertion du lemme 2.5, forme duale), prouvons qu'il est strict, *i.e.* que si $\mathrm{Hom}_W(X, \emptyset_{\mathcal{M}}) \neq \emptyset$, on a $X = \emptyset_{\mathcal{M}}$. En effet, si on avait $u : X \longrightarrow \emptyset_{\mathcal{M}}$ dans $\mathcal{M}W^{-1}$, u serait représenté par

$$X = X_0 \xleftarrow{W} X_1 \longrightarrow X_2 \xleftarrow{W} \cdots X_{2n-2} \longrightarrow X_{2n-1} \xleftarrow{W} X_{2n} = \emptyset_{\mathcal{M}}.$$

On procède par récurrence sur la demi-longueur de cette chaîne pour voir que $X = \emptyset_{\mathcal{M}}$. En effet, l'hypothèse sur W implique que $X_{2n-1} = \emptyset_{\mathcal{M}}$, puis celle que $\emptyset_{\mathcal{M}}$ est strict implique $X_{2n-1} = \emptyset_{\mathcal{M}}$, d'où la conclusion.

Prouvons la surjectivité de $\mathrm{Hom}_{\mathcal{M}}(e, X) \longrightarrow \mathrm{Hom}_W(e, X)$ pour $X \neq \emptyset_{\mathcal{M}}$, en montrant que tout chemin réduit de longueur 2n+1 est "homotope" à un chemin réduit de longueur $2n - 1$: [page 14']

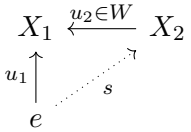
$$e = X_0 \longrightarrow X_1 \xleftarrow{W} X_2 \longrightarrow X_3 \longleftarrow \cdots \longleftarrow X_{2n} \longrightarrow X_{2n+1} = X.$$

En effet, on peut remplacer la section

$$e = X_0 \xrightarrow[u_1]{} X_1 \xleftarrow[u_2]{W} X_2 \xrightarrow[u_3]{} X_3 \xleftarrow{W} X_4$$

(s : $X_0 \longrightarrow X_2$)

par [p. 11]



$$e \xrightarrow[u_3 s]{} X_3 \xleftarrow{W} \cdots,$$

où s est une section de X_2 sur e telle que

$$u_2 s = u_1 \qquad \textit{dans} \qquad \mathcal{M}W^{-1}\ .$$

Cela prouve donc par récurrence sur n que le chemin est homotope à un chemin de longueur 1, $e \longrightarrow X$, q.e.d.

Il faut donc, dans le cas actuel, vérifier 1°) (c'est essentiellement le corollaire 2.12.), et 2°)

.

Mais comme $u_2 \in W$, on a $\pi_0(u_2)$ isomorphisme, donc surjectif, donc $\exists$ s tel que $u_2 s$ soit homotope à u_1 dans Cat, ce qui implique $u_2 s = u_1$ dans Hot_W, q.e.d. [page 15']

Commentaire final. L'axiome de connexité Loc (5) diffère de tous les autres axiomes Loc (1) à Loc (8) (mais à l'exception de Loc (8 bis) d'accessibilité) par le fait que ce n'est pas un axiome de stabilité. Les autres axiomes Loc (1) à Loc (8) (et aussi Loc (8 bis) d'accessibilité et même les axiomes ultérieures d'exactitude[7]) sont satisfaits si $W = \mathrm{Fl}\,\mathcal{M}$ - l'axiome de connexité est donc le seul qui s'oppose à la *trivialité* de la théorie homotopique définie par W.

7. il n'y en aura en fait pas besoin, grâce à la providentielle théorie de K. S. Brown !

C'est dire qu'il ne peut être conséquence de l'un des autres. Par contre, l'axiome Loc (4) des sommes directes n'est pas indépendant des autres. Signalons à ce propos (rappel) :

Loc (4 a_0)	est conséquence de l'axiome Loc (6 a) du carré cocartésien (forme directe).
Loc (4 a)	est conséquence de Loc (6 a) précédent + l'axiome des limites inductives filtrantes Loc (8).
Loc (4 b)	est conséquence de l'axiome Loc (7) des fibrations. Donc
Loc (4)	est conséquence de Loc (6 a, 7, 8).

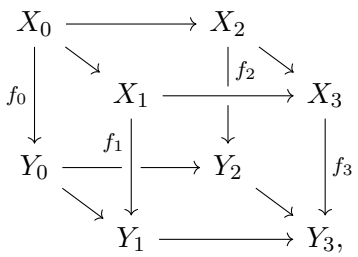
Commentary · Exposition [ms. 15'] [page 16']

Shortening localization words and preserving emptiness

Lemma 2.14 is a useful statement about localization words, rather than a calculus-of-fractions theorem. A morphism is a finite zigzag; it need not have a single denominator. If a zigzag ends at a strict initial object 0, the prohibition on W-arrows $0 \to X$ with $X \neq 0$ forces the adjacent object to be 0. Strictness then forces the preceding object to be 0, and induction runs through the zigzag. This proves strictness after localization. The repeated subscript $2n-1$ in the printed proof is an edition slip: the second conclusion is $X_{2n-2} = 0$.



For a word beginning at e, the lifting condition replaces $e \to X_1 \leftarrow X_2$ by a genuine map $e \to X_2$ having the same localized composite. Composing with the next arrow shortens the word by two. In Cat, (5) supplies this lifting because every component of X_1 has a representative in X_2, while a zigzag inside a component becomes equality of points after localization. The citation of Corollary 2.12 when checking condition (1) is circular as printed; that condition follows directly from (5), or from the empty-target argument of Corollary 2.13. Neither slip affects the corrected induction.

There is a useful logical division in the final commentary. The class of all functors satisfies every purely closure-type axiom under discussion, so no conjunction of those axioms can force (5). Conversely, sum closure need not be an independent axiom once a gluing theory is available: a coproduct is the union of two disjoint open subcategories, giving finite closure from (6a), and its finite partial unions give arbitrary closure after adding filtered-colimit stability. Reflection on a summand still comes from the separate base-change requirement. This is why (6a,7,8), rather than just (6a,8), appears in the correct final implication to (4).

3 Axiome Loc (6) du carré cocartésien (ou de "Mayer-Vietoris", ou des W-cofibrations) [8]

Je vois plusieurs variantes, et n'ai pas encore l'esprit totalement net sur les implications mutuelles. Je commence par la variante plus compliquée, mais dont on aura besoin en tous cas :

Loc 6 (Axiome des W-cofibrations, ou lemme des 5, ou axiome des homomorphismes de carrés cocartésiens). Considérons dans Cat un diagramme commutatif cubique

8. C'est le nom "*axiome des W-cofibrations*" qui m'apparaît à présent comme le meilleur, – c'est ce nom qui me paraît le mieux saisir la signification conceptuelle et non technique de l'axiome.

homomorphisme $f = (f_0, f_1, f_2, f_3)$ d'un diagramme carré X dans un autre Y. On suppose que X provient d'un objet X_3 de Cat de deux ouverts X_1, X_2 de X_3 *recouvrant* X_3, et de leur intersection $X_0 = X_1 \cap X_2$, et de même pour Y. (Appelons ces diagrammes dans Cat des diagrammes MV ("*ouverts*") - "*Mayer-Vietoris*".) On a alors ce qui suit [9] :

a) $f_0, f_1, f_2 \in W \Longrightarrow f_3 \in W$ [10].

b) $f_1, f_2, f_3 \in W \Longrightarrow f_0 \in W$.

c) $f_0, f_3 \in W \Longrightarrow f_1, f_2 \in W$ [11].

Commentary · Exposition [ms. 16']

The three cube rules measure different phenomena

An open subcategory here is a sieve: whenever an arrow has target in it, its source belongs to it as well. If $X = U \cup V$ is a cover by two sieves and $S = U \cap V$, every nerve simplex lies wholly in U or wholly in V, by looking at its last vertex. Therefore

$$NX = NU \amalg_{NS} NV.$$

Both inclusions are simplicial monomorphisms, so this strict simplicial pushout also represents the homotopy pushout of spaces. For cosieves the same reasoning uses the first vertex. This elementary geometry underlies the forward cube rule (6a).

The reverse rule (6b) is a different assertion: equivalences on the two pieces and the union must detect an equivalence on the intersection. A homotopy pushout does not ordinarily have this property. The third rule (6c) asks for detection on both pieces from the intersection and union. It is consequently misleading to call all three rules merely different forms of the ordinary gluing lemma. Their implications require arguments and, for the converse involving (6c), the stated retract hypothesis.

The manuscript's evolving terminology should be followed literally. Footnotes 11 and 13 remove (6c) from the name Loc (6), but Loc (6) still means *both* (6a) and (6b). Only (6a) is the familiar forward gluing property of ordinary weak homotopy equivalences. The commentary to XIIb-a, ms. 78–79, and XII Appendix, ms. 6–17, already separates these rules and gives the acyclic-link obstruction to reverse excision for W_∞; those examples need not be duplicated here. The finite-dimensional examples below settle the particular prediction made on the present page.

The small cubes in Proposition 3.1 can be checked by recording their vertical tuples. For Q the tuple is $(\mathrm{id}, i_1, \mathrm{id}, j_1)$; for Q' it is $(i_1, \mathrm{id}, j_1, \mathrm{id})$. Substitution immediately gives all three implications. The printed second occurrence of f_1 in the explanation of Q' means f_2. The doubtful id label belongs to the front vertical edge $X_1 \to X_1$, as the diagram and the edition both confirm.

N.B. Je distingue ces conditions comme Loc (6 a), Loc (6 b), Loc (6 c). Je présume qu'on n'aura jamais à faire usage à Loc (6 b), sans supposer également Loc (6 a), mais l'inverse n'est sûrement pas le cas. Ainsi, $W_0 = \{f \in \mathrm{Fl}\,\mathrm{Cat} \mid \pi_0(f) \text{ bijectif}\}$ satisfait a), mais non

9. Il est bon d'introduire des propriétés du diagramme

1°) $f_0 \in W$.

2°) f_1 et f_2 dans W.

3°) f_3 dans W.

et de formuler les parties a) b) c) de Loc (6) ainsi

a) $1° + 2° \Longrightarrow 3°$.

b) $2° + 3° \Longrightarrow 1°$.

c) $1° + 3° \Longrightarrow 2°$.

10. N.B. il semble que dans Loc (6 a), il suffit de l'énoncé en supposant f_0, f_2 des *isomorphismes, cf.* p. 22.

11. Il ne faudrait pas inclure c dans Loc 6 *cf.* p. 26.

12. N.B. On verra plus bas (3.3) que Loc 6 c implique déjà Loc (6 a, b), *i.e.* Loc (6) tout entier. Et si W satisfait Loc (1 bis), *i.e.* stable par facteurs directs, alors Loc (6 a, b) $\Longrightarrow$ Loc (6 c).

13. Je vais désigner par Loc (6) l'axiome Loc (6 a, b), sans y inclure c.

b). Je présume (sans avoir vérifié) que c'est pareil pour les W_n, $n \in \mathbf{N}$, de la "*n-équivalence homotopique*".

Il se pourrait que Loc (6 a) et Loc (6 a, b) soient équivalentes à la forme plus faible, et plus simple, suivante. (Si oui, c'est sous la forme la plus simple, bien sûr, qu'il convient de les énoncer.)

Loc 6′ (Axiome des carrés cocartésiens, ou de Mayer-Vietoris). Soit

$$\begin{array}{ccc} X_0 & \xrightarrow{i_2} & X_2 \\ {\scriptstyle i_1}\searrow & & \searrow{\scriptstyle j_1} \\ & X_1 & \xrightarrow{j_2} X_3 \end{array}$$

un diagramme MV dans Cat. Alors

a) Si $i_1 \in W$, $j_1 \in W$.

b) Si $j_1 \in W$, $i_1 \in W$.

Proposition 3.1. [page 18']

$$\begin{aligned} \text{Loc (6 a)} &\implies \text{Loc (6′ a)}, \\ \text{Loc (6 b)} &\implies \text{Loc (6′ b)}, \\ \text{Loc (6 c)} &\implies \text{Loc (6′ a, b)}\,[14]. \end{aligned}$$

Commentary · Examples [ms. 17']

A reverse-excision counterexample in every finite degree

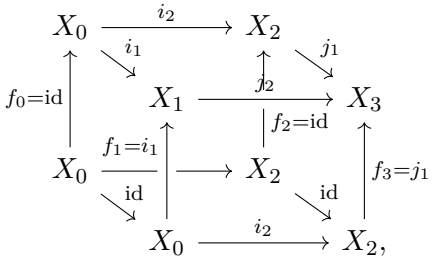
Let W_n consist of functors inducing a bijection on components and isomorphisms on homotopy groups through degree n, for every choice of base point. Grothendieck's prediction is correct for every finite $n \geq 0$: W_n satisfies forward gluing, but fails (6b).

Here is one uniform finite example. Let K be the boundary of an $(n+1)$-simplex, so $|K| = S^n$, and take its two simplicial cones $a * K$ and $b * K$. For a simplicial complex L, let $F(L)$ be the poset of its nonempty faces, ordered by inclusion. Its nerve is the barycentric subdivision of L. The inclusions

$$F(K) \subset F(a * K), \qquad F(K) \subset F(b * K)$$

are sieves, and the two cone face posets cover

$$F((a * K) \cup_K (b * K)).$$

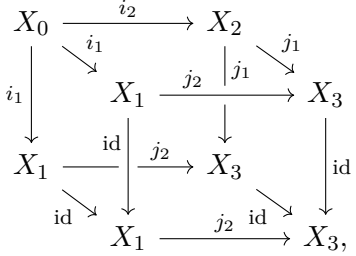


Thus they form an MV square. Map this entire square to the square all of whose vertices are e. The two piece maps are ordinary weak equivalences because cones are contractible. The union has homotopy type S^{n+1}, so its map to e belongs to W_n. The intersection has homotopy type S^n, so its map to e does not belong to W_n: for $n = 0$ it has two components, and for $n > 0$ its nth homotopy group is $\mathbb{Z}$. This is exactly a failure of (6b), using finite posets throughout.

For completeness, the forward assertion can be seen from the universal property of n-truncation. A map is an n-equivalence exactly when it induces equivalences of derived mapping spaces into all n-types. Mapping from a homotopy pushout into an n-type gives a homotopy pullback of mapping spaces. Equivalences on its three entries therefore give an equivalence on the result. Since an MV square has the homotopy-pushout realization just proved, (6a) follows. This proves the source's conjectural example rather than merely restating it. Notice that passage from S^n to its suspension is the mechanism of failure: the union moves the first detectable homotopy group one degree beyond the range being tested.

14. N.B. on a même Loc (6 c) $\implies \underbrace{\text{Loc 6 (a, b)}}_{\text{Loc (6)}}$.

Ça se voit sur le diagramme cubique



(Q)

où les f_0, f_1, f_2, f_3 de l'énoncé de Loc (6) deviennent id_{X_0}, i_1, id_{X_2}, j_1. Loc (6 a) donne donc $i_1 \in W \Longrightarrow j_1 \in W$, *i.e.* Loc (6′ a), et Loc (6 c) $j_1 \in W \Longrightarrow i_1 \in W$, *i.e.* Loc (6′ b). Pour Loc (6 b) $\Longrightarrow$ Loc (6′ b), on utilise (*cf.* XII, p. 78) le cube

p. 14

(Q′)

où $f_0 = i_1$, $f_1 = \mathrm{id}_{X_1}$, $f_1 = j_1$, $f_3 = \mathrm{id}_{X_3}$, donc

$$j_1 \in W \Longrightarrow i_1 \in W, \quad \textit{i.e.}\ \text{Loc (6 b)} \Longrightarrow \text{Loc (6′ b)},$$

et si on a Loc (6 c), on voit que $i_1 \in W \Longrightarrow j_1 \in W$, *i.e.* Loc (6′ a).

Commentaire 3.2. Loc (6 a) m'apparaît comme le "minimum vital" pour établir l'existence d'une théorie des cofibres W-homotopique dans Cat. Pour cela, il faut en effet disposer d'un critère serviable assurant qu'une flèche $i : A \longrightarrow B$ dans Cat est dans Cof_W.

On trouve, quand on dispose de Loc (6 a) (sous forme duale, *i.e.* pour les *fermés,* c'est kif-kif), que les *immersions ouvertes de Dwyer* sont dans Cof_W, ce qui suffit pour avoir *une bonne théorie des cofibres W-homotopiques, dans laquelle les carrés MV sont W-cocartésiens* (chose a laquelle on tient absolument). [page 19]

Quant à Loc (6 b), si je dispose à la place de Loc (6′ b) + Loc (6 a), je dois m'en tirer pour prouver Loc (6). Dans XII Appendice (pages 265 ff.) je prouve, paraît-il, que (avec les notations actuelles) Loc (6′) implique Loc (6), et même Loc (6 c) si W est stable par facteurs directs (condition Loc (1 bis)). Mais la démonstration est incomplète, puisque j'admets tacitement que les immersions de Dwyer sont dans Cof_W, chose que je n'avais établie que moyennant l'axiome W (7), en fait moyennant Loc (6 a) (ce qui est une partie de W (7)).

Mais ici me vient l'idée du lemme de K. S. Brown, cité par Baues, que je vais redonner ici : [page 20]

Commentary · Exposition [ms. 19]

The Dwyer neighborhood and the missing gluing step

A Dwyer inclusion $A \hookrightarrow B$ is a sieve whose inclusion into its generated cosieve U has a right adjoint $r : U \to A$ restricting to the identity on A. Thus $A \to U$ is a categorical homotopy equivalence. Put $V = B \setminus A$ and $T = U \cap V$. Both U and V are cosieves, and $B = U \cup_T V$. On pushing $A \to B$ out along $A \to A'$, one obtains the corresponding cover

$$B' = U' \cup_T V, \qquad U' = U \amalg_A A'.$$

The inclusion $A' \to U'$ again has a right-adjoint retraction, induced by r, so is in every W. This is the neighborhood calculation in Thomason (1980, Definition 4.1 and Proposition 4.3, pp. 313–317);

its proof does not require the claim elsewhere in that paper that all retracts of Dwyer maps are Dwyer maps, disproved in Cisinski (1999).

It explains both uses of the excision axioms here. If $A \to A'$ is in W, then $U \to U'$ is in W by the two homotopy-equivalent neighborhoods. The cube from the first closed cover to the second has its intersection and V maps equal to identities. The restricted case of (6a) therefore gives $B \to B' \in W$. This proves that Dwyer inclusions are intrinsic cofibrations, since their pushouts are again Dwyer inclusions.

Alternatively, suppose $A \to B$ itself is in W and assume (6′a,b). Then $U \to B$ is in W. The reverse single-square rule, applied to $B = U \cup_T V$, gives $T \to V \in W$. The forward rule in the new cover gives $U' \to B' \in W$, hence $A' \to B' \in W$. Thus trivial Dwyer inclusions are stable under every pushout. Opposite invariance justifies using closed covers in both arguments. This is precisely condition (4) in Brown's lemma, and makes explicit where both directions of (6′) enter the second proof.

The other factorization hypothesis also has a concrete explanation. Let $J = (0 \to 1 \leftarrow 2)$ and form

$$M(f) = (A \times J) \amalg_{A \times \{2\}} B$$

for $f : A \to B$. The inclusion of $A \times \{0\}$ is Dwyer: its cosieve neighborhood is $A \times (0 \to 1)$, with right-adjoint projection to A. The projection $M(f) \to B$ is a categorical homotopy equivalence. Indeed, the endomorphism of J sending 0 to 1 and fixing $1, 2$ receives natural transformations from both id_J and the constant functor at 2, stationary at 2; these descend after the pushout and contract $M(f)$ onto B. Hence every functor factors as a Dwyer inclusion followed by a member of W. No transfinite construction or functorial factorization axiom is needed for this particular factorization.

Lemme 3.2.1. (K. S. Brown) *Soit $(\mathcal{M}, W)$ un localiseur (W modérément saturé), muni d'un ensemble $C \subset \mathrm{Fl}\,\mathcal{M}$ satisfaisant les conditions :*

1) *C stable par composition et par cochangement de base* (N.B. *on n'a à supposer l'existence des sommes amalgamées* $\begin{array}{ccc} X_0 & \xrightarrow{i_1} & X_1 \\ {\scriptstyle i_2}\searrow & & \searrow \\ & X_2 & \longrightarrow X_3 \end{array}$ *que si $i_1 \in C$), contient les isomorphismes.*
2) *$\mathcal{M}$ contient un objet initial, $\emptyset_{\mathcal{M}}$, et pour tout objet X de $\mathcal{M}$, $\emptyset_{\mathcal{M}} \longrightarrow X$ est dans C.* (N.B. (1) *et* (2) *impliquent que $\mathcal{M}$ est stable par sommes finies.*)
3) *Toute flèche f de $\mathcal{M}$ se factorise en pi, avec $i \in C$, $p \in W$.*
4) *$C \cap W$ est stable par cochangement de base,* i.e. *si*

(∗)
$$\begin{array}{ccc} X_0 & \xrightarrow{i_1} & X_1 \\ {\scriptstyle i_2}\searrow & & \searrow \\ & X_2 & \xrightarrow[j_1]{} X_3 \end{array}$$

est cocartésien et $i_1 \in C \cap W$, alors $j_1 \in C \cap W$. (N.B. *$j_1 \in C$ est déjà contenu dans* (1), *il reste à exiger $j_1 \in W$.*) p. 15

Sous ces conditions, on a $C \subset \mathrm{Cof}_W$.

On peut aussi énoncer le lemme ainsi

Corollaire 3.2.2. *Supposons que C satisfait* (1), (2), (3). *Alors les conditions suivantes sur C sont équivalentes.* [page 21]

a) *Condition* (4) *ci-dessus,* i.e. *stabilité de $C \cap W$ par cochangement de base.*
a′) *$C \cap W \subset W^{\mathrm{univ}}$.*
b) *$C \subset \mathrm{Cof}_W$.*
b′) *Pour tout carré cocartésien*

$$\begin{array}{ccc} X_0 & \xrightarrow{i} & X_1 \\ {\scriptstyle p}\searrow & \textit{coc.} & \searrow{\scriptstyle q} \\ & X_0' & \xrightarrow{j} X_1' \end{array}$$

avec $i \in C$, $p \in W$, on a $q \in W$.

Démonstration. On a

$$\begin{aligned} \mathrm{b} &\iff \mathrm{b}' \\ \mathrm{a} &\iff \mathrm{a}' \end{aligned}$$

car C est stable par cochangement de base. On a $\mathrm{b} \Longrightarrow \mathrm{a}'$ car $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$ grâce à l'hypothèse 3°). On a $\mathrm{a} \Longrightarrow \mathrm{b}'$ par le lemme de Brown.

On va appliquer ceci au cas $\mathcal{M} = \mathrm{Cat}$, $C =$ immersions ouvertes de Dwyer. Les conditions 1), 2) ne dépendent pas de W, elles sont vérifiées, et 3) aussi dès que W est un localiseur fondamental. Quant à 4), c'est une conséquence de l'ancien W (7 bis), *i.e.* Loc (6′) (on a besoin apparemment de Loc (6′ a *et* b).) On en conclut $C \subset \mathrm{Cof}_W$ - c'est merveilleux! (Mais je ne sais pas prouver le lemme …) [page 22]

Commentary · Exposition [ms. 21]

A complete proof of the Brown lemma used here

The relevant historical result is the dual of the properness argument for categories of fibrant objects, not just the isolated factorization lemma: see Brown (1973, Part I, §1, pp. 420–422, and §4, Lemmas 1–2, pp. 428–429). A modern one-sided formulation appears in Rădulescu-Banu (2009, §§1.3–1.4). Here is a proof directly under the four displayed hypotheses, filling the gap Grothendieck explicitly acknowledges on ms. 22.

First, Brown's functor criterion. A functor F from such a category to a category with a two-out-of-three class of equivalences preserves all W-maps if it preserves $C \cap W$. For $w : X \to Y$ in W, factor

$$(w, \mathrm{id}_Y) : X \amalg Y \xrightarrow{k} Z \xrightarrow{p} Y, \qquad k \in C,\ p \in W.$$

The restrictions k_X, k_Y belong to C, because coproduct inclusions do, and both are in W by two-out-of-three. Their images under F are equivalences. Since $pk_Y = \mathrm{id}_Y$, $F(p)$ is an equivalence, and so is $F(w) = F(p)F(k_X)$.

Second, change the initial object. For each A, consider the category $\mathcal{C}_A$ of arrows $A \to X$ belonging to C, with all maps under A. Take equivalences and cofibrations to be those whose underlying maps are in W and C. It satisfies the same hypotheses: its initial object is id_A, pushouts and factorizations are inherited, and composing a factorization's first map with $A \to X$ keeps the new object in $\mathcal{C}_A$. For any $u : A \to A'$, the functor

$$u_! : \mathcal{C}_A \longrightarrow \mathcal{C}_{A'}, \qquad (A \to X) \longmapsto (A' \to A' \amalg_A X)$$

preserves trivial cofibrations by condition (4). The functor criterion shows that it preserves all equivalences. This assertion concerns maps *between* cofibrant objects under A, and is not yet the desired properness statement; the distinction prevents a circular proof.

Third, prove properness. We must show that the pushout of $w : A \to A'$ in W along $i : A \to B$ in C is a W-map $B \to P$. Applying the factorization of the first paragraph to $(w, \mathrm{id}_{A'})$ writes $w = pj$, where $j \in C \cap W$ and p has a section $s \in C \cap W$. Pushing out j is covered by (4). We are reduced to the case $ws = \mathrm{id}_{A'}$, with $s : A' \to A$ a trivial cofibration.

Form $B_1 = A \amalg_{A'} B$, using $s : A' \to A$ and $is : A' \to B$. The map $q : B \to B_1$ is a pushout of s, hence a trivial cofibration. There is a retraction $g : B_1 \to B$ induced by (i, id_B), so $g \in W$. The structural maps $A \to B_1$ and $A \to B$ belong to C: the former is a pushout of $is \in C$. Consequently g is an equivalence in $\mathcal{C}_A$. Apply $w_!$. Since $ws = \mathrm{id}_{A'}$, associativity of pushouts gives

$$A' \amalg_A B_1 \simeq B, \qquad A' \amalg_A B = P.$$

Under these identifications, $w_!(g)$ is precisely $B \to P$, which is therefore in W. Stability of C under pushouts makes the same argument apply to every cobase change of i, proving $C \subset \mathrm{Cof}_W$.

For the converse in Corollary 3.2.2, suppose $C \subset \mathrm{Cof}_W$, let $i : A \to B$ be in $C \cap W$, and push it out along an arbitrary $f : A \to A'$. Factor $f = pj$ with $j \in C$ and $p \in W$. Pushing i out along j gives a W-map because j is an intrinsic cofibration. Pushing p out along that new C-map gives another W-map. Two-out-of-three, applied to their composite and p, proves that the final pushout of i is in W. This verifies all four equivalent conditions without assuming the equality $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$ as an unexplained extra theorem. The argument only uses identities and two-out-of-three in W; retract closure and functorial factorizations are unnecessary here.

Cela légitime la démonstration faite dans XII *loc. cit.*, et on trouve la

Proposition 3.3. *La condition* Loc (6′) (*axiome du carré cocartésien, forme forte* (a) *et* (b)) équivaut *à* Loc (6 a, b) (*axiome des homomorphismes des carrés cocartésiens*) *et est* impliqué *par* Loc (6 c). *Si W satisfait à* Loc (1 bis), i.e. *est stable par facteurs directs, alors* Loc (6′) équivaut *à* Loc (6 c) *et à* Loc (6 a b c).

Commentaire 3.4. Ainsi, on trouve une théorie des cofibres W-homotopiques *soit* sous l'hypothèse Loc (6′) (équivalente à Loc (6) plus compliquée), soit sous l'hypothèse plus faible (et plus compliquée) Loc (6 a).

Dans le premier cas, c'est une théorie de nature très particulière, puisque les carrés W-cocartésiens sont "réversibles" (*i.e.* on a non seulement $i_1 \in W \Longrightarrow j_1 \in W$, mais aussi l'implication inverse).

Il reste donc la question si Loc (6′ a) suffit pour une théorie des cofibres W-homotopiques, ou ce qui revient sûrement au même, si ça implique déjà Loc (6 a) (donc lui est équivalent). C'est entièrement suspendu à la *question* :

p. 16 [page 23] ? ‖

l'axiome Loc (6′ a) (axiome du carré cocartésien, forme directe) implique-t-il que l'ensemble des immersions ouvertes de Dwyer qui sont dans W (immersions de Dwyer W-triviales) est stable par cochangement de base ? En fait, on voit qu'il suffirait pour cela de vérifier l'axiome du cube (ou des homomorphismes de carrés cocartésiens), forme directe Loc (6 a), dans le cas où f_0 et f_2 sont des identités, donc à prouver qu'alors $f_1 \in W \Longrightarrow f_3 \in W$ (ce qui donnerait directement $\mathrm{Dw} \subset \mathrm{Cof}_W$). Mais je ne vois aucun moyen de le prouver …

Supposons maintenant que la condition Loc (6 a) est vérifiée, donc qu'on dispose d'une "bonne théorie des cofibres W-homotopiques", donc aussi d'une théorie des carrés W-cocartésiens (*cf.* XII, p. 258-262). Il y a deux questions qui se posent, concernant la validité, avec ces hypothèses plus faibles, des développements de XII :

1°) Soit un carré commutatif

$$\begin{array}{ccc} X_0 & \longrightarrow & X_2 \\ \searrow & & \searrow \\ & X_1 & \longrightarrow & X_3 \end{array}$$

dans Cat, est-il vrai que ce carré est W-cocartésien si et seulement si la flèche

$$\text{canonique } \int \begin{array}{ccc} & & X_1 \\ X_0 & \nearrow & \\ & \searrow & \\ & & X_2 \end{array} \longrightarrow X_3 \text{ est dans } W \text{ ?}$$ [15]

[page 24]

2°) Est-il encore vrai que si A est dans Cat, et $u : F \hookrightarrow G$ un homomorphisme dans $A^\wedge$, alors $u \in \mathrm{Cof}_{W_A}$, et si $u \in W$, $u \in W_A^{\mathrm{univ}}$, donc a-t-on

$$\mathrm{Mono}_{A^\wedge} \subset \mathrm{Cof}_{W_A}, \qquad \mathrm{Mono}_{A^\wedge} \cap W_A \subset W_A^{\mathrm{univ}} \text{ ?}$$ [16]

---

15. Mieux, dans tous les cas, quand on a un diagramme $\begin{array}{ccc} & & X_1 \\ X_0 & \nearrow & \\ & \searrow & \\ & & X_2 \end{array}$, son intégrale $\int$ est une somme amalgamée W-homotopique dudit diagramme (moyennant Loc (6 a) sans plus, et même seulement Loc (6′ a)).

16. N.B. Loc (6′ a) suffit au lieu de (Loc (6 a)).

Mais 1°) est prouvé dans XII, prop. 20, p. 262 - je viens de vérifier que la démonstration est valable dans les hypothèses actuelles [17], pourvu que je vérifie que le corollaire 3, p. 149 dans XII est valable, *i.e.*

1° bis) Si $\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X \end{array}$ est un carré MV dans Cat, alors $\int \begin{array}{ccc} & & X_1 \\ X_0 & \nearrow & \\ & \searrow & \\ & & X_2 \end{array} \longrightarrow X$ est dans W (donc, moyennant 1°), le carré est W-cocartésien).

Pour le vérifier, je suis amené à vérifier que le théorème 4 dans loc. cit. (p. 146) est encore valable. p. 17

Je viens de le faire, et ai annoté en conséquence le théorème 4 et ses corollaires (certains résultats (cor. 4 et cor. 5) utilisant W (7 bis) dans toute sa force, *i.e.* Loc (6′), *i.e.* Loc (6 a *et* b). Mais le corollaire 3 du théorème 4 est O.K.

Je viens aussi de vérifier la validité de 2°), en vérifiant la démonstration du corollaire du théorème 5 (XII, p. 168) et en l'annotant en conséquence.

3.5. Résumons : on a [page 25]

$$\text{Loc (6 c)} \implies \text{Loc (6)} \iff \text{Loc (6}') \tag{3.5.1}$$

et

$$\text{Si } W = W^{\natural}, \text{ on a Loc (6 c)} \iff \text{Loc (6)} \iff \text{Loc (6}'). \tag{3.5.2}$$

D'autre part

$$\text{Loc (6 a)} \implies \text{Loc (6}' \text{ a)}, \tag{3.5.3}$$

et j'ignore si l'implication inverse

$$\text{Loc (6}' \text{ a)} \overset{?}{\implies} \text{Loc (6 a)}$$

est valable [18]. Pour établir Loc (6 a), il suffit de le faire en tous cas quand f_0 et f_2 sont des isomorphismes.

L'axiome Loc (6 a) semble le "minimum vital" pour que W donne lieu à une "bonne théorie des cofibres W-homotopiques", donc aussi des carrés W-cocartésiens. De façon plus précise, j'ai envie de prouver ceci :

Proposition 3.6. *L'axiome* Loc (6 a) *équivaut à la conjonction des deux propriétés suivantes.*

Loc (6 A) Cat a "assez de W-cofibrations", *i.e.* toute flèche f de Cat se factorise en $f = pi$, avec $i \in \mathrm{Cof}_W$ et $p \in W$. (Cela signifie aussi que Cat muni de (W, Cof_W) est une catégorie à cofibrations de K. S. BROWN - ANDERSON, et tous les résultats de la théorie de BROWN-QUILLEN sont applicables. En particulier, on a une bonne théorie des carrés W-cocartésiens.) p. 18 [page 26]

Loc (6 B) Si X dans Cat est réunion de deux ouverts U, V, d'intersection S, alors le carré

$$\begin{array}{ccc} S & \longrightarrow & U \\ \downarrow & & \downarrow \\ V & \longrightarrow & X \end{array}$$

17. Mais elle utilise de plus Loc (3 bis). Mais avec une autre démonstration plus simple que je viens de rajouter (p 264), on peut s'en passer (et on obtient une vison plus complète de la situation).

18. C'est le cas en présence de Loc (8, 9).

est W-cocartésien [19].

D'autre part, la condition Loc (6 A) peut être remplacée par la condition (en apparence plus faible)

Loc (6 A′) Tout morphisme de Dwyer est dans Cof_W.

Corollaire 3.7. *La condition* Loc (6), i.e. Loc (6 a, b) (*ou encore la condition équivalente* Loc (6′)) *équivaut à la conjonction des conditions* Loc (6 A) (*ou* Loc (6 A′)) *et* Loc (6 B) *ci-dessus*), *et de la condition*

Loc (6 C) Pour tout carré W-cocartésien

$$\begin{array}{ccc} X_0 & \xrightarrow{i} & X_1 \\ \downarrow & & \downarrow \\ X_2 & \xrightarrow{j} & X \end{array}$$

dans Cat, $j \in W \Longrightarrow i \in W$.

D'autre part, je soupçonne que Loc (6 c) n'est guère vérifiée que si $W = W^{\natural}$ (cas qui est le plus commun bien sûr), auquel cas Loc (6 c) *équivaut* à Loc (6). Il n'y a sans doute pas lieu de l'inclure dans Loc (6), pas plus que $W = W^{\natural}$ dans Loc (1). [page 27]

Commentary · Present state [ms. 25]

What the excision reformulations establish

The new contribution of the present argument, relative to the earlier cube calculations in XIIb-a and XII Appendix, is the missing cofibration criterion. The Dwyer-neighborhood proof and Brown's lemma establish it from (6′a,b), so the earlier passage from single-square reversibility to the two cube rules can now be used without assuming the desired cofibration theory in advance. The source's equivalence

$$(6\mathrm{a}, 6\mathrm{b}) \Longleftrightarrow (6'\mathrm{a}, 6'\mathrm{b})$$

should be read with that repair. Closure of W under retracts is a separate premise for the converse implication to (6c); it concerns W, not closure of the class of Dwyer inclusions under retracts. The latter closure is false (Cisinski, 1999, pp. 228–229).

There is also a short direct check of the cover comparison in question (1° bis). Let G be the Grothendieck construction on the span $S \to U$, $S \to V$, and $q : G \to X$ its canonical functor. For $x \in U$, the sieve condition gives $U/x = X/x$ and $V/x = S/x$. Thus G/x is the integral of the span $S/x \to X/x$, $S/x \xrightarrow{\mathrm{id}} S/x$. The redundant branch contracts by a zigzag of natural transformations, leaving X/x, which has terminal object id_x. The same argument applies if $x \in V$. Hence every G/x is contractible and $q \in W$ by (3). This proves the cover comparison without (3 bis), in agreement with the revised proof mentioned in footnote 17. For general spans, identifying their integral with the intrinsic homotopy pushout still uses the cofibration theory; the earlier commentary to XIIb-b, ms. 120–149, discusses that distinction in detail.

The statements about monomorphisms of presheaves on ms. 24 refer to W_A as defined using the category of elements. They are claims about the induced relative category, not a claim that every fully faithful functor in Cat is a cofibration. Nor does "enough intrinsic cofibrations" by itself provide both lifting systems of a Quillen model structure. The conclusion licensed at this stage is Brown's one-sided cofibration theory, with its homotopy pushouts. Proposition 3.6 and footnote 19 further reduce the issue to enough such cofibrations; the promised implication (6A)⇒(6B) is addressed at ms. 66–68, not proved at its first announcement here.

The bare implication (6′a)⇒(6a) is explicitly left as a question in this passage; footnote 18 supplies the additional assumptions (8,9), not an unconditional answer. Likewise the final suggestion that (6c) might force retract closure is a conjectural observation. For strong localizers retract closure follows independently from later saturation theory, but that does not answer the question for the

19. En fait, Loc (6 B) est conséquence de Loc (6 A), laquelle donc est *équivalente* à Loc (6 a). (*Cf.* esquisse de démonstration dans 4.4.15, pages 66-68.)

weak framework of Definition 1.1. No result settling these precise weakest-hypothesis formulations was found in the sources checked. The next two blocks instead extract a definite, and rather restrictive, consequence of the reverse cube axiom itself.

Commentary · Development (commentators') [ms. 27]

Integral homology supplies a reversible localizer

Homological Theorem A and reversible excision. [ours] Let $C_*(A) = C_*(NA;\mathbb{Z})$ be the integral nerve chain complex and define

$$W_{H\mathbb{Z}} = \{f : A \to B \mid H_k(NA;\mathbb{Z}) \xrightarrow{\sim} H_k(NB;\mathbb{Z}) \text{ for all } k \geq 0\}.$$

This is a strongly saturated fundamental localizer satisfying (3 bis), (5), and all three cube rules (6a,b,c). We include the proof because the ensuing minimality statement needs the actual Theorem A hypothesis, not just the observation that homology has a Mayer–Vietoris sequence. The ingredients are classical; the formulation and proof assembled here are offered as a development of this passage, with no priority claim.

The local-to-global assertion. For $u : A \to S$, use the first-quadrant double complex $D(u)_{p,q}$ freely generated by strings

$$a_0 \longrightarrow \cdots \longrightarrow a_q, \qquad u(a_q) \longrightarrow s_0 \longrightarrow \cdots \longrightarrow s_p.$$

The vertical faces compose or omit arrows in the A-string, including composition with the connecting arrow when a_q is omitted. The horizontal faces do the same for the S-string. Use unnormalized chains for this description and total differential $d_v + (-1)^q d_h$. There is an augmentation

$$r_A : \operatorname{Tot} D(u) \longrightarrow C_*(A)$$

which forgets s_0 in horizontal degree zero and is zero in positive horizontal degrees. For a fixed A-string, the horizontal complex is that of $u(a_q)\backslash S$. Its initial object is $\mathrm{id}_{u(a_q)}$, so its augmented chain complex is contractible. Filtering the total complex therefore proves that r_A is a quasi-isomorphism for every u.

Now take a triangle $A \xrightarrow{f} B \to S$. It induces $D(A \to S) \to D(B \to S)$. For a fixed string $s_0 \to \cdots \to s_p$, the corresponding vertical complexes are precisely $C_*(A/s_0)$ and $C_*(B/s_0)$. If all the comma comparisons are integral homology equivalences, this map is a quasi-isomorphism in every such column. The other first-quadrant filtration consequently makes the map on totals a quasi-isomorphism. There is no convergence issue: in each total degree only finitely many bidegrees occur. The naturality square for the two augmentations r_A, r_B identifies the resulting map with $C_*(f)$, proving (3 bis). Taking $B = S$ and using the terminal objects of S/s also proves the weak axiom (3).

For readers wishing to check the comparison with the ordinary homological Theorem A directly, there is a second augmentation $r_S : \operatorname{Tot} D(u) \to C_*(S)$, forgetting the A-string in vertical degree zero. The signed concatenation

$$h(a_\bullet, u(a_q) \to s_\bullet) = (-1)^q \big[u(a_0) \to \cdots \to u(a_q) \to s_0 \to \cdots \to s_p\big]$$

satisfies $dh + hd = r_S - u_* r_A$. The internal faces cancel in pairs; deleting the sole A-vertex when $q = 0$ yields r_S, and deleting the sole S-vertex when $p = 0$ yields $-u_* r_A$. If each A/s has the homology of a point, the vertical filtration makes r_S a quasi-isomorphism as well. This explicit homotopy verifies that the isomorphism produced by the two filtrations is induced by the given functor, rather than merely an abstract isomorphism between homology groups.

The other localizer axioms. A terminal object contracts the nerve, giving (2). Identities, two-out-of-three, mild saturation, and retract closure follow by applying integral homology. Strong saturation follows too: homology factors through $\mathrm{Cat}[W_{H\mathbb{Z}}^{-1}]$, so any arrow inverted in that localization already induces a homology isomorphism. In degree zero, a functor induces the free abelian map on its function of components; such a map is an isomorphism exactly when the function is a bijection. This proves (5).

The three cube rules. For an open MV square, the nerve decomposition gives a natural short exact sequence of normalized chain complexes

$$0 \longrightarrow C_*(S) \xrightarrow{(i_*,-j_*)} C_*(U) \oplus C_*(V) \longrightarrow C_*(X) \longrightarrow 0.$$

A map of MV squares gives a map of these short exact sequences. If two of the three vertical maps are quasi-isomorphisms, so is the third, by their long exact homology sequences. This yields (6a) and (6b). For (6c), the two outer quasi-isomorphisms force the middle map to be a quasi-isomorphism. That middle map is block diagonal, so each of its two summand maps is a quasi-isomorphism separately. These arguments apply to disconnected and empty categories as written. The same proof works for closed covers, or one may pass to opposite categories. Thus the homological class is an actual example of the reversible theory sought here, rather than an analogy with an exact sequence.

Commentary · Development (commentators') [ms. 27]

The least localizer satisfying reverse cube excision

Minimality forced by one suspension. [ours] Among weak fundamental localizers in the sense of Definition 1.1 satisfying (6b), the least one is $W_{H\mathbb{Z}}$. In particular, the least such localizer satisfying both directions of Loc (6), or satisfying all three cube rules, is again $W_{H\mathbb{Z}}$. The previous block proves the required upper bound. We now prove that every such W contains every integral homology equivalence. This gives a precise consequence of Grothendieck's reversibility requirement; it does not claim that every larger reversible weak localizer is strong or saturated.

By Cisinski (2006a, Theorem 6.1.18), $W_\infty \subset W$ even under the weak axioms. Let $f : A \to B$ be an integral homology equivalence. Its map on components is a bijection, and its restriction to each matched pair of components is a homology equivalence: homology is the direct sum over components and the induced map respects this decomposition. Write these maps as $f_i : A_i \to B_i$, with each category nonempty and connected. If there are no components, f is $\mathrm{id}_\emptyset$ and the assertion is immediate.

For a nonempty category C, form C_- and C_+ by adjoining one new terminal object in each case, and let ΣC be the category obtained by adjoining both objects, with no morphisms between them. Then

$$\begin{array}{ccc} C & \longrightarrow & C_- \\ \downarrow & & \downarrow \\ C_+ & \longrightarrow & \Sigma C \end{array}$$

is an open MV square: both cones are sieves, their intersection is C, and their union is ΣC. The nerve realizes the union of the two ordinary cones on $|NC|$, hence the unreduced suspension of $|NC|$. Each cone is contractible. Because C is connected, its suspension is simply connected, by van Kampen, and the suspension isomorphism identifies its reduced integral homology with that of C, shifted one degree.

Apply this construction to each f_i. The map on either cone is in W_∞. The map $|N\Sigma A_i| \to |N\Sigma B_i|$ is a homology equivalence between simply connected CW complexes. The homological Whitehead theorem makes it a weak homotopy equivalence (Hatcher, 2002, Corollary 4.33, pp. 367–368). Thus the three maps on the pieces and union belong to $W_\infty \subset W$. Reverse cube excision (6b) forces $f_i \in W$.

One must not finish by taking a sum of these conclusions unless sum closure has been assumed. Instead take the disjoint union of the entire componentwise cube diagrams *before* applying (6b). This is a single open MV cube whose intersection map is the original f. The two cone maps and the union map are ordinary weak equivalences globally: their component functions are the same bijection, and their restrictions are the weak equivalences already established. Therefore they belong to W without any use of (4), and (6b) directly gives $f \in W$. This proves the lower bound and the theorem.

The conclusion also locates the obstruction to identifying reversible excision with ordinary homotopy theory. Noncontractible acyclic spaces, such as the example recalled in Hatcher (2002, discussion following Corollary 4.33, p. 368), have the homology of a point but a nontrivial fundamental group; categorical models give maps in $W_{H\mathbb{Z}} \setminus W_\infty$. Such examples were already used in the commentary on Chapter XII to disprove reverse excision for W_∞. The new content here is the

universal lower bound: reverse cube excision forces *every* integral homology equivalence, not just the particular acyclic examples. We did not find this precise least-localizer formulation in the primary sources examined; its proof is included in full so that the assertion can be assessed independently of any priority question.

p. 19

4 Axiome Loc (7) des W-fibrations

4.1. Rappelons la notion de *W-fibration faible* (XII p. 51, 52) : la version la plus forte des 8 conditions équivalentes pour que $f : X \longrightarrow S$ soit une fibration faible est celle-ci.

(Ff) $\forall\ S'' \longrightarrow S'$ dans Cat/S, avec S', S'' *contractiles,* le morphisme correspondant $X'' = X \times_S S'' \longrightarrow X' = X \times_S S'$ est dans W.

Quand W est fortement saturé, alors ceci implique la condition, en apparence plus forte :

(Ff′) $\forall\ S'' \longrightarrow S'$ dans Cat/S, telle que $S'' \longrightarrow S'$ soit un homotopisme, $X'' \longrightarrow X'$ est dans W.

Je désigne par Fibf_W l'ensemble des fibrations faibles. Je résume dans un diagramme d'inclusions les principales classes de flèches dans Cat que nous avons rencontrées, s'apparentant à des classes de "fibrations" (pour W, dans un sens convenable) :

[page 28]

$$\begin{array}{ccccccccc} & & & & \mathrm{Fib}_W & & & & \\ & & & & \downarrow & & & & \\ \mathrm{Parf}_\omega & \longrightarrow & \mathrm{Parf}_W & \longrightarrow & \mathrm{Fibf}_W & \longleftarrow & \underbrace{\mathrm{Catfib}^W}_{\mathcal{F}_W} & \longleftarrow & \underbrace{\mathrm{Catfib}^\omega}_{\mathcal{F}_\omega}\ , \end{array}$$

où Fib_W désigne les W-fibrations ($f : S' \longrightarrow S$ est dans Fib_W si et seulement si le foncteur changement de base $X \longmapsto X' = X \times_S S'$ de Cat/S dans Cat/S' est compatible avec les localiseurs W_S et $W_{S'}$), Catfib les Cat-fibrations, Catfib^W (resp. Catfib^ω) les Cat-fibrations telles que les foncteurs changement de base soient dans W (resp. soient dans W_ω, *cf.* déf. plus bas) [20], Parf_W les morphismes W-parfaits, *i.e.* W-lisses et W-propres, enfin Parf_ω les morphismes W_ω-parfaits, où W_ω est le plus petit localiseur satisfaisant Loc (1, 2, 3). Parmi les espèces de "fibrations" envisagées, c'est cette dernière seulement, avec Catfib^ω, qui est indépendante de W.

À ce titre, elle me paraît jouer un rôle similaire, dual, à celui des morphismes de Dwyer, et je présume qu'on peut leur faire jouer un rôle similaire. En tous cas, on sait que toute flèche [page 29]
f de Cat se factorise en pi, avec $i \in W_\omega$ et $p \in \mathrm{Parf}_\omega$, donc $i \in W$ pour tout W satisfaisant Loc (1, 2, 3). On sait aussi que Catfib^ω satisfait l'énoncé de factorisation forte, f se factorise en $f = pi$, $i \in W_\omega$, $p \in \mathrm{Catfib}_0^\omega$. [21]

Commentary · Exposition [ms. 28]
Three meanings of fibration

Grothendieck is looking for maps along which an ordinary pullback already performs the correct homotopical operation. This explains the change of terminology at the beginning of the section: the class now called Fib_W is defined by the operation it makes possible, whereas the former fibrations, now Fibf_W, are recognized by tests over contractible categories. The difference is the central issue of the next forty manuscript pages.

20. N.B. $\mathrm{Catfib}_0^W = \mathrm{Catfib} \cap \mathrm{Fibf}_W$, $\mathrm{Catfib}_0^\omega = \mathrm{Catfib} \cap \mathrm{Fibf}_{W_\omega}$

21. Donc la propriété de factorisation est valable pour toutes ces classes, sauf peut-être Fib_W.

For clarity, write W_S for the maps over S whose underlying functor belongs to W, and write W_S^{u} for maps which remain in W after every change of base $T \to S$. If $p : X \to S$, its intrinsic fibration property says that every W-equivalence $T' \to T$ over S induces a W-equivalence

$$X \times_S T' \longrightarrow X \times_S T.$$

Both T and T' vary. Testing only maps $T' \to S$ misses the required stability after a first change of base. By contrast, weak fibrancy makes the same demand only when T and T' are contractible in the categorical homotopy sense used in the preceding chapters. A category with contractible nerve need not admit a contraction through a finite chain of natural transformations; these two meanings should not be interchanged in reading the test.

The third notion, a Grothendieck fibration, concerns Cartesian lifts of arrows of S. A cleavage gives inverse-image functors $\alpha^* : X_t \to X_s$ for $\alpha : s \to t$. Membership in $\mathcal{F}_W$ means that these functors belong to W. Thus $\mathcal{F}_W$ combines strict categorical transport with homotopical local constancy. It supplies convenient representatives of families, but its definition does not say that pullback preserves every equivalence of bases.

Perfect maps enter from a different direction. Smoothness controls one comma-category comparison and properness the opposite comparison; perfection imposes both. The comparison with strict bifibrations was already discussed in the commentary on Chapter VI, manuscript p. 186. Here perfection matters because it supplies replacements, and because the class of perfect maps is closed under composition. Those facts make Brown's argument available. No lifting-property definition of a Quillen fibration is being introduced.

The inclusion diagram is consequently asymmetric in a useful way. The geometric classes $\mathcal{F}_W$ and Parf_W sit inside the class detected on contractible bases; the intrinsic class Fib_W also sits there, but its inclusion in the other direction is a substantive assertion about W. Proving that reverse inclusion is the purpose of Loc (7).

Notons aussi que Parf_ω et Parf_W, ainsi que Fib_W, sont stables non seulement par changement de base (c'est le cas des 5 classes envisagées, qui de plus contiennent tous les isomorphismes), mais aussi par composition. (De plus, Fib_W est stable par facteurs directs, et je présume qu'il en est de même de Liss_W et de Prop_W, donc de Parf_W, en particulier de Parf_{W_ω}, mais je n'ai pas pris la peine de le vérifier.) Par contre, a priori Fibf_W n'est pas en général stable par composition, et Catfib^W, Catfib^ω n'ont pas de raison non plus d'être p. 20
stables par composition [22].

4.2. Finalement, il paraît plus "éclairant" d'introduire, au lieu du localiseur fondamental W_ω bien déterminée, un localiseur fondamental

$$W_0 \subset \mathrm{Fl}(\mathrm{Cat}),$$

qui jouera le rôle d'une sorte de "localiseur de référence" pour formuler certaines propriétés de W. On supposera toujours que

$$W \supset W_0.$$

Suivant les cas, W_0 pourra être W_ω, ou quelque autre localiseur fondamental défini comme [page 30]
le "plus petit" satisfaisant à des axiomes de stabilité donnés. Ou ça pourra être $\mathbf{W}_\infty$ (les équivalences faibles habituelles), quand on s'intéresse aux localiseurs qui contiennent $\mathbf{W}_\infty$ (les seuls, apparemment, avec lesquels on ait travaillé jusqu'à présent en homotopie). Ça pourra être aussi W, et les énoncés obtenus en spécialisant les résultats obtenus au cas où $W = W_0$ ne sont nullement tautologiques. Le diagramme de la page 28 se remplace alors par le diagramme

22. il faudrait expliciter par des exemples.

d'inclusions suivant, plus éclairant pour notre propos :

(4.2.1)
$$\begin{array}{ccccc} & & \mathrm{Fib}_W & & \\ & & \downarrow & & \\ \mathrm{Parf}_W & \longrightarrow & \mathrm{Fibf}_W & \longleftarrow & \mathcal{F}_W \\ \uparrow & & \uparrow & & \uparrow \\ \mathrm{Parf}_{W_0} & \longrightarrow & \mathrm{Fibf}_{W_0} & \longleftarrow & \mathcal{F}_{W_0} \\ & & \uparrow & & \\ & & \mathrm{Fib}_{W_0}, & & \end{array}$$

où pour tout localiseur fondamental W, je pose pour abréger

$$\mathcal{F}_W = \mathrm{Catfib}^W,$$

ce qui définit donc également $\mathcal{F}_{W_0}$. La classe Fib_W doit être regardée comme le point de mire de notre attention ; la plupart des propriétés de W que nous allons passer en revue ici, s'exprimeront par une inclusion de la forme [page 31]

$$\mathcal{F} \subset \mathrm{Fib}_W,$$

où $\mathcal{F}$ est une des sept autres classes du diagramme (4.2.1) ; à l'exception tout au plus du cas $\mathcal{F} = \mathrm{Fib}_{W_0}$, *i.e.* de l'inclusion $\mathrm{Fib}_{W_0} \subset \mathrm{Fib}_W$. Comme propriété sur W, cette inclusion paraît très faible et pour cela pas utile à grand chose, sauf bien sûr dans le cas où $\mathrm{Fib}_{W_0} \longrightarrow \mathrm{Fibf}_{W_0}$ est une égalité, de sorte que l'inclusion envisagée équivaut à $\mathrm{Fibf}_{W_0} \subset \mathrm{Fib}_W$ (et implique que Parf_{W_0} et $\mathcal{F}_{W_0}$ sont eux aussi contenus dans Fib_W). C'est là par contre, comme nous allons voir, une propriété assez forte et fort utile de W, impliquant notamment le fait que $(\mathrm{Cat}, W, \mathrm{Fib}_W)$ est une catégorie à fibrations.

p. 21
[page 32]

Commentary · Exposition [ms. 31]

Why a reference localizer is retained

The second localizer allows Grothendieck to separate the construction of a family from the equivalences which that family must preserve. A map may have transport belonging to a smaller class W_0, while the desired base-change theorem concerns the larger class W. This distinction is valuable precisely when changing the homotopy theory makes more maps into equivalences: additional equivalences of bases need not remain harmless for an existing family.

From $W_0 \subset W$ one immediately obtains

$$\mathcal{F}_{W_0} \subset \mathcal{F}_W, \qquad \mathrm{Fibf}_{W_0} \subset \mathrm{Fibf}_W, \qquad \mathrm{Parf}_{W_0} \subset \mathrm{Parf}_W.$$

Each defining condition on the left asks specified comparison functors to belong to the smaller class. There is no corresponding formal inclusion $\mathrm{Fib}_{W_0} \subset \mathrm{Fib}_W$. Here the quantified class of equivalences of bases has also enlarged. This is why the intrinsic fibrations appear at opposite ends of the diagram rather than in its vertical chain.

The pointwise pullback test at ms. 36 follows from this same distinction. For a class $\mathcal{F}$ stable under arbitrary base change, it suffices to check the outermost square with a map in W at its bottom. Indeed, to test $p \in \mathcal{F}$ against a map $T' \to T$ over S, first pull p back to T; the resulting map still belongs to $\mathcal{F}$, so the proposed single-square test applies. This proves the full intrinsic fibration property, with no assumption about the saturation of W beyond the ordinary equivalence calculus.

The observation about retracts at ms. 29 deserves the same care as in the commentary on Chapter XII, manuscript p. 209. If W is closed under retracts, then Fib_W is closed under retracts: every pullback comparison for a retract of p is a retract of the corresponding comparison for p. Without that hypothesis this argument does not establish the assertion. We retain the source's claim in the audit, with this dependency explicit, rather than silently replacing mild saturation by retract closure. It has no role in the composition and replacement arguments below.

Aux fins de référence ultérieure, je vais formuler maintenant les divers aspects principaux de *l'axiome des W-fibrations* Loc (7). La formulation à laquelle j'étais parvenu (*cf.* I, VI, XII) utilisait la notion que j'appelle à présent "W-fibrations *faible*" (l'ex W-fibration, désormais détrônée !), et sous sa forme la plus forte s'écrivait comme l'inclusion

$$\mathrm{Fibf}_W \subset \mathrm{Fib}_W.$$

Cette notion de W-fibration faible, tout comme celle de morphisme W-parfait, si utiles soient-elles, m'apparaît cependant un peu technique, et je préfère donner une formulation qui ne fasse appel qu'à des notions plus familières et d'apparence plus élémentaires. C'est pourquoi je vais remplacer Fibf_W par la sous-classe $\mathcal{F}_W = \mathrm{Catfib}^W$, ce qui (on le verra) revient en fait au même.

Cette classe $\mathcal{F}_W$ est extrêmement naturelle, et s'impose même dans le yoga des dérivateurs. [page 33] En effet, dans la construction de $\mathrm{HOT}_W(S)$ pour S dans Cat, on passe à une catégorie de fractions de la catégorie

$$\mathrm{Cat}(S) = \underline{\mathrm{Hom}}(S, \mathrm{Cat}),$$

par un localiseur $W(S)$ (que nous avions généralement noté W_S^{g} ou W_S^{u} …). Cette catégorie $\mathrm{Cat}(S)$ est d'autre part isomorphe à la catégorie

$$\mathrm{Fibsc}\, S$$

des catégories fibrées et scindées sur S, avec comme flèches les S-foncteurs qui respectent le scindage (et en particulier cartésiens) (*cf.* VI, et notamment le diagramme p. 175). On a vu (*loc. cit.*) que la catégorie localisée $\mathrm{HOT}_W(S)$ est équivalente à la catégorie localisée de la catégorie très voisine

$$\mathrm{Fib}\, S \qquad \text{(que je préférerais maintenant noter } \mathrm{Catfib}\, S \text{ ou } \mathrm{Catfib}_S\text{)},$$

formé des catégories *fibrées* sur S, avec comme flèches les seuls foncteurs cartésiens. (On [page 34] fera attention cependant que le foncteur canonique $\mathrm{Fibsc}\, S \longrightarrow \mathrm{Fib}\, S$ est fidèle mais non pleinement, néanmoins il induit une équivalence sur les catégories localisées, en définissant de façon évidente, par la W-équivalence fibre par fibre, *i.e.* comme W_S^{u}, le localiseur pertinent sur $\mathrm{Fib}\, S$.) Donc pour cette raison de principe, et d'ailleurs tout au long du développement de la théorie de HOT_W, la catégorie $\mathrm{Fib}\, S$ et par là, les foncteurs fibrants, ont joué un rôle essentiel. La classe de flèches que nous notons ici $\mathcal{F}_W$ ou Catfib^W (on pourrait aussi la noter Fib^W, si ce n'était pour le risque de confusion avec Fib_W) s'interprète alors très naturellement à partir de là. Une flèche $f : X \longrightarrow S$ est dans $\mathcal{F}_W$ si et seulement si elle est a) fibrante, et par là définit de façon particulièrement directe un objet de $\mathrm{HOT}_W(S)$, puisque à S-équivalence près, X/S provient d'un objet de $\mathrm{Fibsc}\, S$ ou encore de $\mathrm{Cat}(S)$, et b) l'objet dans $\mathrm{HOT}_W(S)$ défini [page 35] par f est dans $\mathrm{HOT}_W^{\mathrm{lc}}(S)$, *i.e.* dans l'image essentielle de la sous-catégorie strictement pleine $\mathrm{Fibsc}_0^W S$ de $\mathrm{Fibsc}\, S$ (par le foncteur canonique $\mathrm{Fibsc} \longrightarrow \mathrm{HOT}_W(S)$), ou ce qui revient au [p. 22] même (du moins si W est fortement saturée) que le foncteur

$$\begin{array}{ccc} S^\circ & \longrightarrow & \mathrm{Hot}_W \\ s & \longmapsto & \mathrm{hot}_W(X_s) \end{array}$$

soit un foncteur "localement constant". Ainsi, on considérera les $f \in \mathcal{F}_W$ comme les flèches les plus économiques et les plus naturelles dans Cat, qui définissent des W-types d'homotopie relative localement constants.

Notons aussi que toutes les classes de flèches (4.2.1) sont stables par changement de base (et elles contiennent les isomorphismes). Les catégories Fib_W, Parf_W et leurs variantes W_0 sont aussi stables par composition, par contre, ce n'est pas le cas pour Fibf_W et $\mathcal{F}_W$ et leurs variantes W_0, sauf axiomes particuliers sur W ou sur W_0). Il en résulte aussitôt que si $\mathcal{F}$ est [page 36]

une de ces classes, la condition

$$\mathcal{F} \subset \mathrm{Fib}_W$$

équivaut à celle ci :

Commentary · Exposition [ms. 35]

Local constancy belongs to the coherent family

Grothendieck's preferred representatives carry their coherence with them. A split Grothendieck fibration is described, in the variance used here, by a strict functor $S^{\mathrm{op}} \to \mathrm{Cat}$; forgetting the splitting leads to a pseudofunctor with canonically coherent transport. The display at ms. 33 prints $\underline{\mathrm{Hom}}(S, \mathrm{Cat})$, whereas the displayed fibre functor at ms. 35 has the required opposite. We use the latter convention. The change is recorded as an edition slip and is not silently applied to his text.

The equivalence after localization between split and unsplit presentations does not mean that the forgetful functor is full before localization. A Cartesian functor may preserve chosen lifts only up to the unique vertical isomorphisms supplied by their universal property. Splitting replacements account for this discrepancy. The commentary on Chapter VI, manuscript pp. 26 and 53–59, treats the comparison itself; its role here is to justify using either presentation when formulating the axiom.

There is also a distinction between saying that a coherent family is locally constant and retaining only its diagram in the ordinary homotopy category. The former is the object of $\mathrm{HOT}_W(S)$ together with the assertion that its transition maps are equivalences. Passing to $S^{\mathrm{op}} \to \mathrm{Hot}_W$ is a test for this property when W is strongly saturated. It is not a reconstruction theorem for the family: higher compatibility data can disappear in the ordinary homotopy category. The commentary on Chapter VI, manuscript pp. 7 and 73–74, gives the relevant examples; we do not repeat them here.

The modern comparison is especially transparent for ordinary homotopy types. Cisinski (2009, Definitions 1.1–1.2, Theorem 1.3, and Corollary 1.28) characterize weak homotopy equivalences of indexing categories by their effect on locally constant homotopy-coherent diagrams. This is the later form of the geometric intuition behind Grothendieck's use of $\mathrm{HOT}^{\mathrm{lc}}_W$. The theorem concerns that coherent localization, with its coefficient category allowed to vary, and does not identify it with the category of ordinary functors into Hot.

In the present argument the practical benefit is more elementary. The free split-fibration replacement $X \to \Phi_S(X)$ is natural in X, and for a weakly W_0-fibred $X \to S$ its comparison is universally a W_0-equivalence over S. Naturality will later let one replace not merely two objects but also the arrow between them. That extra feature is exactly what transfers condition B.

Pour tout diagramme cartésien

(4.2.2)
$$\begin{array}{ccc} X & \xleftarrow{q} & X' \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow[p]{} & S', \end{array}$$

avec $f \in \mathcal{F}$ et $p \in W$, on a $q \in W$.

(N.B. On a aussi $f' \in \mathcal{F}$, par la stabilité rappelée plus haut.)

4.3. Voici donc (*cf.* plus bas) l'axiome pertinent, Loc (7) avec ses trois aspects a, b, c [23]. On a vu (et on reverra) que l'on a les implications

$$\text{a} \quad \Longrightarrow \quad \text{b} \quad \Longrightarrow \quad \text{c} \quad (\Longrightarrow \quad \text{F}).$$

Quand on référera à Loc (7) sans autre précision, il sera entendu qu'il s'agit de la forme la plus forte Loc (7 a), qui implique donc les deux autres. Il n'en faut pas moins pour être totalement à l'aise. Mais je rappelle que la variante affaiblie Loc (7b) est suffisante pour faire la théorie des foncteurs $f_!$ pour les catégories $\mathrm{HOT}_W(S)$ [24] (*cf.* VI).

23. J'y ai rajouté finalement un quatrième F (comme "fibration").

24. Ici ma mémoire me joue un tour - on n'a nullement besoin pour cela de l'axiome déjà très fort Loc (7b), mais seulement de Loc (3 bis), dont il semble bien qu'il soit vérifiée pour tous les localiseurs fondamentaux "raisonnables". [page 37]

Commentary · Later developments [ms. 36]

Intrinsic fibrations and sharp maps

The definition chosen here has a later name which makes its independence of auxiliary lifting classes particularly clear. It is the definition of a sharp map in Rezk (1998, Section 2): pullback along the map, after an arbitrary preliminary base change, preserves weak equivalences. In a right proper model category Rezk's Proposition 2.7 identifies these maps with those whose ordinary pullback squares are homotopy Cartesian. His Proposition 2.2 says that all model fibrations are sharp exactly when the model category is right proper.

These statements explain the intended geometry of Fib_W, but they do not identify it with the fibrations of an arbitrary chosen model structure. Nor do they turn a weakly W-fibred category into an intrinsic fibration merely by changing terminology. The latter conclusion is Loc (7), whose failure for connected-component equivalences is demonstrated below.

A useful consequence can already be read directly from the definition. Intrinsic fibrations are stable under composition: if $X \to Y \to S$ have this property and $T' \to T$ is a W-equivalence over S, first pull it back to Y, and then to X. Both comparison maps lie in W. They are also stable under every base change, because a test over the new base is already a test over the original one. These two elementary operations are the structural resources which the weaker class must acquire if it is to replace Fib_W.

C'est d'ailleurs une chose surprenante, puisque via le yoga général des dérivateurs associés aux catégories de modèles, on s'attendrait plutôt que pour avoir des adjoints à gauche $f_!$ des foncteurs f^* d'image inverse, il faut faire sur W des hypothèses du type *W-cofibration* (essentiellement, Loc (6 a)). Il me semble peu probable que Loc (7 b), ni même Loc (7), p. 23
implique Loc (6 a), ni même sa variante plus faible Loc (6′ a) (axiome du carré cocartésien, ou de Mayer-Vietoris, forme faible). Si d'autre part ces axiomes ne sont pas *vérifiés,* alors que Loc (7) l'est, il y a des chances que cela donnera un exemple où il y a un formalisme des $f_!$, sans que l'axiome d'exactitude à gauche soit vérifié.

Quant à la forme Loc (7 c), plus faible encore, elle suffit pourtant (comme nous le verrons plus bas) à assurer que Cat admet suffisamment de W-fibrations (résultat qui n'a rien d'évident, [page 38]
et ne pouvait m'apparaître qu'après avoir pris connaissance du substantiel lemme de K. S. Brown, dans son beau travail où il introduit les catégories à fibrations et à cofibrations).

Nous donnerons aussi plus bas des cas fort simples, où la condition Loc (7 b) entraîne déjà Loc (7) (W fortement saturé, *i.e.* Loc (1 bis)), voire même où Loc (7 c) entraîne Loc (7) (cas où W satisfait à l'axiome Loc (8) des limites inductives). Je signale en passant que je ne connais pas de localiseur fondamental satisfaisant l'axiome Loc (8) (qui implique déjà $W = W^{\natural}$, *i.e.* Loc (1 bis)), sans que W soit fortement saturé (*i.e.* en satisfasse même Loc (1 ter)).

Loc (7)

a) On a $\mathcal{F}_W \subset \mathrm{Fib}_W$, *i.e.* pour tout diagramme cartésien (4.2.2) dans Cat, avec $f \in \mathcal{F}_W$ (*i.e.* f Cat-fibrant et faiblement W-fibrant) et $p \in W$, on a $q \in W$.

b) Pour tout diagramme commutatif

$$\begin{array}{ccc} X & \xrightarrow{\ f\ } & Y \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & S & \end{array}$$

avec $p, q \in \mathcal{F}_W$ et $f \in W$, on a $f \in W_S^{\mathrm{u}}$ (ou, ce qui revient au même comme X, Y sont W-lisses sur S, $f_s \in W$ pour tout $s \in \mathrm{Ob}\, S$) [25]. [page 39]

c) On a

$$\mathcal{F}_W \cap W \subset W^{\mathrm{u}},$$

25. **N.B.** La démonstration de $B(\mathcal{F}_W) \Longrightarrow B(\mathrm{Fibf}_W)$ montre en fait qu'il suffit de postuler b) lorsque f est cartésien, et même lorsque X, Y sont scindées sur S et f compatible avec le scindage.

en d'autres termes, pour toute flèche $f : X \longrightarrow S$ dans Cat telle que $f \in \mathcal{F}_W$ (on pourrait appeler ces flèches des Cat-W-fibrations, étant entendu qu'elles sont aussi des Cat-fibrations, mais non nécessairement des W-fibrations), si $f \in W$, alors $f \in W_S^{\mathrm{u}}$ (ou, ce qui revient au même, les fibres X_s de f ($s \in \mathrm{Ob}\, S$) sont W-asphériques).

p. 24

F) [26] Cat a suffisamment de W-fibrations, *i.e.* Cat muni de (W, Fib_W) est une catégorie à cofibrations (propre, et même de Brown, *i.e.* $X \longrightarrow e$ est dans Fib_W pour tout X dans Cat.

Il est clair que c est le cas particulier de b obtenu en prenant $Y = S$, $q = \mathrm{id}_S$, donc b $\Longrightarrow$ c. L'implication a $\Longrightarrow$ b est moins évidente, elle est établie d'abord dans XII, et nous y reviendrons ci-dessous (4.4.2 ci-dessous). Le reste du présent paragraphe est consacré à étudier diverses variantes des conditions a) b) c) précédentes et les implications entre celles-ci.

[page 40]

Commentary · Exposition [ms. 39]

The three tests measure different operations

Grothendieck separates three assertions which are easily conflated if one thinks only of familiar topological fibrations. Condition A concerns changing the base of an arbitrary W-equivalence. Condition B concerns changing the base of a W-equivalence between two suitable objects already lying over the same base. Condition C concerns one suitable map which is itself a W-equivalence. The implication from B to C uses the identity family $S \to S$ as the second object.

For a Grothendieck fibration in $\mathcal{F}_W$, the strict fibres are good representatives of the appropriate relative homotopy fibres. This accounts for the fibrewise reformulations of B and C. It does not remove their force: a total-space equivalence between locally constant families need not induce an equivalence on each strict fibre for a coarser homotopy theory. The covering obstruction at the end of the section will make this failure explicit in degree zero.

The added assertion F says only that every functor admits a factorization

$$X \xrightarrow{i} \bar{X} \xrightarrow{p} S, \qquad i \in W, \quad p \in \mathrm{Fib}_W.$$

The word "cofibrations" in its printed definition is a slip for "fibrations". A separate dependency concerns the assertion that every object is intrinsically fibrant over the final category: this is exactly stability of W under the functors $X \times -$. The editorial qualification to Rappel 2.3 must therefore be carried here; that product stability is established under Loc (3 bis), not by the cited argument from the weak axioms alone. Factorizations by themselves should not silently be identified with an all-objects-fibrant Brown structure without this additional fact. There is no resulting gap in the implication from D: every $X \to e$ is perfect directly from its comma-category definition, so $\mathrm{Parf}_{W_0} \subset \mathrm{Fib}_W$ independently supplies all the required terminal fibrations, and therefore product stability. F still does not say that the already available class $\mathcal{F}_W$ consists of intrinsic fibrations.

The footnote correcting the recollection about $f_!$ is mathematically significant. Construction of the left homotopy Kan extensions is controlled here by relative Theorem A, Loc (3 bis); it should not be attributed to the much stronger B merely because B had accompanied earlier arguments. This is consistent with the later exposition of Maltsiniotis (2005, pp. 3–4). Smooth and proper base-change formulas, locally constant families, and existence of Kan extensions remain distinct pieces of the formalism.

The speculative independence from the cofibration axioms at ms. 37 is therefore a question about the scope of an abstract presentation, not a reason to distrust the familiar homotopy theory of spaces. Its present status must take account of the minimum-localizer theorem, discussed at ms. 65 below.

4.4. Soit, plus généralement,

$$\mathcal{F} \subset \mathrm{Fl}(\mathrm{Cat})$$

un ensemble de flèches dans Cat, en pensant plus particulièrement au cas où $\mathcal{F}$ est un des sept ensembles du diagramme (4.2.1) (p. 30) autres que Fib_W. Nous pouvons formuler trois

26. rajouté après coup.

propriétés similaires pour $\mathcal{F}$ à celles formulées dans Loc (7 a b c) dans le cas de $\mathcal{F}_W$, notons ces propriétés

$$\mathrm{A}(\mathcal{F})\,,\ \mathrm{B}(\mathcal{F})\,,\ \mathrm{C}(\mathcal{F})\,,\ ^{27}$$

donc

$$(4.4.1)\qquad \begin{cases} \mathrm{A}(\mathcal{F}) & : \ \mathcal{F} \subset \mathrm{Fib}_W. \\ \mathrm{B}(\mathcal{F}) & : \ \mathrm{Fl}(\mathcal{F}_S) \cap W_S \subset W_S^{\mathrm{u}} \\ & \quad (\text{où } \mathcal{F}_S \text{ désigne la sous-catégorie pleine de } \mathrm{Cat}/S \\ & \quad \text{formée des } f : X \longrightarrow S \text{ avec } f \in \mathcal{F}). \\ \mathrm{C}(\mathcal{F}) & : \ \mathcal{F} \cap W \subset W^{\mathrm{u}}. \end{cases}$$

Il est clair qu'on a $\mathrm{B}(\mathcal{F}) \Longrightarrow \mathrm{C}(\mathcal{F})$, et je vais donner une condition sur $\mathcal{F}$ qui implique qu'on a aussi $\mathrm{A}(\mathcal{F}) \Longrightarrow \mathrm{B}(\mathcal{F})$.

(Nous l'appliquerons dans les cas suivants : [page 41]

$$(4.4.2)\qquad \mathcal{F} \ = \ \mathcal{F}_W,\ \mathrm{Fibf}_W,\ \mathrm{Parf}_W,\ \mathcal{F}_{W_0},\ \mathrm{Fibf}_{W_0}.$$

Je signale d'ailleurs que l'on verra plus bas (cor. 4.4.10) que

$$(4.4.3)\qquad \mathrm{A}(\mathcal{F}_W) \iff \mathrm{A}(\mathrm{Fibf}_W), \qquad \mathrm{A}(\mathcal{F}_{W_0}) \iff \mathrm{A}(\mathrm{Fibf}_{W_0}),$$

et de même pour les variantes B, C, de sorte que pour l'implication que nous voulons établir, il n'y a pas lieu de distinguer les cas de $\mathcal{F}_W$ et Fibf_W, de $\mathcal{F}_{W_0}$ et Fibf_{W_0}. D'ailleurs il suffira de regarder les ensembles $\mathcal{F}_{W_0}$, Fibf_{W_0}, Parf_{W_0}, puisque le cas des ensembles relatifs à W en sont un cas particulier (en prenant $W_0 = W$). [28]

Lemme 4.4.1. [29] *Supposons que $\mathcal{F}$ satisfasse la condition suivante : toute flèche f de* Cat *se factorise en $f = pi$, avec $i \in W$, $f \in \mathcal{F}$. Alors la condition* $\mathrm{A}(\mathcal{F})$ *sur $\mathcal{F}$ implique que dans* Cat *il y a "assez de W-fibrations", et par suite (par un argument formel bien connu), que l'on a* $\mathrm{B}(\mathrm{Fib}_W)$, *et a fortiori (comme par hypothèse $\mathcal{F} \subset \mathrm{Fib}_W$)* $\mathrm{B}(\mathcal{F})$. p. 25 [page 42]

Commentary · Examples [ms. 41]

An identity needed by the formal scheme

Grothendieck now abstracts the three tests so that one proof can serve several classes of maps. The six classes to which he applies the scheme all contain the identities. That small hypothesis is needed for the assertion, made for an arbitrary $\mathcal{F}$, that B implies C.

Here is a complete test of the literal statement without it. Take $W = \mathbf{W}_\infty$ and let $\mathcal{F}$ consist only of the inclusion $j : e \to [1]$ selecting 0. The full subcategory $\mathcal{F}_{[1]}$ has one object and only its identity endomorphism; for other bases it is empty. Thus every weak equivalence between its objects remains a weak equivalence after every base change, and $\mathrm{B}(\mathcal{F})$ holds. Both e and $[1]$ are contractible, so $j \in W$. Pulling j back along the inclusion of 1, however, gives $\varnothing \to e$, which is not a weak homotopy equivalence. Hence $\mathrm{C}(\mathcal{F})$ fails.

The repair is simply to require $\mathrm{id}_S \in \mathcal{F}$ for every S. Apply B to the arrow $p : (X \to S) \to (S \to S)$ whenever $p \in \mathcal{F} \cap W$; the resulting universal equivalence is exactly C. All subsequent applications satisfy this hypothesis. This is a missing condition in the unrestricted formal sentence, not a defect in the six geometric cases.

A second notational repair keeps the scheme readable. In Lemma 4.4.1 the right factor is $p \in \mathcal{F}$, not the printed $f \in \mathcal{F}$. The literal latter requirement would demand that every map already belong to $\mathcal{F}$, which is neither used nor intended. The same distinction between the original arrow and its right factor recurs at ms. 50.

27. **N.B.** Ces conditions ont un sens si $\mathcal{F} \subset \mathrm{Fl}(\mathcal{M})$, si $(\mathcal{M}, W)$ est une catégorie de modèles quelconque.

28. Cela fera donc a priori $3 \times 6 = 18$ conditions différentes, mais à cause de (4.4.3) il n'y en a (à équivalence près) que $4 \times 3 = 12$, et en fait deux parmi ces quatre triples de conditions se réduisent à une seule (pour $\mathcal{F} = \mathcal{F}_W$ et $\mathcal{F} = \mathcal{F}_{W_0}$), de sorte qu'il ne reste au total que *huit* conditions différentes, que nous résumons dans le diagramme récapitulatif (4.4.7.1) de la page 48. Il y en a même seulement *quatre,* A_{W_0}, B_{W_0}, C_{W_0}, D_{W_0}, comme fonctions de W_0, les quatre autres A, B, C, D s'obtiennent en spécialisant au cas où $W_0 = W$.

29. Vaut dans une catégorie de modèles quelconque.

N.B. Il est clair en effet que si on a $\mathcal{F} \subset \mathcal{F}'$, alors

$$(*) \qquad \mathrm{A}(\mathcal{F}') \Longrightarrow \mathrm{A}(\mathcal{F}) \qquad \text{et de même pour B, C.}$$

Or la condition préliminaire sur $\mathcal{F}$ est bien satisfaite dans le cas d'un ensemble de l'une des formes $\mathcal{F} = \mathcal{F}_W$, Fibf_W, Parf_W. Il suffit de le voir dans le cas des sous-ensembles $\mathcal{F}_W$, Parf_W de Fibf_W, *i.e.* que toute flèche f de Cat se factorise en

$$f = pi,$$

avec $i \in W$, et p étant, au choix, dans Parf_W, ou dans $\mathcal{F}_W$. Or dans le cas de Parf_W, c'est ce qui est établie dans VII (Catégories de chemins (2)) grâce au formalisme des $\underline{\mathrm{Ch}}(S) \longrightarrow S \times S$. Pour trouver une factorisation avec $f = qj$, $j \in W$, $q \in \mathcal{F}_W$, il suffit de voir que p se factorise ainsi en $p = q_0 j_0$, on aura ‖

$$f = \underbrace{q_0}_{\in \mathcal{F}_{W_0}} \underbrace{(j_0 i)}_{\in W},$$

donc on peut supposer $f \in \mathrm{Parf}_W$. Mais si X est W-parfait sur S, donc un W-fibré faible sur S, alors dans la factorisation [page 43]

$$\begin{array}{ccc} X & \xrightarrow{\ i\ } & \Phi_S(X) \\ & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle p} & \\ & S & \end{array}$$

avec $i \in W$ et $p \in \mathrm{Catfib}$ (*cf.* VI), on sait que p est aussi une W-fibration faible, *i.e.* $p \in \mathcal{F}_W$, d'où la conclusion. Ainsi on trouve le

Corollaire 4.4.2. *Supposons que $\mathcal{F}$ soit l'un des six ensembles* (4.4.2) (i.e. *l'un des ensembles du diagramme* (4.2.1), *à l'exclusion de Fib_W et Fib_{W_0}). Alors on a*

$$\mathrm{A}(\mathcal{F}) \implies \mathrm{B}(\mathcal{F}) \implies \mathrm{C}(\mathcal{F})\,.$$

Lemme 4.4.3. *Soit $(\mathcal{M}, W)$ une catégorie de modèles, et soit $\mathcal{F} \subset \mathrm{Fl}(\mathcal{M})$ satisfaisant les conditions suivantes*

1) *$\mathcal{F}$ stable par changement de base, composition, contient les isomorphismes.*
2) *$\mathcal{M}$ a un objet final, et pour tout $X \in \mathrm{Ob}\,\mathcal{M}$, $X \longrightarrow e$ est dans $\mathcal{F}$.*
3) *Toute flèche f de $\mathcal{M}$ se factorise en $f = pi$, avec $i \in W$, $p \in \mathcal{F}$ (c'est la condition du lemme* 4.4.1).

Alors les conditions $\mathrm{A}(\mathcal{F})$, $\mathrm{B}(\mathcal{F})$, $\mathrm{C}(\mathcal{F})$ *sur $\mathcal{F}$ sont équivalentes.* p. 26

En effet, en vertu de 4.4.1, il reste à prouver l'implication

$$\mathrm{C}(\mathcal{F}) \implies \mathrm{A}(\mathcal{F}),$$

[page 44]

Commentary · Exposition [ms. 43]

Why enough intrinsic fibrations gives B

The first implication has a short proof which clarifies why factorization is relevant. Suppose every map admits a factorization as a W-equivalence followed by an intrinsic W-fibration. Let $u : X \to Y$ be a W-equivalence over S, where both structural maps $X \to S$ and $Y \to S$ are intrinsically fibrant. We must show that u remains a W-equivalence after an arbitrary base change $t : T \to S$.

Factor that base change, rather than u, as

$$T \xrightarrow{a} Z \xrightarrow{b} S, \qquad a \in W, \quad b \in \mathrm{Fib}_W.$$

Since b is intrinsically fibrant, its pullback preserves u, so $u_Z : X \times_S Z \to Y \times_S Z$ lies in W. The structural maps of these two pullbacks over Z are again intrinsically fibrant. Consequently the maps

$$X \times_S T \longrightarrow X \times_S Z, \qquad Y \times_S T \longrightarrow Y \times_S Z$$

induced by a both belong to W. In the commutative square formed by these maps and u_Z, two-out-of-three gives $u_T \in W$. The map t was arbitrary, which proves $u \in W_S^{\mathrm{u}}$.

If $\mathcal{F} \subset \mathrm{Fib}_W$ and every map factors through $\mathcal{F}$ after a W-equivalence, the assumed intrinsic factorizations exist. The argument therefore proves $\mathrm{A}(\mathcal{F}) \Rightarrow \mathrm{B}(\mathrm{Fib}_W)$, and restriction gives $\mathrm{B}(\mathcal{F})$. It also explains why the statement concerns the full subcategory of maps over S, rather than merely Cartesian arrows between fibred categories: no Cartesian condition on u was used.

The remaining input in Corollary 4.4.2 is the availability of the six factorizations. Perfect replacement is inherited from the path-category construction in VII. Applying Φ_S to a weakly fibred representative gives the locally constant Grothendieck-fibration replacement. For the latter argument, the underbrace $q_0 \in \mathcal{F}_{W_0}$ at ms. 42 should be read with W in place of W_0, unless the entire argument has first been carried out relative to W_0. Both versions are available; their parameters should not be mixed within one factorization.

This completes the "formal well-known argument" suppressed in the source. It uses base change, two-out-of-three, and the specified factorizations. No claim about full faithfulness of a localization functor, and no strong saturation assumption, is needed.

i.e. ceci : si $\mathcal{F}$ satisfait aussi la condition

4) $\mathcal{F} \cap W \subset W^{\mathrm{u}}$ (ou ce qui revient au même, comme $\mathcal{F}$ est stable par changement de base, que $\mathcal{F} \cap W$ est stable par changement de base),

alors on en conclut

$$\mathcal{F} \subset \mathrm{Fib}_W.$$

Or ceci n'est autre que le lemme de K. S. Brown, sous la forme duale de celle donnée plus haut (3.2.1, page 20).

Parmi les six ensembles de flèches envisagés dans (4.4.2), les hypothèses 1) 2) 3) sont satisfaites pour Parf_W et Parf_{W_0}, à l'exclusion des quatre autres. (Les autres satisfont à toutes les conditions, à la seule exception de la stabilité par composition [30]). On trouve donc :

Corollaire 4.4.4. *Les conditions* $\mathrm{A}(\mathrm{Parf}_W)$, $\mathrm{B}(\mathrm{Parf}_W)$, $\mathrm{C}(\mathrm{Parf}_W)$ *sont équivalentes* (nous désignons cette condition sur W par D). *De même les conditions* $\mathrm{A}(\mathrm{Parf}_{W_0})$, $\mathrm{B}(\mathrm{Parf}_{W_0})$, $\mathrm{C}(\mathrm{Parf}_{W_0})$ *sont équivalentes.*

(On désignera la condition obtenue sur le couple $W \supset W_0$ de localiseurs fondamentaux par D_{W_0}.) [page 45]

Ainsi on a (comme $\mathrm{Parf}_{W_0} \subset \mathrm{Parf}_W$)

$$\mathrm{D} = \mathrm{D}_W \implies \mathrm{D}_{W_0}\,, \tag{4.4.4}$$

et si $W_0' \subset W_0$, on aura

$$\mathrm{D}_{W_0} \implies \mathrm{D}_{W_0'}\,. \tag{4.4.5}$$

Corollaire 4.4.5. *Désignons par* A, B, C *respectivement les conditions* Loc (7 a), Loc (7 b), Loc (7 c). *On a alors les implications*

$$\mathrm{A} \implies \mathrm{B} \implies \mathrm{C}\,. \tag{4.4.5.1}$$

De plus, si on désigne (*pour un ensemble* $\mathcal{F}$ *de flèches de* Cat) *par* $\mathrm{Comp}(\mathcal{F})$ *la condition sur* $\mathcal{F}$ *que* $\mathcal{F}$ *soit stable par composition, on a les équivalences*

$$\mathrm{A} \iff (\mathrm{C} + \mathrm{Comp}(\mathcal{F}_W)) \iff (\mathrm{C} + \mathrm{Comp}(\mathrm{Fibf}_W)). \tag{4.4.5.2}$$

Démonstration. La première assertion est contenue dans le corollaire 4.4.2, appliqué au cas $\mathcal{F} = \mathcal{F}_W$. D'autre part, si $\mathcal{F}_W$ satisfait à Comp($\mathcal{F}_W$), il satisfait aux conditions 1) 2) 3) du lemme de Brown 4.4.3, donc joint à C, il implique A. Il reste, pour la première équivalence, à prouver que

$$A \implies \mathrm{Comp}(\mathcal{F}_W).$$

[page 46]

Commentary · Context [ms. 45]

The precise contribution of Brown's lemma

Grothendieck's enthusiasm comes from a reversal of the expected direction of verification. To prove that a candidate fibration class preserves all weak equivalences under pullback, one may first verify that its trivial members remain trivial after pullback. If the class is closed under composition and base change, contains the maps to the final object, and supplies weak-equivalence–fibration factorizations, Brown's theory promotes this apparently smaller assertion to the full base-change theorem.

In the original paper, the factorization lemma is in Part I, §1, pp. 421–422, and the relevant pullback theorem is Part I, §4, Lemma 2, pp. 428–429 (Brown, 1973). Lemma 1 of that section first proves invariance of base change between fibrant objects over a fixed base; Lemma 2 then treats a weak equivalence of bases. The full dual argument has been supplied in the commentary to XVI, ms. 20–22. Here it yields $\mathrm{C}(\mathcal{F}) \Rightarrow \mathrm{A}(\mathcal{F})$ under the hypotheses of Lemma 4.4.3.

Perfect maps satisfy the composition requirement before Loc (7) is imposed. The locally constant Grothendieck fibrations need not. This single difference explains why each triple for Parf_W or Parf_{W_0} immediately collapses to the condition denoted D, while the corresponding triples for $\mathcal{F}_W$ and $\mathcal{F}_{W_0}$ remain separated for the moment.

Footnote 28 has these classes interchanged: its unconditional collapse concerns perfect maps. It is not evidence for an unproved unconditional use of Brown's lemma on $\mathcal{F}_W$. The body of the argument, especially Corollaries 4.4.4–4.4.6, keeps the missing composition condition visible.

Mais on a par définition

$$(*) \qquad \mathcal{F}_W = \mathrm{Catfib} \cap \mathrm{Fibf}_W$$

et on sait que Catfib est stable par composition. Donc $\mathcal{F}_W$ l'est aussi, pourvu que le composé gf de deux flèches dans $\mathcal{F}_W$ soit dans Fibf_W. Or par hypothèse A, qui signifie $\mathcal{F}_W \subset \mathrm{Fib}_W$, on a $f, g \in \mathrm{Fib}_W$, donc $gf \in \mathrm{Fib}_W$, puisque Fib_W est stable par composition, a fortiori $gf \in \mathrm{Fibf}_W$.

D'autre part, la formule précédente $(*)$ montre que $\mathrm{Comp}(\mathrm{Fibf}_W) \Longrightarrow \mathrm{Comp}(\mathcal{F}_W)$, donc on a gratis l'implication $\Longleftarrow$ dans la deuxième équivalence (4.4.5.2). L'implication en sens inverse revient alors à

$$\mathrm{A} \implies \mathrm{Comp}(\mathrm{Fibf}_W),$$

ce qui sera évident grâce au résultat (donné plus bas) [page 47]

$$\mathrm{A} = \mathrm{A}(\mathcal{F}_W) \iff \mathrm{A}(\mathrm{Fibf}_W) \qquad \text{et de même pour B, C,}$$

qui signifie donc que

$$\mathcal{F}_W \subset \mathrm{Fib}_W \qquad \text{implique} \qquad \mathrm{Fibf}_W \subset \mathrm{Fib}_W \qquad (\text{donc } \mathrm{Fibf}_W = \mathrm{Fib}_W),$$

or Fib_W étant stable par composition, il en est de même pour Fibf_W, q.e.d.

Corollaire 4.4.6. *Supposons que $\mathcal{F}_{W_0}$ soit stable par composition, ce qui est le cas notamment (par* 4.4.5.2 *appliqué à W_0 au lieu de W) si W_0 satisfait* Loc (7). *Alors les conditions* $\mathrm{A}(\mathcal{F}_{W_0})$, $\mathrm{B}(\mathcal{F}_{W_0})$, $\mathrm{C}(\mathcal{F}_{W_0})$ *(que nous notons aussi simplement* A_{W_0}, B_{W_0}, C_{W_0})

30. **N.B.** Pour Fib_{W_0}, ce sont les conditions 1) 2) qui sont vérifiées, et par contre, la condition 3) qui fait problème. Notons là $\mathrm{F}(W_0)$. Si elle est satisfaite (*i.e.* si Cat a assez de W_0-fibrations), alors on a aussi équivalence des conditions $\mathrm{A}(\mathrm{Fib}_{W_0})$, $\mathrm{B}(\mathrm{Fib}_{W_0})$, $\mathrm{C}(\mathrm{Fib}_{W_0})$.

sont équivalentes. (***N.B.*** *Si on ne fait pas l'hypothèse précédente sur* W_0*, on aura seulement* $\mathrm{A}_{W_0} \Longrightarrow \mathrm{B}_{W_0} \Longrightarrow \mathrm{C}_{W_0}$*, en vertu de* 4.4.2.)

4.4.7. On a fait le tour à présent de toutes les conditions de type "fibration" sur W, ou sur le couple (W, W_0), qui m'ont parues utiles. Je vais les déployer ici dans un diagramme (plus ou moins) récapitulatif :

[page 48]

Commentary · Examples [ms. 47]

A finite failure of composition

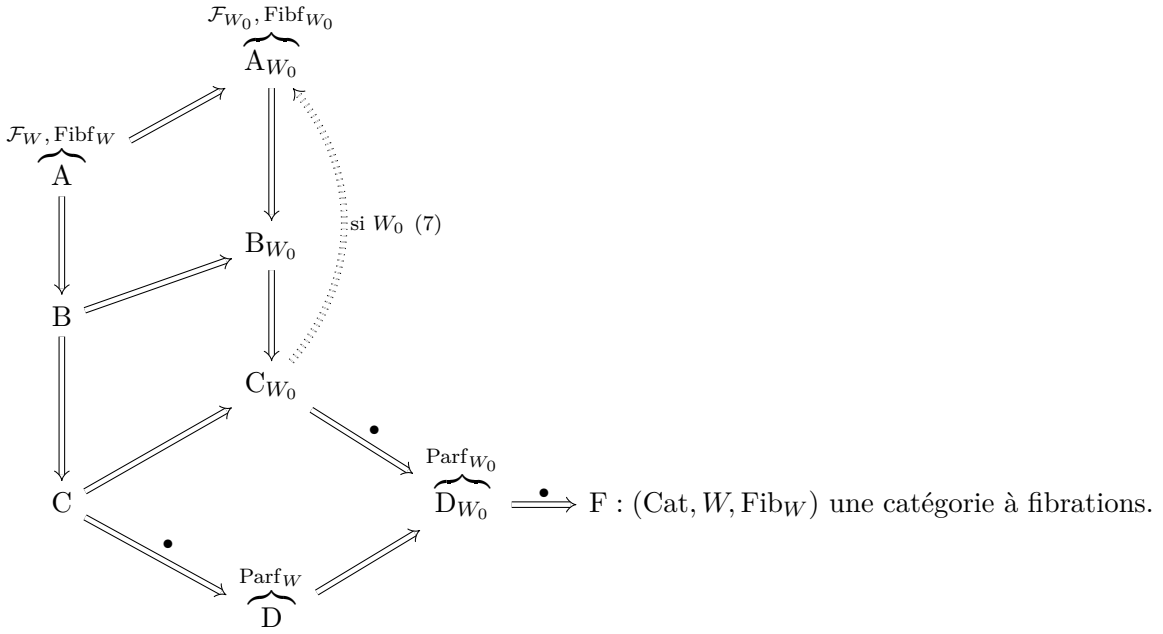
The composition condition in Corollary 4.4.5 can be tested on a very small family. The commentary on Chapter I, manuscript pp. 118 and 122, already examined failures of composition. The following presentation singles out the precise class $\mathcal{F}_W$ used here and needs only connected components.

Put $W = \mathbf{W}_0$, the class of functors inducing bijections on π_0, and let G be a nontrivial finite group. Define a category B with two objects b_0, b_1 by

$$\mathrm{Hom}_B(b_0,b_0) = G, \quad \mathrm{Hom}_B(b_1,b_1) = \{1\}, \quad \mathrm{Hom}_B(b_0,b_1) = G, \quad \mathrm{Hom}_B(b_1,b_0) = \varnothing.$$

Write $a_h : b_0 \to b_1$ for the arrow labelled by h and prescribe $a_h g = a_{hg}$. There is a Grothendieck fibration $q : B \to [1]$ with fibres BG and e. Its inverse-image functor along $0 \to 1$ is $e \to BG$. Since both categories are connected, $q \in \mathcal{F}_{\mathbf{W}_0}$.

Let E be a transitive G-set with more than one element. The functor $r : B \to BG$ sending g and a_g to g pulls the corresponding locally constant discrete family on BG back to a discrete fibration $p : A \to B$. Every transport map of this family is a bijection of sets. Thus p lies in $\mathcal{F}_{\mathbf{W}_0}$, and in fact its transports are isomorphisms of discrete categories.



The composite qp is again a Grothendieck fibration. Its fibre over 0 is the action groupoid $E /\!\!/ G$, which is connected by transitivity; its fibre over 1 is the discrete category E. The inverse-image functor between these fibres is the inclusion of the objects of the action groupoid. On connected components it is the map

$$E \longrightarrow E/G = \{*\},$$

which is not bijective. Consequently $qp \notin \mathcal{F}_{\mathbf{W}_0}$, although both p and q belong to that class. Taking $G = C_2$ with its regular action gives a base B with two objects and five arrows, and A with four objects and ten arrows; all categories in the example are finite.

The mechanism is the loss of monodromy information when a transport functor is required to preserve only connected components. A second locally constant family can detect precisely the information the first equivalence discarded. Corollary 4.4.5 says that C together with composition closure prevents this phenomenon. It does not say that C can be used without checking composition.

p. 28

$\overset{\bullet}{\Longrightarrow}$ F : $(\mathrm{Cat}, W, \mathrm{Fib}_W)$ une catégorie à fibrations.

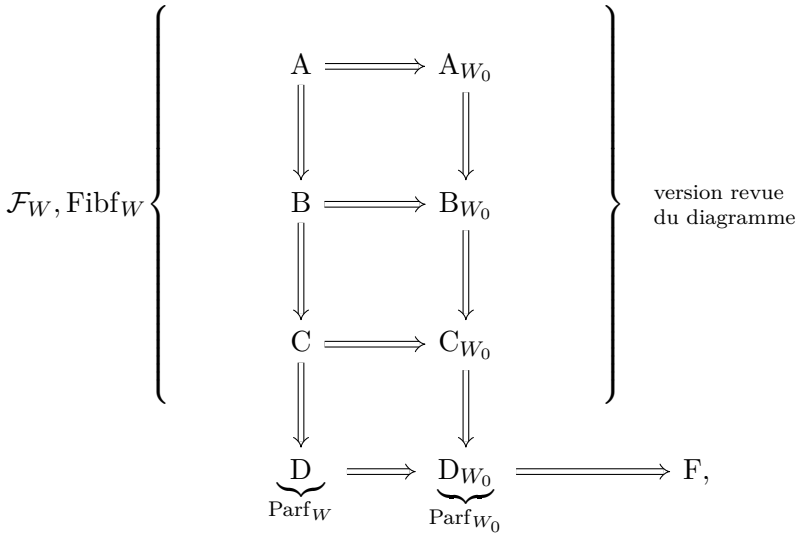


diagramme que je vais commenter. Toutes les implications en traits pleins du diagramme ont été déjà obtenues ou sont tautologiques, à l'exception des trois $\overset{\bullet}{\Longrightarrow}$ sur lesquels je vais revenir. L'implication en pointillés $\mathrm{C}_{W_0} \dashrightarrow \mathrm{A}_{W_0}$ est une implication conditionnelle, soumise à la condition marquée sur le diagramme comme W_0 (7), ce qui signifie : W_0 satisfait à Loc (7). Cette implication, *i.e.* l'équivalence de A_{W_0}, B_{W_0}, C_{W_0} sous la condition W_0 (7), a été vue dans 4.4.6. J'ai marqué, au dessus des deux groupes (A, B, C) et (A_{W_0}, B_{W_0}, C_{W_0}) ainsi qu'au dessus de D et de D′ (qui correspondent chacun à un tel groupe de conditions $\mathrm{A}(\mathcal{F})$, $\mathrm{B}(\mathcal{F})$, $\mathrm{C}(\mathcal{F})$ toutes équivalentes, avec $\mathcal{F} = \mathrm{Parf}_W$ ou $\mathcal{F} = \mathrm{Parf}_{W_0}$) les ensembles de flèches [page 49]
qui leur donnent naissance respectivement : on notera qu'il y en a deux pour les pour les deux triplets nommés en premier, A, B, C pouvant se définir via $\mathcal{F}_W$ ou Fib_W indifféremment, et de même A_{W_0}, B_{W_0}, C_{W_0} via $\mathcal{F}_{W_0}$ ou Fib_{W_0}, comme déjà énoncé (4.4.3) et comme nous le verrons plus bas (cor. 4.4.10, pages 54-55). Par contre, les triplets réduits D et D_{W_0} sont définis chacun par un $\mathcal{F}$ seulement, savoir par Parf_W et

Parf_{W_0} respectivement. (En tout, cela fait intervenir six ensembles $\mathcal{F}$ distincts, à savoir p. 29
les six ensembles du diagramme (4.2.1) autres que Fib_W et Fib_{W_0}.)

L'implication non tautologique C $\overset{\bullet}{\Longrightarrow}$ D est un cas particulier de l'implication $\mathrm{C}_{W_0} \overset{\bullet}{\Longrightarrow}$ D_{W_0}, laquelle est contenue dans ce qui a été annoncé à l'instant, à savoir $\mathrm{C}_{W_0}(\mathcal{F}_{W_0}) \Longrightarrow$ $\mathrm{C}_{W_0}(\mathrm{Fib}_{W_0})$, compte tenu que $\mathrm{Parf}_{W_0} \subset \mathrm{Fibf}_{W_0}$ (*cf.* (∗), p. 42). Faisant $W_0 = W$, on trouve [page 50]

donc l'implication A $\Longrightarrow$ D, qui est cependant contenue dans les autres implications du diagramme, comme composée dans la chaîne d'implications

$$\mathrm{A} \Longrightarrow \mathrm{B} \Longrightarrow \mathrm{C} \Longrightarrow \mathrm{D} \Longrightarrow \mathrm{D}_{W_0} \overset{\bullet}{\Longrightarrow} \mathrm{F}.$$

Il reste, dans ces commentaires généraux, à dire un mot de cette dernière implication

$$\mathrm{D}_{W_0} \overset{\bullet}{\Longrightarrow} \mathrm{F},$$

i.e. du fait que la plus faible de toutes les conditions A à D_{W_0} envisagées ici implique déjà que Cat a assez de W-fibrations, *i.e.* est une catégorie à cofibrations pour (W, Fib_W). C'est clair quand on prend D_{W_0} sous la forme $\mathrm{A}(\mathrm{Parf}_{W_0})$, *i.e.*

$$\mathrm{Parf}_{W_0} \subset W.$$

Comme toute flèche f de Cat se factorise en $f = pi$, avec

$$i \in W_0 \subset W \quad \text{et} \quad f \in \mathrm{Parf}_{W_0} \subset \mathrm{Fib}_W\,,$$

on trouve la factorisation avec $i \in W$, $f \in \mathrm{Fib}_W$.

4.4.8. Pour terminer d'établir les implications du diagramme p. 48, il reste seulement à établir les équivalences [page 51]

$$\text{(4.4.8.1)} \qquad \begin{cases} \mathrm{A}(\mathcal{F}_{W_0}) & \Longleftrightarrow & \mathrm{A}(\mathrm{Fibf}_{W_0}) \\ \mathrm{B}(\mathcal{F}_{W_0}) & \Longleftrightarrow & \mathrm{B}(\mathrm{Fibf}_{W_0}) \\ \mathrm{C}(\mathcal{F}_{W_0}) & \Longleftrightarrow & \mathrm{C}(\mathrm{Fibf}_{W_0}), \end{cases}$$

qui donneront les équivalences similaires pour W, en prenant $W_0 = W$.

Commentary · Exposition [ms. 50]

How to read the rectangle of conditions

The large diagram records a small number of operations. Moving down a column first specializes from arbitrary base equivalences to equivalences between families, then to a family equivalent to its base, and finally replaces weakly fibred families by perfect ones. Moving to the right restricts the admissible families from W to W_0. The first three downward arrows ultimately depend on the natural comparison with Φ_S, whereas the perfect-map triple has already been handled by Brown's lemma.

The last arrow, $\mathrm{D}_{W_0} \Rightarrow \mathrm{F}$, has an especially direct meaning. Given $f : X \to S$, take its path factorization

$$X \xrightarrow{i} \bar{X} \xrightarrow{p} S, \qquad i \in W_0 \subset W, \quad p \in \mathrm{Parf}_{W_0}.$$

The condition D_{W_0}, in its A-form, says that p is an intrinsic W-fibration. This is the required factorization for F. The isolated display $\mathrm{Parf}_{W_0} \subset W$ in the source is therefore an edition slip for $\mathrm{Parf}_{W_0} \subset \mathrm{Fib}_W$; it is not an additional theorem asserting that all perfect maps are equivalences. The subsequent occurrences of f as the right factor should likewise be p.

This interpretation also explains the role of the smallest reference localizer. It supplies the largest scope for the existence argument, because asking its perfect maps to preserve W is the weakest of the displayed perfect-map conditions. The existence of replacements remains separate from the claim that every weakly W-fibred family is already a suitable replacement. The connected-component example will satisfy the first assertion and fail the second.

None of the solid arrows in this rectangle relies on the conditional arrows which return upwards. Those additional arguments enter only after the natural replacement lemma is established. Reading the diagram in that order avoids a circular use of the equivalence between $\mathcal{F}_{W_0}$ and Fibf_{W_0}.

La première équivalence (4.4.8.1) sera conséquence du lemme (± tautologique) suivant :

Lemme 4.4.9. *Soient* $(\mathcal{M}, W)$ *une catégorie de modèles,* $\mathcal{F}, \mathcal{G} \subset \mathrm{Fl}(\mathcal{M})$, *tels que tout* $f \in \mathcal{F}$, $f : X \longrightarrow S$, *s'écrive* $f = pi$, *avec* $i \in W_S^u$, $p \in \mathcal{G}$. *Alors* $\mathrm{A}(\mathcal{G}) \Longrightarrow \mathrm{A}(\mathcal{F})$, i.e.

$$\mathcal{G} \subset \mathrm{Fib}_W \implies \mathcal{F} \subset \mathrm{Fib}_W, \tag{4.4.9.1}$$

et de même $\mathrm{C}(\mathcal{G}) \Longrightarrow \mathrm{C}(\mathcal{F})$, i.e.

$$\mathcal{G} \cap W \subset W^u \implies \mathcal{F} \cap W \subset W^u. \tag{4.4.9.2}$$

Démonstration. A) En effet, si $\mathcal{G} \subset \mathrm{Fib}_W$, la factorisation $f = pi$ de f est telle que $p \in \mathrm{Fib}_W$. Or un composé pi, avec $p \in \mathrm{Fib}_W$ et $i \in W_S^{\mathrm{u}}$, est dans Fib_W, comme on vérifie aussitôt sur le diagramme de carrés cartésiens p. 30

$$\begin{array}{ccccc}
X & \longleftarrow & X' & \longleftarrow & X'' \\
{\scriptstyle W_S^{\mathrm{u}}}\downarrow & & {\scriptstyle (W)}\downarrow & & {\scriptstyle (W)}\downarrow \\
\overline{X} & \longleftarrow & \overline{X'} & \xleftarrow{(W)} & \overline{X''} \\
{\scriptstyle \mathrm{Fib}_W}\downarrow & & \downarrow & & \downarrow \\
S & \longleftarrow & S' & \xleftarrow{W} & S''
\end{array}$$

sur lequel on lit que $X'' \longrightarrow X'$ est dans W, q.e.d.

Ce lemme s'applique notamment au cas où $\mathcal{F} = \mathrm{Fibf}_{W_0}$, $\mathcal{G} = \mathcal{F}_{W_0}$, car f se factorise en [page 52]

$$\begin{array}{ccc}
X & & \\
{\scriptstyle f}\downarrow & \searrow^{i} & \\
 & & \Phi_S(X) \\
 & \swarrow_{p} & \\
S, & &
\end{array}$$

et on sait que $i \in W_{0S}^{\mathrm{u}} \subset W_S^{\mathrm{u}}$, et $p \in \mathcal{F}_{W_0} \subset \mathcal{F}_W$, ce qui sont les conditions voulues.

C) Démonstration similaire : Soit $f \in \mathcal{F} \cap W$, factorisant en $f = pi$, avec $i \in W_S^{\mathrm{u}}$, $g \in \mathcal{G}$, on aura alors $g \in W$, donc $g \in \mathcal{G} \cap W \subset W^{\mathrm{u}}$ (par hypothèse $\mathrm{C}(\mathcal{G})$), a fortiori on a $g \in W_S^{\mathrm{u}}$, donc $f \in W_S^{\mathrm{u}}$ comme composé de deux flèches de W_S^{u}, et comme le but de f est S lui-même, cela signifie $f \in W^{\mathrm{u}}$, q.e.d.

$$\begin{array}{ccc}
X & & \\
 & \searrow^{i \in W_S^{\mathrm{u}}} & \\
{\scriptstyle \mathcal{F} \cap W}\downarrow & & \bar{X} \\
 & \swarrow_{g} & \\
S & &
\end{array}$$

Je ne vois pas de façon pour prouver également

$$\mathrm{B}(\mathcal{G}) \qquad \Longrightarrow \qquad \mathrm{B}(\mathcal{F}),$$

avec les seules hypothèses du lemme précédent sur le couple $\mathcal{F}$, $\mathcal{G}$. Il faudrait que pour tout S dans $\mathcal{M}$, et toute flèche $u : X \longrightarrow Y$ dans $\mathcal{M}/S$, on puisse insérer le diagramme obtenu dans [page 53] $\mathcal{M}$

$$\begin{array}{ccc}
X & \xrightarrow{u} & Y \\
 & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle g} & \\
 & S &
\end{array}$$

p. 31

dans un diagramme commutatif ci-dessous

(4.4.9.3)
$$\begin{array}{ccc} X & \xrightarrow{u} & Y \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle j} \\ \bar{X} & \xrightarrow{\bar{u}} & \bar{Y} \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & S & \end{array}$$

avec

$$f = pi, \qquad g = qj, \qquad i, j \in W_S^{\mathrm{u}}, \qquad p, q \in \mathcal{G}.$$

Ce sera le cas en tous cas si pour tout S, et un objet variable X de $\mathcal{M}/S$, on peut trouver une factorisation *fonctorielle en* X de son morphisme structural f_X en $p_X i_X$, avec $i_X \in W_S^{\mathrm{u}}$ et $p_X \in \mathcal{G}$, *i.e.* si i, p se déduisent d'un foncteur

$$\varphi : \mathcal{F}_S \longrightarrow \mathcal{M}/S \ ^{31},$$

et d'un morphisme de foncteurs

$$i : \underbrace{\mathrm{inc}_{\mathcal{F}_S}}_{\substack{\text{foncteur} \\ \text{d'inclusion}}} \longrightarrow \varphi.$$

Admettant l'existence d'un diagramme ayant les propriétés dites, pour toute flèche u dans $\mathcal{F}_S$, ou seulement toute flèche u qui soit aussi dans W_S, nous pouvons prouver maintenant que $u \in W_S \Longrightarrow u \in W_S^{\mathrm{u}}$, pourvu que la propriété similaire soit vrai pour $\mathcal{G}$ à la place de $\mathcal{F}$.

En effet, l'hypothèse sur $u \in W$ implique $\bar{u} \in W$, et l'hypothèse sur $\mathcal{G}$ implique dès lors $\bar{u} \in W_S^{\mathrm{u}}$. Comme W_S^{u} est un localiseur dans $\mathcal{M}/S$, on en conclut bien $u \in W_S^{\mathrm{u}}$, q.e.d. [page 54]

Ainsi on a obtenu

Corollaire 4.4.10. *Supposons, sous les conditions du lemme* 4.4.9, *que tout diagramme commutatif triangulaire* $\begin{array}{ccc} X & \xrightarrow{u} & Y \\ & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle g} & \\ & S & \end{array}$ *s'insère dans un diagramme du type* (4.4.9.3) *comme ci-dessus* (*avec les relations explicites sur les flèches qui y figurent*). *Alors*

$$\mathrm{B}(\mathcal{G}) \implies \mathrm{B}(\mathcal{F}).$$

Donc si de plus $\mathcal{G} \subset \mathcal{F}$, *de sorte que* $\mathrm{A}(\mathcal{F}) \Longrightarrow \mathrm{A}(\mathcal{G})$ *tautologiquement, et de même pour* B *et pour* C, *on trouve*

$$\begin{aligned} \mathrm{A}(\mathcal{F}) &\iff \mathrm{A}(\mathcal{G}) \\ \mathrm{B}(\mathcal{F}) &\iff \mathrm{B}(\mathcal{G}) \\ \mathrm{C}(\mathcal{F}) &\iff \mathrm{C}(\mathcal{G}). \end{aligned}$$

Nous pouvons appliquer ce corollaire dans le cas qui nous occupe ici, avec

$$\mathcal{G} \overset{\text{déf}}{=} \mathcal{F}_{W_0} \subset \mathcal{F} \overset{\text{déf}}{=} \mathrm{Fibf}_{W_0},$$

vu que dans ce cas on a bien une factorisation *fonctorielle* d'un $f \in \mathrm{Fibf}_{W_0}$, $f : X \longrightarrow S$, en $f = pi$, $i \in W_{0S}^{\mathrm{u}} \subset W_S^{\mathrm{u}}$, $p \in \mathcal{F}_{W_0} = \mathcal{G}$, savoir celle rappelée page 43 : p. 32 [page 55]

$$\begin{array}{ccc} X & \xrightarrow{i_X} & \bar{X} = \Phi_S(X) \\ & {\scriptstyle f=f_X}\searrow \quad \swarrow{\scriptstyle p_X} & \\ & S. & \end{array}$$

31. $\mathcal{F}_S$ est la sous-catégorie pleine de $\mathcal{M}/S$ formée des X tels que $f_X \in \mathcal{F}$.

Commentary · Exposition [ms. 54]

Why universal comparison maps transfer the tests

Grothendieck's replacement lemma isolates the exact information needed from a comparison map. A global weak equivalence is insufficient because the tests concern all base changes. Suppose that every structural map $f : X \to S$ in $\mathcal{F}$ has a factorization

$$X \xrightarrow{i} \bar{X} \xrightarrow{p} S, \qquad i \in W_S^{\mathrm{u}}, \quad p \in \mathcal{G}.$$

The notation W_S^{u} concerns changes of the base S, not arbitrary changes of the codomain $\bar{X}$. That relative condition is exactly sufficient.

For A, let $T' \to T$ be a W-equivalence over S. The two comparison maps $i_{T'}$ and i_T lie in W. If A holds for $\mathcal{G}$, the map $\bar{X}_{T'} \to \bar{X}_T$ also lies in W. Commutativity and two-out-of-three then put $X_{T'} \to X_T$ in W. This proves A for $\mathcal{F}$.

For C, suppose f itself lies in W. Since $i \in W$, two-out-of-three gives $p \in W$. If C holds for $\mathcal{G}$, every map $p_T : \bar{X}_T \to T$ lies in W. Composing it with i_T gives $f_T \in W$ for every $T \to S$. Thus f is universally a W-equivalence. The change from p to g in the printed proof is only a change of name, but should not be mistaken for a second factorization.

B involves a further datum: an arrow between two families. Suppose a W-equivalence $u : X \to Y$ over S fits into a commuting square

$$\begin{array}{ccc} X & \xrightarrow{u} & Y \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle j} \\ \bar{X} & \xrightarrow[\bar{u}]{} & \bar{Y} \end{array} \qquad i, j \in W_S^{\mathrm{u}}, \quad \bar{X}, \bar{Y} \in \mathcal{G}_S.$$

The square first implies $\bar{u} \in W$. Assuming B for $\mathcal{G}$, every pullback $\bar{u}_T$ is in W. The pulled-back square, with $i_T, j_T \in W$, then gives $u_T \in W$. Notice that the square is needed only for those u which are in W; a replacement functor defined on all arrows is a convenient sufficient construction, not a logically necessary extra assumption.

The free split-fibration construction supplies such a functor. For weakly W_0-fibred objects, its unit lies in $W_{0,S}^{\mathrm{u}} \subset W_S^{\mathrm{u}}$, and the resulting structural map belongs to $\mathcal{F}_{W_0}$. Applying the three arguments with $\mathcal{G} = \mathcal{F}_{W_0}$ and $\mathcal{F} = \mathrm{Fibf}_{W_0}$ gives every announced equivalence. The reverse implications are restrictions along $\mathcal{G} \subset \mathcal{F}$.

This proof explains why it is legitimate to postpone the equivalences earlier in the section: they depend on a particular natural replacement, not on any assertion that all weakly fibred families are intrinsically fibrant. It also states the genuine limit of Lemma 4.4.9. Its objectwise hypotheses prove A and C; the text does not establish the B-transfer under those hypotheses alone. We leave that unrestricted assertion unclaimed.

Cela prouve donc les équivalences annoncées (4.4.8.1) et achève d'établir la validité des implications du diagramme de la page 48.

Ces implications, à la seule exception de l'implication en pointillés $\mathrm{C}_{W_0} \dashrightarrow \mathrm{A}_{W_0}$ (qui suppose qu'on ait W_0 (7)), ne font appel à aucune hypothèse particulière sur les localiseurs fondamentaux W et W_0 (à part l'inclusion $W \supset W_0$). Mais nous pouvons, en utilisant le lemme 4.4.10, donner des implications conditionnelles remarquables, sous la seule condition que W, ou W_0, satisfassent à l'anodin *axiome des limites* Loc (8), et même seulement sous la forme faible de stabilité des localiseurs par $\varinjlim$ de *suites*. Donnons-les d'abord sous forme technique, avant de déployer les conséquences dans un théorème scholie : [page 56]

Corollaire 4.4.11. *Supposons que W_0 satisfasse à l'axiome* Loc (8), *ou seulement* Loc (8 bis) (*stabilité par $\varinjlim$ de suites*). *Alors* $\mathrm{D}_{W_0} \Longrightarrow \mathrm{A}_{W_0}$ (*donc les conditions* A_{W_0}, B_{W_0}, C_{W_0}, D_{W_0} *sont équivalentes*). *En particulier* (*faisant $W_0 = W$*), *si W satisfait à* Loc (8 bis), *alors on a* $\mathrm{D}_W \Longrightarrow \mathrm{A}_W$ (*donc les conditions* A_W, B_W, C_W, D_W *sont équivalentes*).

En effet, l'implication à prouver s'écrit aussi

$$\mathrm{A}(\mathrm{Parf}_{W_0}) \iff \mathrm{A}(\mathrm{Fibf}_{W_0}).$$

L'implication non tautologique $\Longrightarrow$ est justiciable du lemme 4.4.9. Il faut vérifier que

moyennant Loc (8 bis) pour W_0, tout $f \in \mathrm{Fib}_{W_0}$, $f : X \longrightarrow S$, se factorise en $f = pi$, avec $i \in W_0^{\mathrm{u}}$, $p \in \mathrm{Parf}_{W_0}$. Or on sait [32] (VI, p. 193 ff.) que l'axiome Loc (8 bis) implique que [page 57]
$f \in \mathrm{Fibf}_{W_0}$ se factorise en

$$\begin{array}{ccc} X & \xrightarrow{i_\infty} & \bar{X} = \Phi_\infty(X) \\ & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle p_\infty} & \\ & S, & \end{array}$$

(catégorie de chemins infinis d'un côté, relativisée sur S, *i.e.* des couples (x, c), avec $x \in \mathrm{Ob}\, X$ et $c : f(x) \longrightarrow s$ un chemin infini dans S, de source $f(x)$.)

avec $p_\infty \in \mathrm{Parf}_{W_0}$ (comme on veut), et $i_\infty \in W_{0S}^{\mathrm{u}}$, et comme $W_{0S}^{\mathrm{u}} \subset W_S^{\mathrm{u}}$, on a bien $i_\infty \in W_S^{\mathrm{u}}$.

Corollaire 4.4.12. *Supposons que* W et W_0 *satisfassent à* Loc (8 bis). *Alors on a* $\mathrm{D}_{W_0} \Longrightarrow \mathrm{A}$ (*donc les huit conditions* A, B, C, D, A_{W_0}, B_{W_0}, C_{W_0}, D_{W_0} *sont équivalentes*).

Cela signifie en effet que p. 33

$$\mathrm{A}(\mathrm{Parf}_{W_0}) \implies \mathrm{A}(\mathrm{Fibf}_W),$$

et c'est encore justiciable du lemme 4.4.9. En effet, la factorisation ci-dessus d'une flèche f ne dépend pas du choix d'un localiseur, et p_∞ est W-parfait pour *tout* localiseur satisfaisant Loc (8 bis), donc en particulier pour W_0. Et la flèche i_∞ est dans W_S^{u}, pour tout localiseur satisfaisant Loc (8 bis), donc pour W_0.

Je vais récapituler les résultats obtenus dans cette section dans un théorème, qui constituera [page 58]
le résultat principal du présent paragraphe sur les axiomes de W-fibrations.

Commentary · Examples [ms. 57]

The two localizers have different jobs

The infinite-path argument is designed to improve a family until both comma-category comparisons are controlled. Alternating the two one-sided constructions gives

$$X \longrightarrow \Phi(X) \longrightarrow \Psi\Phi(X) \longrightarrow \Phi\Psi\Phi(X) \longrightarrow \cdots .$$

The odd and even subsequences are cofinal. Under sequential-colimit stability they show that the resulting object is both smooth and proper. If the input is weakly W-fibred, the successive comparison maps are universally W-equivalent over the base, and so is their colimit. This is the argument of VI, ms. 193–195 (Grothendieck, 1990b); the commentary on Chapter VI, manuscript p. 194, treats the alternation in detail.

Corollary 4.4.12 uses two independent conclusions from that construction. To transfer A from Parf_{W_0} to Fibf_W, one needs a right factor in Parf_{W_0} and a comparison unit in W_S^{u}. The underlying construction does not depend on a localizer. Its perfection uses Loc (8 bis) for W_0, while the unit's universal W-equivalence uses Loc (8 bis) for W and weak W-fibrancy of the input. Lemma 4.4.9 then applies with exactly the required parameters.

The last sentence of the printed proof goes further, asserting the universal unit conclusion for W_0 as well. That conclusion is not available for an arbitrary weakly W-fibred input. The qualification is explicit in VI: for a general input the unit is a global equivalence, while the stronger relative conclusion requires weak fibrancy for the same localizer.

One can see the obstruction without a complicated path calculation. Let $G \neq 1$ and take the Grothendieck fibration over [1] classified by

$$F(0) = e, \qquad F(1) = BG, \qquad F(1) \longrightarrow F(0) \text{ the unique functor.}$$

Its total category has an initial object, so its nerve is contractible. The map is weakly $\mathbf{W}_0$-fibred, since both fibres are connected, but it is not weakly $\mathbf{W}_\infty$-fibred. A perfect ordinary-homotopy replacement has contractible homotopy fibres over the contractible base: its total space is weakly equivalent to the original contractible total space. Consequently its fibre over 1 is contractible,

32. et c'est là une trouvaille tout à fait inattendue, un peu comme le lemme de K. S. Brown …

whereas the original strict fibre is BG. The unit on that fibre cannot be a weak homotopy equivalence. This rules out the extra $W_0 = \mathbf{W}_\infty$ assertion while leaving the $W = \mathbf{W}_0$ assertion intact.

Thus the theorem is repaired by using the weaker unit statement it actually needs. No additional axiom and no change to the conclusion of Corollary 4.4.12 is necessary.

Théorème 4.4.13. *Soit W un localiseur fondamental dans* Cat. *Pour tout localiseur W_0 contenu dans W, on a explicité un ensemble de quatre conditions sur la paire W_0, W, qui pour W fixé, dépendent de W_0 seul, notées*

(4.4.13.1) $$\mathrm{A}_{W_0},\ \mathrm{B}_{W_0},\ \mathrm{C}_{W_0},\ \mathrm{D}_{W_0},$$

et définies respectivement comme

$$\mathrm{A}(\mathcal{F}_{W_0}),\ \mathrm{B}(\mathcal{F}_{W_0}),\ \mathrm{C}(\mathcal{F}_{W_0}), \qquad \textit{et}$$

$$\mathrm{A}(\mathrm{Parf}_{W_0})\Big(\iff \mathrm{B}(\mathrm{Parf}_{W_0}) \iff \mathrm{C}(\mathrm{Parf}_{W_0})\Big),$$

avec les notations A(·), B(·), C(·) *introduites dans* (4.4.1). *Faisant $W_0 = W$, on trouve les conditions sur W*

(4.4.13.2) $$\mathrm{A},\ \mathrm{B},\ \mathrm{C},\ \mathrm{D}$$

avec $\mathrm{A} = \mathrm{A}_W$, $\mathrm{B} = \mathrm{B}_W$, $\mathrm{C} = \mathrm{C}_W$, $\mathrm{D} = \mathrm{D}_W$, *dont les trois premières ne sont autres que* Loc (7 a), Loc (7 b), Loc (7 c) (cf. 4.3, *page* 38).

① *On a pour ces conditions les implications suivantes.*

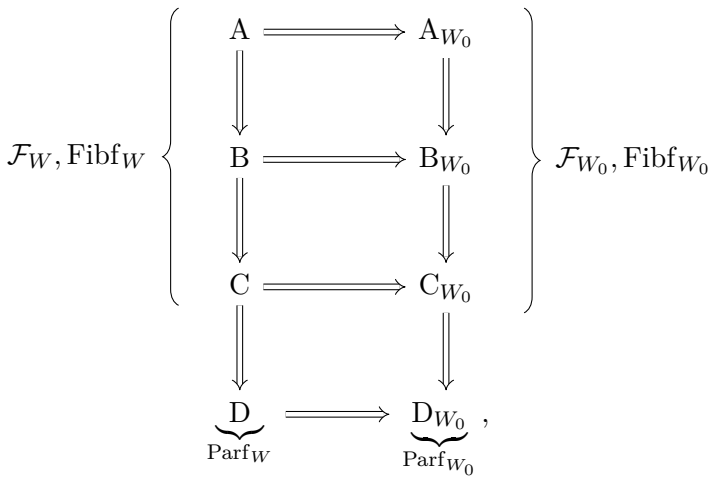
a) *On a les implications*

(4.4.13.3) $$\mathrm{A}_{W_0} \implies \mathrm{B}_{W_0} \implies \mathrm{C}_{W_0} \implies \mathrm{D}_{W_0},$$

(*d'où en particulier*

[page 59]

(4.4.13.4) $$\mathrm{A}_W \implies \mathrm{B}_W \implies \mathrm{C}_W \implies \mathrm{D}_W\ ).$$



b) *Si $W_0' \subset W_0$ est un localiseur fondamental contenu dans W_0, on a* (*tautologiquement*)

$$\mathrm{A}_{W_0} \implies \mathrm{A}_{W_0'}, \qquad \mathrm{B}_{W_0} \implies \mathrm{B}_{W_0'}, \qquad \mathrm{C}_{W_0} \implies \mathrm{C}_{W_0'}.$$

On trouve donc, par (a) *et* (b) (*y faisant pour le couple (W, W_0) comme (W_0, W_0')*), *le rectangle d'implications*

p. 34

(4.4.13.5)

où on a rappelé, à côté des accolades, quels sont l'ensemble, ou les ensembles $\mathcal{F} \subset \mathrm{Fl}(\mathrm{Cat})$ *qui définissent les conditions envisagées (comme l'une des conditions* $\mathrm{A}(\mathcal{F})$, $\mathrm{B}(\mathcal{F})$, $\mathrm{C}(\mathcal{F})$ *ou* $\mathrm{D}(\mathcal{F}) = \mathrm{A}(\mathcal{F})$ *dans le cas où les trois conditions sont équivalentes). La plus faible des huit conditions envisagées est* D_{W_0}*, la plus forte* A. (*Et pour* W_0 *variable, on trouve la condition la plus faible de toutes en prenant* D_{W_ω}*, où* W_ω *est le plus petit des localiseurs fondamentaux dans* Cat.)

c) *On a de plus, pour la condition la plus faible* D_{W_0}*, l'implication*

$$\mathrm{D}_{W_0} \implies \mathrm{F},$$

où F = Loc (7 F) *est la condition que* Cat *possède suffisamment de* W*-fibrations,* i.e. [page 60] *que c'est une catégorie de fibrations pour* (W, Fib_W).

② *Si* W *et* W_0 *satisfont à* Loc (8 bis) *(axiome des limites dénombrables), alors* $\mathrm{D}_{W_0} \Longrightarrow \mathrm{A}$, i.e. *les 8 conditions envisagées sont équivalentes. Donc si* W *satisfait* Loc (8 bis)*, considérant le plus petit localiseur fondamental* W_L *satisfaisant à* Loc (8 bis) *(de sorte que* $W \supset W_L$*), on voit que les huit conditions*

$$\mathrm{A},\ \mathrm{B},\ \mathrm{C},\ \mathrm{D},\ \mathrm{A}_{W_L},\ \mathrm{B}_{W_L},\ \mathrm{C}_{W_L},\ \mathrm{D}_{W_L}$$

sont équivalentes[33]*. En particulier, sous la même hypothèse (fort anodine) sur* W*, les conditions* Loc (7) = Loc (7 a), Loc (7 b) *et* Loc (7 c) *sont équivalentes, et elles équivalent aussi à la condition* $\mathrm{D} = \mathrm{A}(\mathrm{Parf}_W)$, i.e. *à*

$$\mathrm{Parf}_W \subset \mathrm{Fib}_W \qquad (\textit{cas particulier de Loc (7 a)}),$$

et à ses deux variantes d'apparence plus faible $\mathrm{B}(\mathrm{Parf}_W)$, $\mathrm{C}(\mathrm{Parf}_W)$ *(cas particulier de* Loc (7 b) et de Loc (7 c) *respectivement).*

③ *Supposons que* W_0 *satisfasse à* Loc (8 bis) *(sans hypothèse particulière sur* W*). Alors les* p. 35 *quatre conditions* A_{W_0}, B_{W_0}, C_{W_0}, D_{W_0} *sont équivalentes, et le diagramme d'implications de* [page 61] 1°) *(p.* 59*) se réduit donc au diagramme linéaire*

$$\mathrm{A} \implies \mathrm{B} \implies \mathrm{C} \implies \mathrm{D} \implies \mathrm{D}_{W_0}\ (\Longleftrightarrow \mathrm{A}_{W_0} \ldots),$$

dont le premier terme est Loc (7 a) = Loc (7)*, et le dernier équivaut à l'inclusion*

$$\mathcal{F}_{W_0} \subset \mathrm{Fib}_W,$$

cas particulier de A = Loc (7 a)*, ou encore à l'inclusion (en apparence plus forte)*

$$\mathrm{Fibf}_{W_0} \subset \mathrm{Fib}_W,$$

(cas particulier de la forme équivalente

$$\mathrm{Fibf}_W \subset \mathrm{Fib}_W,$$

de l'axiome Loc (6 a)).

④ *Enfin, on a les implications plus techniques conditionnelles suivantes.*

33. N.B. La forme la plus faible, D_{W_L}, de ces conditions, est la relation $\boxed{\mathrm{Parf}_{W_L} \cap W \subset W^{\mathrm{u}}.}$

a) *Si W_0 satisfait à Loc (7 F), alors les conditions* A_{W_0}, B_{W_0}, C_{W_0} *sont équivalentes, donc le diagramme (4.4.13.5) se réduit au diagramme*

$$\begin{array}{ccc} \mathrm{A} & & \\ \Downarrow & & \\ \mathrm{B} & & \\ \Downarrow & & \\ \mathrm{C} & \Longrightarrow & \mathrm{C}_{W_0} \\ \Downarrow & & \Downarrow \\ \mathrm{D} & \Longrightarrow & \mathrm{D}_{W_0}\ . \end{array}$$

b) *Si W est fortement saturé* (*axiome* Loc (1 ter), *qui est satisfait dans la grande majorité des cas, et est même impératif pour construire un prédérivateur satisfaisant à l'axiome de localisation* Der 2) *et satisfait à* Loc (3 bis) (*axiome de localisation fort,* cf. §1), *alors on a* $\mathrm{B} \Longrightarrow \mathrm{A}$, *donc* [page 62]

$$\mathrm{A} \iff \mathrm{B},$$

i.e. Loc (7 a) = Loc (7) *équivaut à* Loc (7 b).

Commentary · Exposition [ms. 61]

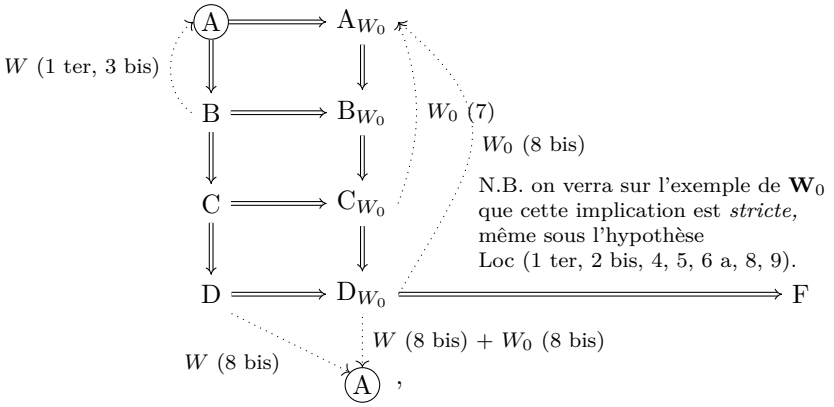
The summary theorem and its printed hypotheses

The theorem gathers a substantial amount of reasoning, and its hypotheses should be read from the proved statements rather than from the abbreviated labels alone. With no extra hypotheses, there are the two downward chains, the restrictions to the reference localizer, and the implication from the weakest perfect-map condition to enough intrinsic fibrations. Sequential-colimit stability of W_0 collapses its column; stability for both localizers identifies the two columns. These are precisely Corollaries 4.4.11 and 4.4.12.

Two local errors in the summary can otherwise change its meaning. At the end of part 3, $\mathrm{Fibf}_W \subset \mathrm{Fib}_W$ is called Loc (6 a); it is Loc (7 a). In part 4(a), the printed assumption is Loc (7 F) for W_0. The proof previously supplied in Corollary 4.4.6 assumes Loc (7), which ensures that $\mathcal{F}_{W_0}$ is closed under composition. The diagram at ms. 63 also labels the upward arrow by $W_0(7)$. Footnote 30 does discuss the weaker F, but there the class is Fib_{W_0}, not $\mathcal{F}_{W_0}$. Substituting the former class for the latter requires an argument which that footnote does not provide.

Accordingly, the direct proof in this section establishes part 4(a) under Loc (7). This observation is a dependency correction, not a counterexample to the printed conclusion. A later argument using minimality settles the relevant comparison without that extra hypothesis, as explained next. It is better to distinguish these two proofs than to pretend that the summary's F follows from the preceding paragraphs.

Part 4(b) has its own independent mechanism. The previous proof in XII, Proposition 1, ms. 54–56, interprets a pullback comparison as the map on homology with locally constant coefficients. The equivalence of the locally constant coefficient categories supplies an isomorphism in Hot_W; strong saturation then returns membership in W. Loc (3 bis) supplies the homotopy Kan extensions used for the interpretation (Grothendieck, 1990–1991f). This explains both hypotheses, and why strong saturation cannot simply be replaced in that proof by closure under retracts.



Démonstration. Tout ce qui est énoncé a été vu dans les pages précédentes, à la seule exception de 4°, b. Mais cette implication $\mathrm{B} \Longrightarrow \mathrm{A}$ pour W fortement saturé est prouvé dans XII (prop. 1, p. 54). Je rappelle que la démonstration utilise de façon essentielle le formalisme p. 36
du prédérivateur HOT_W (construit et étudié surtout dans VI), et la théorie des foncteurs

$f_!$, et notamment le résultat (valable si W satisfait à Loc (3 bis, 7 b)) que pour une flèche $f : S' \longrightarrow S$ dans W, la flèche correspondante

$$f^*_{\mathrm{lc}} : \mathrm{HOT}^{\mathrm{lc}}_W(S) \longrightarrow \mathrm{HOT}^{\mathrm{lc}}_W(S')$$

est une équivalence de catégories. Donc l'implication B $\Longrightarrow$ A, elle aussi, est un résultat qui n'a rien d'évident.

4.4.14. Je résume les implications obtenues jusqu'à présent, y compris les implications conditionnelles, dans le diagramme récapitulatif suivant : [page 63]

où j'ai cerclé la condition la plus forte et la plus importante de toutes, A = Loc (7), qui apparaît en deux extrémités opposées du diagramme.

Je voudrais encore faire un commentaire sur les ingrédients des résultats prouvés ici, et notamment de l'équivalence des huit conditions A à D_{W_0}, quand W et W_0 satisfont Loc (8 bis) : [page 64]

1) La théorie des *catégories de chemins* $\underline{\mathrm{Ch}}(X)$ (VII), s'appuyant sur celle des *morphismes lisses, propres, parfaits.*
2) Le lemme de K. S. Brown (3.2.1, page 20).
3) Pour l'implication B $\Longrightarrow$ A, *i.e.* Loc (7 b) $\Longrightarrow$ Loc (7) (sous l'hypothèse W (1 ter, 3 bis)), j'utilise la théorie du prédérivateur Hot_W (VI), et plus particulièrement celle des foncteurs $f_!$ (définis sous la seule hypothèse W (3 bis), renforçant la condition automatique W (3) (faisant partie de la définition d'un localiseur fondamental)).

Il est clair que je ne serais pas arrivé à y voir clair, sans le travail fondamental de K. S. Brown. Il reste pourtant encore des questions ouvertes. Ainsi, si on ne suppose pas que W satisfasse à Loc (8 bis), mais au besoin à Loc (3 ter) (et je n'ai pas eu l'occasion encore de travailler avec un localiseur qui n'y satisfasse …), est-il vrai néanmoins que l'on a encore l'implication p. 37

$$\mathrm{D} \quad \Longrightarrow \quad \mathrm{A},$$

de façon que les conditions A, B, C, D soient équivalentes (et en particulier Loc (7 c) implique déjà Loc (7) dans toute sa force) ? Il est clair dans tout cela que je ne me suis pas suffisamment attaché à développer des exemples et des contre-exemples. Sans compter qu'il me semble que tous les localiseurs fondamentaux sur Cat qu'on rencontre "en pratique" satisfont déjà à Loc (8) et a fortiori à Loc (8 bis), donc pour eux on a bien l'implication escomptée. La même remarque s'applique à l'implication hypothétique [page 65]

$$\mathrm{D}_{W_0} \overset{?}{\Longrightarrow} \mathrm{A},$$

sous hypothèse Loc (8 bis) sur W_0 et sur W. Un candidat évident pour un contre-exemple déjà à la première question serait W_ω = plus petit localiseur fondamental sur Cat, un qu'il

est presque évident qu'il ne satisfait *pas* à Loc (8) ni même Loc (8 bis). Mais il n'y a aucune raison qu'il satisfasse non plus à F, de telle façon que (s'il n'y satisfait pas, donc non plus à D) l'implication D $\Longrightarrow$ A est bel et bien valable. Cela nous amène à la question, plus substantielle, si on n'aurait pas l'implication [page 66]

$$\mathrm{F} \overset{?}{\Longrightarrow} \mathrm{A}\ ^{34},$$

du moins sous des conditions convenables assez anodines sur W, genre Loc (1 ter, 3 bis, 8 bis).

Commentary · Later developments [ms. 64]

Why ordinary homotopy types satisfy A

The ordinary localizer provides a useful verification of the axioms, as well as the eventual answer to the minimum question. Start with a Grothendieck fibration $p : X \to S$ all of whose inverse-image functors are weak homotopy equivalences. For $s \in S$, the inclusion of the strict fibre X_s into the comma category $s\backslash X$ has a right adjoint: it sends $(x, a : s \to p(x))$ to a Cartesian inverse image a^*x. The counit is the chosen Cartesian arrow. Hence this inclusion induces a homotopy equivalence on nerves. The transition functors between these comma categories induce, through these comparisons, the given inverse-image functors on strict fibres.

Quillen's theorem B, applied to the opposite categories, therefore identifies the strict fibres with the homotopy fibres of Np. A precise published formulation is Cisinski (2004, paragraph 2.3.1 and Theorem 2.3.2, p. 136); the comma-category variance is why taking opposites is convenient here. If p also belongs to $\mathbf{W}_\infty$, its homotopy fibres are weakly contractible. Thus every strict fibre X_s is weakly contractible.

After any change of base $T \to S$, the resulting Grothendieck fibration has these same strict fibres. The dual theorem-A criterion now makes its projection a weak homotopy equivalence: the appropriate comma categories retract by adjunction onto the fibres, so they too are weakly contractible. We have proved C for $\mathbf{W}_\infty$, including its universal conclusion, without first assuming A. Empty bases cause no exception: a category mapping to the empty category is itself empty.

To recover A from this verification, the already proved Corollary 4.4.11 applies because $\mathbf{W}_\infty$ is stable under sequential filtered colimits. This stability can be seen without an additional axiom. The nerve commutes with filtered colimits: an n-simplex is a finite string of composable arrows, and the equations defining such a string are finite. The simplicial fibrant replacement Ex^∞ also commutes with filtered colimits, since each simplex of $\mathrm{Ex}^k K$ is specified by a map from the finite simplicial set $\mathrm{Sd}^k \Delta^n$, and its sequential union commutes with filtered colimits. A filtered colimit of Kan complexes is Kan because each horn has only finitely many simplices. Its components, its based homotopy classes of spheres, and the identifications given by homotopies are consequently represented at finite stages. A filtered diagram of weak equivalences therefore induces a bijection on components and isomorphisms on all homotopy groups in its colimit. Applying this to the nerves proves the required closure.

This gives the converse needed in the following status discussion: ordinary weak homotopy equivalences satisfy C, hence D, and then A by the infinite-path comparison. The use of filtered-colimit stability here proves a property of the ordinary localizer; it does not assert that an arbitrary weak fundamental localizer has that stability. Nor does the argument identify every categorical functor with a fibration. It identifies the particular locally constant Grothendieck fibrations with maps whose pullbacks perform the correct homotopy operation, and the natural replacement lemma extends that conclusion to the chapter's weak fibrations.

Commentary · Present state [ms. 65]

The minimum settles the implication questions

Grothendieck is testing whether sequential limits are genuinely needed or merely belong to the replacement method he has available. The proposed candidate W_ω turns out to answer that question in the opposite direction from his prediction. Cisinski (2006a, Theorem 6.1.18, pp. 242–243) proves that ordinary weak homotopy equivalences form the smallest *weak* fundamental localizer.

34. C'est faux, *cf.* plus bas, l'implication Loc (7 D_{W_ω}) $\Longrightarrow$ Loc (7 F) est *stricte.*

The definition used there is given in paragraph 6.1.12, p. 240, and uses the nonrelative theorem-A condition. Thus the theorem applies to the minimum of this chapter:

$$W_\omega = \mathbf{W}_\infty.$$

The distinction from the earlier minimum theorem for the stronger relative axiom is essential. The assertion that W_ω almost certainly fails Loc (8 bis) is therefore false: ordinary weak homotopy equivalences are stable under filtered colimits, as verified above.

Combining weak minimality with the fibre-detection theorem in §6 settles the whole rectangle, without imposing Loc (8 bis) on the two arbitrary localizers. For weak fundamental localizers $W_0 \subset W$, all eight conditions are equivalent, and they hold precisely in the following two cases:

$$W = \mathrm{Fl}(\mathrm{Cat}) \qquad \text{or} \qquad W = W_0 = \mathbf{W}_\infty.$$

Here is the deduction, with the role of connectedness made explicit. Each of the eight conditions implies D_{W_0}, which implies D_{W_ω} by monotonicity of the perfect classes. If W is all arrows, every test is automatic. Assume otherwise. Then D_{W_ω} itself forces Loc (5); one need not assume the potentially problematic converse from mere nondegeneracy to Loc (5).

Indeed, an empty W-aspherical category would put $\varnothing \to e$ in W. Theorem A would then put $\varnothing \to X$ in W for every X, and two-out-of-three would give all arrows. If a nonempty W-aspherical A were disconnected, choose $a : e \to A$ and factor it as $e \to E \xrightarrow{p} A$, with the first map in W_ω and p W_ω-perfect. The category E is connected because $e \to E$ lies in the tautological subclass $W_\omega \subset \mathbf{W}_\infty$. The map p belongs to W and is universally in W by D_{W_ω}. Its strict fibre over a different component of A is empty, again giving the contradiction $\varnothing \to e \in W$. Thus every W-aspherical category is connected and nonempty.

Now factor any $f \in W$ as a W_ω-equivalence followed by a W_ω-perfect p. Every strict fibre of p is W-aspherical by D, hence connected and nonempty. The inclusion $W_\omega \subset \mathbf{W}_\infty$ makes p ordinarily perfect, so it compares these fibres with the corresponding comma categories by ordinary weak equivalences. The connected-component version of Theorem A therefore makes $\pi_0(p)$ bijective. The left factor also induces a bijection on components, so $\pi_0(f)$ is bijective. This proves Loc (5) directly. The commentary at ms. 85 gives the full fibre-detection argument and this nondegenerate reduction.

Theorem 6.1 now gives $W \subset \mathbf{W}_\infty$; weak minimality gives the reverse containment. Finally $\mathbf{W}_\infty \subset W_0 \subset W$ forces $W_0 = \mathbf{W}_\infty$. Conversely ordinary weak homotopy equivalences satisfy A by the preceding theorem-B argument, so all eight tests hold in the second case too.

Consequently both questions D ⇒ A and D_{W_0} ⇒ A have affirmative answers, without sequential-colimit assumptions. The suggested example at ms. 37 satisfying Loc (7) while failing ordinary excision cannot occur: the ordinary and the all-arrow localizers both satisfy the excision axiom. This is a deduction from later weak minimality and the present chapter's perfect-replacement arguments, not the proof Grothendieck had in hand. F remains strictly weaker, as the connected-component example shows. The proper coarse localizer remembering only emptiness is not an exception to the result: it fails D, and the argument does not treat nontriviality alone as connectedness.

C'est sans doute là la question la plus substantielle et la plus intéressante qui est soulevée par le diagramme de la page 63, et qui ne fait plus appel à l'introduction d'un localiseur fondamental W_0 auxiliaire. Vu le lemme de Brown, il ne me semble pas absolument exclu qu'un tel miracle ait bel et bien lieu !

4.4.15 (Digression sur l'axiome Loc (6) des cofibrations.) Cela attire mon attention sur la question en quelque sorte duale : Si Cat a assez de W-*co*fibrations, *i.e.* si muni de (W, Cof_W) c'est une catégorie à cofibrations, cela implique-t-il déjà l'axiome Loc (6 a) (qui avait été dégagé, essentiellement, pour assurer qu'il en soit bien ainsi). La proposition 3.6. (p. 25) nous dit qu'il revient au même de prouver que, si W satisfait Cof, alors les carrés de M. V. ouverts sont W-cocartésien. Mais il me semble à présent que nous pouvons le prouver, sous la seule [page 67]
condition supplémentaire Loc (3 bis) [35], laquelle assure l'existence des foncteurs $f_!$, et en p. 38

35. et peut-être, de plus, Loc (1 ter), *i.e.* W fortement saturée.

particulier la construction de Holim d'un diagramme $\begin{array}{ccc} & & X_1 \\ & \nearrow & \\ X_0 & & \\ & \searrow & \\ & & X_2 \end{array}$ comme $\int \begin{array}{ccc} & & X_1 \\ & \nearrow & \\ X_0 & & \\ & \searrow & \\ & & X_2 \end{array}$.

Donc dire qu'un diagramme de $\mathcal{M}$ ouvert $\begin{array}{ccccc} & & X_1 & & \\ & \nearrow & & \searrow & \\ X_0 & & & & X \\ & \searrow & & \nearrow & \\ & & X_2 & & \end{array}$ est W-cocartésien, doit revenir à dire que la flèche canonique

$$\int \begin{array}{ccc} & & X_1 \\ & \nearrow & \\ X_0 & & \\ & \searrow & \\ & & X_2 \end{array} \longrightarrow X$$

est dans W ; du moins si W est supposé fortement saturé. Or cela a été bel et bien vu dans XII 3.4 (théorème 4 et son *corollaire* 3, p. 149). Dans loc. cit. j'énonce les conclusions sous l'hypothèse que j'appelais W (7 bis) (l'actuel Loc (6)), mais je viens de vérifier que pour sa partie *directe,* donc aussi pour ses corollaires 1 à 3, on n'a pas besoin de cette hypothèse (comme je l'indique en annotations marginales). [page 68]

Commentary · Exposition [ms. 67]

Why an open cover gives the needed integral comparison

The brief digression uses a geometric fact already isolated in XII: an actual open cover has a homotopically faithful categorical integral. The commentary on Chapter XII, manuscript p. 149, treats the cover criterion separately from the stronger converse-excision assertions. That separation matters here, because Grothendieck is trying to avoid assuming the very cofibration axiom he hopes to recover.

Let $X = U_1 \cup U_2$ be a cover by full open subcategories, in the convention that each U_i is closed under predecessors, and put $U_0 = U_1 \cap U_2$. Let J have arrows $0 \to 1$ and $0 \to 2$, and form the Grothendieck construction E of the diagram $U_0 \to U_1$, $U_0 \to U_2$. There is a canonical augmentation $q : E \to X$. We can verify directly that it is in every weak fundamental localizer.

For an object $x \in X$, consider the comma category E/x. If $x \in U_1 \setminus U_2$, every arrow $u \to x$ starts in U_1, since U_1 is open. In particular an occurrence labelled by 2 must have $u \in U_0$. Forgetting the label defines $T : E/x \to U_1/x$, with section I selecting label 1. Define $H : E/x \to E/x$ by changing label 2 to label 0 and keeping labels $0, 1$. This is well-defined because every label-2 occurrence now lies in the intersection; it sends an arrow from label 0 to label 2 to the corresponding arrow within label 0. The arrows of the span give natural transformations $H \to \mathrm{id}_{E/x}$ and $H \to IT$, while $TI = \mathrm{id}$. Thus T is a categorical homotopy equivalence. Since U_1/x has terminal object x, the category E/x is W-aspherical. The case $x \in U_2 \setminus U_1$ is symmetric.

If $x \in U_0$, all objects occurring in E/x lie in U_0, and the construction is the product of the span index J with U_0/x. The first factor has initial object 0 and the second has terminal object x. Their categorical contractions give a contraction of the product by a finite chain of natural transformations; no general product-stability assertion about W is needed. Hence it is aspherical. The theorem-A axiom now gives $q \in W$.

The homotopy-colimit interpretation identifies the class of E with the homotopy pushout of the span; relative Theorem A supplies the needed Kan-extension formalism. Strong saturation permits one to read an isomorphism in the localized category back as membership in W. Combined with the comparison criterion of Proposition 3.6, this is the intended route from enough intrinsic cofibrations to Loc (6 a). The source explicitly labels its verification provisional. The open-cover comparison itself is secure; extending its argument to arbitrary pushout squares without the indicated hypotheses would reintroduce the invalid converse-excision principle already audited in XII.

4.16. Le résultat que je viens de prouver (sans vérifier avec soin la démonstration) me paraît aussi délicat, qu'il est satisfaisant. Cela rend la "conjecture" hésitante de 4.4.14, savoir

que

$$\mathrm{F} \overset{?}{\Longrightarrow} \mathrm{A} \qquad \text{donc} \qquad \mathrm{F} \Longleftrightarrow \mathrm{A}$$

en supposant que W satisfait Loc (1 ter, 3 bis, 8 bis), nettement plus engageante. Car on commence à s'habituer aux miracles les plus époustouflants …

Pourtant, je viens de vérifier que cette conjecture est fausse, sur l'exemple de

$$\mathbf{W}_0 = \{f \in \mathrm{Fl}(\mathrm{Cat}) \mid \pi_0(f) \text{ iso}\},$$

qui satisfait à F, mais pas à A, ni même à D_{W_ω}. Ainsi l'implication

$$\mathrm{D}_{W_\omega} \implies \mathrm{F}$$

et a fortiori les implications

$$\begin{cases} \text{Loc (7 a)} \implies \mathrm{F},\ \text{Loc (7 b)} \implies \mathrm{F},\ \text{Loc (7 c)} \implies \mathrm{F} \\ \mathrm{D}_{W_0} \implies \mathrm{F} \end{cases}$$

sont *strictes,* même en se limitant à des localiseurs fondamentaux W satisfaisant (comme $\mathbf{W}_0$) à

$$\text{Loc (1 ter, 2, 3 bis, 4, 5, 6 a, 8, 9)} \ ^{36}.$$

p. 39 [page 69]

Que $\mathbf{W}_0$ satisfasse à cet ensemble d'axiomes se vérifie par AQT `[âne qui trotte]`. (**N.B.** Qu'il satisfasse à Loc (1 ter, 2, 3 bis) est déjà conséquence du fait que $\mathbf{W}_0$ est de la forme $W_{\mathbf{D}}$, où $\mathbf{D}$ (= $\mathbf{D}_{\mathbf{W}_0}$ en l'occurrence) est un prédérivateur satisfaisant Der (3, 4, 5), ce qui est bien le cas pour $\mathbf{D}_{\mathbf{W}_0}$, qui est un vrai *dérivateur.*) Il faut vérifier que tout f dans Cat se factorise en $f = pi$, avec $i \in \mathbf{W}_0$, p une $\mathbf{W}_0$-fibration. Or si $f : X \longrightarrow Y$, $I = \pi_0(X)$, on prend $\bar{X} = \coprod_{\alpha \in I} Y_{f(\alpha)}$, d'où une factorisation $f = pi$, où $\pi_0(i)$ est un isomorphisme, *i.e.* $i \in \mathbf{W}_0$, et où $p : \bar{X} \longrightarrow Y$ est, au dessus de la composante connexe Y_j de Y, donné par le produit $\bar{X}|Y_j \simeq Y_j \times \underbrace{\pi_0(f)^{-1}(j)}_{\text{catégorie discrète}}$. Le morphisme p est bien une $\mathbf{W}_0$-fibration, car grâce à Loc (4), il suffit de le vérifier sur chaque Y_j, et là c'est déduit d'une flèche $I_j \longrightarrow e$ (une $\mathbf{W}_0$-fibration) par changement de base $Y_j \longrightarrow e$.

D'autre part, que $\mathbf{W}_0$ ne satisfait *pas* même à D_{W_ω} a déjà été vu (I, p. 87), en réalisant l'application du n-revêtement $f : S^1 \longrightarrow S^1$ dans Cat par un morphisme W_ω-parfait (en fait, par une Cat-fibration localement triviale), chose très facile [37]. [page 70]

Commentary · Examples [ms. 69]

Enough fibrations can be computed from components

Grothendieck's counterexample is effective because its replacement can be calculated completely. Put $W = \mathbf{W}_0$, and let $f : X \to Y$ be any functor. Write $I = \pi_0 X$, $J = \pi_0 Y$, and $\phi = \pi_0 f$. Define

$$\bar{X} = \coprod_{\alpha \in I} Y_{\phi(\alpha)},$$

where Y_j is the full connected component of Y indexed by j. Send an object x of X to the copy of $f(x)$ indexed by the component of x; arrows remain in that copy. This defines $i : X \to \bar{X}$, and the projections of the copies define $p : \bar{X} \to Y$ with $f = pi$.

Each summand of $\bar{X}$ is connected and nonempty, so the summands are exactly its connected components. Thus $\pi_0(i)$ is the identity on I, and $i \in \mathbf{W}_0$. To verify the stronger property of p, let

36. **N.B.** $\mathbf{W}_0$ ne satisfait *pas* Loc (6 b), ni Loc (7 D_{W_ω}) (*cf.* plus bas), par contre Loc (7 F).

37. Autre façon de le voir : on *sait* (XII) que W (5, 7 D_W) $\Longrightarrow W \subset \mathbf{W}_\infty$, or on a $\mathbf{W}_\infty \subset \mathbf{W}_0$, et l'inclusion est *stricte !*

$T \to Y$ be arbitrary. The pullback is a disjoint union of the components of T, with a copy indexed by each α whose target component agrees with theirs. Consequently there is a natural identification

$$\pi_0(T \times_Y \bar{X}) \cong \pi_0 T \times_J I.$$

If $T' \to T$ is a $\mathbf{W}_0$-equivalence over Y, it gives a bijection on the first factor, compatible with the maps to J. Its pullback therefore gives a bijection on the displayed fibre products. Hence $p \in \mathrm{Fib}_{\mathbf{W}_0}$, proving F for all functors. The formula includes empty categories: if I is empty then both the replacement and every pullback are empty.

This factorization keeps precisely the component data of the source and fills each selected target component with a whole copy of that component. It does not try to preserve a nontrivial local system already present in $X \to Y$. That explains why enough intrinsic fibrations can coexist with failure of A, B, C, and even D_{W_ω}.

For the latter failure, take a transitive action of a group G on a finite set E with $|E| > 1$. The action-groupoid projection $E /\!\!/ G \to BG$ has connected source and target, and so belongs to $\mathbf{W}_0$. It is locally trivial with discrete fibre E, hence perfect for every fundamental localizer. Pullback to the unique object of BG gives $E \to e$, which is not a $\mathbf{W}_0$-equivalence. Thus $\mathrm{C}(\mathrm{Parf}_{W_\omega})$ fails. This is the covering obstruction discussed in the commentary on Chapter VI, manuscript p. 43, expressed in a form suited to the present factorization.

Je pense qu'à présent l'ensemble des différentes variantes de l'axiome des W-fibrations est à peu près compris, à cela près qu'il n'est toujours pas clair, en dehors de l'axiome Loc (8 bis), si les implications du diagramme

$$\begin{array}{ccc}
\mathrm{A} & \Longrightarrow & \mathrm{A}_{W_0} \\
\Downarrow & & \Downarrow \\
\mathrm{B} & \Longrightarrow & \mathrm{B}_{W_0} \\
\Downarrow & & \Downarrow \\
\mathrm{C} & \Longrightarrow & \mathrm{C}_{W_0} \\
\Downarrow & & \Downarrow \\
\mathrm{D} & \Longrightarrow & \mathrm{D}_{W_0}
\end{array}$$

sont strictes ou non. Mais il me semble que tous les localiseurs fondamentaux intéressants rencontrés jusqu'à présent satisfont Loc (8), et même Loc (1 ter, 2, 3 bis, 4, 5, 6 a, 8, 9) (peut-être même Loc (7 F) - il faudrait que je teste sur les $\mathbf{W}_n$), donc la perplexité non résolu ? me paraît sans grande conséquence.

[page 71]

Commentary · Development (commentators') [ms. 70]

The component-monodromy criterion

Grothendieck's counterexample suggests a more precise question: which locally constant categorical families really are intrinsic fibrations for connected-component equivalences? A complete answer can be given inside the class of Grothendieck fibrations. It explains both the covering obstruction and the unusually simple replacement just constructed.

Component-monodromy criterion. [ours] Let $p : X \to S$ be a Grothendieck fibration whose transport functors induce bijections on connected components. Let

$$L : S^{\mathrm{op}} \longrightarrow \mathrm{Ens}, \qquad L(s) = \pi_0(X_s),$$

be its component functor. For each connected component C of S, put $I_C = \mathrm{colim}_{C^{\mathrm{op}}} L$. Then the following conditions are equivalent: $p \in \mathrm{Fib}_{\mathbf{W}_0}$; every canonical map $L(s) \to I_C$, for $s \in C$, is a bijection; the monodromy action of the fundamental groupoid of C on L is trivial. Here trivial

means that every loop acts identically, not that a chosen identification of the different fibres was part of the original data.

We first justify the component calculation on which the proof depends. For any Grothendieck fibration $Z \to T$, not necessarily locally constant, there is a canonical bijection

$$\pi_0 Z \cong \operatorname{colim}_{T^{\mathrm{op}}} \pi_0(Z_t).$$

A connected component on the left is generated by vertical arrows in the fibres and by arrows lying over arrows of T. Cartesian factorization writes every arrow as a vertical arrow followed by a Cartesian arrow. Its relation on components is therefore exactly the relation identifying a component of Z_t with its inverse image in Z_s along $s \to t$. These are precisely the relations in the set colimit. Conversely each such relation is represented by a Cartesian arrow. This proves both surjectivity and injectivity of the canonical map. The construction is natural in changes of base and in functors over the base.

Assume first that p is intrinsically $\mathbf{W}_0$-fibrant. For any $s \in C$, the functor $e_s \to C$ is a $\mathbf{W}_0$-equivalence. Pull it back along $X|_C \to C$. The resulting functor $X_s \to X|_C$ induces a bijection on components. By the calculation above this is exactly $L(s) \to I_C$. Thus the second condition is necessary.

Conversely suppose all these canonical maps are bijections. They are natural in s, so they identify L on each C with the constant functor of value I_C. For any $t : T \to S$, the pullback fibration has component functor $L \circ t^{\mathrm{op}}$. Applying the component calculation component by component gives the natural formula

$$\pi_0(X \times_S T) \cong \coprod_{D \in \pi_0 T} I_{\pi_0(t)(D)}.$$

A $\mathbf{W}_0$-equivalence $u : T' \to T$ over S bijects the indexing components and preserves their image in $\pi_0 S$. On the corresponding summands its map is the identity of I_C. Hence it induces a bijection on the displayed component sets. This is the full intrinsic fibration test, proving the first condition.

It remains to identify the second condition with monodromy. All arrows of L are bijections, so L extends uniquely to the groupoid obtained from S by formally inverting its arrows. Within a connected component, choose an object s. Every element of the colimit can be transported to $L(s)$ along a zigzag, and two elements of $L(s)$ have the same image precisely when they lie in the same orbit of the loop group at s. Thus $L(s) \to I_C$ is the orbit map. It is bijective precisely when every orbit has one element, equivalently when every loop acts trivially. This completes the proof, including components with empty fibres.

For $S = BG$, the criterion says exactly that a locally constant family with fibre component set E is intrinsically $\mathbf{W}_0$-fibrant if and only if the G-action on E is trivial. A transitive nontrivial action fails; a constant discrete family succeeds. The replacement at ms. 69 succeeds because its component functor is already the constant family indexed by the copies of each target component.

This is our explicit development of the source's example, not a priority claim. We checked the general smooth-functor treatment in Maltsiniotis (2005, Theorem 1.2), the sharp-map account in Rezk (1998, Section 2), and the component and covering discussions in the commentary on the earlier chapters. Those sources supply the surrounding notions; we did not find this exact component-monodromy formulation there. The proof above is independent of any unverified identification with a particular model structure.

p. 40

5 Axiome des limites Loc (8), et l'axiome Loc (9) d'accessibilité

C'est l'axiome :

Loc (8) W est stable par $\varinjlim$ filtrantes.

Une variante affaiblie utile est la suivante :

Loc (8 bis) W est stable par $\varinjlim$ dénombrables.

Explicitement, si on a deux systèmes inductifs filtrants dans Cat

$$\underline{X} = (X_i)_{i \in I}$$
$$\underline{Y} = (Y_i)_{i \in I},$$

et une flèche

$$\underline{f} = (f_i)_{i\in I} : \underline{X} \longrightarrow \underline{Y},$$

donnée par des $f_i : X_i \longrightarrow Y_i$, posant $X = \varinjlim X_i$, $Y = \varinjlim Y_i$, $f = \varinjlim f_i : X \longrightarrow Y$, Loc (8) nous dit que si les $f_i \in W$, alors $f \in W$. Ici I est une (petite) catégorie filtrante quelconque, [page 72] et quitte à la remplacer par une catégorie cofinale, on peut supposer I un ensemble ordonné. L'axiome Loc (8 bis) correspond au cas où $I = \mathbf{N}$.

Commentary · Exposition [ms. 71]

Two different ways of controlling size

Grothendieck now asks whether a homotopy theory can be recovered from its small pieces. The two conditions he separates answer different parts of that question. Filtered-colimit stability says that a compatible family of already known equivalences remains an equivalence upon passage to the union. Accessibility says that equivalences have witnesses within a bounded range of sizes. Neither condition should be read as the assertion that a particular finite stage of an arbitrary convergent diagram is already an equivalence.

For example, let A be a countable connected category. Its finite subcategories need not be connected, and a finite collection of arrows need not even generate a finite category: one endomorphism can generate infinitely many powers. An infinite cardinal bound behaves better. Closing at most κ arrows under identities and finite composition still gives at most κ arrows. This is why the canonical presentations below use an infinite cardinal and allow enlargement of a stage.

There is a terminological change between these pages and contemporary accessible-category theory. Here "$\aleph_0$-accessible" means generated, in the specified filtered-colimit sense, by categories or functors with at most countably many arrows. It does not mean generated by finitely presentable objects. In modern regular-cardinal terminology, a category with at most κ arrows is κ^+-presentable. Indeed, a functor out of it is specified by at most κ choices of objects and arrows, subject to at most κ equations. In a κ^+-filtered colimit those choices and equations can be realized at a common stage. The same argument applies to commutative squares between functors, hence to the arrow category. This elementary verification is enough to translate the size estimates used here without silently shifting the cardinal index.

The path replacement serves a different purpose. It converts the question about an arbitrary arrow into a question about the fibres of one specially controlled arrow. The argument needs the replacement functor to commute with filtered colimits. It does not require its two output classes to be closed under those colimits. Grothendieck's parenthetical prediction on manuscript page 73 nevertheless contains an error: W_ω is in fact $\mathbf{W}_\infty$, and is filtered-colimit stable. We return to the precise minimality theorem after the proof of 6.1.

Notons que grâce à la construction de la catégorie des chemins, nous avons une factorisation, fonctorielle en f, de toute flèche $f : X \longrightarrow Y$ de Cat en $f = pi$:

$$X \xrightarrow{i=i_f} \bar{X}(f) = \bar{X} \xrightarrow{p=p_f} Y,$$

avec $i \in W_\omega$, $p \in \mathrm{Parf}_{W_\omega}$, a fortiori $i \in W$, $p \in \mathrm{Parf}_W$. Ce foncteur $f \longmapsto (\bar{X}(f), p_f)$ commute aux limites inductives. Ainsi, si on applique ceci à chacun des $f_\alpha : X_\alpha \longrightarrow Y_\alpha$, le factorisant en

$$X_\alpha \xrightarrow{i_\alpha} \bar{X}_\alpha \xrightarrow{p_\alpha} Y_\alpha,$$

on trouve un système inductif de diagrammes de type $\mathbf{\Delta}^2$ (factorisant les f_i), et en passant à la $\varinjlim$ on trouve

$$X \xrightarrow{i} \bar{X} \xrightarrow{p} Y,$$

qui n'est autre que la factorisation canonique de $f = \varinjlim f_i$ en pi, avec $i \in W_\omega$, $p \in \mathrm{Parf}_{W_\omega}$ [page 73] (N.B. Alors que ni W_ω, ni Parf_{W_ω} ne sont stables par $\varinjlim$ filtrantes, à coup sûr !). On a donc $i \in W$, et la condition $f \in W$, *i.e.* $pi \in W$, équivaut donc à $p \in W$. Cela nous ramène, pour vérifier l'axiome Loc (8) (resp. Loc (8 bis)) au cas où les f_i sont dans Parf_{W_ω}.

Supposons maintenant que W satisfasse à D_{W_ω} (la plus faible de toutes les variantes envisagées ici de l'axiome des W-fibrations Loc (7), à la seule exception de F). Alors on a

$$p \in W \qquad \Longleftrightarrow \qquad \text{les fibres de } p \text{ sont } W\text{-asphériques},$$

l'implication $\Longrightarrow$ résultant de l'hypothèse D_{W_ω} $\mathrm{Parf}_{W_\omega} \cap W \subset W^{\mathrm{u}}$, et $\Longleftarrow$ résultant du sorite des morphismes W-lisses *etc.*, via Loc (3). De même, l'hypothèse que les $f_i \in W$ équivaut à celle que les fibres des p_i sont W-asphériques. D'autre part, il est immédiat que toute fibre de p est isomorphe à la $\varinjlim_I$ des fibres correspondantes des p_α. De cette façon, on trouve : p. 41 [page 74]

Proposition 5.1. *Supposons que W satisfasse l'axiome des W-fibrations* Loc (7 D_{W_ω}) (*ce qui est donc le cas s'il satisfait un des axiomes plus forts* Loc (7 a *ou* b *ou* c)). *Pour que W satisfasse à* Loc (8) (resp. *à* Loc (8 bis)), *il faut et il suffit que l'ensemble des objets dans* Cat *qui sont W-asphériques soit stable par* $\varinjlim$ *filtrante* (resp. *par* $\varinjlim$ *de suites dénombrables*).

5.2. Notons que la catégorie Cat est un paratopos, a fortiori elle est *accessible* (*cf.* XVIII, §8), et il en est donc de même de $\underline{\mathrm{Fl}}(\mathrm{Cat})$. Ainsi on a dans $\mathrm{Fl}(\mathrm{Cat}) = \mathrm{Ob}\,\underline{\mathrm{Fl}}(\mathrm{Cat})$ la notion de *partie accessible.* On dira donc qu'une partie W de $\mathrm{Fl}\,\mathrm{Cat}$ (plus généralement d'une catégorie $\mathrm{Fl}(\mathcal{M})$, où $\mathcal{M}$ est une catégorie accessible) est *accessible,* si elle l'est par rapport à la catégorie ambiante $\underline{\mathrm{Fl}}\,\mathrm{Cat}$. Ceci posé, l'axiome Loc (9) est le suivant. [page 75]

Commentary · Exposition [ms. 74]

Taking a fibre after a filtered colimit

Grothendieck wants to replace a closure condition on arrows by a closure condition on aspherical categories. Proposition 5.1 achieves exactly this, provided the path fibration is an intrinsic W-fibration. One small indexing choice makes the proof literal.

Write $p_i : E_i \to B_i$ for the perfect replacements and $p : E \to B$ for their filtered colimit. Choose $b \in B$. After replacing the indexing category by a cofinal filtered poset, choose a stage i_0 and $b_{i_0} \in B_{i_0}$ representing b. For $i \geq i_0$ let b_i be its image. There is then a canonical isomorphism

$$E_b \cong \operatorname*{colim}_{i \geq i_0} (E_i)_{b_i}.$$

To see surjectivity on objects, represent an object of E_b at a stage. The equality of its image with b holds at a later stage, since equality in a filtered colimit of sets is eventually witnessed. The same argument applies to arrows, including the requirement that their image be the identity of b_i. Eventual equality also gives injectivity. Composition is inherited from a common later stage. This proves the displayed isomorphism directly; equivalently, filtered colimits commute with the finite-limit data defining categories and their strict fibres.

Suppose now that W-aspherical categories are closed under the relevant colimits. Since $f_i = p_i i_i$ and $i_i \in W_\omega \subset W$, each $f_i \in W$ implies $p_i \in W$. The hypothesis D_{W_ω} makes each p_i universally a W-equivalence, so every fibre $(E_i)_{b_i}$ is W-aspherical. The displayed formula makes E_b aspherical. The colimit replacement p is again W_ω-perfect because it is the canonical replacement of colim f_i, not because arbitrary filtered colimits of perfect maps have been shown perfect. The aspherical-fibre criterion gives $p \in W$, and then $f \in W$ by two-out-of-three. Conversely, apply closure of W to the maps $X_i \to e$. The proof for sequences is identical, using a tail of the sequence.

This is also the correction needed when a basepoint is chosen on manuscript page 82. A point of a colimit has a representative at some stage; it does not have an image in every earlier stage. Once a representative is fixed, the later images form the based diagram needed for iterated loops.

Loc (9) W est une partie *accessible* de $\mathrm{Fl}(\mathrm{Cat}) = \mathrm{Ob}\,\underline{\mathrm{Fl}}(\mathrm{Cat})$.

5.3. Rappelons que cette notion un peu technique se simplifie considérablement, si on suppose que W satisfait l'axiome de limites Loc (8). Alors W est accessible si et seulement si il existe une *petite* partie W_0 de $\mathrm{Fl}(\mathrm{Cat})$, telle que W soit la "L_1-enveloppe" de W_0, *i.e.* la plus petite partie de $\mathrm{Fl}(\mathrm{Cat})$ contenant W_0 et L_1-stable (*i.e.* stable par $\varinjlim$ filtrantes). S'il en est ainsi, il est clair qu'on peut prendre W_0 de la forme

$$W_\pi = W \cap \mathrm{Fl}_\pi(\mathrm{Cat}),$$

où π est un cardinal infini convenable, et où $\mathrm{Fl}_\pi(\mathrm{Cat}) \overset{\text{déf}}{=} \mathrm{Fl}(\underline{\mathrm{Cat}}_\pi)$, $\underline{\mathrm{Cat}}_\pi$ désignant la sous-catégorie strictement pleine de Cat formée des objets X tels que $\mathrm{card}\, X \leq \pi$ (où par définition, $\mathrm{card}\, X = \mathrm{card}\, \mathrm{Fl}\, X$).

Notons que la filtration qu'on vient de décrire sur Cat (indexée par les petits cardinaux infinis) n'est autre que sa filtration canonique, *i.e.* $\underline{\mathrm{Cat}}_\pi$ est la sous-catégorie pleine de Cat formée des objets π-accessibles de Cat, et de même dans $\underline{\mathrm{Fl}}(\mathrm{Cat})$. On trouve ainsi, grâce aux développements de XVIII, §13, la caractérisation suivante, que je rappelle ici pour mémoire (en me bornant pour simplifier au cas où W satisfait à Loc (8)) : [page 76]

Proposition 5.3.1. [38] *Soit W une partie de* $\mathrm{Fl}(\mathrm{Cat})$ *stable par* $\varinjlim$ *filtrantes, et soient pour tout cardinal infini π, $W_\pi = W \cap \mathrm{Fl}_\pi(\mathrm{Cat})$, et $\underline{W}$, $\underline{W}_\pi$ les sous-catégories pleines correspondantes de* $\underline{\mathrm{Fl}}(\mathrm{Cat})$. *On dit que W est* π-accessible *si W est la L-enveloppe de W_π (donc W est accessible si et seulement s'il existe un cardinal infini π tel que W soit π-accessible). Ceci posé, les conditions suivantes sont équivalentes :* p. 42

a) *W est π-accessible.*

b) *Pour tout système inductif $(f_i)_{i\in I}$, L_1-π-adapté dans* $\underline{\mathrm{Fl}}\,\mathrm{Cat}$ (cf. *ci-dessous*), *de limite inductive f, on a $f \in W$ si et seulement si la sous-catégorie pleine I_W des $i \in Ob I$ tels que $f_i \in W$ est cofinale dans I.* [page 77]

b′) (*Quand on a choisi, pour tout $f \in \mathrm{Fl}(\mathrm{Cat})$, une représentation L_1-π-adaptée de f comme* $\varinjlim$) : *Si $f \in W$, alors la sous-catégorie pleine I_W définie dans* b) *est cofinale dans I.*

Rappelons ici la notion de système inductif L_1-π-adapté. Il s'agit des conditions :

1°) I est grand devant π, et stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$.

2°) Le foncteur $i \longmapsto x_i : I \longrightarrow \underline{\mathrm{Fl}}(\mathrm{Cat})$ commute aux $\varinjlim$ en question.

3°) Les x_i sont dans $\underline{\mathrm{Fl}}(\mathrm{Cat})_\pi \overset{\text{déf}}{=} \underline{\mathrm{Fl}}_\pi(\mathrm{Cat})$.

Notons que dans le cas d'un "paratopos parabélien" tel que Cat ou $\underline{\mathrm{Fl}}\,\mathrm{Cat}$, il y a une façon canonique, π étant donné, de représenter un objet f comme $\varinjlim$ d'un système inductif L_1-π-adapté. Ici,

$$f : X \longrightarrow Y$$

étant donné, on considère l'ensemble I des couples $(X_i \subset X, Y_i \subset Y)$ de sous-catégories de X et de Y, telles que l'on ait $X_i, Y_i \in \mathrm{Ob}\,\mathrm{Cat}_\pi$ (*i.e.* $\mathrm{card}\,(X_i), \mathrm{card}\,(Y_i) \leq \pi$) et que $f(X_i) \subset Y_i$. Il est immédiat que I est filtrant, pour la relation d'ordre évidente [page 78]

$$(X_i, Y_i) \subset (X_j, Y_j) \qquad \Longleftrightarrow \qquad X_i \subset Y_i \ \text{ et } \ X_j \subset Y_j,$$

et même grand devant π, que I est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi$, et que le foncteur

$$i \longmapsto (f_i : X_i \longrightarrow Y_i) : I \longrightarrow \underline{\mathrm{Fl}}\,\mathrm{Cat}$$

commute auxdites $\varinjlim$, enfin les f_i sont dans $\underline{\mathrm{Fl}}(\mathrm{Cat})_\pi$ par construction. Ainsi on a un système inductif L_1-π-adapté, et il est clair que sa limite inductive est canoniquement isomorphe à f. Ceci vu :

Corollaire 5.3.2. *La condition que W soit π-accessible signifie donc que pour tout $f : X \longrightarrow Y \in W$, et pour toute sous-catégorie X_i de X et Y_i de Y, de cardinal $\leq \pi$ (avec $f(X_i) \subset Y_i$), mais en fait c'est inutile, quitte à agrandir Y_i), il existe des sous-catégories $X_j \supset X_i$ et $Y_j \supset Y_i$ de cardinal $\leq \pi$, telles que f induise $f_j : X_j \longrightarrow Y_j$ et que l'on ait $f_j \in W$.* [page 79]

38. *cf. loc. cit.* 13.36.

Commentary · Examples [ms. 78]

Enlarging a countable subfunctor

The order on pairs of subcategories is meant to describe simultaneous approximation of a functor, rather than separate approximation of its source and target. In the displayed formula on this page the right-hand side must be read as $X_i \subset X_j$ and $Y_i \subset Y_j$. The printed comparisons $X_i \subset Y_i$ and $X_j \subset Y_j$ do not even compare two stages. We retain that edition slip in the transcription.

Fix an infinite cardinal κ and a functor $f : X \to Y$. Any collection of at most κ pairs (A_i, B_i) has an upper bound: take the subcategory of X generated by all arrows of the A_i, and the subcategory of Y generated by all arrows of the B_i together with their necessary images under f. Each still has at most κ arrows. A filtered union of at most κ such pairs is itself a pair of the permitted size. Every arrow of X or Y occurs at some stage. These observations verify, without an appeal to abstract accessibility, the canonical adapted presentation used in Corollary 5.3.2.

Here is the admitted Lemma 5.6 in that presentation. Suppose $\pi_0(f)$ is bijective and begin with a countable subfunctor $f_0 : A_0 \to B_0$. We construct increasing countable subfunctors $f_m : A_m \to B_m$. At the next stage perform two operations. For every object $b \in B_m$, choose an object $a \in X$ whose image lies in the connected component of b, and choose a finite zigzag in Y from $f(a)$ to b. Adjoin a, this zigzag, and their images to the relevant categories. Next, for every pair $a, a' \in A_m$ whose images are connected in B_m, choose a finite zigzag between a and a' in X. Such a zigzag exists by injectivity of $\pi_0(f)$. Adjoin it and its image. There are countably many choices to make, each with finite support. Closing under identities and composition preserves countability.

Let $A_\infty = \bigcup_m A_m$ and $B_\infty = \bigcup_m B_m$. Every object of B_∞ occurs at some stage, so the first operation makes $\pi_0(A_\infty) \to \pi_0(B_\infty)$ surjective. If two objects of A_∞ have connected images in B_∞, the finite zigzag witnessing this lies at some stage containing both objects. The second operation at the next stage makes them connected in A_∞. Thus the map is injective. We have found a countable enlargement belonging to $\mathbf{W}_0$.

Finally, π_0 preserves colimits because it is left adjoint to the discrete-category functor. A filtered colimit of bijections is a bijection, so $\mathbf{W}_0$ satisfies Loc (8). The enlargement criterion now proves its asserted countable accessibility. Taking the target to be the terminal category gives the analogous result for connected categories. A small initial subcategory can therefore be enlarged to a connected one; it need not have been connected at the outset.

La notion d'accessibilité de W me semble aussi bien comprise que celle de limites, je n'y vois plus aucun mystère. D'autre part, il me semble que tous les localiseurs fondamentaux utilisés à ce jour y satisfont (tout comme à l'axiome Loc (8)). Ici, je vais me borner à établir :

Théorème 5.4.[39] *Le localiseur fondamental* $\mathbf{W}_\infty$ *(équivalences faibles "habituelles") satisfait à l'axiome* Loc (9) (*en fait, il satisfait à* tous *les axiomes vu jusqu'à présent, savoir* Loc (1 ter, 2, 3 bis, 4, 5, 6, 7, 8, 9)). *Plus précisément,* $\mathbf{W}_\infty$ *est* $\aleph_0$*-accessible (où* $\aleph_0$*, ou* π_0*, est le premier cardinal infini).* p. 43

Je ne reviens pas ici sur la vérification des autres axiomes, et me borne à prouver Loc (9), l'accessibilité, en utilisant ce qui peut m'être utile. Je me borne à indiquer la démonstration (assez technique) dans ses grandes lignes. Pour le moment, W est à nouveau un localiseur fondamental quelconque, sauf qu'il satisfait à Loc (8). [page 80]

Commentary · Exposition [ms. 79]

A direct completion of the accessibility argument

Grothendieck's theorem concerns a concrete size bound, and one can prove it without completing the unfinished general statement of Lemma 5.5(b). We give that proof because it identifies exactly which witnesses must be added. The accessibility assertion of Theorem 5.4 is correct. Its parenthetical list of all axioms must, however, be qualified: the reverse cube condition Loc (6b), if included in the bare label Loc (6) as in Section 3, is not valid for ordinary weak homotopy equivalences. The valid direct excision assertion is Loc (6a).

39. Mérite bien le nom de *théorème,* surtout si on y inclut toute la liste des axiomes Loc mentionnés ci-contre ! Ce théorème n'a rien d'évident, à partir de la définition cohomologique de $\mathbf{W}_\infty$ - c'est un résultat ("bien connu") qui me paraît profond.

Put $R(A) = \mathrm{Ex}^{\infty} N(A)$. This is a Kan complex with the weak homotopy type of the nerve; the Kan construction and its proof are recalled in Cisinski (2006a, Proposition 2.1.39). Two elementary finiteness facts drive the argument. First, if A has countably many arrows, then $R(A)$ has countably many simplices. In each degree, Ex is the set of maps from the finite simplicial set $\mathrm{Sd}\,\Delta^n$, and countably many finite choices remain countable. Iteration and the sequential union preserve that bound. Second, every finite simplicial configuration in $R(A)$ has support in a finitely generated subcategory of A. It appears at some finite Ex stage and involves finitely many original simplices; their finitely many arrows generate a countable subcategory. The same statement holds for a configuration together with a finite simplicial homotopy. These facts also show that R commutes with filtered colimits.

Let $f : A \to B$ be in $\mathbf{W}_{\infty}$ and let $A_0 \to B_0$ be a countable subfunctor. We build a sequence of countable enlargements. At stage m, first carry out the connected-component operations of the previous block. For each object $a \in A_m$, each $n \geq 1$, and each element of

$$\pi_n(R(B_m), f(a)),$$

choose a preimage in $\pi_n(R(A), a)$. Choose simplicial representatives and a homotopy exhibiting that the image of the chosen representative equals the prescribed class in $R(B)$. Adjoin the support of these choices. Next, for every element of $\pi_n(R(A_m), a)$ whose image is zero in $\pi_n(R(B_m), f(a))$, choose a null homotopy in $R(A)$ and adjoin its support. These choices exist because $R(f)$ is a weak equivalence. A countable Kan complex has countably many homotopy classes in every degree, so there are only countably many requirements over all a and n. After adjoining images under f and closing under composition, the next stage remains countable.

At the union, the connected-component argument still applies. To prove surjectivity of a positive homotopy group at an object a, represent a target class by a finite simplicial sphere in $R(B_{\infty})$. Its support and the object a occur at some stage. The next stage supplies the selected preimage and the required comparison homotopy. For injectivity, represent a class in $R(A_{\infty})$ and a null homotopy of its image in $R(B_{\infty})$. Both are finite configurations, so they occur together at some stage. The next stage supplies a null homotopy in the source. Consequently $A_{\infty} \to B_{\infty}$ is a weak equivalence. This proves the enlargement condition of Corollary 5.3.2 for $\kappa = \aleph_0$.

The remaining closure condition is equally finite. Given a filtered diagram of weak equivalences, a sphere, a null homotopy, or an equality of homotopy classes in its Kan replacement is represented at a stage. Bijectivity on components and homotopy groups therefore passes to the colimit. This proves Loc (8) for $\mathbf{W}_{\infty}$ and completes the accessibility theorem. The construction is a direct proof of the known assertion of 5.4, rather than a claim of a new result.

The final reformulation of Lemma 5.5(b) also needs a qualification before it is used outside this example. The literal inclusion $\mathrm{Asph}_W \subset \mathrm{Cat}_{\mathrm{connected}}$ follows from Loc (5); without it, the total localizer makes even the empty category aspherical. The unfinished extra hypothesis in the manuscript cannot be reconstructed uniquely, but this particular missing condition is visible.

Lemme 5.5. [40]

a) *Pour que le critère* 5.3.1 b) *de π-accessibilité de W soit satisfait, il faut et il suffit qu'il le soit lorsque les f_i sont W_ω-parfaits.*

b) *Supposons que $Parf_{W_\omega} \cap W \subset W^u$,* i.e. *que W satisfait à* Loc (7 D_{W_ω}) (*la plus faible des variantes de l'axiome des W-fibrations, à l'exception seulement de* Loc (7 F)). *Supposons de plus (pour être tranquille) que W satisfait* `[phrase non terminée]. [?Alors]` *W est π-accessible si et seulement si l'ensemble* $\mathrm{Asph}_W \subset \mathrm{Ob}\,\mathrm{Cat}$ *des objets W-asphériques de* Cat *est π-accessible. Ou encore, que la partie* $\mathrm{Asph}_W \subset \mathrm{Ob}\,\mathrm{Cat}_{0\text{-}connexe}$ *soit π-accessible, où* $\mathrm{Cat}_{0\text{-}connexe}$ *désigne la sous-catégorie pleine de* Cat *formée des objets* 0*-connexes.*

Pour l'essentiel, la démonstration est la même que celle de 5.1, en un peu plus technique. L'outil essentiel est toujours la factorisation fonctorielle $f = pi$ d'une flèche de Cat, avec $i \in W_\omega$, $p \in \mathrm{Parf}_{W_\omega}$, et la propriété de commutation aux $\varinjlim$ filtrantes de ladite factorisation. [page 81]

Revenons maintenant au cas de $W = \mathbf{W}_{\infty}$. On doit prouver que $\mathrm{Asph}_{\mathbf{W}_\infty} \subset \mathrm{Ob}\,\mathrm{Cat}_{0\text{-connexe}}$ est π_0-accessible. Donc à prouver le critère correspondant à 5.3.1 b), en se plaçant maintenant

40. On suppose que W satisfasse à Loc (8).

dans $\mathrm{Cat}_{0\text{-connexe}}$ au lieu de $\mathrm{Fl}\,\mathrm{Cat}$. On a donc

$$X = \varinjlim_{i\in I} X_i,$$

représentation L_1-π-admissible de X $\mathbf{W}_\infty$-asphérique, à prouver que pour tout i dans I, $\exists j$ dans I et $i \longrightarrow j$, avec X_j $\mathbf{W}_\infty$-asphérique.

J'admets ici le lemme AQT `[âne qui trotte]` :

Lemme 5.6. *Soit* $\mathbf{W}_0 = \{f \in \mathrm{Fl}\,\mathrm{Cat} \mid \pi_0(f)$ *isomorphisme*$\}$. *Alors* $\mathbf{W}_0$ *est* π_0*-accessible (et* L_1*-stable). A fortiori, l'ensemble des objets* 0*-connexes de* Cat *est* π_0*-accessible.*

Ceci nous ramène, quitte à remplacer I par une catégorie cofinale, à supposer que les X_i sont 0-connexes. (Mais j'ai oublié que cette réduction est déjà faite ! Donc il faut voir 5.6 comme ingrédient

de la démonstration de 5.5 b).) p. 44

Soit x un objet (point) de X, x_i son image dans X_i. Considérons (via ma construction standard des catégories de chemins) les $\Omega^1(X,x)$, $\Omega^1(X_i,x_i)$. On trouve [page 82]

$$\Omega^1(X,x) \simeq \varinjlim_{I} \Omega^1(X_i,x_i),$$

et on vérifie que c'est là encore un système inductif L_1-π_0-adapté. En itérant, on trouve pour $n \in \mathbf{N}^*$

$$\Omega^n(X,x) \simeq \varinjlim_{I} \Omega^n(X_i,x_i),$$

limite inductive L_1-π_0-adaptée. Utilisant 5.6, on en conclut que pour tout n, le sous-ensemble (supposons I un ensemble ordonné, que diable ça suffit !)

$$I_n = \{i \in I \mid \Omega^n(X_i,x_i) \ \text{ est 0-connexe}\}$$

est cofinal dans I, de plus il est stable par $\varinjlim$ filtrantes de cardinal $\leq \pi_0$. Donc

$$I_\infty \overset{\text{déf}}{=} \bigcap I_n$$

est aussi cofinal dans I (*cf.* XVIII, 13.10.2, p. 302).

Or $i \in I_\infty$ signifie que tous les $\Omega^n(X_i,x_i)$ sont 0-connexes, ce qui signifie aussi que [page 83]
X_i est $\mathbf{W}_\infty$-asphérique (puisqu'il est déjà 0-connexe) (*cf.* XII, cor. p. 190). Cela achève la démonstration du théorème 5.4.

Commentary · Exposition [ms. 82]

Why the countable intersection is cofinal

Grothendieck's loop argument eliminates the homotopy groups one at a time. The final passage from each degree separately to all degrees together is a small diagonal argument, and its closure hypothesis is essential.

Let I be a directed poset in which every increasing countable sequence has a supremum. Suppose each $J_n \subset I$ is cofinal and closed under suprema of increasing countable sequences contained in J_n. Choose a sequence $n(0), n(1), \ldots$ in which every positive integer occurs infinitely often. Starting above an arbitrary $i \in I$, choose successively

$$i \leq i_0 \leq i_1 \leq \cdots, \qquad i_k \in J_{n(k)}.$$

Cofinality makes every choice possible. Put $j = \sup_k i_k$. For a fixed n, the subsequence with $n(k) = n$ is cofinal in this increasing sequence. It has the same supremum j, and all its terms belong to J_n. Hence $j \in J_n$. This holds for every n, so $j \in \bigcap_n J_n$. Since $j \geq i$, the intersection is cofinal.

Applied to the I_n of the text, the argument finds a stage at which all iterated loop categories are connected. Connectedness of the original stage is already part of the reduction; together these conditions say that all homotopy groups vanish. The loop-detection comparison itself was treated in

the commentary on Chapter XII, manuscript p. 190. Here the new issue is making countably many conditions hold at one stage.

Two apparent defects should therefore be distinguished. The point x must first be represented at a stage, as explained above. By contrast, the cardinal π_0 in the bound $\leq \pi_0$ is not a misprint: Theorem 5.4 has expressly used π_0 as another notation for $\aleph_0$. Replacing it is unnecessary and would erase the author's declared convention.

6 La condition Loc (5, 7 D_{W_ω}) implique $W \subset \mathbf{W}_\infty$

Je vais redonner ici, pour mémoire, la démonstration du théorème 1 de XII :

Théorème 6.1. *Soit W un localiseur fondamental satisfaisant à* D_{W_ω} *(où W_ω est le plus petit de tous les localiseurs fondamentaux). Alors on a $W = \mathrm{Fl}\,\mathrm{Cat}$,* ou *$W \subset \mathbf{W}_\infty$ (suivant que W ne satisfait pas à l'axiome de connexité* Loc (5), *ou qu'il y satisfait.)*

Je vais faire la démonstration en supposant que W satisfait à Loc (5). Pour la démonstration du fait que dans le cas contraire, on a $W = \mathrm{Fl}(\mathrm{Cat})$, je renvoie à XII, th. 2, p. 20. (Voir aussi le résultat très voisin, plus général et plus faible, rappelé dans prop. 2.7, page 12.)

Lemme 6.2. *Soient W, W' deux localiseurs fondamentaux, W satisfaisant à* Loc (7 D_{W_ω}). *Pour qu'on ait $W \subset W'$, il faut et il suffit qu'on ait* $\mathrm{Asph}_W \subset \mathrm{Asph}_{W'}$.

Il suffit bien sûr de prouver "il suffit", donc supposons que tout objet W-asphérique est [page 84]
W'-asphérique, et prouvons que $W \subset W'$. Soit donc $f : X \longrightarrow Y$ dans W, prouvons $f \in W'$. Pour ceci, j'utilise la factorisation canonique $f = pi$,

$$X \xrightarrow{i \in W_\omega} \bar{X} \xrightarrow{p \in \mathrm{Parf}_{W_\omega}} Y.$$

On a donc aussi $i \in W$, et comme $f = pi \in W$, on a $p \in W$, donc $p \in \mathrm{Parf}_{W_\omega} \cap W$. Or D_{W_ω} p. 45
signifie que cet ensemble est contenu dans W^{u}, donc on a $p \in W^{\mathrm{u}}$, et en particulier les fibres de p sont W-asphériques. Elles sont donc W'-asphériques, et comme p est W_ω-parfait et a fortiori W'-parfait, il s'ensuit que $p \in W'$. On a aussi $i \in W_\omega \subset W'$, donc $i \in W'$, donc aussi $f = pi \in W'$, q.e.d.

Revenons alors à la démonstration de 6.1. En vertu du lemme, il suffit de prouver que si X dans Cat est W-asphérique, il est $\mathbf{W}_\infty$-asphérique. Mais par hypothèse Loc (5) on sait déjà que X est 0-connexe, et choisissant un point x dans X, qu'il soit $\mathbf{W}_\infty$-asphérique s'exprime par la condition que les $\Omega^n(X, x)$ (pour $n \geq 1$) sont 0-connexes (*cf.* XII, cor. p. 190 déjà cité). [page 85]
Pour ceci, à cause de Loc (5) il suffit de prouver qu'ils sont W-asphériques, et par induction il suffit de prouver que $\Omega^1(X, x)$ l'est. Or par définition de $\Omega^1(X, x)$, c'est là la fibre en x d'une flèche dans Cat

$$E = \underline{\mathrm{Ch}}(X, x, -) \xrightarrow{p \in \mathrm{Parf}_{W_\omega}} X,$$

où la source E est W_ω-asphérique, a fortiori W-asphérique. Comme X l'est également, on a donc $p \in W$, donc $p \in \mathrm{Parf}_{W_\omega} \cap W \subset W^{\mathrm{u}}$, donc p est à fibres W-asphériques, et en particulier $\Omega^1(X, x)$ est W-asphérique, q.e.d.

Corollaire 6.3. (Caractérisation de $\mathbf{W}_\infty$.) $\mathbf{W}_\infty$ *est le plus grand localiseur fondamental satisfaisant à* Loc (5, 7 D_{W_ω}) *- donc aussi le plus grand localiseur fondamental satisfaisant à* Loc (5, 7).

Je pense que nous trouverons plus bas une caractérisation "interne" de $\mathbf{W}_\infty$, via un "axiome de descente" (très fort) Loc (10), comme l'unique localiseur fondamental satisfaisant Loc (5, 7 D_{W_ω}, 10) (ou encore Loc (5, 7, 10)). [page 86]

Commentary · Exposition [ms. 85]

The fibration axiom recovers every homotopy group

Grothendieck's comparison theorem explains why the seemingly modest axiom D_{W_ω} is so restrictive. Its role is not merely to furnish some factorization. It makes the fixed categorical path

replacement valid for the chosen equivalences W, and that replacement retains all ordinary homotopy groups.

The proof has two logically separate steps. First, under D_{W_ω} a class W is detected by its aspherical objects. If every W-aspherical category is W'-aspherical and $f \in W$, factor $f = pi$ with $i \in W_\omega$ and p W_ω-perfect. Then $p \in W$. The axiom makes all its fibres W-aspherical, hence W'-aspherical. Perfectness for W_ω implies perfectness for W', and the aspherical-fibre criterion gives $p \in W'$. Since $i \in W'$, we have $f \in W'$. Only the source localizer W needs the fibration axiom in this argument.

Second, let X be W-aspherical and assume Loc (5). It is connected and nonempty, so choose $x \in X$. The categorical based-path construction gives a map $E_xX \to X$ with E_xX W_ω-aspherical and with fibre the categorical loop object. Both total space and base are W-aspherical, so the map is in W. Since it is also W_ω-perfect, its fibre is W-aspherical. Repeat at the constant loop. Loc (5) says that every resulting loop category is connected. Thus all ordinary positive homotopy groups of NX vanish. The first step, with $W' = \mathbf{W}_\infty$, now proves $W \subset \mathbf{W}_\infty$.

The connectedness hypothesis supplies the basepoint and turns asphericity into vanishing of components at every loop stage. The conclusion $W \subset \mathbf{W}_\infty$ cannot hold for the total localizer $W = \mathrm{Fl}(\mathrm{Cat})$, which satisfies the universal-fibration condition but contains all functors. The shorter recollection on manuscript page 102 must therefore retain that exception or the explicit Loc (5) hypothesis.

The total-localizer branch, cited rather than proved in the source, admits the following direct completion. Suppose that W satisfies D_{W_ω} and that a W-aspherical category A is disconnected. Choose an object a in one component and an object b in another. Since $A \to e$ is in W, two-out-of-three makes $a : e \to A$ a W-equivalence. Factor it canonically as

$$e \xrightarrow{i} E \xrightarrow{p} A, \qquad i \in W_\omega, \quad p \in \mathrm{Parf}_{W_\omega}.$$

The tautological inclusion $W_\omega \subset \mathbf{W}_\infty$ makes E weakly contractible, in particular nonempty and connected. This inclusion only uses that $\mathbf{W}_\infty$ is a fundamental localizer; it does not use the later equality with W_ω. The image of p is consequently contained in the component of a. Its strict fibre over b is empty. On the other hand, $p \in W$ by two-out-of-three, so D_{W_ω} makes its empty fibre W-aspherical. Thus $\varnothing \to e$ belongs to W.

The same conclusion holds immediately if the original aspherical category is empty. Once $\varnothing$ is aspherical, Loc (3) applies to $\varnothing \to B$ for every category B: each of its comma categories is empty and hence aspherical. Therefore $\varnothing \to B$ is in W for all B. For any $f : B \to C$, two-out-of-three applied to $\varnothing \to B \to C$ gives $f \in W$. Hence W is total.

Consequently, if W is not total, every W-aspherical category is nonempty and connected. The loop argument above uses exactly this property: it applies to X and successively to all its W-aspherical loop categories. It therefore proves $W \subset \mathbf{W}_\infty$ in the nontotal case, and in particular implies Loc (5). This completes the whole dichotomy without a product-preservation or strong-saturation assumption. It also avoids the separate dependency issue with Proposition 2.7 discussed in the Section 2 audit; that general issue is not being used to withhold the stronger conclusion available under D_{W_ω}.

6.4. *Commentaire sur les axiomes des W-fibrations du types* Loc (7 …), *et notamment sur* Loc (7 D_{W_ω}). *Relation conjecturale avec les* "types d'homotopie simples" *de* Whitehead.

a) Il me semble que *tous* les localiseurs fondamentaux avec lesquels on a travaillé tacitement jusqu'à présent (les $\mathbf{W}_n$ ($n \in \mathbf{N}^*$), équivalence homologique et cohomologique, équivalence rationnelle …) correspondent à des localiseurs $W \supset \mathbf{W}_\infty$. Par le théorème 6.1, il s'ensuit donc qu'*aucun* d'eux, à part $\mathbf{W}_\infty$ lui-même, ne satisfait à la plus faible version D_{W_ω} de toutes de l'axiome Loc (7 …), à la seule exception de Loc (7 F). Ainsi, les localiseurs W qui y satisfont sont à l'exception de D_{W_ω} lui-même, d'un type tout nouveau - des localiseurs qui sont strictement contenus dans $\mathbf{W}_\infty$.

b) Ceci soulève, bien sûr, la question de l'existence de localiseurs fondamentaux contenus dans $\mathbf{W}_\infty$ et distincts de $\mathbf{W}_\infty$. Je n'ai pas même prouvé que $W_\omega \neq \mathbf{W}_\infty$, alors que je n'ai pas [page 87]
le moindre doute que tel est bien le cas. `[Cisinski a démontré que` $W_\omega = \mathbf{W}_\infty$`.]` A fortiori, j'ignore si le plus petit localiseur fondamental satisfaisant Loc (7 D_{W_ω}) est différent de $\mathbf{W}_\infty$.

Je serais tout particulièrement intéressé par le plus petit localiseur $\tilde{\mathbf{W}}_\infty \subset \mathbf{W}_\infty$ satisfaisant tous les axiomes de stabilité Loc (1 ter, 2, 3 bis, 4, 6, 7, 8) (**N.B.** il satisfait nécessairement Loc (5) car $\tilde{\mathbf{W}}_\infty \subset \mathbf{W}_\infty \subset \mathbf{W}_0$, de plus Loc (7) équivaut, en présence de Loc (8), à la forme très faible Loc (7 D_{W_ω}) : $\mathrm{Parf}_{W_\omega} \cap W \subset W^{\mathrm{u}}$. Enfin, on montre que Loc (4) est conséquence des autres axiomes, *cf.* plus bas.) Je conjecture à présent que $\tilde{\mathbf{W}}_\infty$ (qui donne lieu à un formalisme homotopique tout aussi complet que la sempiternelle "équivalence faible") est bel et bien différent de $\mathbf{W}_\infty$ `[non par Cisinski]`. Et je suspecte que la catégorie $\mathrm{Hot}_{\tilde{\mathbf{W}}_\infty}$ mérite d'être appelée catégorie des *"types d'homotopie simples"* (à la Whitehead) [41]. Un premier test décisif, c'est de vérifier que l'invariant cohomologique principal de Whitehead d'un type d'homotopie simple, savoir un élément dans un $K(\mathbf{Z}[\pi_1])$ (si je me rappelle bien [42]) - ou quelque chose d'approchant, peut se définir déjà en termes des objets dans $\mathrm{Hot}_{\bullet\,\tilde{\mathbf{W}}_\infty}$ (le Hot pointé). Et deuxio, si on associe à une "maquette simpliciale" finie (décrivant combinatoirement une triangulation finie) l'ensemble ordonné de ses simplexes, vu comme un objet de Cat, et l'objet correspondant dans $\mathrm{Hot}_{\tilde{\mathbf{W}}_\infty}$, celui-ci ne change pas [43], à isomorphisme canonique près, quand on effectue sur ce "polyèdre" envisagé une opération élémentaire à la Whitehead. Cela suggère d'ailleurs d'essayer de définir de telles opérations élémentaires dans Cat tout entier, ou tout au moins dans la sous-catégorie des (petits) ensembles ordonnés, dans l'espoir de parvenir (peut-être) à une construction plus directe du localiseur pertinent pour le type d'homotopie simple.

p. 46

[page 88]

[page 89]

Commentary · Later developments [ms. 87]

The weak minimality theorem settles the finer-localizer hopes

Grothendieck is looking for a homotopy theory finer than weak homotopy equivalence while retaining the elementary local axioms. The subsequent minimality theorem rules out that particular route. The exact result needed here is stronger than minimality among localizers satisfying the relative Theorem A axiom.

Cisinski (2006a, Theorem 6.1.18, pp. 242–243) proves that the weak homotopy equivalences of nerves form the least *weak* fundamental localizer. His Definition 6.1.12 uses the ordinary aspherical-functor axiom, corresponding to this chapter's Loc (3). Thus it applies to Definition 1.1 here, and gives

$$W_\omega = \mathbf{W}_\infty.$$

The earlier strong-localizer theorem alone would not justify this substitution. The weak theorem does. The bracketed correction on manuscript page 87 is consequently valid in the precise axiom system of these pages.

Combining this equality with Theorem 6.1 gives a particularly transparent consequence. If W satisfies Loc (5) and D_{W_ω}, then

$$\mathbf{W}_\infty = W_\omega \subset W \subset \mathbf{W}_\infty,$$

so $W = \mathbf{W}_\infty$. There is no additional size or countable-colimit assumption in this deduction. With the completed dichotomy in the preceding block, D_{W_ω} alone allows exactly the two possibilities $W = \mathrm{Fl}(\mathrm{Cat})$ and $W = \mathbf{W}_\infty$. In particular, the theory sought here cannot retain more information than ordinary homotopy types by choosing a smaller fundamental localizer.

The proposed $\widetilde{\mathbf{W}}_\infty$ requires a further reading decision. With Loc (6) understood as the intended direct condition Loc (6a), $\mathbf{W}_\infty$ satisfies the defining list, and the same sandwich makes the intersection equal to $\mathbf{W}_\infty$. Literally, however, Section 3 defines Loc (6) to include the reverse condition (6b). No fundamental localizer contained in $\mathbf{W}_\infty$ can satisfy that full list: weak minimality would make it $\mathbf{W}_\infty$ itself, which fails (6b). Equivalently, Loc (5) together with Loc (7) forces $W = \mathbf{W}_\infty$, contradicting reverse excision. Thus the literal requested nondegenerate family is empty. One cannot call its purported minimum $\mathbf{W}_\infty$ without making the direct-excision qualification explicit. This is the same distinction required in the parenthesis of Theorem 5.4.

41. Canulé (?), *cf.* commentaire page 92.

42. non, c'est un invariant plus fin …

43. C'est évident même pour W_ω, puisque le type d'homotopie *stricte ne change pas !* - Non, il y a ici confusion entre homotopie topologique et homotopie combinatoire, *cf.* p. 92 …

The theorem does not say that every weak fundamental localizer satisfies relative Loc (3 bis). Minimality is an inclusion statement about the least class; relative locality is an additional property of an arbitrary larger class. Keeping these separate is necessary when reading the disputed recovery argument in 7.7.2.

c) Je termine par un commentaire sur le sens de l'axiome Loc (7 D_{W_ω}), par opposition avec l'axiome plus faible Loc (7 F) qui assure seulement l'existence d'une "structure à fibrations" (W, Fib_W) sur Cat. Je signale aussi en passant que Loc (7 F), tout comme Loc (5) et comme Loc (9), et à la différence de tous les autres axiomes passés en revue jusqu'à présent, n'est *pas* un axiome de stabilité : il affirme, non que certaines flèches (sous des hypothèses convenables) sont dans W, mais l'existence d'une factorisation. Aussi il n'est nullement clair que l'intersection [page 90]
de deux localiseurs fondamentaux satisfaisant à Loc (7 F) y satisfasse.

Loc (7 D_{W_ω}) est exactement ce qu'il faut pour assurer que la factorisation canonique d'une flèche $f : X \longrightarrow Y$ de Cat en $f = pi$, avec $i \in W_\omega$, $p \in \mathrm{Parf}_{W_\omega}$, est aussi une factorisation du type stipulé par l'axiome de factorisation Loc (7 F) : on a (bien sûr) $i \in W$, mais aussi $p \in \mathrm{Fib}_W$ (car D_{W_ω} équivaut à sa forme forte $\mathrm{Parf}_{W_\omega} \subset \mathrm{Fib}_W$). Cela signifie aussi que la factorisation canonique de f peut être utilisée pour "calculer" ses fibres homotopiques, non seulement en les points de Y, mais aussi par rapport à un morphisme de changement de base $Y' \longrightarrow Y$.

En l'absence de cet axiome, admettant seulement Loc (7 F), on sait qu'il existe une [page 91]
théorie des fibres W-homotopiques, mais on n'a a priori aucun moyen pratique pour "calculer" p. 47
lesdites fibres, faute de disposer d'un critère maniable suffisant pour assurer $p \in \mathrm{Fib}_W$. J'ai donc l'impression que l'axiome Loc (7 F) va être d'un maigre usage. (Il est vrai que l'exemple de $\mathbf{W}_0$ devrait me rendre prudent ! Il me faudrait regarder le cas des $\mathbf{W}_n$, s'ils satisfont Loc (7 F) …). À mon sens, l'axiome Loc (7 D_{W_ω}) est l'exact "minimum vital" pour être à l'aise dans le maniement des fibres W-homotopiques. Il est remarquable que ceci implique qu'on doive avoir $W \subset \mathbf{W}_\infty$, et que cela exclut du même coup *toutes* les variantes considérées à ce jour de la notion de type d'homotopie !

Commentary · Examples [ms. 90]

Why ordinary paths fail after truncation

Grothendieck distinguishes a usable prescribed replacement from the bare existence asserted by Loc (7F). A familiar example shows why that distinction survives even when a localized homotopy theory is completely well behaved.

Use the convention that $\mathbf{W}_n$ detects components and homotopy groups through degree n, and choose a connected based space $X = K(G, n+1)$ with $G \neq 0$; for $n = 0$ any nontrivial group is allowed, and for $n \geq 1$ take an abelian group. The based path space $P_x X$ is contractible, so

$$p : P_x X \longrightarrow X$$

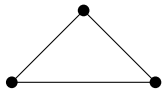
is a $\mathbf{W}_n$-equivalence. Its ordinary fibre is ΩX, whose homotopy group in degree n is G (whose components are G if $n = 0$). Hence $\Omega X \to e$ is not a $\mathbf{W}_n$-equivalence. Pulling p back along the basepoint therefore destroys the equivalence.

The same calculation can be made with categorical models and the categorical path construction used in these pages: its nerves represent the indicated path space and loop space. It disproves universality of this particular $\mathbf{W}_n$-equivalence. It does not show that the localized theory has no homotopy fibre. Indeed, after n-truncation, both $P_x X$ and X become terminal, so the homotopy fibre of the induced map in the localized theory is terminal. The nontrivial ordinary loop object was the wrong replacement for that calculation.

This explains the force of D_{W_ω}. It insists that one path construction, which knows all homotopy groups, continue to calculate fibres after changing the equivalences. Truncation deliberately forgets a homotopy group of the base that becomes a visible homotopy group of the ordinary fibre. The obstruction is therefore structural. For $\mathbf{W}_0$, the explicit factorization at manuscript page 69 gives a useful replacement by copies of connected components; it avoids this obstruction and proves the weaker Loc (7F). For every finite n, the proper localized Thomason models discussed at page 124

likewise prove Loc (7F). Thus the source's caution about the usefulness of F should be read as a concern about calculations, not as a theorem of nonexistence.

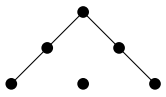
[page 92]



6.5. Finalement, la relation entrevue avec les "types d'homotopie simples" de Whitehead s'évanouit [44] : en effet, ces derniers sont strictement plus fin que les types d'homotopie (*stricts*) ordinaires, et l'invariant de Whitehead n'est *pas* un invariant du type d'homotopie ordinaire. Il est vrai que lorsqu'on considère le squelette simplicial d'un polyèdre triangulé comme objet de Cat, l'homotopie (continue) ordinaire entre deux tels polyèdres s'interprète, dans Cat, non pas (me semble-t-il) par l'existence d'un homotopisme entre les objets correspondants de Cat, mais par leur isomorphie dans $\mathrm{Hot}_{\mathbf{W}_\infty} \overset{\text{déf}}{=} \mathrm{Cat}(\mathbf{W}_\infty)^{-1}$. Mais le procédé d'approximations simpliciales de Brouwer montre que si les polyèdres X et Y sont homotopes, alors il existe des subdivisions simpliciales X' et Y' de X et de Y qui sont "combinatoirement homotopes" (dans un sens convenable). Donc je présume que les maquettes simpliciales de X' et de Y' sont alors homotopes dans Cat. Il s'ensuivrait que X et Y, j'entends leurs maquettes, sont [page 93] bien homotopes dans Cat, s'il est vrai qu'une subdivision simpliciale (il suffirait la subdivision barycentrique, en itérant …) X' de X a une maquette dans Cat qui lui est homotope. La question soulevée ici me paraît intéressante, il faut visiblement en trouver la réponse. Elle se pose déjà pour tout ensemble ordonnée I, qu'on va supposer fini pour simplifier, en prenant l'ensemble (ordonné par inclusion) $I' = \mathrm{sd}(I)$ des parties totalement ordonnées de I. On sait que les réalisations topologiques de I et de $\mathrm{sd}(I)$ sont canoniquement isomorphes, mais I et $\mathrm{sd}(I)$ sont-ils homotopes dans Cat ? On a bien une application croissante canonique

$$f : \mathrm{sd}(I) \longrightarrow I,$$

qui associe à toute partie totalement ordonnée de I son plus grand élément. Mais existe-t-il une application croissante en sens inverse, qui soit un homotopisme inverse du précédent à homotopie près ? Je viens de vérifier dans le cas



manque [page 94]

du bord du 2-simplexe [page 95]

ou

,

subdivision barycentrique p. 48

ou

(hexagone), que pour toute application croissante $g : I \longrightarrow \mathrm{sd}(I)$, sa réalisation topologique est homotope à une application constante, donc g ne peut être un homotopisme dans Cat (car cela impliquerait que sa réalisation topologique est un homotopisme).

Ceci montre donc que la notion d'homotopisme dans Cat est *strictement plus fine* que celle pour les réalisations topologiques, ce qui redonne à nouveau substance à l'espoir que l'invariant de Whitehead pourrait se définir comme invariant d'homotopie sur Cat, ou du moins sur une sous-catégorie pleine convenable, telle celle des ensembles ordonnés (éventuellement restreints à être finis), ou des maquettes simpliciales. Et même, que l'ensemble des Wh-types d'homotopie (types d'homotopie simples) peut se plonger canoniquement dans un Hot_W [page 96] convenable, où W serait un localiseur fondamental strictement plus fin que $\mathbf{W}_\infty$, p.ex. (qui sait ?) $\tilde{\mathbf{W}}_\infty$. Le premier travail qu'on aurait envie de faire, c'est de construire un tel W *ad hoc*, pour que l'invariant de Whitehead puisse s'écrire comme un foncteur sur $\mathrm{Hot}_{\bullet W}$. Pour

44. Mais peut-être quand même pas - la question reste ouverte.

commencer, il faudrait déjà s'assurer que cet invariant peut être vu comme un invariant du type d'homotopie, *i.e.* qu'il s'interprète comme un foncteur sur $\mathrm{Hot}_\bullet\mathrm{Cat} \simeq \mathrm{Cat}(\underbrace{\text{homotop}}_{\substack{\text{ensemble des}\\ \text{homotopismes}}})^{-1}$.

Ce travail suggérera peut-être aussi la définition des "invariants de Whitehead supérieurs" (impliquant les π_i, non seulement le π_1), lesquels pourraient peut-être servir (avec celui de dimension 1) à décrire le localiseur hypothétique W ("de Whitehead").

Commentary · Development (commentators') [ms. 95]

A sharp degree bound for the polygon examples

Grothendieck's six-point example is decisive because subdivision doubles the number of edges without giving a categorical homotopy inverse. We can make its obstruction quantitative, and thereby see that the phenomenon persists through every iterated subdivision.

For $m \geq 3$, let C_m be the height-one poset with minimal elements v_i and maximal elements e_i, indexed by $i \in \mathbf{Z}/m$, and with the only strict relations

$$v_i < e_i, \qquad v_{i+1} < e_i.$$

It is the face poset of a polygonal circle. Its order complex is a circle with $2m$ edges. A choice of the cyclic ordering fixes the sign of the degree of a map of realizations.

Degree spectrum for crowns. [ours] For $m, n \geq 3$, the degrees of the maps $|NC_m| \to |NC_n|$ induced by monotone maps $C_m \to C_n$ are exactly the integers d satisfying $|d|n \leq m$.

Proof. A monotone map induces a simplicial map of the order complexes. Each of the $2m$ domain edges maps either to a single target edge or to a vertex. Give every target edge length one, and lift the image of the oriented domain circle to the universal covering line of the target circle, starting at a chosen lift of its initial vertex. Each traversed domain edge changes the lifted coordinate by at most one in absolute value. After all $2m$ edges the displacement is $2nd$, where d is the degree. Therefore $2n|d| \leq 2m$.

For the converse, choose a closed walk of m steps in the set of polygon vertices of the target. Its first $n|d|$ steps go around the polygon $|d|$ times, in the sign prescribed by d; all remaining steps are stationary at the initial vertex. Send the ith minimal element of C_m to the ith vertex of this walk. If a step traverses a target edge, send the corresponding maximal element to that edge. If the step is stationary, send the maximal element to the same target vertex. In either case the images of both adjacent minimal elements are less than or equal to the image of the maximal element. This defines a monotone map. Its realized walk has degree d, as required. □

The nonempty-chain poset $\mathrm{sd}(C_m)$ is isomorphic to C_{2m}: its minimal elements are the singleton chains, and its maximal elements are the two-element chains, arranged in the subdivided cycle. Induction gives $\mathrm{sd}^r(C_m) \cong C_{2^r m}$. For every $r \geq 1$ the proposition forces every monotone map

$$C_m \longrightarrow \mathrm{sd}^r(C_m)$$

to have degree zero. Maps between circles of degree zero are null-homotopic, whereas the maximum map in the other direction has degree one. No categorical homotopy inverse can exist. Taking $m = 3$ and $r = 1$ proves the claim on manuscript page 95 in full.

There is also a direct categorical rigidity check. If an endomap $h : C_m \to C_m$ satisfies $h \geq \mathrm{id}$, it fixes the maximal elements. The image of v_i must then lie below both e_{i-1} and e_i and above v_i, forcing $h(v_i) = v_i$. Thus $h = \mathrm{id}$. Dually $h \leq \mathrm{id}$ also forces equality. Any finite zigzag of natural transformations starting at the identity is therefore constant. A categorical homotopy equivalence between two crowns would have strictly inverse composites and hence be an isomorphism; crowns of different sizes cannot be categorically homotopy equivalent.

The general distinction between finite-space homotopy and simple homotopy is established in the literature discussed next. We did not find this explicit degree-spectrum calculation in the consulted finite-space papers. We include it as an elementary development of Grothendieck's example, without a priority claim.

Commentary · Later developments [ms. 96]

The finite-poset version of simple homotopy

Grothendieck's attempted localizer is ruled out by minimality, but his suggestion to work directly with finite ordered sets has a substantial later realization. These are two different claims, and the failure of the first does not diminish the second.

For a finite T_0 space, regarded as a finite poset, Barmak and Minian define elementary simplifications by deleting a weak point: a point whose strict lower set or strict upper set is contractible. Their Theorem 3.10 identifies the resulting simple-equivalence classes with simple homotopy types of finite simplicial complexes, through the order-complex and face-poset constructions. Their Theorem 4.13 gives the corresponding statement for maps (Barmak and Minian, 2008). This is a precise version of the finite combinatorial program suggested here. It is not a fundamental localizer on all of Cat finer than $\mathbf{W}_\infty$.

The crown calculation explains why strict categorical homotopy equivalence is too fine for the desired comparison. A polygon and its subdivision have the same simple homotopy type, while their face posets have different strict categorical homotopy types. The elementary finite-space operations therefore must allow more than deletion of a point with a genuine order-theoretic deformation retraction. Conversely, passing all the way to weak homotopy equivalence forgets the simple structure. The successful theory sits between these two equivalence relations on finite models.

The invariant mentioned on manuscript page 88 also needs its classical input. For a homotopy equivalence $f : K \to L$ of connected finite CW complexes, Whitehead torsion is an element

$$\tau(f) \in \mathrm{Wh}(\pi_1 L) = K_1(\mathbf{Z}[\pi_1 L])/\langle \pm g \mid g \in \pi_1 L \rangle.$$

It vanishes exactly when the equivalence is simple, with the usual finite CW structures. It is attached to an equivalence and its simple structures, rather than being a canonical element attached to an unmarked homotopy type (Milnor, 1966, Section 7). Thus a proposed functorial invariant must specify its objects and morphisms before one asks whether it factors through a localization. The manuscript's suggestion of higher invariants does not specify enough data to identify it with a particular later torsion theory.

The page marked 94 is explicitly missing in the edition. The surrounding argument still supplies the finite counterexample and its purpose; we do not reconstruct an absent manuscript page from those conclusions.

7 Commentaires sur les axiomes

7.1. La principale raison d'être d'un localiseur fondamental W, c'est de définir une théorie d'homotopie', et plus précisément un prédérivateur HOT_W, dont on espère que ce sera même un dérivateur, ou qu'il satisfasse du moins à certains des axiomes des dérivateurs. Les axiomes Loc (1) à Loc (9) sont en majeure partie orientés vers cet objectif, à cela près que Loc (1, 2, 3) constitue un "minimum vital" absolu, pour pouvoir commencer à travailler avec W. Les principales questions qui se posent me paraissent les suivantes :

1) Quand Cat munie de (W, Cof_W), resp. de (W, Fib_W), est-elle une catégorie à cofibrations resp. à fibrations, de façon que les résultats de K. S. Brown soient applicables ?
2) Sous quelles conditions, sur W et sur f, $f_!$ et f_* existent-ils ? Et quand a-t-on, de plus, exactitude des carrés cocartésiens resp. cartésiens ?
3) Plus généralement, en termes des axiomes imposés à W, quelles sont les axiomes Der (…) que sont vérifiés pour le prédérivateur HOT_W ? (Ce qui pourrait aussi dépendre du choix du domaine Diag $\subset$ Cat. Le prédérivateur est défini a priori sur Cat tout entier). En particulier, [page 98]
4) quand HOT_W est-il bel et bien un dérivateur sur Cat tout entier, *i.e.* quand satisfait-il à tous les axiomes ? p. 49

Une question qui me paraît moins importante (notamment que 1°) est la suivante :

1 bis) Quand W s'insère-t-il dans un triple de Quillen clos (W, C, F) (propre de préférence).

Je vais passer en revue ces questions une à une.

7.2. On a vu (mais sans que j'aie fait une vérification soigneuse pour la réciproque) que (W, Cof_W) définit une structure à cofibrations si l'axiome *Loc (6 a)* est satisfait, et que cette condition est aussi nécessaire si Loc (3 bis) est satisfait [45].

Alors les immersions ouvertes de Dwyer (ou au choix les immersions fermées de Dwyer) [page 99] sont dans Cof_W, et la construction standard du mapping-cone définit, pour toute flèche f dans Cat, une factorisation *fonctorielle*

$$f = pi \quad \begin{array}{l} i \text{ immersion ouverte de Dwyer (donc dans } \mathrm{Cof}_W), \\ p \in W. \end{array}$$

Cela, plus la construction du foncteur $f_!$, et en particulier des W-sommes amalgamées $\int X_0 \begin{array}{c} \nearrow X_1 \\ \searrow X_2 \end{array}$, données dans VI (théorie de HOT_W) et XII, nous donne une maîtrise parfaite (il me semble) sur la "structure homotopique gauche" définie par W, sous le seul axiome Loc (6 a) (Axiome du cube, forme directe). Je rappelle que les foncteurs $f_!$ sont construits dans VI sous la seule hypothèse *Loc (3 bis)* (f flèche quelconque de Cat), mais sauf erreur, la construction et l'interprétation W-homotopique de $\int X_0 \begin{array}{c} \nearrow X_1 \\ \searrow X_2 \end{array}$ donnée dans XII ne [page 100] dépend pas même de cette hypothèse [46] - mais je ne peux le garantir. Il me semble que XII (et notamment le long §5 sur les sommes amalgamées) est écrit sous l'hypothèse que W (1, 2, 3), *i.e.* Loc (1, 2, 3bis), sont satisfaits.

7.3. C'est une chose assez extraordinaire que les foncteurs $f_!$ pour HOT_W existent, sous la seule hypothèse *Loc (3 bis)* (axiome de localisation, forme forte) - et ils se "calculent" d'une façon féeriquement simple ! Je suis à peu près sûr que sous cette seule hypothèse, *l'axiome d'exactitude pour les carrés cocartésiens* n'est *pas* satisfait [47]. Je ne vois aucun moyen de le vérifier, sauf via la théorie de Brown, sous l'hypothèse *Loc (6 a)* (*cf.* 7.2).

Mais sous la seule condition Loc (3 bis) le calcul standard des fibres d'un $f_!(\xi)$ est valable, p. 50 en d'autre termes le prédérivateur HOT_W satisfait Der (4*, 5*) - et de plus Der (6*) (exactitude [page 101] "à gauche") si W satisfait Loc (6 a).

7.4. Venons-en à la question si Cat muni de (W, Fib_W) est une catégorie à fibrations. C'est l'axiome *Loc (7 F),* mais je ne connais guère de moyen de le vérifier (en dehors du cas très, très particulier $W = \mathbf{W}_0$) que moyennant tout au moins l'axiome *Loc (7 D_{W_ω}),* ou l'une ou l'autre des variantes plus fortes de Loc (7). De Loc (7 D_{W_ω}) il a été abondamment question précédemment, *cf.* notamment 6.4 (pages 89-91). En mon sens, cet axiome assure une maîtrise comparable sur la structure W-homotopique droite (fibres W-homotopiques, suites exactes de cosuspension) que Loc (6 a) pour la structure gauche. En particulier, on a la factorisation [page 102] *fonctorielle* de toute flèche f de Cat en

$$f = pi, \qquad i \in W_\omega \subset W,\ p \in \mathrm{Parf}_{W_\omega} \subset \mathrm{Fib}_W.$$

45. Vérifier quand même si Loc (3 bis) n'est pas déjà utilisé dans la partie directe ! **O.K.**
46. *cf.* XII, page 264
47. Il faudrait un exemple !

Mais *l'axiome Loc (7 D_{W_ω}) me paraît de nature considérablement plus forte que Loc (6 a),* lequel (si je ne m'abuse) est vérifié pour tous les localiseurs qui ont été envisagés jusqu'à présent. (Mais j'avoue n'avoir pas regardé le cas des $\mathbf{W}_n$, $n \in \mathbf{N}$, sauf $\mathbf{W}_0$.) Par contre, l'axiome Loc (7 D_{W_ω}) implique $W \subset \mathbf{W}_\infty$ (théorème 6.1), relation vraiment draconienne (*cf.* commentaire 6.4 a).

Par ailleurs, le seul axiome Loc (7 D_{W_ω}), pour autant que je sache, n'implique pas l'existence de f_* pour *toute* flèche dans Cat, mais seulement pour des flèches de la forme [page 103]
$f \times \mathrm{id}_X : S \times X \longrightarrow T \times X$, où $f : S \longrightarrow T$ est un morphisme entre ensembles ordonnés finis. Ou plus généralement, entre ensembles ordonnés S, T tels que S° soit artinien, *i.e.* S noethérien, et que $\mathrm{Esp}(S^\circ)$ soit noethérien (cette dernière hypothèse étant inutile sous l'axiome Loc (8) des limites, *cf.* XVII, th. 3.1, p. 50). Donc ce n'est pas le résultat rêvé.

7.5. Le seul cas que je connaisse où f_* existe pour *toute* flèche dans Cat, est le cas où W satisfait à

(∗) *Loc (6 a, 8, 9)* [48] [49],

c'est à dire l'axiome des W-cofibrations faibles, déjà abondamment mentionné et enfin ceux des limites et d'accessibilité, *i.e.* W est L_1-accessible dans $\underline{\mathrm{Fl}}(\mathrm{Cat})$. Le résultat-clef pertinent est donné dans XV 8.4 (p. 105-107), qu'il faut joindre à XV 7.4 (p. 98-99) pour en faire bon usage, et en déduire le théorème 10.1 (XV, p. 134-135). Mieux que l'existence des f_*, [page 104]
l'ensemble d'axiomes étonnamment faible que je viens d'expliciter suffit à assurer que HOT_W est un *dérivateur* sur Cat tout entier, en plein sens du terme, *i.e.* qu'il satisfait à Der (1, 2, 3, 4, 5, 6, 4*, 5*, 6*). Ceci est obtenu en remplaçant (grâce à XV 8.4) Cat par $A^\wedge$, où A est p. 51
une catégorie-test convenable, W par $W_A \subset \mathrm{Fl}\, A^\wedge$, et en prouvant que W_A s'insère dans un triple de Quillen clos (W, C, F), avec $C = \mathrm{Mono}(A^\wedge)$, ce qui détermine F comme $(C \cap W_A)_*$. On applique alors XV 7.4 à cette situation (résultats résumés dans XIX, th. 2.3 (p. 19), 2.6 (p. 25), 2.9 (p. 28). On retrouve l'existence des $f_!$ (avec un mode de calcul bien différent de celui dans Cat !), et en plus on trouve l'existence de f_* (plus l'exactitude dans cor. [?] 5 des [page 105]
carrés W-cartésiens) - ce qui pour moi, pendant un bon moment, était *le* gros problème pour la théorie de HOT_W !).

Commentary · Exposition [ms. 104]

A presentation supplies operations at every diagram shape

The shift from Cat to a presheaf category is a change of computational model. Its purpose is to make the homotopy theory of diagrams available uniformly. A homotopy category alone contains too little information for this task: an object of $\mathrm{Ho}(\mathcal{M})^S$ is a diagram whose relations commute only after localization, whereas an object of $\mathrm{Ho}(\mathcal{M}^S)$ retains a coherent realization of those relations. A derivator keeps the latter categories, their restrictions, and their homotopy Kan extensions. This distinction is why the existence of f_* for every shape is stronger than the ability to write down a fibre for a single arrow.

Modern statements require some translation before they can be applied here. In Groth (2013, Definition 1.5), Der (1) concerns arbitrary small coproducts of shapes, Der (2) says that evaluations jointly detect isomorphisms, Der (3) gives both Kan adjoints, and Der (4) calculates them pointwise. Grothendieck's original numbering separates the existence, calculation, and exactness assertions into Der (4)–(6) and their starred partners; his Der (3) is a contractibility condition. Moreover, the convention here uses presheaves $\mathcal{M}(S) = \mathcal{M}^{S^{\mathrm{op}}}$. Passing to opposite shapes translates this convention into the covariant diagrams used by many modern authors. Numbers and the words "left" and "right" cannot safely be transferred without that translation.

For a combinatorial model category the modern realization theorem is Groth (2013, Proposition 1.30). The proof uses diagram model structures to derive restriction and ordinary Kan extension. It supplies the uniform operations sought in these pages. A complementary comparison is Lenz

49. Vérifier s'il ne faut pas aussi la condition Loc (3 bis) en plus de Loc (6 a, 8, 9). Vérification faite, c'est O.K. (sans Loc (3 bis)).

50. **N.B.** Après nouvelle réflexion, il apparaît qu'il suffit même Loc (6′ a, 8, 9).

(2018, Theorem 3.33): the homotopy prederivator of a cofibration category agrees with that of its quasicategory of frames. Its Corollary 4.1 then obtains the corresponding derivators from complete or cocomplete quasicategories. These are precise realization and comparison results. They do not say that every prederivator is representable by a model category, or that the original class W can automatically be recovered from any equivalent presentation. The latter is a separate recognition argument, undertaken on manuscript pages 111–118.

Je trouve époustouflant qu'on parvienne à un résultat aussi fort avec des axiomes aussi ridiculement faibles. Plus particulièrement, qu'on ait toutes les propriétés désirables de la structure homotopique droite, sans avoir à faire sur W aucune hypothèse du type W-fibration ! Ces axiomes n'impliquent *pas* l'axiome Loc (7) (équivalent à Loc (7 D_{W_ω}) en présence de Loc (8)), comme on a vu sur l'exemple de $\mathbf{W}_0$. Impliquent-ils tout au moins Loc (7 F), *i.e.* l'existence d'assez de W-fibrations ? Je ne hasarderais aucune conjecture à ce sujet ! Mais il faut bien se dire qu'en l'absence de Loc (7) (et même en admettant Loc (7 F)), tout en [page 106] sachant que la structure homotopique droite associée à W est parfaite à tous égards, on n'a a priori aucune maîtrise sur celle-ci, notamment pour le calcul des fibres W-homotopiques et la construction des carrés W-cartésiens. Même en ramenant toutes ces constructions à $A^\wedge$ (prenant, si on y tient, $A = \mathbf{\Delta}$, *i.e.* se ramenant au contexte semisimplicial), quoi qu'on sache qu'il y a une factorisation *fonctorielle* $f = pi$ avec $i \in \mathrm{TC} \subset W_A$, $p \in F \subset \mathrm{Fib}_{W_A}$, je ne vois aucune façon concrète de l'expliciter. À moins que la considération des chemins infinis, qui (en l'absence de Loc (7)) s'avère inopérante dans Cat sauve la mise dans $\mathbf{\Delta}^\wedge$? ?

Question qui devrait être facile à élucider, mais sur laquelle je ne veux pas m'attarder à [page 107] présent.

Notons en passant que le résultat de saturation forte de Quillen, pour les triples de Quillen clos, montre que l'ensemble d'axiomes $(*)$ implique l'axiome Loc (1 ter), *i.e.* que W est *fortement saturé.*

Notons aussi que contrairement à ce qui a lieu pour les $f_!$, je ne sais prouver l'existence de f_*, et notamment des suites de cosuspension, que sous des conditions (soit Loc (7 D_{W_ω}), soit Loc (6a, 8, 9)) qui assurent déjà que les carrés W-cartésiens sont exacts, et par suite les suites de cosuspension exactes.

Je pense que dans les pages précédentes, j'ai dit tout ce que je sais dire de pertinent, concernant les questions 1, 2, 4 soulevées dans 7.1. Ces réponses me paraissent satisfaisantes [page 108] - plus satisfaisantes que je ne l'aurais osé espérer pendant les premiers deux mois de mes cogitations ! Il reste les questions 3 et 1 bis, que je vais à présent examiner.

7.6. Sur les différents axiomes des dérivateurs : sous quelles conditions sur W un de ces p. 52 axiomes est-il satisfait pour HOT_W [51] ? Pour ce qui est des axiomes Der (4, 5, 6, 4^*, 5^*, 6^*), je crois avoir dit tout ce que je sais en dire, et avoir des critères ce validité parfaitement maniables, dans les pages précédentes. Résumons pourtant :

structure à cofibrations	:	Loc (6) (+ Loc (3 bis) ?)
structure à fibrations	:	Loc (7 D_{W_ω})
Der (4^*, 5^*)	:	Loc (3 bis)
Der (4^*, 5^*, 6^*)	:	Loc (3 bis, 6a) ou Loc ($6'$ a, 8, 9)
Der (4, 5, 6) (sur Cat) (et tout le reste !)	:	Loc ($6'$ a, 8, 9)
Der (4, 5, 6) (sur Diag = ens. ordonnés finis)	:	Loc (7 D_{W_ω}) (ou seulement Loc (7 F)).

Il reste les axiomes Der (1) (décomposition), Der (2) (localisation), Der (3) (objet unité), que je vais passer à présent en revue. On vérifie de façon quasi-tautologique que l'axiome Der [page 109]

51. Pour les axiomes Der (1) à Der (5^*), *cf.* I, p. 67-68. Les axiomes Der (6, 6^*) sont les axiomes d'exactitude, dont la nécessité m'est apparue seulement ultérieurement.

1 est satisfait sans condition sur W (pas même Loc (2, 3) !) - en fait, il est satisfait pour tout prédérivateur $\mathbf{D}_{(\mathcal{M},W)}$ défini par une catégorie de modèles.

L'axiome de localisation Der (2) est par contre de nature délicate. Il est valable, plus généralement, pour une catégorie de modèles $(\mathcal{M}, W)$ (définissant un prédérivateur $\mathbf{D} = \mathbf{D}_{(\mathcal{M},W)}$) et un objet S de Cat, lorsque $(\mathcal{M}(S), W(S))$ est associé à une structure à fibrations ou à cofibrations, ce qui par K. S. Brown implique que toute flèche de $\mathrm{HO}_W(S) = \mathcal{M}(S)W(S)^{-1}$ se "réalise" par une flèche de $\mathcal{M}(S)$ - et alors le résultat est évident. La condition que je viens de dire est satisfaite lorsque $(\mathcal{M}, W)$ lui-même est associé à une structure de cofibrations ou de fibrations, et si de plus on suppose que l'on est dans l'un de deux cas suivants : [page 110]

a) S est un ensemble ordonné fini (ce qui nous amène à nous restreindre, à défaut de mieux, à Diag = sous-catégorie de Cat formée des ensembles ordonnés finis).

b) La factorisation stipulée dans l'axiome de factorisation $f = pi$ (avec $i \in \mathrm{Cof}$, $p \in W$ (cas de cofibrations) ou $i \in W$, $p \in \mathrm{Fib}$ (cas de fibrations)) peut être choisie fonctorielle en f.

Or, dans le cas de Cat, dans les cas où on sait prouver que W est associé à une structure à cofibrations (axiome *Loc (6 a)*) où à fibrations (axiome *Loc (7 D_{W_ω})*), on trouve bel et bien une factorisation fonctorielle. Donc chacun de ces axiomes implique Der (2).

Commentary · Examples [ms. 109]

Finite coproducts of shapes and the length of a zigzag

The assertion called quasi-tautological is correct in its original scope. Chapter I, manuscript page 67, footnote 3, defines Der (1) for a *finite* sum of shapes. Let $(\mathcal{C}, U)$ and $(\mathcal{E}, V)$ be relative categories, with identities among their weak equivalences. There is a canonical equivalence

$$(\mathcal{C} \times \mathcal{E})[(U \times V)^{-1}] \simeq \mathcal{C}[U^{-1}] \times \mathcal{E}[V^{-1}].$$

Here is the mechanism. Every ordinary arrow (a, b) factors as $(a, 1)$ followed by $(1, b)$. A formal inverse of (u, v) decomposes in the same fashion, using the inverses of $(u, 1)$ and $(1, v)$. Horizontal and vertical arrows commute in every rectangle. The same commutation holds when one or both arrows are inverted, by multiplying the commutative square by the relevant inverses. Thus a word in the localized product can be rearranged into a word in the first coordinate followed by a word in the second. Conversely, two localized coordinate words define such a composite; the defining composition, identity, and inverse relations in either coordinate remain valid in the product localization. These operations are mutually inverse on hom-sets and preserve composition. This proves the equivalence, including its faithfulness.

Induction gives finite products. Since

$$\mathcal{M}^{(S \amalg T)^{\mathrm{op}}} \cong \mathcal{M}^{S^{\mathrm{op}}} \times \mathcal{M}^{T^{\mathrm{op}}},$$

and objectwise weak equivalences correspond under this isomorphism, localizing proves finite Der (1). The empty shape gives the terminal category as well. No localizer axiom is needed.

An explicit example explains why the same reasoning must not be extended to infinitely many factors without hypotheses. For $n \geq 1$, let J_n have objects $0, \ldots, n$, with precisely the nonidentity arrows between adjacent vertices directed from the even vertex to the odd vertex. Thus every nonidentity arrow has length one, and no two nonidentity arrows compose. Let $\mathcal{M} = \coprod_{n \geq 1} J_n$ and declare every arrow a weak equivalence. In $\mathcal{M}^{\mathbb{N}}$ take objects x and y whose nth coordinates are the vertices 0 and n in J_n. Each coordinate has a finite zigzag joining these vertices, so their images are isomorphic in $\prod_n \mathrm{Ho}(\mathcal{M})$.

There is nevertheless no arrow from x to y in $\mathrm{Ho}(\mathcal{M}^{\mathbb{N}})$. Such an arrow would be represented by a finite word of, say, k ordinary arrows and formal inverses. In coordinate n, each letter changes the vertex by at most one. Hence the word can travel at most k edges, whereas the endpoints in J_n are n edges apart. Taking $n > k$ gives a contradiction. The comparison to the infinite product is therefore not full. The obstruction is the absence of a uniform finite zigzag, not a defect in Grothendieck's finite axiom. Modern arbitrary-coproduct Der (1) requires the additional homotopical structure supplied by the realization theorems. A related bounded-length obstruction already occurs in Thomason (1980, p. 307), where the fundamental group of an infinite product of elementary categorical circles gives bounded integer families rather than all integer families.

Reste l'axiome de contractibilité : si S dans Cat est contractile, est-il HOT_W-asphérique, *i.e.* le foncteur [page 111]

$$\mathrm{HOT}_W(e) = \mathrm{Hot}_W \longrightarrow \mathrm{HOT}_W(S)$$

est-il pleinement fidèle ? Quand on dispose de la théorie de $f_!$ "version Cat" (donc sous le seul axiome *Loc (3 bis)*), on trouve ceci (noté dans VI, p. 202) [52] : p. 53

> Soit $f : S \longrightarrow T$ une flèche dans Cat. Pour que ce soit une HOT_W-équivalence, *i.e.* pour que $f^* : \mathrm{HOT}_W(T) \longrightarrow \mathrm{HOT}_W(S)$ induise un foncteur *pleinement fidèle* sur la sous-catégorie des objets constants de $\mathrm{HOT}_W(T)$, il faut et il suffit que $\mathrm{hot}_W(f) : \mathrm{hot}_W(S) \longrightarrow \mathrm{hot}_W(T)$ soit un isomorphisme. Donc il *suffit* que $f \in W$, et cette condition est aussi nécessaire si W est fortement saturé (axiome Loc (1 ter)).

Par acquit de conscience, j'explicite ici la démonstration. L'existence des foncteurs $f_!$, en particulier des objets d'homologie $H_\bullet^{\mathrm{HOT}_W}(S, \xi)$ (où simplement $H_\bullet^W(S, \xi)$) pour $\xi \in \mathrm{HOT}_W(e) = \mathrm{Hot}_W$, permet d'interpréter homologiquement la condition de HOT_W-équivalence, comme signifiant que pour tout $\xi = \mathrm{hot}_W(X)$ dans Hot_W, la flèche canonique dans Hot_W [page 112]

$$(*) \qquad H_\bullet^W(S, \xi) \longrightarrow H_\bullet^W(T, \xi)$$

est un isomorphisme. Or le calcul des $f_!$ (dans le cas de $p : S \longrightarrow e$ et de $T \longrightarrow e$) nous montre que les deux membres de $(*)$ ne sont autres (à isomorphisme près) que $\mathrm{hot}_W(X \times S)$ et $\mathrm{hot}_W(X \times T)$, la flèche étant induite par

$$(*) \qquad \mathrm{id}_X \times f : X \times S \longrightarrow X \times T.$$

Donc la condition envisagée signifie que cette flèche est un isomorphisme dans Hot_W pour tout X dans Cat. Prenant $X = e$, on voit que cela implique que $\mathrm{hot}_W(f)$ est un isomorphisme, et cela suffit, vu que le foncteur $\mathrm{hot}_W : \mathrm{Cat} \longrightarrow \mathrm{Hot}_W$ commute aux produits finis (il suffit de Loc (1, 2, 3)) `[plutôt Loc (1, 2, 3 bis)]` et que la flèche $(*)$ dans Hot_W s'identifie à [page 113]

$$\mathrm{id}_{\mathrm{hot}_W(X)} \times \mathrm{hot}_W(f)\,.$$

Cela montre donc que si S est un objet W-asphérique, *i.e.* tel que $S \longrightarrow e$ soit dans W (et a fortiori, si S est contractile), alors $S \longrightarrow e$ est HOT_W-asphérique.

Commentary · Exposition [ms. 110]

What it means to realize a localized arrow

The word "realize" in the proof of Der (2) permits replacement of the source and target by weakly equivalent objects. It does not say that the localization functor is full on the original, fixed pair of objects. Even a formal inverse of a weak equivalence need not be represented by an ordinary arrow in the reverse direction between those same objects.

In a model category, the precise calculation uses a cofibrant replacement $QX \to X$ and a fibrant replacement $Y \to RY$. Every arrow $X \to Y$ in the homotopy category is represented by an ordinary map $QX \to RY$. Applied in a suitable diagram model category, this gives a map of replacement diagrams. If every component of the original localized arrow is an isomorphism, every component of the representing map is an isomorphism in the base homotopy category. Strong saturation of model weak equivalences makes those components weak equivalences. The representing map is therefore an objectwise weak equivalence, and becomes an isomorphism in the localized diagram category. The weak-equivalence replacements show that the original arrow is also invertible. This proves the pointwise conservativity required by Der (2).

Grothendieck invokes the analogous Brown calculation for a cofibration or fibration category. In the finite-poset case, one constructs the necessary replacement diagram inductively, placing an object after its already treated predecessors and factoring the resulting latching map, or dually using

52. moyennant Loc (3 bis).

matching maps. A functorial factorization can instead be applied directly to natural transformations; functoriality makes the chosen middle objects into a diagram. This is the specific advantage of the functorial constructions recalled on pages 99 and 102.

For all small shapes, a modern cofibration-category theorem carries more structure than a finite Brown theorem. Lenz (2018, Definition 1.5 and Warning 1.7) explicitly includes coproduct and sequential-colimit conditions in the ABC framework. The distinction matters: a proof that works by finite induction cannot simply be reindexed by an arbitrary small category. Conversely, a theorem proved for ABC cofibration categories should not be used to certify an unqualified claim about every finite Brown category. Lenz's Example 1.49 also exhibits a general relative category whose homotopy prederivator fails even weak strength. A class of denominators alone supplies a prederivator; the homotopical factorization and gluing conditions do substantive work.

Pour résumer, on trouve le tableau

$$\begin{cases} \text{Der (1)} & : & \text{sans hypothèse sur } W \\ \text{Der (2)} & : & \text{Loc (6 a) } ou \text{ Loc (7 D}_{W_\omega}\text{)} \\ \text{Der (3)} & : & \text{Loc (3 bis) } ou \text{ Loc (6}' \text{ a, 8, 9)} \ ^{53}. \end{cases}$$

7.7. Il faut seulement justifier encore que Loc (6′ a, 8, 9) implique Der (3). Mais alors, on l'a vu, HOT_W peut être défini par un triple de Quillen très spécial. Mais même pour un triple de Quillen spécial sans plus $(\mathcal{M}, W)$, le prédérivateur **D** qu'il définit satisfait (en plus de Der (4*, 5*, 6*)) aux conditions Der (1) (trivialement), Der (2)

(*cf.* p. 110, cas b)) et *de plus* Der (3). (Donc dans le cas d'un triple de Quillen *très* spécial, le prédérivateur obtenu est bel et bien un dérivateur.) Je vais expliciter ici la démonstration. p. 54 [page 114]

Commentary · Exposition [ms. 113]

Recovering the equivalences from constant diagrams

The recognition calculation is a particularly useful part of this survey. It also records exactly where the later circular argument will enter. Let $\mathbb{D} = \mathrm{HOT}_W$, let $p_S : S \to e$, and write $c_S = p_S^*$. Assuming the left Kan extensions constructed under Loc (3 bis), set

$$H(S, \xi) = p_{S!} c_S \xi.$$

Adjunction identifies

$$\mathrm{Hom}_{\mathbb{D}(S)}(c_S\xi, c_S\eta) \cong \mathrm{Hom}_{\mathbb{D}(e)}(H(S,\xi), \eta).$$

For $f : S \to T$, restriction on constant objects corresponds under this identification to precomposition with the canonical map

$$H(S, \xi) \longrightarrow H(T, \xi).$$

Consequently restriction is fully faithful on constants precisely when these maps are isomorphisms for every ξ. For the nontrivial direction, bijectivity of the displayed hom-set maps for every η implies the assertion by the ordinary Yoneda criterion for an isomorphism. This is the exact reason that a condition on all morphisms between constants can be tested by homology objects.

Write $q : \mathrm{Cat} \to \mathrm{Hot}_W$ for localization. Every object ξ of this homotopy category is represented by a category X. The categorical Kan-extension calculation gives

$$H(S, qX) \cong q(X \times S), \qquad H(T, qX) \cong q(X \times T),$$

with the comparison induced by $1_X \times f$. Taking $X = e$ shows that full faithfulness on constants forces $q(f)$ to be an isomorphism. Conversely, the product calculation identifies the comparison with $1_{qX} \times q(f)$, so invertibility of $q(f)$ implies all the required isomorphisms. The argument thus identifies the class of $\mathbb{D}$-equivalences with

$$\{f \mid q(f) \text{ is an isomorphism}\}.$$

53. **N.B.** On verra plus bas que Loc (6 a, 8, 9) implique déjà Loc (3 bis).

It identifies that class with W itself only when W is strongly saturated. This qualification is expressly present on page 111.

There are two different localization facts in this proof. The preceding block used finite products of *categories being localized* to prove finite Der (1). Here one needs the cartesian product operation on Cat to descend to its localization and to agree with the products used in the homology formula. That uses the localizer's stability properties and the preceding Kan-extension theory. Grothendieck's bracketed correction from Loc (1,2,3) to Loc (1,2,3 bis) is therefore retained in the audited reading; a formal finite-product localization lemma cannot remove the hypothesis from the whole recognition argument.

For $T = e$, a W-aspherical S has $q(S) \cong e$, so the comparison is invertible for every X. Thus c_S is fully faithful. This verifies the contractibility axiom in this setting without identifying a contractible diagram shape with an arbitrary diagram category: constant diagrams embed fully faithfully, while nonconstant diagrams can still contain substantial information.

Je vais désigner par $(\mathcal{M}, \Sigma)$ la catégorie de modèles donnée ($\Sigma \subset \mathrm{Fl}\,\mathcal{M}$), par $\mathbf{D} = \mathbf{D}_{\mathcal{M},W}$ le prédérivateur correspondant, et par

$$W = W_D$$

le localiseur dans Cat associé, formé des "$\mathbf{D}$-équivalences". On voit tout de suite que W est fortement saturé (vrai pour tout $W_{\mathbf{D}}$, $\mathbf{D}$ un prédérivateur), *i.e.* satisfait Loc (1 ter), a fortiori Loc (1), d'autre part il satisfait à Loc (3 bis*), comme conséquence du fait que $\mathbf{D}$ satisfait à Loc (4*, 5*). A fortiori il satisfait à Loc (3*), et pour voir que tout X contractile dans Cat est W-asphérique, *i.e.* $X \longrightarrow e$ dans W, on sait (*cf.* §1) qu'il suffit de prouver qu'il en est ainsi si [page 115]
X a un objet initial (axiome Loc (2*) dual de l'axiome Loc (2)). À ce moment, on saura que W est un localiseur fondamental, et de plus il satisfait Loc (3* bis), donc aussi Loc (3 bis) (forme forte de l'axiome de localisation).

Donc *on peut supposer* que si S a un objet initial, alors S est W-asphérique, *i.e.* $S \longrightarrow e$ est dans W, *i.e.* $p^* : \mathbf{D}(e) \longrightarrow \mathbf{D}(S)$ est pleinement fidèle. Il revient au même de dire que la flèche d'adjonction

$$p_! p^* \xi \longrightarrow \xi$$

est un isomorphisme, pour tout ξ dans $\mathbf{D}(e)$. Or le calcul de $p_!(\eta)$ (pour $\eta \in \mathrm{Ob}\,\mathbf{D}(S)$, *i.e.* $\eta \in \mathrm{Ob}\,\mathcal{M}(S)$) se fait ainsi : on choisit une flèche

$$\eta' \xrightarrow{\Sigma_S} \eta$$

avec η' "cofibrant" (pour la structure à cofibrations pertinente sur $\mathcal{M}(S)$), et on pose[54] [page 116]

$$p_!(\mathrm{ho}_{W,S}(\eta)) = \mathrm{ho}_W(p_!(\eta')).$$

Quand $\eta = p^*(\xi)$, la flèche d'adjonction pertinente dans $\mathrm{Ho}_\Sigma = \mathbf{D}(e)$ s'obtient par composition

$$(*) \qquad p_!(\eta') \longrightarrow p_!(p^*(\xi)) \xrightarrow{\text{adj.}} \xi,$$

où ici $p_!$ est encore pris dans le sens ordinaire ($\mathcal{M}(S) \longrightarrow \mathcal{M}(e) = \mathcal{M}$). Or S ayant un objet initial 0, on a

$$\begin{aligned} p_!(\eta') &\simeq \eta'(0) \\ p_!(p^*(\xi)) &\simeq p^*(\xi)(0) \simeq \xi, \end{aligned}$$

et la flèche d'adjonction dans $(*)$ est l'identité, la première flèche est la flèche $\eta'(0) \longrightarrow \eta(0)$ induite par $\eta' \longrightarrow \eta$, elle est dans Σ, donc $(*)$ est dans Σ, donc c'est un isomorphisme dans $\mathrm{Ho}_\Sigma = \mathbf{D}(e)$, q.e.d.

Le même argument marche d'ailleurs si $\mathcal{M}$ est seulement une catégorie à cofibrations ou à p. 55
fibrations, mais en se bornant alors au cas où S est un ensemble ordonné fini. [page 117]

Je vais dégager à part ce qu'on vient d'obtenir :

Commentary · Exposition [ms. 116]

Why the initial object computes this left adjoint

There is no initial-versus-terminal mistake in the displayed calculation. Its direction records the presheaf convention. An object of $\mathcal{M}(S)$ is a functor $S^{\mathrm{op}} \to \mathcal{M}$. If 0 is initial in S, it is terminal in S^{op}, and hence

$$p_!\eta = \operatorname*{colim}_{S^{\mathrm{op}}} \eta \cong \eta(0).$$

For completeness, the cocone is given by the unique arrows $s \to 0$ in S^{op}. A cocone from η to an object z is uniquely determined by its component $\eta(0) \to z$, since compatibility forces every other component to be its composite with $\eta(s) \to \eta(0)$. This proves the universal property and the natural isomorphism.

Now take an object $\xi \in \mathcal{M}$, let $c\xi = p^*\xi$, and choose a cofibrant replacement of this diagram,

$$q : Q(c\xi) \longrightarrow c\xi,$$

whose components belong to Σ. The derived counit of $\mathbf{L}p_! \dashv p^*$ is represented by

$$p_!Q(c\xi) \longrightarrow p_!c\xi \longrightarrow \xi.$$

Under the displayed evaluation isomorphisms this is simply $q_0 : Q(c\xi)(0) \to \xi$, because the second arrow is the identity. It is a weak equivalence, so the derived counit is an isomorphism. A right adjoint is fully faithful exactly when its counit is an isomorphism. Therefore the constant-diagram functor is fully faithful, which is the required asphericity conclusion for this shape.

The argument proves a property of the derivator produced by the model structure. It has no need to identify its associated fundamental localizer with a previously given W. That is why Proposition 7.7.1 can be used to verify the original Der (3) independently of the disputed recognition statement. The symbols W and Σ in the surrounding text should still be distinguished: Σ denotes weak equivalences in the chosen model category, whereas $W_{\mathbb{D}}$ is a class of functors between small categories. Several printed subscripts switch them inadvertently; the correction ledger records those slips without rewriting the edition.

Proposition 7.7.1. *Soit* $(\mathcal{M}, W)$ *une catégorie de modèles, associée à un triple de Quillen clos* spécial (W, C, F). *Alors le prédérivateur* $\mathbf{D} = \mathbf{D}_{\mathcal{M},W}$ *sur* Cat *satisfait aux axiomes* Der (1, 2, 3, 4*, 5*, 6*). *Si de plus le triple de Quillen est* très *spécial* (*donc en particulier* $C = \mathrm{Mono}(\mathcal{M})$), *alors il satisfait de plus à* Der (4, 5, 6), i.e. *c'est un dérivateur au plein sens du terme. D'autre part, le localiseur* $W = W_{\mathbf{D}}$ *dans* Cat *associé à* $\mathbf{D}$ (*dans le cas d'un triple de Quillen spécial sans plus*) *est un* localiseur fondamental, *satisfaisant de plus* Loc (1 ter, 3 bis).

N.B. Ce qui est dit ici pour le cas d'un triple de Quillen très spécial (qui ne fait pas appel à la théorie des localiseurs fondamentaux dans Cat) montre à nouveau que si W localiseur fondamental dans Cat satisfait à Loc ($6'$ a, 8, 9), alors HOT_W est un vrai dérivateur. On a vu de plus dans 7.6 (page 111) que l'on a alors $W = W_{\mathrm{HOT}_W}$ [55], donc il s'ensuit : [page 118]

Corollaire 7.7.2 : *On a l'implication*

$$\text{Loc } (6' \text{ a, 8, 9}) \implies \text{Loc(1 ter, 3 bis)} \text{ [56]}.$$

Notons aussi, pour mémoire :

Corollaire 7.7.3. *Soit* $(\mathcal{M}, W)$ *une catégorie de modèles, associée à une catégorie à cofibrations. Alors sur le domaine* Diag *formé des ensembles ordonnés finis, le prédérivateur* $\mathbf{D} = \mathbf{D}_{\mathcal{M},W}$ *satisfait aux axiomes* Der (1, 2, 3, 4*, 5*, 6*), *et dualement. Donc si* W *est associé à la fois à une structure de cofibrations et de fibrations,* $\mathbf{D}$ *est un dérivateur sur* Diag. [page 119]

54. opération $p_!$ au niveau de $\mathcal{M}(S)$.
55. Mais c'était sous l'hypothèse Loc (3 bis) ! Gare au cercle vicieux.
56. Loc (3 bis) pas prouvé, probablement faux.

[Les six lignes qui suivent semblent hors contexte.]

Commentary · Present state [ms. 118]

The circular inference and the separate recognition problem

The two authorial footnotes are mathematically decisive. The proof that a suitable presheaf presentation yields a derivator concerns the prederivator HOT_W. Proposition 7.7.1 then associates a strongly saturated fundamental localizer $W_{\mathbb{D}}$ satisfying the relative locality axiom to that derivator. To conclude the same relative locality assertion for the original W, one still needs

$$W = W_{\mathrm{HOT}_W}.$$

The proof on pages 111–113 establishes this equality under strong saturation *and* Loc (3 bis). Applying it to prove Loc (3 bis) therefore assumes the very conclusion under consideration. The derivator existence theorem does not remove that logical dependence. This is the circle explicitly marked by footnote 55 and acknowledged in footnote 56.

Strong saturation has a different route. If the presentation identifies the original weak equivalences with the inverse image of the model weak equivalences, the model category's saturation theorem supplies Loc (1 ter). That statement does not require the invalid recognition inference. Thus the two conclusions in Corollary 7.7.2 should not receive a single undifferentiated verdict: the saturation argument has already been given on page 107, while the proposed proof of relative locality fails. The claim register records the latter argument as a sketch with a circularity gap. A circular proof does not by itself refute its conclusion, and no counterexample to that exact implication is asserted here.

Nor does weak minimality solve this separate problem. Theorem 6.1.18 of Cisinski (2006a) identifies the *least* weak fundamental localizer. It does not say that every weak fundamental localizer satisfies the relative axiom. The distinction remains necessary throughout this commentary. The verified modern model-existence theorem near the end of the chapter assumes a strong basic localizer, so it cannot be used to supply the missing implication by changing terminology mid-proof.

There is also a broader recognition question: how much of a homotopy theory survives passage to all its diagram homotopy categories? A precise positive result is Arlin (2020, Theorem 37), read in the February 2020 arXiv revision. A map of quasicategories whose induced prederivator morphism is an equivalence is itself an equivalence. The proof recovers equivalences on mapping spaces from diagram categories. This detects a given map; it does not assert that every abstract prederivator has a quasicategorical or model presentation. Together with Lenz's comparison theorem, it explains the strength of the derivator perspective while leaving the hypotheses of the particular equality $W = W_{\mathrm{HOT}_W}$ visible.

alors la flèche de changement de base

$$p^* f_! \longrightarrow f'_! q^*$$

entre foncteurs $\mathrm{HOT}_W(X) \longrightarrow \mathrm{HOT}_W(S')$ *est un isomorphisme.*

C'est pratiquement trivial, compte tenu, dans le cas f W-lisse, que si Z sur X est W-lisse sur X, il l'est sur S ; et dans le cas p W-propre, en utilisant le dernier énoncé ("oubli") dans ⑥, p. 199.

7.8. Je termine en mettant en vedette ce qui, à présent, me paraît la substance principale de tous ces "rappels" et comme la quintessence de la théorie des localiseurs fondamentaux développée jusqu'à présent : p. 56

$$\begin{cases} \text{Loc (3 bis)} & \Longrightarrow & \text{Der (4*, 5*)} \\ \text{Loc (3 bis, 6 a)} & \Longrightarrow & \text{Der (1, 2, 3, 4*, 5*, 6*)} \\ \text{Loc (6' a, 8, 9)} & \Longrightarrow & \text{tous les axiomes des dérivateurs (+ Loc (1 ter)).} \end{cases}$$

Je considère les axiomes Loc (3 bis), Loc (8), Loc (9) comme des axiomes "anodins" - tous les localiseurs qu'on définit par voie cohomologique ou homotopique ordinaire, y satisfont. Il reste l'axiome Loc (6 a) ou Loc (6′ a) des W-cofibrations (forme faible), qui visiblement joue un rôle crucial dans la théorie de HOT_W. Par contre, les axiomes Loc (4) (décomposition), [page 120]

Loc (5) (connexité) et Loc (7) et ses variantes (et bien sûr aussi Loc (6 b)) n'interviennent absolument pas ! C'est particulièrement impressionnant, en ce qui concerne l'axiome des W-fibrations Loc (7) et ses variantes (toutes équivalentes à Loc (7) en présence de Loc (8), à la seule exception de Loc (7 F)). Comme on a vu, Loc (7) n'est nullement impliqué par Loc (6 a, 8, 9) ($\mathbf{W}_0$ n'y satisfait pas), tout au plus se pourrait-il que Loc (7 F) le soit. Il en est de même de l'axiome de connexité Loc (5), comme on voit sur l'exemple de $W = \mathrm{Fl}(\mathrm{Cat})$, qui satisfait à tous les axiomes vus jusqu'à présent, à la seule exception de Loc (5). Quant à [page 121] la question de l'indépendance de l'axiome Loc (4) par rapport à Loc (6 a, 8, 9), nous allons examiner ce genre de questions au paragraphe suivant.

Commentary · Exposition [ms. 119]

The detached base-change assertion

The edition expressly marks six lines as out of context. Their symbols determine the square they refer to, but do not recover all of its missing hypotheses. The evident intended arrangement is

$$\begin{array}{ccc} X' & \xrightarrow{q} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ S' & \xrightarrow[p]{} & S. \end{array}$$

The printed comparison is $p^* f_! \to f'_! q^*$, with the variance of these pages. The following explanation distinguishes two sufficient geometric situations: f is W-smooth, or p is W-proper. It invokes stability of smoothness under composition in the first case and the previously established "forgetting" statement on page 199 in the second. It would be unsafe to turn this fragment into a theorem for arbitrary commutative squares.

The structural meaning is clear. A base-change assertion says that restricting a homotopy Kan extension and extending the restricted diagram agree. It requires a square for which the two pointwise indexing constructions are homotopically equivalent. For comparison, Groth (2013, Proposition 1.24) gives an exact modern statement: a pullback square of categories is homotopy exact if its right vertical map is a Grothendieck fibration or its bottom horizontal map is a Grothendieck opfibration, in that article's covariant-diagram convention. The proof reduces the pointwise calculation to actual fibres using adjunctions. This illustrates the mechanism; it does not identify all W-smooth or W-proper functors with Grothendieck fibrations, nor does it reconstruct the absent surrounding sentence. The fragment and its editorial warning therefore remain in the text.

L'ensemble d'axiomes Loc (6′ a, 8, 9) me paraît à présent si important, que j'ai envie de lui donner un nom, et d'appeler *localiseur* (fondamental) *spécial* dans Cat [57], un localiseur fondamental qui y satisfait. Ce sont donc aussi ceux pour lesquels nous savons que HOT_W est un vrai *dérivateur*. Si on ne peut écarter comme "pathologique" une structure aussi riche et délicate qu'un dérivateur, il s'ensuit aussitôt que l'on ne peut non plus écarter les localiseurs spéciaux dans Cat (même si on affecte de regarder de haut les localiseurs fondamentaux [page 122] généraux !). En effet, W se récupère de façon unique à l'aide de $\mathbf{D} = \mathrm{HOT}_W$, ou de tout dérivateur équivalent à celui-ci, comme l'ensemble des $\mathbf{D}$-équivalences dans Cat [58] : c'est le localiseur fondamental (correspondant à une notion d'équivalence "universelle", *i.e.* dans la catégorie Cat de tous les "espaces" élémentaires) canoniquement associé au dérivateur. Ce n'est donc nullement un localiseur de référence fixe assez fin, tel $\mathbf{W}_\infty$, qui est apte à jouer un rôle !

Cela nous amène à nouveau à une question du genre déjà soulevé : si $W \subset \mathbf{W}_\infty$ est le plus petit localiseur qui satisfait à Loc (6′ a, 8) (ou Loc (3 bis, 6′ a, 8)), peut-on dire a) que W est même *spécial*, *i.e.* satisfait également Loc (9) (accessibilité) ?, et de plus b) a-t-on $W \neq \mathbf{W}_\infty$? [page 123] Je suis persuadé que c'est le cas (il y a moins de mérite pour ce W-là d'être différent de $\mathbf{W}_\infty$, que pour le $\tilde{\mathbf{W}}_\infty$ envisagé dans 6.4 (p. 87)). p. 57

57. J'hésite si je ne dois pas rajouter l'axiome Loc (3 bis), qui assure que $W = W_{\mathbf{D}}$, $\mathbf{D} = \mathrm{HOT}_W$.
58. Mais ceci n'est prouvé que moyennant Loc (3 bis).

7.9. Oubli : la question 1 bis (p. 98), sur l'existence d'une structure de Quillen close sur Cat, correspondant à W. Le seul résultat que je connaisse dans ce sens est celui de Thomason, construisant explicitement une telle structure de Quillen (de plus propre), dans le cas où $W = \mathbf{W}_\infty$. Je n'ai pas vraiment regardé la démonstration de Thomason, et ignore si celle-ci peut s'étendre à des localiseurs fondamentaux plus généraux, par exemple à ceux satisfaisant Loc (6′ a, 8, 9). S'il en était ainsi, cela prouverait d'ailleurs que ces localiseurs ont assez de [page 124]
cofibrations et assez de fibrations, donc qu'ils satisfont Loc (6 a) et Loc (7 F). (Pour ce qui est de Loc (6 a), il semble qu'on puisse le prouver directement très simplement, *cf.* le paragraphe suivant. Mais ici encore, il faudrait regarder quelques exemples (équivalences homologiques ou cohomologiques, $\mathbf{W}_n$, *i.e.* les n-équivalences d'homotopie), et regarder déjà si Loc (7 F) est satisfait.)

Commentary · Later developments [ms. 123]

Both proposed minima give ordinary homotopy types

The two minima asked for on pages 122–123 have an unequivocal answer. Let $W^{(a)}$ be the least weak fundamental localizer satisfying Loc (6′a,8), and let $W^{(b)}$ be the least one satisfying Loc (3 bis,6′a,8). The ordinary class $\mathbf{W}_\infty$ satisfies both lists: here the cube condition is explicitly the direct, weak form, so the reverse-excision problem of page 87 does not arise. It is therefore a member of each class being intersected. Conversely, weak minimality puts $\mathbf{W}_\infty$ in every weak fundamental localizer. Hence

$$\mathbf{W}_\infty \subset W^{(a)} \subset \mathbf{W}_\infty, \qquad \mathbf{W}_\infty \subset W^{(b)} \subset \mathbf{W}_\infty.$$

Both equalities follow. By the accessibility theorem proved above, both minima satisfy Loc (9). Thus part (a), accessibility, is affirmative, whereas part (b), strict inequality with ordinary weak homotopy equivalences, is negative. These answers use Cisinski (2006a, Theorem 6.1.18), not merely a theorem asserting minimality among already strong localizers.

The conclusion does not make other localizers irrelevant. Coarser localizers can distinguish different localizations of ordinary homotopy theory, and their derivators can retain different homotopy-limit and homotopy-colimit operations. What fails is this specific expectation of a new theory obtained by imposing the stated axioms below $\mathbf{W}_\infty$. The separate proposal to encode Whitehead torsion needs additional finite or relative structure, as in the finite-space construction discussed at page 96.

Il ne me semble pas que la théorie de Thomason ait été jusqu'à présent `[mots illisibles]` être très utile, techniquement parlant. Psychologiquement, je crois qu'il a été important, pour donner confiance que Cat est vraiment une excellente catégorie de modèles pour Hot. J'ai été vraiment enchanté et stimulé d'apprendre ce théorème. Mais la notion d'application de Dwyer (que j'ai apprise en 1983 dans l'article de Thomason) a été, techniquement, beaucoup plus importante pour moi : c'était exactement ce qui manquait à ma panoplie de notions et d'intuitions "homotopiques" dans Cat …

Commentary · Later developments [ms. 124]

Generalized Thomason models and the role of properness

The model-existence question has a substantial positive answer with precise hypotheses. Cisinski (2006a, Theorem 5.2.15, p. 225) constructs, for every accessible *strong* basic localizer W, a cofibrantly generated model structure on Cat with weak equivalences W and Thomason cofibrations. It is left proper. It is right proper exactly when the localizer is proper in the sense used there. The reference is the published Astérisque version; its pagination differs from the shorter author preprint. This theorem extends the classical structure recalled in the preceding Theorem 5.2.12. Its adjunction uses $\mathrm{cat}\,\mathrm{Sd}^2$ and $\mathrm{Ex}^2 N$; the two subdivisions are part of the construction, rather than an identification of every categorical homotopy with a simplicial one.

This answers the generalized Thomason question in a large specified class. It does not prove that Grothendieck's weak axioms Loc (6′a,8,9), without relative locality, imply that class of hypotheses. His phrase about extending Thomason's structure can naturally include its explicitly mentioned

properness. With that reading, the ensuing conclusion about enough intrinsic cofibrations and fibrations is justified. If one only knows existence of an arbitrary Quillen structure, however, identifying its fibrations with the intrinsic class Fib_W requires an additional argument. The properness qualification explains exactly what makes the intended inference work.

The implication supplied by properness is elementary and worth making explicit. Suppose (W, C, F) is a right proper model structure on a category with pullbacks, and let $p : E \to B$ belong to F. For any $B' \to B$, the pullback $p' : E' \to B'$ is again a model fibration. If $a : A \to A'$ is a weak equivalence over B', pull back p' first to A'. Right properness applied to that fibration shows

$$E' \times_{B'} A \longrightarrow E' \times_{B'} A'$$

is a weak equivalence. Thus every base change of p preserves weak equivalences under pullback: p is an intrinsic W-fibration. The model factorization of f as a trivial cofibration followed by a fibration is therefore a factorization as a W-equivalence followed by an intrinsic W-fibration. This gives enough such fibrations, namely the content needed for Loc (7F). Cisinski records the corresponding comparison in Example 6.1.14.

Dually, in a left proper model structure, a model cofibration remains one after cobase change, and pushout along it preserves weak equivalences. Hence it is an intrinsic W-cofibration. Factoring any map as a cofibration followed by a trivial fibration gives the required cofibration factorization. In the generalized Thomason theorem this conclusion is available because left properness is part of the theorem. The fibration conclusion requires the additional right properness hypothesis. One should therefore separate the affirmative realization theorem from the intrinsic-fibration question for an arbitrary localizer.

The finite-truncation examples specifically requested here do satisfy the stronger hypothesis. In Cisinski (2006a, Section 9.2.1, p. 364), $\mathbf{W}_n$ is generated by making the simplex category $\Delta/\partial\Delta^{n+2}$ aspherical. It is accessible and has aspherical generators; Corollary 4.3.28 proves such a localizer proper. Corollary 9.2.15, p. 369, identifies its simplicial weak equivalences with the maps inducing a bijection on components and isomorphisms on homotopy groups through degree n, so this is the class meant in the manuscript, not merely a similarly named localization. Theorem 5.2.15 therefore gives a proper model on Cat for every finite $n \geq 0$. Applying the preceding pullback argument proves that $\mathbf{W}_n$ has enough intrinsic fibrations. This answers the particular Loc (7F) question on pages 91 and 124 affirmatively, even though D_{W_ω} fails for each of these strict truncations.

This distinction also resolves the apparent tension with the earlier truncated examples. A theory can possess valid derived right Kan extensions through a model presentation even though the fixed ordinary path replacement is invalid for its weak equivalences. Derived constructions use the fibrant replacements and lifting conditions of the localized model. They need not be the ordinary loop categories that retain every homotopy group. The explicit $\mathbf{W}_0$ factorization at manuscript page 69 supplies a concrete instance; the $K(G, n+1)$ example at page 90 explains why the unmodified ordinary path construction cannot provide a universal replacement for all truncations.

Overview · XVI

Chapter XVI, manuscript pages 1–124: equivalences before models.

Grothendieck returns to the axioms because he wants to understand which part of a homotopy theory belongs to the equivalences themselves. A useful factorization supplies a way of calculating a homotopy fibre or a homotopy pushout; it should not determine what that construction means. This conviction explains both the long inventory in these pages and its recurrent changes of emphasis. The object being studied is a class W of functors between small categories. From it one wants to recover the localization Hot_W, categories of coherent coefficients over every index category, and the operations relating those categories. The chapter asks how much geometry is forced by a few closure properties of W, and how much must still be supplied by an axiom of descent, a factorization, or a smallness condition.

The letter to Thomason of 2 April 1991 states this position particularly clearly: a category with weak equivalences is the underlying datum, while cofibrations and fibrations are additional means of constructing its homotopy theory. The same letter recalls the observation that a derived category "ne vient jamais seule": diagrams of complexes have their own derived categories, whose relationships carry information lost on passing immediately to diagrams in a single derived category (Grothendieck, 1991a, §§1–2). Chapter XVI belongs to that project. Its geometric language of fibres, open and closed subcategories, and integration is a language for constructing coherent diagram theories. The connection with the theory of coefficients is structural, rather than an analogy added after the constructions have been made.

The first distinction: absolute and relative localization.

The starting axioms are deliberately modest. They impose the specified saturation conditions, declare a category with a terminal object to be aspherical, and require an aspherical functor to be an equivalence. Here asphericity of $u : A \to B$ is tested on the comma categories A/b. The stronger axiom Loc (3 bis) concerns a map $A \to B$ over an arbitrary third category S, and tests the maps $A/s \to B/s$. This difference governs much of the chapter. The first condition controls individual objects and functors with contractible fibres in the comma sense. The second permits the comparison of two varying families. In later terminology the first system defines a *weak* fundamental localizer; the usual definition of a fundamental localizer incorporates the relative condition.

The comparison with split Grothendieck fibrations in §1 makes this distinction geometric. Replacing a category over S by its free split fibration turns comma categories into actual fibres. The comparison with the original category has an adjoint and is therefore already harmless for the weak axioms. What remains is exactly the question whether fibrewise equivalences of two families are equivalences of their total categories. The commentary spells out the variance in this replacement: Grothendieck fibrations are described by contravariant category-valued functors, and their fibres are compared with undercategories over the base. Interchanging these conventions silently would change the argument.

The connectedness axiom of §2 rules out the degenerate theories in which all nonempty categories become indistinguishable. It allows π_0 to descend through localization and explains the special role of discrete categories. The converse characterization by nontriviality invokes an earlier product argument whose editors explicitly require (3 bis); its weak-axiom generality is therefore not established by that reference. This section also contains a useful warning about localization arguments. Adjunctions that preserve the designated equivalences descend by their units and counits. An identification between the localization of an infinite product of relative categories and the product of their localizations requires additional justification. The finite and infinite cases must therefore be separated. Moreover, the literal formulation of Lemma 2.5 with an arbitrary class of arrows omits an identity hypothesis needed even in the finite case. The audit isolates this defect without disturbing the intended application to localizers, which already contain the identities.

Excision and the two meanings of fibration.

The next two sections study complementary ways of making constructions invariant. For pushouts, the intrinsic class Cof_W consists of maps along which cobase change preserves W-equivalences. The forward Mayer–Vietoris condition is an excision principle for a cover by two sieves, or dually by two cosieves. Dwyer inclusions supply enough explicit maps with which to work. Brown's lemma is the decisive bridge from stability of trivial cofibrations to stability of arbitrary equivalences under these pushouts (Brown, 1973). The commentary gives the missing argument, retaining the distinction between Grothendieck's sketch, the cited general result, and its application in Cat.

Forward excision must be distinguished from the reverse implication, which tries to recover an equivalence on the intersection from equivalences on the two pieces and their union. The latter is substantially stronger. It fails for ordinary weak homotopy equivalences, and the blanket assertion in Theorem 5.4 that the ordinary localizer satisfies Loc (6) must be read with this defect exposed: its forward part is valid, its reverse part is not. Cone and suspension constructions explain why this is a mathematical issue rather than a matter of terminology. They also give a useful further development: reverse cube excision forces the inversion of integral homology equivalences. The detailed proof appears at the end of the commentary on §3, with its precise scope and the literature checked.

For pullbacks, Fib_W is defined intrinsically by preservation of W-equivalences under base change. It is not the class of fibrations in an arbitrarily chosen Quillen model structure. Nor is it the class of Grothendieck fibrations with W-equivalent transition functors. The latter is an explicit source of candidate maps, and §4 asks when those candidates belong to the intrinsic class. Universal equivalences, weak fibrations, perfect maps, and the auxiliary localizer $W_0 \subseteq W$ provide progressively different tests. The many implications labelled A, B, C, D and F record which tests are sufficient for which calculations. Their hypotheses matter: a statement about maps over a fixed base does not automatically assert stability under every change of target, and the existence of enough intrinsic fibrations does not identify a prescribed geometric class with those fibrations.

These pages are exploratory, but their main mechanism is robust. A factorization by a sufficiently well behaved class reduces preservation of all equivalences to preservation of trivial maps in that class. Repeated path constructions then turn local constancy into the stronger comparison needed for arbitrary base change. The commentary follows this mechanism through the diagram of implications, provides the missing intermediate verifications, and distinguishes genuine proof gaps from incorrectly copied indices and from slips already present in the edition. A worked analysis of component monodromy gives a concrete test for the difference between locally constant Grothendieck fibrations and intrinsic fibrations for π_0-equivalences.

What the minimality theorem changes.

The most consequential later result for these pages is stronger than the minimality theorem in its familiar formulation. Cisinski proves that ordinary weak homotopy equivalences form the least *weak* fundamental localizer (Cisinski, 2006a, Theorem 6.1.18, pp. 242–243). Consequently Grothendieck's W_ω, defined here using only the weak axioms, equals $\mathbf{W}_\infty$. This settles the suggestions that W_ω might fail the filtered-colimit axiom, and that a fundamental localizer strictly contained in $\mathbf{W}_\infty$ might retain simple homotopy information. It is essential to cite this stronger theorem: the relative theorem alone would not justify its application to the definition used at the beginning of Chapter XVI.

Theorem 6.1 gives a second consequence. Its fibration hypothesis, together with connectedness, forces $W \subseteq \mathbf{W}_\infty$. Minimality supplies the opposite inclusion. The other branch can be proved directly: a disconnected W-aspherical category, after perfect replacement of a chosen point, produces an empty fibre; universal base change then forces every functor into W. This supplies the missing dependency without invoking the general nontriviality criterion. Consequently D_{W_ω} permits exactly the ordinary localizer and the total localizer; Loc (5),

or non-totality under this fibration hypothesis, selects the former. The eight conditions in the main rectangle are therefore equivalent, while F remains strictly weaker. This explains why the stronger fibre calculations exclude the truncated and homological examples that otherwise belong naturally to the theory. The finite truncation localizers do have enough intrinsic fibrations: their proper generalized Thomason models answer the question about F positively (Cisinski, 2006a, §9.2.1, Corollary 9.2.15 and Theorem 5.2.15).

One qualification is necessary for the list on ms. 87: its bare Loc (6), if read as including reverse excision, is incompatible with the simultaneous connectedness and fibration requirements. Equality with $\mathbf{W}_\infty$ describes the intended forward-excision version, not that inconsistent literal list.

The finite-poset calculation in §6 nevertheless retains its independent interest. Ordinary homotopy of realizations is weaker than homotopy through natural transformations of functors. Subdivision preserves the realization but need not provide a categorical homotopy inverse. The commentary proves the cycle example explicitly and distinguishes categorical homotopy, weak homotopy type, and simple homotopy type. Minimality prevents the proposed refinement from being encoded by a fundamental localizer on all small categories; it does not identify these three notions or erase the finer finite combinatorics.

Smallness and the passage to derivators.

Accessibility in §5 supplies the finiteness principle needed to construct models. The relevant smallness is a bounded-subcategory property: a prescribed small part of an equivalence can be enlarged, without exceeding the chosen cardinal bound, to a small equivalence. The argument for $\mathbf{W}_\infty$ uses a countable succession of homotopy witnesses. The notation π_0 in the cardinal estimate is expressly used for $\aleph_0$ and is not a transcription error. Translating this passage into modern presentability language requires care about successor cardinals; one must not identify a countable-category bound with finite presentability. The commentary gives an explicit closure construction and supplies the cofinal-tail choice needed to represent a basepoint in a filtered system.

The final section returns to the goal of the axioms. It asks when HOT_W has homotopy Kan extensions, detects isomorphisms pointwise, and satisfies the required exactness properties. The source's numbering of the derivator axioms is kept separate from modern numbering. In particular its decomposition axiom concerns finite sums. Its assertion for arbitrary relative categories is therefore not refuted by a failure involving infinite products. Likewise, the calculation of a colimit at an initial object in §7.7 is correct with the manuscript's contravariant diagram convention.

Two later theorems give firm landmarks. Accessible fundamental localizers in the relative sense admit the generalized Thomason model structures constructed by Cisinski; left properness is part of the theorem, whereas right properness requires the corresponding properness condition (Cisinski, 2006a, Theorem 5.2.15). Suitable model categories produce derivators, with homotopy Kan extensions and their pointwise formulas (Cisinski, 2003; Groth, 2013). These results answer the model-existence problem under explicit hypotheses. They do not validate the circular inference in Corollary 7.7.2, where the identification of W with the localizer detected by HOT_W uses the very relative axiom it is meant to establish. The edition preserves the warning about that circle, and so does the audit. For the remaining weak-axiom variants, the results found are kept apart from the implications that the sources checked do not settle.

Commentary · Exposition [ms. 1]

The relative latching map measures a new attachment

Grothendieck wants a condition on a map of diagrams which survives taking their colimits. The condition must record how the new value at an index is attached to everything already constructed. Merely asking that each component be a cofibration loses precisely this information. The pushout in $(*)$ isolates the additional attachment, and the rest of the preliminaries explains how to assemble these attachments without losing control of the resulting map.

We use the order convention of the manuscript: there is a unique arrow $i \to j$ when $i \leq j$, and an open subset is a lower ideal. Thus $\mathcal{M}(I^\circ)$ here means the category of covariant functors $I \to \mathcal{M}$; the circle belongs to Grothendieck's indexing convention, not to a reversal of the arrows in the diagrams being considered. Put

$$L_iX = \operatorname*{colim}_{j<i} X_j, \qquad \rho_i(u) : X_i \amalg_{L_iX} L_iY \longrightarrow Y_i.$$

1. **N.B.** Ces préliminaires seront complètement repris et dépassés dans le paragraphe 2. À ne pas lire !
2. Condition stable par passage de I à un sous-ensemble ordonné *ouvert* I' de I.
3. Dire aussi que l'on a

b′) *Si $i' \leq i$, alors dans le diagramme similaire à $(*)$,*

$$\begin{array}{ccc} X'_{i'} & \longrightarrow & X'_i \\ \downarrow & \text{cocart.} & \downarrow \\ Y'_{i'} & \longrightarrow & \tilde{Y}'_i \\ & & \downarrow{\scriptstyle u_{i',i}} \\ & & Y'_i\ , \end{array}$$

on a $u_{i',i} \in C$ (on retrouve $(*)$ en faisant $i' = i_0$, $i = i_0 + 1$). Le cas b) s'obtient en faisant $i' = 0$, i quelconque, d'où $(X'_i \longrightarrow Y'_i) \in C$. L'appliquant à $i + 1$ au lieu de i, on trouve $(u_i : X_i \longrightarrow Y_i) \in C$.

The map $\rho_i(u)$ is the relative latching map. In section 1, membership in C_I means exactly that all these maps belong to C. When i is minimal, both latching objects are initial and $\rho_i(u) = u_i$. At a nonminimal index, the latching object includes every incoming relation, rather than just a chosen list of immediate predecessors. This matters even for finite posets: two paths from an earlier object have to impose the same identification in the colimit.

The hypotheses on C say that attachments may be transported by pushout and composed, including through a continuous ordinal sequence. They do not require lifting properties, retract closure, or a choice of generating cofibrations. Accordingly, the first proposition is a statement about colimits and a class of morphisms; weak equivalences enter only in the corollary. Throughout these paragraphs a transfinite composite means the composite along a small ordinal-indexed chain whose value at a limit stage is the colimit of its preceding values.

For a lower ideal $J \subset I$, the incoming category at any $j \in J$ is unchanged by restriction: every $i < j$ also lies in J. Consequently $L_j(X|_J) = L_j X$, and the relative latching test restricts to J. This proves the assertion in footnote 2 and explains why lower ideals, rather than arbitrary full subposets, organize the argument. The same observation will allow us to apply a colimit statement to all predecessors of a single index and recover a statement about its component.

There is a change of definition ahead. In section 2, C_I will be defined by all open subsets of each principal lower ideal, even for a poset that is not artinian. The present one-latching test and that stronger definition agree for artinian posets under the stated closure hypotheses. They need not agree for an arbitrary poset. Keeping track of this change prevents the later counterexample from appearing to contradict Proposition 1.

Démonstration du corollaire. Supposons $u_\bullet \in (TC)_I$, alors par la proposition, $\varinjlim_{i\in I} u_i$ est dans TC, ou ce qui revient au même, dans W. D'autre part, appliquant ce même résultat aux systèmes inductifs induits sur $I_{<i_0}$, on trouve que dans $(*)$, la flèche α_{i_0} est dans TC, donc aussi β_{i_0} par cochangement de base, donc aussi $u_{i_0} = \tilde{u}_{i_0}\beta_{i_0}$. Donc il reste à prouver qu'inversement, si on suppose les $u_{i_0} \in W$, alors les $\tilde{u}_{i_0}$ sont eux aussi dans W (i.e. dans $TC = C \cap W$), ou ce qui revient au même, que les β_{i_0} sont dans W, ou encore dans TC. Mais comme TC est stable par cochangement de base, il suffit pour cela de prouver que $\alpha_{i_0} \in TC$, ou encore $\alpha_{i_0} \in C$. Donc on est ramené à prouver que

c) $u \in W_{I^\circ} \cap C_I \Longrightarrow (\varinjlim_{i<i_0} u_i) \in W$ pour tout $i_0 \in I$,

donc, changeant de notation, à prouver `[phrase incomplète]`. Nous prouverons ensemble a) b) c) par induction transfinie sur le nombre ordinal α tel que $I \simeq I_\alpha = \{\text{ensemble des ordinaux } i < \alpha\}$.

1°) Cas $\alpha = 0$, i.e. $I = \emptyset$: il est trivial.

[page 4]

2°) Si c'est ok pour I_α, aussi pour $I_{\alpha+1} = \{\beta \mid \beta \leq \alpha\}$. Ici, $I_{\alpha+1}$ ayant un plus grand élément α, a) est contenu dans b) (pour $i = \alpha$, plus grand élément de $I_{\alpha+1}$.) Pour prouver b), il reste à prouver que $u_\alpha \in C$. On regarde le diagramme $(*)$ pour $i_0 = \alpha$. Par l'hypothèse de récurrence (forme a), appliquée à I_α, on a $\alpha_{i_0} \in C$, donc par cochangement de base $\beta_{i_0} \in C$, donc par composition $u_{i_0} = \tilde{u}_{i_0}\beta_{i_0} \in C$. Pour prouver c), il reste à prouver que $\varinjlim_{i<\alpha} u_i \in W$. Mais par l'hypothèse de récurrence appliquée à $I_\alpha = \{i \mid i < \alpha\}$, on sait déjà que $(u_i)_{i<\alpha} \in (TC)_{I_\alpha}$, donc par la partie prouvée du corollaire ou de la proposition, $\varinjlim_{i<\alpha} u_i \in TC$.

3°) Si α est un ordinal limite, et si a) b) c) sont vrais pour I_β avec $\beta < \alpha$, ils le sont aussi pour I_α. Cette fois, b) est contenu dans l'hypothèse de récurrence, il faut prouver a), i.e. que

[page 5]

$$u_\alpha \overset{\text{déf}}{=} \varinjlim_{i<\alpha} u_i \ : \ \underbrace{X_\alpha}_{\overset{\text{déf}}{=}\varinjlim_{i<\alpha} X_i} \longrightarrow \underbrace{Y_\alpha}_{\overset{\text{déf}}{=}\varinjlim_{i<\alpha} Y_i}$$

est dans C. Quant à c), il est déjà contenu dans la hypothèse de récurrence. Donc il reste finalement à prouver

$$u_\alpha \ \in \ C$$

quand on suppose que la proposition est prouvée pour les ordinaux $\beta < \alpha$.

On va construire un troisième système ordinal sur I_α, en introduisant pour tout $0 \leq i < \alpha$, i.e. $i \in I_\alpha$, Z_i par le carré cocartésien p. 3

$$\begin{array}{ccc} X_i & \longrightarrow & X_\alpha \\ \downarrow & \text{cocart.} & \downarrow \\ Y_i & \longrightarrow & Z_i \ . \end{array}$$

Les flèches de transition entre les Z_i sont évidentes, et on aura $\varinjlim_i Z_i \xrightarrow{\sim} Y_\alpha$. Ainsi, $u_\alpha : X_\alpha (= Z_{-1}) \longrightarrow Y_\alpha$ est décomposé en composé transfini de morphismes [page 6]

$$(*) \qquad Z_i \xrightarrow{v_{i+1}} Z_{i+1} \qquad (-1 \leq i < \alpha)$$

et

$$(**) \qquad \varinjlim_{i<i_0} Z_i \xrightarrow{v_{i_0}} Z_{i_0} \qquad i_0 \text{ ordinal limite } < \alpha.$$

(**N.B.** Le cas où i_0 n'est *pas* ordinal limite n'est autre que $(*)$ pour $i = \beta_0 - 1$.) Tout revient à prouver que ces flèches sont dans C (donc leur composé transfini aussi).

Cas $(*)$.

4

$$\begin{array}{ccccc} X_i & \longrightarrow & X_{i+1} & \longrightarrow & X_\alpha \\ {\scriptstyle u_i}\downarrow & \text{cocart.} & {\scriptstyle \beta_{i+1}}\downarrow & \text{cocart.} & \downarrow \\ Y_i & \longrightarrow & \tilde{Y}_{i+1} & \longrightarrow & Z_i \\ & & {\scriptstyle \tilde{u}_{i+1}}\downarrow & \text{cocart.} & \downarrow{\scriptstyle v_{i+1}} \\ & & Y_{i+1} & \longrightarrow & Z_{i+1} \ . \end{array}$$

Comme $\tilde{u}_{i+1} \in C$, $v_{i+1} \in C$ par cochangement de base, OK. Il faut cependant traiter à part le cas $i = 0$, i.e. la flèche $X_\alpha \longrightarrow Z_0$, qui est incluse dans

$$\begin{array}{ccc} X_0 & \longrightarrow & X_\alpha = Z_{-1} \\ {\scriptstyle u_0}\downarrow & \text{cocart.} & \downarrow{\scriptstyle v_0} \\ Y_0 & \longrightarrow & Z_0 \ , \end{array}$$

où $u_0 \in C$, donc $v_0 \in C$, OK.

Cas $(**)$. Si $i_0 < \alpha$ est ordinal limite, inspectons $(**)$. On a par passage à la limite

$$Z'_{i_0} \overset{\text{déf}}{=} \varinjlim_{i<i_0} Z_i \ \simeq \ Y'_{i_0} \amalg_{X'_{i_0}} X_\alpha$$

(cf. diagramme $(*)$ pour la définition de X'_{i_0}, Y'_{i_0}), s'insérant dans le diagramme suivant greffé sur $(*)$

$$\begin{array}{ccccc} X'_{i_0} & \longrightarrow & X_{i_0} & \longrightarrow & X_\alpha \\ {\scriptstyle \alpha_{i_0}}\downarrow & \text{cocart.} & {\scriptstyle \beta_{i_0}}\downarrow & \text{cocart.} & \downarrow \\ Y'_{i_0} & \longrightarrow & \tilde{Y}_{i_0} & \longrightarrow & Z'_{i_0} \\ & & {\scriptstyle \tilde{u}_{i_0}}\downarrow & \text{cocart.} & \downarrow{\scriptstyle v_{i_0}} \\ & & Y_{i_0} & \longrightarrow & Z_{i_0} \ . \end{array}$$

p. 4
[page 7]

4. Pour se donner confiance – on pourrait traiter toute de suite le cas général.

On a $\tilde{u}_{i_0} \in C$ par hypothèse, donc $v_{i_0} \in C$, ce qui achève la démonstration.

Commentary · Exposition [ms. 7]

A continuous filtration of the colimit map

The auxiliary objects Z_i put all stages over the fixed object X_α, so that their successive changes are pushouts of the relative latching maps. This is the right idea. Their indexing becomes more transparent if the value immediately before an attachment is distinguished from the value immediately after it. In particular, the original diagram X need not itself be continuous at a limit ordinal.

Here is a continuous version of the argument, including the marginal strengthening. Let the indexing ordinal be λ, and write

$$X_{<\beta} = \operatorname*{colim}_{i<\beta} X_i, \quad Y_{<\beta} = \operatorname*{colim}_{i<\beta} Y_i, \quad X = X_{<\lambda}, \quad Y = Y_{<\lambda}.$$

For $0 \le \beta \le \lambda$, set

$$P_\beta = X \amalg_{X_{<\beta}} Y_{<\beta}.$$

Then $P_0 = X$ and $P_\lambda = Y$. If $\delta \le \lambda$ is a nonzero limit ordinal, the universal property of colimits gives

$$\operatorname*{colim}_{\beta<\delta} P_\beta \simeq X \amalg_{X_{<\delta}} Y_{<\delta} = P_\delta.$$

Indeed, a compatible cocone from the left side consists of a map from X and compatible maps from the $Y_{<\beta}$ agreeing on every $X_{<\beta}$. These are exactly the data defining a map from the displayed pushout. This verifies continuity without an extra exactness assumption on $\mathcal{M}$.

At a successor stage the square

$$\begin{array}{ccc} X_\beta \amalg_{L_\beta X} L_\beta Y & \xrightarrow{\rho_\beta(u)} & Y_\beta \\ \downarrow & & \downarrow \\ P_\beta & \longrightarrow & P_{\beta+1} \end{array}$$

is cocartesian. To check this, a map from its pushout amounts to a map from X and a map from Y_β whose restrictions along every X_i, $i \le \beta$, agree. Since β is terminal in the subposet $i \le \beta$, the resulting object is $X \amalg_{X_\beta} Y_\beta = P_{\beta+1}$. Thus each successor arrow belongs to C, and transfinite closure proves $X \to Y \in C$. Restricting the entire argument to $i \le i_0$ proves $u_{i_0} \in C$.

For the marginal assertion start the same construction at any $\gamma \le \lambda$. It proves

$$X_{<\lambda} \amalg_{X_{<\gamma}} Y_{<\gamma} \longrightarrow Y_{<\lambda} \quad \in C.$$

The proof uses only the cells with indices $\gamma \le i < \lambda$. In particular, it does not need the map $X_{<\gamma} \to Y_{<\gamma}$ to belong to C. The source later checks this map in order to invoke Proposition 1 as already stated; the relative filtration itself is slightly more economical.

This also locates the two harmless indexing slips on manuscript page 6. The predecessor in the parenthesis is $i_0 - 1$, not the printed $\beta_0 - 1$. The special arrow $X_\alpha = Z_{-1} \to Z_0$ has source index -1, although the following sentence calls it the case $i = 0$. Both printed readings are retained; neither affects the pushout argument. The continuous P-filtration avoids counting a nontrivial attachment at a limit as though the original Z-diagram were already continuous there.

Proposition 2. *$(\mathcal{M}, C)$ et le cas échéant W, comme dans proposition 1 et son corollaire, I ensemble ordonné localement fini, i.e. tel que $\forall\ i_0 \in I$, I/i_0 soit fini. Soit*

$$u_\bullet : X_\bullet \longrightarrow Y_\bullet$$

une flèche dans[5] *$\mathcal{M}(I^\circ)_c$ = sous-catégorie pleine de systèmes inductifs sur I, à valeurs dans*

5. en fait, l'hypothèse que $X_\bullet$, $Y_\bullet$ dans $\mathcal{M}(I^\circ)_c$ est inutile, tant dans la proposition 2 que dans ses deux corollaires.

$\mathcal{M}$, tels que $\underbrace{\emptyset_{\mathcal{M}(I^\circ)}}_{\substack{\text{objet}\\ \text{initial}\\ \text{de } \mathcal{M}(I^\circ)}} \longrightarrow Z_\bullet$ *soit dans C_I (définie dans prop. 1), i.e. tel que $\forall\ i_0 \in I$, la flèche*

$$Z'_{i_0} \;=\; \varinjlim_{i<i_0} Z_i \;\longrightarrow\; Z_{i_0}$$

soit dans C, et supposons $u_\bullet \in C_I$. Alors

a) $\varinjlim_{i\in I} u_\bullet : X_I \overset{\text{déf}}{=} \varinjlim_{i\in I} X_i \longrightarrow Y_I \overset{\text{déf}}{=} \varinjlim_{i\in I} Y_i$ *est dans C,* [page 8]
et

b) $\forall\ i_0 \in I$, *on a $\alpha_{i_0}, \beta_{i_0} \in C$ dans le diagramme $(*)$ p. 1.*

Commentary · Later developments [ms. 7]

The later Reedy formulation

The relative latching condition became a standard language for diagrams built in increasing degree. For a finite or locally finite poset, one may assign to an object the maximum length of a strictly increasing chain ending there. Every nonidentity arrow raises this natural-number degree. With inverse arrows restricted to identities, this is a direct Reedy category. The cells in the preceding proof are its relative latching maps.

The general cellular decomposition of a natural transformation is developed in Riehl and Verity (2014, Proposition 6.3); their Lemma 7.1 identifies a Reedy cofibration which is an objectwise weak equivalence by the triviality of all its relative latching maps. These are the two mechanisms used here. The comparison does not import a full model structure into Grothendieck's first propositions: their proofs already work with his stated closure properties.

For cofibration categories, Rădulescu-Banu (2009, Theorem 9.4.1(1)(a,b)) gives the later relative-colimit statement for an open embedding of direct categories. It includes both the transition map for a cofibrant diagram and the relative map associated with a Reedy cofibration. His cofibrancy conventions and existence assumptions are more restrictive than the cocomplete ambient category used in these preliminaries, so the formulations should not be identified without that qualification.

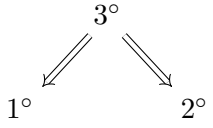
An arbitrary artinian poset need not admit a natural-number degree. Its rank can be a larger ordinal. The transfinite version of the degree convention is treated explicitly, in the dual orientation, by Shulman (2015, Definition 4.6 and Theorem 4.7). The ordinal formulation is the one appropriate to the unification Grothendieck reaches on manuscript pages 23–25.

Corollaire. *De plus (supposant donné W comme dans prop. 1, cor. 1), les conditions suivantes sur une $u_\bullet$ entre $X_\bullet$, $Y_\bullet$ C-cofibrants sont équivalentes.*

1°) $u_\bullet \in (TC)_I$, *i.e. les $\tilde{u}_{i_0} \in TC$ ($\forall\ i_0 \in I$).*

2°) $u_\bullet \in T_I \cap W_{I^\circ}$, *i.e. $\forall\ i_0 \in I$, $\tilde{u}_{i_0} \in C$, $u_{i_0} \in W$.*

3°) *Pour tout $i_0 \in I$, on a*



$$\alpha_{i_0},\ \beta_{i_0},\ \tilde{u}_{i_0},\ u_{i_0} \;\in\; TC$$

(i.e. $\alpha_{i_0}, \tilde{u}_{i_0} \in TC$, ce qui implique $\beta_{i_0} \in TC$, puis $u_{i_0} \in TC$ par cochangement de base et par composition).

Et ces conditions impliquent

4°) *que $u_I : X_I \longrightarrow Y_I$ est dans TC.*

Voyons comment ou dans quelle mesure le corollaire se déduit de la proposition. On a bien sur p. 5

tautologiquement. D'ailleurs, la proposition appliquée à TC au lieu de X montre qu'on a $1° \Longrightarrow 3°$ & $4°$, car en l'appliquant aux ensembles $I_{<i_0}$ on trouve que $\alpha_{i_0} \in TC \ \forall\ i_0 \in I$. Donc la proposition 2 implique

$$(1° \Longleftrightarrow 3°) \Longrightarrow 2° \ (\&\ 4°).$$

[page 9]

Commentary · Exposition [ms. 8]

Why objectwise equivalences become trivial attachments

Grothendieck next wants the same colimit construction to preserve weak equivalences. The essential hypothesis is that $TC = C \cap W$ has the same attachment stability as C. It permits the cellular proof to be used a second time, with TC in place of C. No assertion that arbitrary colimits preserve W is being made.

The reverse implication in the corollary can be written without simultaneous induction on three differently phrased statements. Assume the $\rho_i(u)$ belong to C and the u_i belong to W. Induct through the well-founded indices, assuming that $\rho_j(u) \in TC$ for every $j < i$. Applied to the predecessor diagram, the already established cellular argument for the class TC gives

$$L_iX \longrightarrow L_iY \quad \in TC.$$

Its pushout $X_i \to X_i \amalg_{L_iX} L_iY$ is therefore in TC. Its composite with $\rho_i(u)$ is $u_i \in W$, so the two-out-of-three property gives $\rho_i(u) \in W$. Since the relative latching condition already places it in C, it belongs to TC. The induction starts at a minimal object, where $\rho_i(u) = u_i$.

Conversely, if all $\rho_i(u)$ lie in TC, the same cellular argument shows that every component and the total colimit map belong to TC. Restriction to lower ideals also gives $L_iX \to L_iY \in TC$, and pushout gives the corresponding $\beta_i \in TC$. These are exactly the four maps listed in condition $3°$ of the second corollary. The assertion is an equivalence between two descriptions of trivial diagram cofibrations.

There is a genuine but local misprint in the argument on manuscript page 3. After reducing to $\alpha_{i_0} \in TC$, the text says "ou encore $\alpha_{i_0} \in C$". The proposition already supplies membership in C; what remains is membership in W. The next displayed condition (c) states precisely that remaining assertion. The intended proof therefore survives after replacing the final C in that sentence by W. Similarly the T_I printed in condition $2°$ on manuscript page 8 is C_I in the intended statement, as its immediately following explanation confirms.

Donc pour prouver $2° \Longrightarrow 3°$, il resterait à prouver que $2°$ suffit à impliquer $4°$ (et ceci quel que soit I ensemble ordonné localement fini) – car en appliquant ceci aux $I_{<i_0}$, on trouve que $2°$ implique $\alpha_{i_0} \in TC = C \cap W$ (non seulement $\alpha_{i_0} \in C$, selon la proposition 2), donc $\beta_{i_0} \in TC \subset W$, donc $\tilde{u}_{i_0} \in W$ par saturation, donc $\tilde{u}_{i_0} \in TC$, d'où $3°$.

Notons d'autre part que le b) dans la proposition 2 est conséquence de a), appliqué à la restriction de $u_\bullet$ à $I_{<i_0}$. Au total, il y a donc à prouver seulement les deux choses

$$(*) \qquad \begin{cases} \text{a)} \quad u_\bullet \in C_I \implies u_I \in C \\ \text{b)} \quad u_\bullet \in C_I \cap W \implies u_I \in C \cap W \ (\overset{\text{déf}}{=} TC) \\ \qquad\qquad\qquad\qquad\quad (\text{et } u_\bullet \in (TC)_I) \end{cases}$$

Nous le prouverons par réduction au cas particulier de la proposition 1, déjà prouvée.

J'ai d'ailleurs aussi envie de prouver le

Corollaire 2. *$\mathcal{M}$, C (et éventuellement W). Les hypothèses sur $X_\bullet, Y_\bullet \in \mathcal{M}(I°)_{\mathrm{c}}$ et sur $u_\bullet \in C_I$, enfin sur I localement fini, sont celles de la proposition 2. Pour toute partie J de I, soit*

$$u_J \overset{\text{déf}}{=} \varinjlim_{i \in J} u_i \ : \ X_J \overset{\text{déf}}{=} \varinjlim_{i \in J} X_i \ \longrightarrow \ Y_J \overset{\text{déf}}{=} \varinjlim_{i \in J} Y_i \ .$$

Soient $I' \subset I''$ deux parties ouvertes *de I, et considérons le diagramme*

[page 10]

(∗)
$$\begin{array}{ccc} X_{I'} & \xrightarrow{\tau_X} & X_{I''} \\ {\scriptstyle \alpha=u_{I'}}\downarrow & \text{cocart.} & {\scriptstyle \beta}\downarrow \\ Y_{I'} & \xrightarrow{\tilde{\tau}_Y} & \tilde{Y}_{I''} \\ & {\scriptstyle \tau_Y}\searrow & \downarrow{\scriptstyle \tilde{u}} \\ & & Y_{I''}\ . \end{array} \qquad u_{I''}$$
(défini comme somme amalgamée)

Alors on a p. 6

$$\begin{cases} u_{I'}, u_{I''} \in C \text{ (donc aussi } \beta \in C\text{) (i.e. pour tout } J \text{ ouvert dans } I, \\ u_J : X_J \longrightarrow Y_J \text{ est dans } C)^6, \text{ et } \tau_X, \tau_Y \in C \text{ (donc aussi } \tilde{\tau}_Y \in C\text{)} \\ \text{(i.e. pour } I' \subset I'' \text{ inclusion d'ouverts, et } X_\bullet \text{ } C\text{-cofibrant dans } \mathcal{M}(I^\circ), \\ \text{on a } X_{I'} \longrightarrow X_{I''} \text{ dans } C)^7, \text{ et enfin, même} \\ \qquad\qquad \boxed{\tilde{u} \in C.} \end{cases}$$

N.B. Le cas de la proposition 2 sous la forme (∗) a), page 9, (i.e. aussi le fait que les $u_{I'}$, $u_{I''}$, … sont dans C) est obtenu en prenant $I'' = I$, $I' = \emptyset$, le diagramme devient

$$\begin{array}{ccc} \emptyset & \longrightarrow & X_I \\ {\scriptstyle \mathrm{id}}\downarrow & \text{cocart.} & \downarrow{\scriptstyle \mathrm{id}} \\ \emptyset & \longrightarrow & X_I \\ & & \downarrow{\scriptstyle \tilde{u}=u_I} \\ & & Y_I\ , \end{array}$$

et la conclusion est donc $u_I \in C$ [8]. La *définition* de C_I, i.e. la condition $u \in C_I$, se retrouve en exigeant $\tilde{u} \in C$ dans (∗) ci-dessus, dans le cas $I'' = I/i_0$, $I' = I_{<i_0}$. Il est remarquable que cette définition de C_I donne une conclusion aussi forte que $\tilde{u} \in C$ pour *tout* couple $I' \subset I''$ de sous-ensembles ouverts de I. [page 11]

Commentary · Examples [ms. 10]

Which conclusions need a cofibrant source diagram

The relative comparison map is the main invariant of Corollary 2. Its source combines the whole old X-diagram with the part of Y already constructed, so its being a cofibration does not require either diagram to start cofibrantly. By contrast, the transition map $X_{I'} \to X_{I''}$ concerns the attachment of X itself and does require a condition on X.

This distinction is visible in the two footnotes. Footnote 5 says that the assumptions on the objects are unnecessary in Proposition 2 and both its corollaries. Read literally, this is too broad.

6. C'est bien sûr contenu dans prop. 2, appliquée à $u_\bullet|_J$.

7. C'est pour cette assertion $\tau_X \in C$ (d'où $\tilde{\tau}_Y, \tau_Y \in C$, moyennant $\tilde{u} \in C$) qu'on a besoin de l'hypothèse $X_\bullet \in \mathcal{M}(I^\circ)_{\mathrm{c}}$, $\tilde{u} \in C$ vrai sans cette hypothèse.

8. Le cas $(Y_{I'} \xrightarrow{\tau_Y} Y_{I''}) \in C$ est obtenu en prenant $X_\bullet = \emptyset_\bullet$, on aura

$$\begin{array}{ccc} \emptyset & \xrightarrow[\sim]{\tau_X} & \emptyset \\ \downarrow & \text{cocart.} & \downarrow \\ Y_{I'} & \xrightarrow{\mathrm{id}} & \tilde{Y}_{I''} = Y_{I'} \\ & {\scriptstyle \tau_Y}\searrow & \downarrow{\scriptstyle \tilde{u}=\tau_Y} \\ & & Y_{I''}\ . \end{array}$$

Footnote 7 gives the correct qualification for the transition maps: X must be a cofibrant diagram to deduce $\tau_X \in C$. The relative conclusion $u_{I',I''} \in C$ holds without that hypothesis.

A complete counterexample to the blanket reading takes $\mathcal{M} = \mathrm{Set}$, C the isomorphisms, and $I = \{0 < 1\}$. Let $X = Y$ be the diagram

$$\varnothing \longrightarrow \{*\}, \qquad u = \mathrm{id}_X.$$

At 0, the relative latching map is $\mathrm{id}_\varnothing$. At 1, its source is

$$X_1 \amalg_{X_0} Y_0 = \{*\} \amalg_\varnothing \varnothing = \{*\},$$

and its target is $Y_1 = \{*\}$; the map is again an identity. Thus $u \in C_I$. For the open subsets $I' = \{0\}$ and $I'' = I$, however,

$$\tau_X : X_{I'} = \varnothing \longrightarrow X_{I''} = \{*\}$$

is not an isomorphism. This example satisfies every closure hypothesis on C, including transfinite closure. The failure therefore concerns the missing hypothesis, not the colimit construction.

Under the stated cofibrancy hypothesis the transition conclusions follow formally from the relative one. Apply it first to $\varnothing_I \to X$ to obtain $X_{I'} \to X_{I''} \in C$. Its pushout along $u_{I'}$ is $Y_{I'} \to X_{I''} \amalg_{X_{I'}} Y_{I'}$, hence also lies in C. Composing with $u_{I',I''} \in C$ gives $Y_{I'} \to Y_{I''} \in C$. Thus cofibrancy of Y need not be assumed separately once X is cofibrant and u satisfies the relative latching condition. The useful division is between a condition on the map and a condition on its initial diagram.

C'est finalement sous cette forme qu'on va prouver la proposition 2 – c'est *ça* à présent qui me semble *le* bon énoncé dans cette direction. Avec le complément, bien sûr, que si de plus $u_\bullet \in W_{I^\circ}$, i.e. les u_i sont dans W, alors $u_\bullet$ est même dans $(TC)_I$, ou encore simplement que les $u_{I'}$ *sont dans* TC (d'où il résultera donc que $\tilde{u}$ dans $(*)$, p. 10, est aussi dans TC). p. 7

On va procéder par construction transfinie. On peut supposer bien sûr que $I'' = I$. On va quand même d'abord prouver le cas particulier où $I' = \emptyset$, i.e. prouver au moins que $u_I \in C$. On construit par récurrence transfinie une suite strictement croissante d'ouverts

$$I_\alpha \ \subset \ I,$$

aboutissant à

$$I_{\alpha_0} \ = \ I,$$

en posant

$$\begin{cases} I_0 \ = \ \emptyset\,, \\ I_\alpha \ = \ \bigcup_{\beta<\alpha} I_\beta \qquad \text{si } \alpha \text{ ordinal limite}\,, \\ I_{\alpha+1} \ = \ I_\alpha \cup (I/s_\alpha) \quad \text{si } I_\alpha \neq I, \text{ et en choisissant } s_\alpha \in I \backslash I_\alpha\,. \end{cases}$$

(On finit par avoir $I_{\alpha_0} = I$, bien sûr.) On pose [page 12]

$$\begin{aligned} X_\alpha \ = \ X_{I_\alpha} \ &= \ \varinjlim_{i \in I_\alpha} X_i \\ Y_\alpha \ = \ Y_{I_\alpha} \ &= \ \varinjlim_{i \in I_\alpha} Y_i \\ u_\alpha \ = \ u_{I_\alpha} \ &: \ X_\alpha \longrightarrow Y_\alpha\,, \end{aligned}$$

homomorphisme de systèmes inductifs transfinis. On aura

$$X_{\alpha_0} \ = \ X_I, \qquad Y_{\alpha_0} \ = \ Y_I, \qquad u_{\alpha_0} \ = \ u_I,$$

et on doit donc prouver que $u_{\alpha_0} \in C$. Pour ceci, on applique la proposition 1, il suffit donc de prouver que $(u_\alpha) \in C_{I_{\alpha_0+1}}$ (où $I_{\alpha_0+1} = \{\text{ordinaux } i \mid i < \alpha_0 + 1, \text{ i.e. } i \leq \alpha_0\}$). Donc il faut

prouver que les flèches $\tilde{u}_{i_0}$ dans $(*)$ p. 1 (où cette fois les i, i_0 sont des ordinaux, $i_0 \leq \alpha_0$) sont dans C. Je vais distinguer les deux cas où $\alpha = i_0$ est ordinal limite, qui est trivial car alors $X_{i_0} \xleftarrow{\sim} \varinjlim_{i<i_0} X_i$, $Y_{i_0} \xleftarrow{\sim} \varinjlim_{i<i_0} Y_i$, et $\tilde{u}_{i_0} = \mathrm{id}$, et le cas α non limite, i.e.

$$\begin{array}{ccc} X_{I_{\alpha-1}} & \longrightarrow & X_{I_\alpha} \\ {\scriptstyle u_{\alpha-1}}\downarrow & & {\scriptstyle \beta_\alpha}\downarrow \\ Y_{I_{\alpha-1}} & \longrightarrow & \tilde{Y}_{I_\alpha} \\ & & {\scriptstyle \tilde{u}_\alpha}\downarrow \\ & & Y_{I_\alpha}\ , \end{array} \qquad u_\alpha$$

à prouver que $\tilde{u}_\alpha \in C$. Lorsqu'on suppose de plus $u_0 \in W_{I_0}$, i.e. les $u_i \in W$, il faut de plus p. 8
prouver que $\tilde{u}_\alpha \in TC = C \cap W$. La proposition 2 et son corollaire 1 résulteront de là. Pour [page 13]
prouver $\tilde{u}_\alpha \in C$ resp. $\tilde{u}_\alpha \in TC$, on peut supposer $I_\alpha = I$ (quitte à changer de notation). On pose donc

$$\begin{aligned} I_\alpha &= I, \qquad I_{\alpha-1} = I' \\ I/s_{\alpha-1} &= I_0, \quad I_0 \cap I' = I'_0\ , \end{aligned}$$

de sorte qu'on a un diagramme commutatif d'inclusions ouvertes

$$\begin{array}{ccc} I_0 \cap I' = I'_0 & \hookrightarrow & I_0 \\ \downarrow & & \downarrow \\ I' & \hookrightarrow & I = I_0 \cup I'. \end{array}$$

On utilisera seulement le fait que I_0, donc I'_0, est fini, i.e. que dans le couple $(I' \subset I)$, I peut s'écrire sous la forme $I = I' \cup I_0$, avec I_0 un ouvert *fini,* pour en conclure que dans le diagramme

$$\begin{array}{ccc} X_{I'} & \xrightarrow{\tau^X_{I',I}} & X_I \\ {\scriptstyle u_{I'}}\downarrow & \text{cocart.} & {\scriptstyle u_{I',I}}\downarrow \\ Y_{I'} & \longrightarrow & \tilde{Y}_I \\ & {\scriptstyle \tau^Y_{I',I}}\searrow & {\scriptstyle \tilde{u}=u_{I',I}}\downarrow \\ & & Y_I \end{array} \qquad u_I$$

on a $\tilde{u} \in C$ resp. $\tilde{u} \in TC = C \cap W$.

[page 14]

Commentary · Exposition [ms. 13]

Excision for a cover by lower ideals

Grothendieck reduces an attachment over a large open subset to an attachment over one new principal open subset. The reduction is an ordinary colimit identity. Stating that identity before the larger diagrams makes clear which part of the argument uses the order and which part uses the class C.

Let A, B be lower ideals of a poset, put $H = A \cap B$ and $T = A \cup B$, and let $X : T \to \mathcal{M}$ be any diagram. Then

$$X_T \simeq X_A \amalg_{X_H} X_B.$$

To prove this, maps from the right side into an object Q are cocones on $X|_A$ and $X|_B$ that agree on H. Every arrow of T belongs to A or to B: if its target lies in one of these lower ideals, its source lies there too. The two cocones therefore combine uniquely into a cocone on all of X. This establishes the displayed universal property. The same argument proves that the square of full subcategories with vertices H, A, B, T is a pushout in Cat.

Now let $u : X \to Y$, and define the relative domain

$$R_{A,T} = Y_A \amalg_{X_A} X_T, \qquad u_{A,T} : R_{A,T} \longrightarrow Y_T.$$

We claim that $u_{A,T}$ is a pushout of $u_{H,B}$. Indeed,

$$\begin{aligned} R_{A,T} &\simeq Y_A \amalg_{X_H} X_B \\ &\simeq Y_A \amalg_{Y_H} (Y_H \amalg_{X_H} X_B) = Y_A \amalg_{Y_H} R_{H,B}. \end{aligned}$$

Pushing out $R_{H,B} \to Y_B$ consequently gives

$$R_{A,T} \amalg_{R_{H,B}} Y_B \simeq Y_A \amalg_{Y_H} Y_B \simeq Y_T.$$

These canonical isomorphisms identify the induced comparison map with $u_{A,T}$, proving the claim. If $u_{H,B} \in C$, or in TC, its pushout belongs to the same class. No cofibrancy assumption on X or Y appears in the proof.

For the application in the text, take $A = I'$, $B = I_0$ and $H = I'_0$. Local finiteness ensures that $B = I/s$ is finite; hence the relative problem on $H \subset B$ can be solved by a finite induction before the transfinite assembly of the large index set is attempted. This is the precise role of local finiteness in Proposition 2. It does not imply that the full index set is finite, and here it means that every principal lower ideal is finite, not merely that every interval $[i, j]$ is finite.

The reduction also explains why the square is a cover by opens. For arbitrary subposets A, B, there can be arrows with one endpoint in each complement. Compatible cocones on the two pieces would then fail to include the conditions imposed by those arrows, and their pushout would not compute X_T.

Il faut des notations générales, d'une part pour une inclusion $J \subset K$ d'ouverts de I, donnant lieu au diagramme

(1)
$$\begin{array}{ccc} X_J & \xrightarrow{\tau^X_{J,K}} & X_K \\ {\scriptstyle u_J}\downarrow & \text{cocart} & \downarrow{\scriptstyle \tilde{u}_{J,K}} \\ Y_J & \longrightarrow & Y_{J,K} \\ & {\scriptstyle \tau^Y_{J,K}}\searrow & \downarrow{\scriptstyle u_{J,K}} \\ & & Y_K \end{array} \qquad \begin{array}{l} \\ \\ {\scriptstyle u_K}\ \text{(anciennement } \tilde{Y}_K\text{)} \\ \\ \\ , \end{array}$$

et pour des inclusions de trois ouverts emboîtés $J \subset K \subset L$ de I,

p. 9

(2)
$$\begin{array}{ccccc} X_J & \longrightarrow & X_K & \longrightarrow & X_L \\ {\scriptstyle u_J}\downarrow & \text{cocart} & \downarrow{\scriptstyle \tilde{u}_{J,K}} & \text{cocart} & \downarrow{\scriptstyle \tilde{u}_{J,L}} \\ Y_J & \longrightarrow & Y_{J,K} & \longrightarrow & Y_{J,L} \\ & & {\scriptstyle u_{J,K}}\downarrow & \text{cocart} & \downarrow{\scriptstyle u^L_{J,K}} \\ & & Y_K & \longrightarrow & Y_{K,L} \\ & & & & {\scriptstyle u_{K,L}}\downarrow \\ & & & & Y_L \end{array} \qquad \begin{array}{l} \\ \\ {\scriptstyle \tilde{u}_{K,L}} \\ \\ {\scriptstyle u_{J,L}} \\ \\ , \end{array}$$

donnant lieu à une nouvelle flèche $u^L_{J,K}$, déduite de $u_{J,K}$ par le cochangement de base $Y_{J,K} \longrightarrow Y_{J,L}$. Nous utiliserons ce diagramme dans les deux cas où $(J \subset K \subset L)$ est l'un des deux triplets [page 15]

$$\begin{cases} I'_0 \hookrightarrow I_0 \hookrightarrow I \\ I'_0 \hookrightarrow I' \hookrightarrow I, \end{cases}$$

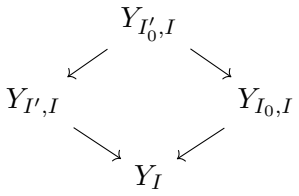
issus du carré cocartésien (dans Cat) (carré MV)

(3)
$$\begin{array}{ccc} I'_0 & \hookrightarrow & I_0 \\ \downarrow & & \downarrow \\ I' & \hookrightarrow & I\ . \end{array}$$

Il faut insérer les deux diagrammes correspondants du type (∗) [de la page 10] dans un même diagramme. On notera à ce propos que les carrés dans $\mathcal{M}$ déduits de (3) en lui appliquant $J \longmapsto X_J$ et $J \longmapsto Y_J$

(4_X) (4_Y)
$$\left.\begin{array}{ccccc} X_{I'_0} & \longrightarrow & X_{I_0} & & \\ \downarrow{\scriptstyle u_{I'_0}} & \searrow & \downarrow & \searrow & \\ X_{I'} & & X_{I'} & \longrightarrow & X_I \\ \downarrow & & \downarrow & & \downarrow{\scriptstyle u_I} \\ Y_{I'_0} & \longrightarrow & Y_{I_0} & \searrow & \\ \downarrow & \searrow & \downarrow & & \\ Y_{I'} & & Y_{I'} & \longrightarrow & Y_I \end{array}\right\} (4)$$

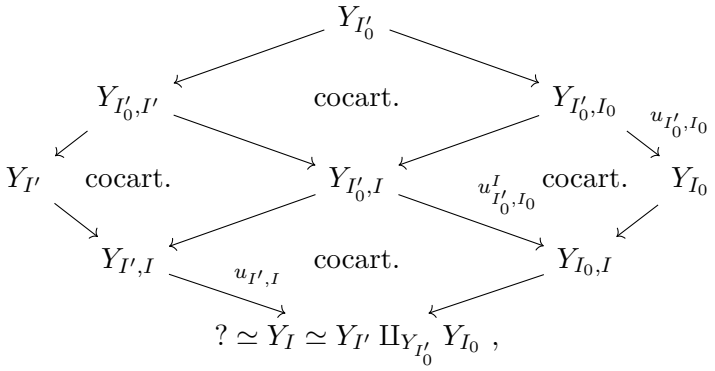
sont cocartésien dans $\mathcal{M}$. (Transitivité des $\varinjlim$ …).



On a un homomorphisme $(u_{I'_0}, u_{I_0}, u_{I'}, u_I)$ déduit de u du carré (4_X) dans les carré (4_Y), [page 16] et cet homomorphisme lui aussi s'insère dans un diagramme, incluant les deux avatars déjà signalé de (2). Voici le diagramme pertinent : p. 10

(5 [9])
$$\begin{array}{ccccc} & & X_{I_0} & \longrightarrow & X_I \\ & \nearrow & \downarrow & \nearrow & \downarrow \\ X_{I'_0} & \longrightarrow & X_{I'} & & \\ \downarrow & & \downarrow & & \\ & & Y_{I'_0,I_0} & \longrightarrow & Y_{I'_0,I} \\ & \nearrow & \downarrow & \nearrow & \downarrow{\scriptstyle u^I_{I'_0,I_0}} \\ Y_{I'_0} & \xrightarrow{u_{I'_0,I_0}} & Y_{I'_0,I'} & & \\ \downarrow & \searrow & \downarrow & & \\ & & Y_{I_0} & \longrightarrow & Y_{I_0,I} \\ & & & \searrow & \downarrow{\scriptstyle u_{I_0,I}} \\ & & & & Y_{I'I} \\ & & \downarrow & \searrow & \downarrow{\scriptstyle u_{I',I}} \\ & & Y_{I'} & & Y_I\ . \end{array}$$

Le cube supérieur est le cube dans $\mathcal{M}$ à 6 faces cocartésiens déduit des trois flèches de $X_{I'_0}$ dans X_{I_0}, $X_{I'}$, $Y_{I'_0}$. On aura besoin de savoir que la *base* du cube est un carré cocartésien. La partie antérieure du diagramme est l'avatar de (2) correspondant aux inclusions $I'_0 \subset I' \subset I$, la partie derrière l'avatar pour l'inclusion $I'_0 \subset I_0 \subset I$. Donc les deux autres carrés verticaux, en dessous du cube supérieur, sont également cocartésiens, ainsi que le carré oblique en pointillés, lequel n'est autre que la base (4_Y) du diagramme (4). De ces caractères du diagramme (5) résulte aisément (quoique j'ai mis une bonne journée de gribouillis en bonheur-la-chance, [page 17]



9. diagramme imbitable, à remplacer par diagramme (6) ci-dessus.

avant de m'en rendre compte enfin …) que le carré en losange à traits pleins

est également cocartésien. On le voit trivialement sur le diagramme déployé p. 11

(6)

qui est finalement le diagramme pertinent (le diagramme (5) ne servait à rien, c'est un mauvais bout par lequel j'ai pris les choses). On voit sur le diagramme (6) que pour prouver $u_{I',I} \in C$ resp. TC, il suffit de prouver $u_{I'_0,I_0} \in C$ resp. TC. Mais c'est là une assertion relative à l'inclusion d'ensembles ordonnés $I'_0 \subset I_0$ *finis.* On est donc réduit à prouver le lemme suivant, où I_0 devient I : [page 18]

Lemme. *Soit I un ensemble ordonné fini, $u_\bullet : X_\bullet \longrightarrow Y_\bullet$ une flèche dans $\mathcal{M}(I^\circ)$, où $\mathcal{M}$ est une catégorie munie d'un ensemble $C \subset \mathrm{Fl}(\mathcal{M})$ de flèches tel que C soit stable par cochangement de base et par composition, et contienne les isomorphismes. On suppose $u_\bullet \in C_I$, i.e. que pour tout $i \in I$, la flèche $u_{I_{<i},I/i}$ est dans C. Alors pour toute partie ouverte I' de I, la flèche $u_{I',I}$ est dans C* [10].

Commentary · Exposition [ms. 18]

The diamond follows from compatible cocones

The long cube is intended to prove one fact: the relative attachment across $I' \subset I$ is inherited from the smaller attachment across $I'_0 \subset I_0$. The preceding excision identity proves it directly. We can also verify the diamond on its own terms, which explains why Grothendieck's second diagram succeeds where the first obscures the calculation.

Continue with $H = A \cap B$, $T = A \cup B$, and write

$$R_{H,T} = Y_H \amalg_{X_H} X_T, \quad R_{A,T} = Y_A \amalg_{X_A} X_T, \quad R_{B,T} = Y_B \amalg_{X_B} X_T.$$

Consider compatible maps $R_{A,T} \to Q$ and $R_{B,T} \to Q$ which agree on $R_{H,T}$. They determine maps $a : Y_A \to Q$ and $b : Y_B \to Q$ agreeing on Y_H, together with one common map $x : X_T \to Q$. The defining pushout conditions say that $x|_{X_A} = a\,u_A$ and $x|_{X_B} = b\,u_B$. Because $X_T = X_A \amalg_{X_H} X_B$, these conditions uniquely determine x from a, b. There is therefore no extra datum beyond the compatible pair a, b. Such pairs are precisely maps $Y_T = Y_A \amalg_{Y_H} Y_B \to Q$. Naturality in Q proves

$$R_{A,T} \amalg_{R_{H,T}} R_{B,T} \simeq Y_T.$$

This is the lower diamond of diagram (6).

10. **N.B.** Bien sûr, $u_{J,K} \in C$ si $J \subset K$ sont deux ouverts de I, comme on voit en appliquant le lemme à K au lieu de I.

The same calculation explains transitivity for three nested lower ideals $J \subset K \subset L$. The map $u_{J,L}$ factors through $R_{K,L}$, and the first factor

$$R_{J,L} \longrightarrow R_{K,L}$$

is the pushout of $u_{J,K} : R_{J,K} \to Y_K$ along the canonical map $R_{J,K} \to R_{J,L}$. Thus relative maps belonging to C compose after one pushout. This is exactly the operation needed when one adds finitely many elements or finitely many principal opens.

Everything here is an identity of ordinary pushouts. The commentary on earlier chapters discussed homotopy pushouts and failures of converse excision; the present calculation requires none of those stronger hypotheses. In particular, the proof does not infer an unknown face of an arbitrary cube from a collection of homotopy-cartesian or homotopy-cocartesian faces. It identifies all the relevant objects by their actual universal properties. For continuity with the earlier commentary, compare the discussion of the cube principle in the commentary on Chapter XII, manuscript pages 78–79; the issue there is different because the asserted faces are homotopical rather than specified ordinary colimits.

Corollaire. *Si de plus* $W \subset \mathrm{Fl}(\mathcal{M})$ *est un localiseur modérément saturé, tel que* $TC \overset{\text{déf}}{=} W \cap C$ *soit stable par cochangement de base (et l'est de toutes façons par composition, et contient les isomorphismes), alors on a*

$$C_I \cap W_{I^\circ} \;=\; (TC)_I,$$

donc si $u_\bullet \in C_I$ *(cf. ci-dessus) et les* $u_i \in W$*, alors* $u_\bullet \in (TC)_I$*, donc en appliquant ce qui est dit pour* C *à* TC*, on a* $u_{I',I} \in TC$ *pour toute partie ouverte* I' *de* I*.* [page 19]

Commentary · Exposition [ms. 18]

A finite induction with the last attachment exposed

The finite lemma supplies the local input for the transfinite construction. It is useful to write its induction so that the exceptional terminal-object case is unavoidable: this is the case in which the latching condition itself must be used, rather than another induction hypothesis.

Fix a finite poset I and a lower ideal K. Enumerate $I \setminus K$ by repeatedly selecting an element minimal among those remaining, and adjoin these elements one at a time. Every intermediate subset is a lower ideal. The transitivity calculation above reduces the problem to $I = K \cup \{i\}$, with all predecessors of i in K. Let $B = I/i$ and $H = B \cap K = I_{<i}$. Excision identifies $u_{K,I}$ as a pushout of $u_{H,B}$.

If $B \neq I$, the ambient poset B has smaller cardinality, so the induction hypothesis applies. If $B = I$, the element i is terminal and $K = I_{<i}$; the map $u_{K,I}$ is exactly $\rho_i(u)$. This proves the assertion for C. The printed condition on manuscript page 19 is $I'_0 \neq I$, but I'_0 excludes i_0 and always differs from I. The condition needed in this dichotomy is $I_0 \neq I$. The following sentence, "Sinon, i_0 est un objet final", confirms that reading.

For the assertion involving W, assume in addition that every component of u is in W. In the terminal case, the induction hypothesis puts u_K in TC. Hence its pushout $X_i \to X_i \amalg_{L_iX} L_iY$ lies in TC. The composite with $\rho_i(u)$ is $u_i \in W$, and two-out-of-three gives $\rho_i(u) \in W$. Together with the already established membership in C, this yields $\rho_i(u) \in TC$. The smaller-poset case and the successive attachments use only pushouts and ordinary composition in TC.

At cardinality zero every comparison is an identity of the initial object, so both inductions have the stated base case. Conversely, if all relative latching maps lie in TC, apply the proved lemma with TC replacing C and $K = \varnothing$; this gives the colimit map in TC. Restriction to each principal ideal gives every component in TC. We have therefore proved the full equality

$$C_I \cap W_{I^\circ} = (TC)_I$$

for finite I, including both implications and all relative maps $u_{K,I}$. Only finite colimits and ordinary composition have been used. The later appeal to transfinite closure is needed to assemble infinitely many such finite pieces; it is not hidden inside the finite lemma.

On prouvera en même temps le lemme et son corollaire, en procédant par récurrence sur $\operatorname{card} I = n$. Si $n = 0$, i.e. $I = \emptyset$, les énoncés sont triviaux. Par transitivité, en utilisant les diagrammes du type (2), on est ramené au cas où $I = I' \cup \{i_0\}$, où $i_0 \in I \backslash I'$. On pose encore $I_0 = I/i_0$, $I'_0 = I_0 \cap I'$, et le raisonnement qu'on vient de faire nous montre qu'il suffit de prouver que $u_{I'_0,I_0} \in C$ resp. $\in TC$. Si $I'_0 \neq I$, cela résulte de l'hypothèse de récurrence. Sinon, i_0 est un objet final de I, et $I' = I_{<i_0}$, et alors $u_{I',I} \in C$ est inclus dans la définition de C_I. Reste à prouver alors que $u_{I',I} \in TC$ si les $u_i \in W$. On a le diagramme p. 12

$$\begin{array}{ccc} X_{I'} & \longrightarrow & X_I \\ {\scriptstyle u_{I'}}\downarrow & \text{cocart.} & \downarrow{\scriptstyle \tilde{u}_{I',I}} \\ Y_{I'} & \longrightarrow & Y_{I',I} \\ & & {\scriptstyle u_{I',I}}\downarrow \\ & & Y_I \end{array} \qquad u_I$$

et l'hypothèse de récurrence implique $u_{I'} \in TC$, donc $\tilde{u}_{I',I} \in TC$ par cochangement de base. [page 20] D'autre part, la flèche $u_I : X_I \longrightarrow Y_I$ s'identifie à $X_{i_0} \longrightarrow Y_{i_0}$ (i_0 étant élément final de I), elle est donc dans W. Donc par saturation, $u_{I',I} \in W$, donc $u_{I',I} \in TC$, q.e.d.

Ainsi, la proposition 2 est prouvée, ainsi que son corollaire 1 – et on voit que si dans la proposition 2 et son corollaire, on suppose I *fini,* alors il est inutile dans les hypothèses pour C, resp. $TC = C \cap W$, de supposer la stabilité par composition *transfinie,* la composition ordinaire suffit. Mais il reste à prouver le corollaire 2, que je viens de prouver dans le cas I *fini,* sans avoir à faire appel à une hypothèse "transfinie". Il faut maintenant prouver que c'est encore OK dans le cas localement fini, en supposant C stable par composition transfinie. (Il n'y a plus à revenir sur le cas de W, car on sait déjà maintenant que $C_I \cap W_{I^\circ} = (TC)_I$, par le corollaire 1 déjà prouvé.)

La démonstration est essentiellement la même que pour le cas particulier déjà traité $I' = \emptyset$, [page 21] $I'' = I$, et on aurait pu aussi bien rédiger la démonstration dans ce cadre, à l'aide d'une suite strictement croissante transfinie d'ouverts dans I, I_α, avec $\boxed{I_0 = I',}$ $I_{\alpha_0} = I''$ $(= I)$, et

$$\begin{array}{lll} I_\alpha & = & I_{\alpha-1} \cup I/s_{\alpha-1} \quad \text{si } \alpha \text{ non limite, } I_{\alpha-1} \neq I, \text{ en choisissant } s_{\alpha-1} \in I \backslash I_{\alpha-1}, \\ I_\alpha & = & \bigcup_{\beta<\alpha} I_\beta \qquad\qquad \text{si } \alpha \text{ limite,} \end{array}$$

et en posant encore

$$X_\alpha = X_{I_\alpha}, \qquad Y_\alpha = Y_{I_\alpha}, \qquad u_\alpha = u_{I_\alpha} : X_\alpha \longrightarrow Y_\alpha.$$

Soit α_0 tel que $I_{\alpha_0} = I$ (indice terminal de la suite), il faut prouver que dans

$$\begin{array}{ccc} X_0 & \longrightarrow & X_{\alpha_0} \\ \downarrow & & \downarrow \\ Y_0 & \longrightarrow & Y_{0,\alpha_0} \\ & & {\scriptstyle u_{0,\alpha_0}}\downarrow \\ & & Y_{\alpha_0} \end{array}$$

on a p. 13

$$u_{0,\alpha_0} \in C. \qquad \text{[page 22]}$$

Commentary · Examples [ms. 20]

A fork whose ordinary colimit loses a circle

The colimit theorem is meant to control the identifications made when diagrams are glued. A small example shows why its latching condition cannot be replaced by objectwise information. Work in simplicial sets, with monomorphisms as cofibrations and weak homotopy equivalences as weak equivalences, and let I have the two arrows $a \leftarrow s \rightarrow b$.

Define diagrams X, Y by

$$X_s = \partial\Delta^1, \qquad X_a = X_b = \Delta^1, \qquad Y_s = \partial\Delta^1, \qquad Y_a = Y_b = \Delta^0.$$

The two structure maps of X are the boundary inclusions. Those of Y collapse the two vertices to a point. Let u_s be the identity and let u_a, u_b be the collapse maps $\Delta^1 \to \Delta^0$. Each component of u is a weak equivalence: the first is an isomorphism and the other two identify contractible realizations. The diagram X is cofibrant, since its latching maps are $\varnothing \to \partial\Delta^1$ and the two inclusions $\partial\Delta^1 \hookrightarrow \Delta^1$. The diagram Y fails the condition at both outer vertices.

The two ordinary colimits are

$$X_I = \Delta^1 \amalg_{\partial\Delta^1} \Delta^1, \qquad Y_I = \Delta^0 \amalg_{\partial\Delta^1} \Delta^0 = \Delta^0.$$

The first simplicial set has two vertices and two nondegenerate edges, with the same endpoints, and no nondegenerate simplices of higher dimension. Its realization is a circle. One can see the obstruction directly in the normalized chain complex:

$$C_1 = \mathbb{Z}e_a \oplus \mathbb{Z}e_b, \quad C_0 = \mathbb{Z}v_0 \oplus \mathbb{Z}v_1, \quad \partial e_a = \partial e_b = v_1 - v_0.$$

Thus $H_1(X_I) = \mathbb{Z}(e_a - e_b)$, whereas $H_1(Y_I) = 0$. The colimit of u is not a weak equivalence.

Its relative latching maps identify the defect exactly. At a and b they are

$$\Delta^1 \amalg_{\partial\Delta^1} \partial\Delta^1 = \Delta^1 \longrightarrow \Delta^0,$$

which are not monomorphisms. Consequently $u \notin C_I$, and the corollary makes no false prediction. This example is also a warning about the future derived colimit: replacing the two collapse maps in Y by the two boundary inclusions produces the cofibrant diagram X with its comparison to Y. The homotopical information is carried by the manner in which the common boundary is attached, even though every individual value has already been compared by a weak equivalence.

Compte tenu du complément marginal à la proposition 1 (qui se prouve de la même façon …), on est ramené à prouver que l'homomorphisme des systèmes ordinaux envisagés est dans $C_{I_{\alpha_0+1}}$ (où I_{α_0+1} est l'ensemble des ordinaux $\leq \alpha_0$). Or qu'il en soit ainsi se prouve exactement comme tantôt, à cela près qu'on doit d'abord faire une vérification de $(*)$ p. 1 ($\tilde{u}_\bullet \in C$) pour $i_0 = 0$. Alors le diagramme $(*)$ p. 1 est

$$\begin{array}{ccc} \emptyset & \longrightarrow & X_0 = X_{I'} \\ \downarrow{\scriptstyle \text{iso}} & & {\scriptstyle \text{iso}}\downarrow{\scriptstyle \text{id}} \\ \emptyset & \longrightarrow & X_0 = X_{I'} \\ & & \downarrow{\scriptstyle u_0 = u_{I'}} \\ & & Y_0 = Y_{I'} \ , \end{array}$$

et il faut donc vérifier $u_0 = u_{I'} \in C$. Or ceci est contenu dans la proposition 2 elle-même, déjà prouvé, qu'on doit donc utiliser. Le reste se prouve comme avant. Ainsi, le corollaire 2 de la proposition 2 est également prouvé.

Commentary · Exposition [ms. 22]

Starting a filtration at an arbitrary open subset

Grothendieck returns to Corollary 2 because the relative statement is the one needed for later Kan extensions. The proof with $I_0 = I'$ can be made completely independent of the behavior of the

map over I' itself. This also supplies the general gluing step that is abbreviated in the lemma on manuscript page 24.

Let $(A_\beta)_{\beta\le\lambda}$ be a continuous increasing chain of lower ideals, with $A_0 = K$ and $A_\lambda = J$. Assume that every relative map $u_{A_\beta,A_{\beta+1}}$ belongs to C. Fix the final X_J and form

$$P_\beta = X_J \amalg_{X_{A_\beta}} Y_{A_\beta}.$$

The initial object of this chain is the domain of $u_{K,J}$ and its final object is Y_J. At a successor stage, the map $P_\beta \to P_{\beta+1}$ is the pushout of $u_{A_\beta,A_{\beta+1}}$ by transitivity of pushouts. At a limit stage it is the colimit of the preceding stages, by the same cocone calculation as in the ordinal proof. It follows that $u_{K,J} \in C$. This relative filtration does not require $u_K \in C$. The source's check at index zero is valid, but belongs to its chosen reduction to the absolute Proposition 1.

For later use, suppose now that J is any small poset and that, for every $j \in J$ and every lower ideal $H \subset J/j$, one knows $u_{H,J/j} \in C$. Choose a well-order of the elements of $J \setminus K$. Starting at K, adjoin the principal lower ideals of these elements in that order, taking unions at limit stages. Repetitions do no harm. If the current ideal is A and the next principal ideal is $B = J/j$, the successor relative map is a pushout of $u_{A\cap B,B}$, by excision. It therefore belongs to C, and the preceding filtration proves $u_{K,J} \in C$.

This argument uses no well-foundedness of the order on J: the stronger hypothesis over every open subset of every principal ideal replaces it. In the locally finite case these local comparisons were supplied by the finite lemma. On manuscript page 24 they are supplied by the definition of the set P. The same construction is the main mechanism behind Theorem 2.1(1), so the preliminary proof is best read as anticipating that theorem's organization.

Commentaires : Il y a un malaise, car les proposition 1 et proposition 2 (ainsi que leurs corollaires) ont essentiellement la même conclusion, avec des hypothèses sur I qui sont différentes : bien ordonné dans un cas, localement fini dans un autre. L'idée naturelle, c'est de donner un énoncé commun, qui coiffe les deux à la fois, avec I artinien, i.e. toute suite décroissante est stationnaire. Ce qu'il faut, c'est une hypothèse sur I d'une part, sur $u_\bullet : X_\bullet \longrightarrow Y_\bullet$ dans $\mathcal{M}(I^\circ)$ d'autre part, qui assure ceci : [page 23]

(∗) $\forall\, i_0 \in I$, et toute partie ouverte J' de $J = I/i_0$, la flèche $u_{J',J}$ dans le diagramme

$$\begin{array}{ccc} X_{J'} & \longrightarrow & X_J \\ {\scriptstyle u_{J'}}\downarrow & \text{cocart} & \downarrow{\scriptstyle \tilde{u}_{J',J}} \\ Y_{J'} & \longrightarrow & Y_{J',J} \\ & & {\scriptstyle u_{J',J}}\downarrow \\ & & Y_J \end{array} \qquad u_J$$

est dans C.

Question : est-il exacte qu'il suffit, pour la validité de (∗), de supposer

a) $u_\bullet \in C_I$, i.e. $u_{J',J} \in C$ quand $J = I/i_0$, $J' = J\setminus\{i_0\}$, et

b) *I localement fini ?*

Commentary · Exposition [ms. 23] p. 14 [page 24]

The artinian induction and the wording of the question

The two successful constructions suggest a common hypothesis: attachments should have no indefinitely descending dependence. For a poset this is well-foundedness. In the usual set-theoretic setting with choice, it is equivalent to the manuscript's artinian condition that every descending sequence eventually stabilizes. An ordinal is well founded, and a poset with finite principal lower ideals is well founded, so this hypothesis includes both of the cases already treated.

One can construct a compatible ordinal filtration directly. Define the rank recursively by

$$r(i) = \sup_{j<i}\big(r(j)+1\big).$$

Choose a well-order within each rank and concatenate the ranks. Every predecessor of an element then occurs earlier. For a specified lower ideal $K \subset J$, apply this construction to $J \setminus K$ and place K first. Adding one element at a time gives lower ideals A_β with $A_0 = K$ and union J. When $A_{\beta+1} = A_\beta \cup \{i\}$, all strict predecessors of i lie in A_β. Excision identifies the successor relative map with a pushout of $\rho_i(u)$. The relative filtration therefore proves $u_{K,J} \in C$ for every $K \subset J$. This is a complete proof of the proposed common generalization.

The literal question on manuscript page 23 asks whether the original latching condition together with local finiteness suffices. It does, and that case has just been proved in Corollary 2. The surrounding discussion, and the immediately following artinian corollary, show that the useful new question is whether local finiteness can be weakened to the artinian condition. We record both the printed wording and its mathematical context, without silently changing the word in the source.

The lemma on manuscript page 24 can also be completed in its stated generality. Suppose every $i < i_0$ belongs to P, set $J = I/i_0$ and $J' = J \setminus \{i_0\}$, and take a lower ideal $K \subset J$. If $K = J$ the relative map is an isomorphism. Otherwise $K \subset J'$. For every $j \in J'$, the assumption $j \in P$ supplies all the local relative comparisons over I/j. The principal-open gluing argument of the preceding block therefore gives $u_{K,J'} \in C$, even if J' is infinite or not well founded. The map $u_{J',J} = \rho_{i_0}(u)$ is in C by hypothesis, so transitivity gives $u_{K,J} \in C$.

Thus P is progressive. Well-founded induction gives $P = I$. The displayed progressive condition in the proof must use $I_{<i_0} \subset P$, not $I/i_0 \subset P$, since the latter already contains i_0 and is tautological. Likewise the element chosen below $x_0 \notin P$ must be $x_1 \notin P$. These printed slips and the repeated case $K = J$ are recorded in the correction register. The missing gluing paragraph is a proof omission repaired by the argument above; the artinian conclusion itself is valid.

Lemme. *Soit $P \subset I$ l'ensemble des $i_0 \in I$ tels que pour tout ouvert K de $J = I/i_0$, la flèche $u_{K,J}$ est dans C. Ceci dit, soit $i_0 \in I$ tel que tout $i < i_0$ soit dans P. Alors $i_0 \in P$.* (On suppose $u_\bullet \in C_I$, mais I quelconque.)

En effet, soit $K \subset J = I/i_0$ un ouvert. Si $K = J$, il est trivial que $u_{K,J} \in C$ (c'est un isomorphisme). Si $K = J$, on a

$$K \ \subset \ J' \overset{\text{déf}}{=} J\backslash\{i_0\} \ \subset \ J,$$

et pour prouver que $u_{K,J} \in C$, il suffit de prouver que $u_{K,J'}, u_{J',J} \in C$. Or $u_{J',J} \in C$ par hypothèse $u_\bullet \in C_I$. Et $u_{K,J'} \in C$ par ce que a été prouvé pour le cas de J', compte tenu que par hypothèse sur i_0, tout $i \in J'$ (i.e. tout $i < i_0$) est dans P.

Corollaire. *Si I est artinien, $P = I$.*

Car toute partie P de I ayant la propriété qu'on vient de dire ($I/i_0 \subset P \Longrightarrow i_0 \in P$) est égale à I. Si en effet il y avait $x_0 \notin P$, il existerait $x_1 < x_0$ avec $x_0 \notin P$, et par récurrence on construirait une suite strictement décroissante dans I, absurde.

[page 25]

Commentary · Development (commentators') [ms. 24]

Well-foundedness detected by maps of set diagrams

Grothendieck's artinian hypothesis is more than a convenient way to arrange the induction. One can characterize it by the validity of the latching test, using only diagrams of sets. The following formulation makes the obstruction independent of any model category. We checked the cellular descriptions in Riehl and Verity (2014, Proposition 6.3 and Corollary 6.8), the ordinal degree formulation in Shulman (2015, Section 4), and the relative-colimit theorem of Rădulescu-Banu (2009, Section 9.4). We did not find this universal converse in those inspected passages. We give our formulation and proof, without a claim of priority.

Recognition by the latching test. [ours] Work with ordinary choice, and let I be a small poset. The following conditions are equivalent: I is well founded; every map of set-valued I-diagrams whose relative latching maps are injective has all its component maps injective; every such map has an injective map on colimits.

Proof. If I is well founded, the preceding relative filtration applies with C the injections in Set. Pushouts of injections are injections: in the disjoint-union description of a pushout, the imposed equivalence relation cannot identify two different elements on the opposite side, because an element in the subobject has at most one representative there. Continuous transfinite composites of injections

are injections, since equality of two representatives in the colimit is witnessed at a common later stage. The filtration consequently proves the colimit assertion, and restriction to I/i proves the component assertion.

Conversely, suppose I is not well founded. By dependent choice there is a strictly descending chain

$$i_0 > i_1 > i_2 > \cdots .$$

Let U be its upward closure:

$$U = \{j \in I \mid i_n \leq j \text{ for some } n\}.$$

For a set A, define a diagram $E(A)$ by $E(A)_j = A$ when $j \in U$ and $E(A)_j = \varnothing$ otherwise. All arrows within U act by the identity of A; all other arrows have empty source. This is a functor because U is upward closed.

For $j \in U$, the poset $U \cap I_{<j}$ is nonempty and connected. To prove both assertions, choose n with $i_n \leq j$; then $i_{n+1} < j$ belongs to it. Given any two of its objects a, b, choose n_a, n_b with $i_{n_a} \leq a$ and $i_{n_b} \leq b$. For $m > \max(n_a, n_b)$, the element i_m lies below both a, b and still lies strictly below j. This supplies the zigzag $a \leftarrow i_m \rightarrow b$. A constant diagram with identity transition maps over a nonempty connected category has colimit A: its cocones are precisely one map $A \rightarrow Q$. The empty values outside U impose no further condition. Therefore

$$L_j E(A) = A \quad (j \in U), \qquad L_j E(A) = \varnothing \quad (j \notin U),$$

and the latching map is an identity in both cases.

Choose the noninjective map $q : \{0, 1\} \rightarrow \{*\}$ and let $u = E(q)$. At $j \in U$ its relative latching map is

$$\{0, 1\} \amalg_{\{0,1\}} \{*\} \xrightarrow{\mathrm{id}} \{*\},$$

an isomorphism; outside U it is $\mathrm{id}_\varnothing$. Nevertheless $u_j = q$ at every $j \in U$, so the component condition fails. The same common-lower-bound argument shows that U itself is nonempty and connected. Hence $\operatorname{colim}_I E(A) = A$, and the colimit of u is again q, so the colimit condition fails as well. This proves the equivalence. □

The obstruction is especially sharp: every relative latching map in the counterexample is an isomorphism. An endless predecessor chain can make the local condition see no new attachment anywhere, although a nontrivial map is present throughout the chain. This is exactly the failure that a well-founded order excludes. The counterexample on manuscript pages 37–38 exhibits a particular instance; the recognition statement explains why the phenomenon occurs for every non-well-founded poset, after extending the descending-chain example by empty values outside its upward closure.

2 Description de $C_I \subset \mathrm{Fl}(\mathcal{M}(I^\circ))$, pour I ensemble ordonné

Soit $\mathcal{M}$ une catégorie, stable par (petites) $\varinjlim$, $C \subset \mathrm{Fl}(\mathcal{M})$ (“cofibrations”). On suppose

(2.1)
$$\begin{cases} \text{a)} \quad C & \text{contient les isomorphismes et est stable} \\ & \text{par cochangement de base.} \\ \text{b)} \quad C & \text{stable par composition transfinie.} \end{cases}$$

Soit I un (petit) ensemble ordonné, et considérons

$$\mathcal{M}(I^\circ) \;=\; \underline{\mathrm{Hom}}(I, \mathcal{M}),$$

on va définir une partie

$$C_I \;\subset\; \mathrm{Fl}(\mathcal{M}(I^\circ))$$

ainsi, pour $u_\bullet : X_\bullet \longrightarrow Y_\bullet$ flèche dans $\mathcal{M}(I^\circ)$:

(2.2)
$$u_\bullet \in C_I \quad \Longleftrightarrow \quad \begin{array}{l} \forall\, i_0 \in I \text{ et pour tout ouvert } J \subset I/i_0 = K, \\ \text{la flèche } u_{J,K} \text{ est dans } C. \end{array}$$

Commentary · Exposition [ms. 25]

A local definition that already sees every open part

Grothendieck restarts the discussion because he wants the useful conclusion of the preliminary arguments to become the definition. The change is substantial. In §1, one tested the single boundary $I_{<i} \subset I/i$ at each object. In §2, one tests every lower open $K \subset I/i$. We shall call these respectively the latching condition and the strong open condition, solely to distinguish the two definitions during this transition. The notation C_I is reused in the source; the meanings agree under the artinian hypothesis, but they must not be identified before that hypothesis has been used.

We write $\downarrow i = \{j \mid j \leq i\}$ and $X_K = \operatorname{colim}_{k\in K} X_k$. Here an open means a lower set, and $\mathcal{M}(I^\circ)$ means the category of covariant diagrams $I \to \mathcal{M}$. For a natural transformation $f : X \to Y$, put

$$Q_f(K,J) = X_J \amalg_{X_K} Y_K, \qquad d_f(K,J) : Q_f(K,J) \longrightarrow Y_J \quad (K \subset J).$$

Thus $Q_f(K,J)$ is Grothendieck's $Y_{K,J}$ and $d_f(K,J)$ is his $u_{K,J}$. The object $Q_f(K,J)$ contains the whole source diagram over J, together with the part of the target already installed over K. The comparison $d_f(K,J)$ attaches the remaining target data. This interpretation explains why its membership in C is the correct relative condition.

Three immediate specializations should be kept available. For $K = \varnothing$ the comparison is $X_J \to Y_J$. For $K = J$ it is an isomorphism. For $J = \downarrow i$ and $K = I_{<i}$ it becomes

$$X_i \amalg_{L_iX} L_iY \longrightarrow Y_i, \qquad L_iX = \operatorname{colim}_{j<i} X_j.$$

This is the relative latching map. On an artinian poset it supplies all the strong open tests; on a general poset it need not even imply that the individual f_i belong to C. The reverse infinite chain on page 38 will isolate precisely this failure.

Theorem 2.1(1) is stronger in a different direction: the strong open tests imply $d_f(K,J) \in C$ for arbitrary lower opens $K \subset J$, without any artinian hypothesis. Its proof is an ordinary cellular argument with principal lower opens as the pieces. All colimits in this assertion are ordinary colimits in $\mathcal{M}$. Neither a homotopy colimit nor a model structure has yet been used.

Voici la définition de $u_{J,K}$. Pour tout ouvert J de I, on pose

$$(2.3) \qquad \begin{cases} X_J = \varinjlim_{i\in J} X_i, & Y_J = \varinjlim_{i\in J} Y_i, \\ u_J : X_J \longrightarrow Y_J, & u_J = \varinjlim_{i\in J} u_i, \end{cases}$$

et on considère, pour $K \subset J$, le diagramme

p. 15
[page 26]

$$\begin{array}{ccccc} X_K & \xrightarrow{\tau^X_{K,J}} & X_J & & \\ {\scriptstyle u_K}\downarrow & \text{cocart} & \downarrow{\scriptstyle u_{K,J}} & \searrow & \\ Y_K & \xrightarrow{\tau^Y_{K,J}} & Y_{K,J} & \xrightarrow{u} & Y_K \amalg_{X_K} X_J \\ & & {\scriptstyle u_{K,J}}\downarrow & \swarrow & \\ & & Y_J\ . & & \end{array}$$

Théorème 2.1. *Soit $\mathcal{M}$ $\mathfrak{U}$-catégorie stable par petites $\varinjlim$, $C \subset \mathrm{Fl}(\mathcal{M})$, satisfaisant les conditions de stabilité* (2.1) *(par cochangement de base et par composition transfinie), I un petit ensemble ordonné, $u_\bullet : X_\bullet \longrightarrow Y_\bullet$ une flèche dans $\mathcal{M}(I^\circ)$.*

1°) *On suppose $u_\bullet \in C_I$ (cf.* (2.2)*). Soient $K \subset J$ deux ouverts de I. Alors $u_{K,J}$ (défini dans* (2.4)*) est dans C.*

2°) *Supposons I artinien. Pour qu'on ait $u_\bullet \in C_I$, i.e. pour que $u_{K,J}$ soit dans C pour tout couple $(K \subset J)$ d'ouverts tel que J ait un plus grand élément, i.e. soit de la forme I/i_0 (i.e. aussi, par 1°), pour* tout *couple d'ouverts $J \subset K$), (il faut et) il suffit qu'il en soit ainsi dans le cas particulier où $J = I/i_0$, $J' = I'/i_0 \overset{déf}{=} I/i_0 - \{i_0\} = \{i \in I \mid i < i_0\}$.* [page 27]

3°) *Supposons encore I artinien*[11]*. Soit $W \subset \mathrm{Fl}(\mathcal{M})$ un localiseur modérément saturé, tel que $TC \overset{déf}{=} C \cap W$ satisfasse également aux conditions de stabilité* (2.1) *(par cochangement de base, par composition transfinie). Les conditions suivantes sur une flèche $u_\bullet : X_\bullet \longrightarrow Y_\bullet$ dans $\mathcal{M}(I^\circ)$ sont équivalentes.*

a) *$u_\bullet \in (TC)_I$, i.e. pour tout $i_0 \in I$ et K ouvert de $J = I/i_0$, la flèche $u_{K,J}$ est dans TC.*

b) *$u_\bullet \in C_I \cap W_{I^\circ}$, i.e. pour tout $i_0 \in I$, on a $u_{i_0} \in W$, et pour tout ouvert K de $I/i_0 = J$, on a $u_{K,J} \in C$.*

Donnons tout de suite les corollaires principaux.

Corollaire 2.2. *Supposons $(u_\bullet : X_\bullet \longrightarrow Y_\bullet) \in C_I$. Alors*

a) *$\forall\ i \in I$, $u_i : X_i \longrightarrow Y_i$ est dans C.*

b) *La flèche*

$$u_I \ : \ X_I \longrightarrow Y_I \tag{2.2.1}$$

est dans C. Plus généralement, pour toute partie ouverte J de I, la flèche

$$u_J \ : \ X_J \longrightarrow Y_J \tag{2.2.2}$$

est dans C.

p. 16

Commentary · Exposition [ms. 27] [page 28]

The three assertions of Theorem 2.1 have different hypotheses

The theorem separates a gluing result from two induction results. Its first part uses the strong open condition and closure of C under pushout and continuous transfinite composition. Its second part identifies that condition with the latching condition when I is artinian. Its third part adds a class W satisfying two out of three and assumes the same closure properties for $TC = C \cap W$; under the artinian hypothesis it identifies trivial diagram cofibrations by the formula

$$(TC)_I = C_I \cap W_{I^\circ}.$$

The corollaries concerning weak equivalences inherit this artinian hypothesis. In particular, Corollary 2.3 is not an additional assertion that this equality holds for every poset. The question on page 38 would make no sense under that reading.

The mechanism of the third assertion is short enough to record independently. Assume, by well-founded induction, that the restrictions below i already satisfy the strong TC condition. If $K \subsetneq\downarrow i$ is lower, then $K \subset I_{<i}$. Applying part (1) with TC to the restricted transformation gives $f_K \in TC$. In the factorization

$$X_i \xrightarrow{a} X_i \amalg_{X_K} Y_K \xrightarrow{d_f(K,\downarrow i)} Y_i,$$

a is a pushout of f_K, hence belongs to TC. The composite is $f_i \in W$. Two out of three gives $d_f(K, \downarrow i) \in W$, while the strong C condition gives membership in C. This proves the induction step. The reverse inclusion follows immediately by taking $K = \varnothing$.

This argument shows exactly why no closure of all of W under pushouts is required. Only the pushout of the already established trivial cofibration f_K is formed. Nor is an arbitrary colimit of objectwise weak equivalences being declared a weak equivalence: the relative cofibration conditions are what allow part (1) to be applied. These distinctions are essential when the theorem is later used to put a cofibration structure on a diagram category.

Corollary 2.4 is the corresponding absolute statement. Taking X to be the initial diagram says that a cofibrant diagram has cofibration maps $Y_K \to Y_J$ for every inclusion of lower opens. This includes the individual structure maps but imposes more than their being cofibrations. At a branching object the entire latching colimit must embed by a cofibration, including the compatibility among different incoming branches.

11. J'ignore si cette hypothèse est nécessaire, cf. commentaire p. 39.

Pour a), on applique 1°) (ou simplement la *définition* de C_I) dans le cas de l'inclusion d'ouverts $\emptyset \hookrightarrow I/i$, vu qu'on a

$$u_{\emptyset,I/i} \simeq u_i .$$

Pour b), on applique 1°) à l'inclusion $\emptyset \longrightarrow I$, vu que

$$u_{\emptyset,I} \simeq u_I ,$$

et plus généralement

$$u_{\emptyset,J} \simeq u_J .$$

Corollaire 2.3. *Supposons $u_\bullet \in C_I \cap W_{I^\circ}$. Alors pour toute inclusion d'ouverts $K \subset J$ de I, on a $u_{K,J} \in TC$, et en particulier (prenant $K = \emptyset$), on a $u_J \in TC$. Enfin, pour tout $i \in I$, on a $u_i \in TC$.*

Corollaire 2.4. *Soit $X_\bullet$ dans $\mathcal{M}(I^\circ)_{\mathrm{c}}$ un système inductif C-cofibrant, i.e. tel que $\emptyset_I \longrightarrow X_\bullet$ soit dans C_I, i.e. tel que pour tout $i_0 \in I$ et tout ouvert K de $J = I/i_0$, la flèche de transition $\tau_{K,J} : X_K = \varinjlim_{i\in K} X_i \longrightarrow X_J \simeq X_{i_0}$ soit dans C. Alors pour* tout *couple d'ouverts $K \subset J$, la flèche*

$$\tau_{K,J} \ : \ \varinjlim_{i\in K} X_i \longrightarrow \varinjlim_{i\in J} X_i$$

est dans C[12]*. En particulier (faisant $K = I/k$, $J = I/j$ pour $k \leq j$), si $k \leq j$ sont dans I, le morphisme de transition*

$$\tau_{k,j} \ : \ X_k \longrightarrow X_j$$

est dans C. Enfin, si $W \subset \mathrm{Fl}(\mathcal{M})$ est comme dans (2.1. 3°)*, et si $\emptyset_I \longrightarrow X$ est dans W_{I°, i.e.* [page 29]
les X_i sont W-coasphériques, alors $X_\bullet$ est dans $\mathcal{M}(I^\circ)_{TC}$ (où $TC = C \cap W$), et pour tout ouvert J de I, $X_J = \varinjlim_{i\in J} X_i$ est dans $\mathcal{M}_{TC}$, donc X_J est W-coasphérique, et pour tout couple d'ouverts $K \subset J$, la flèche de transition $\tau_{K,J}$ est dans TC.

Signalons enfin le complément suivant au théorème 2.1, qui résultera de sa démonstration :

Corollaire 2.5. *Supposons que l'espace topologique associé à I (dont les ouverts sont les ouverts de I, et les I/i forment une base d'ouverts) soit* noethérien*, i.e. toute suite croissante d'ouverts est stationnaire. Alors toutes les conclusions dans le théorème* 2.1 *et ses corollaires restent valables, en supposant seulement la stabilité de C ou de $TC = C \cap W$ par composition simple (au lieu de composition transfinie), en plus des deux autres stabilités.*

p. 17
[page 30]

Commentary · Examples [ms. 29]

A branching diagram and the finite meaning of the noetherian case

Grothendieck's open-set formulation makes a small example particularly instructive. Let I be the square poset with elements a, b, c, d and relations $a < b < d$, $a < c < d$, with b, c incomparable. Take $\mathcal{M} = \mathrm{Set}$ and let C be the injections. A diagram is cofibrant precisely when the maps

$$\varnothing \longrightarrow X_a, \quad X_a \longrightarrow X_b, \quad X_a \longrightarrow X_c, \quad X_b \amalg_{X_a} X_c \longrightarrow X_d$$

are injections. The last condition controls the intersection of the two branches. When all maps have been realized as inclusions into X_d, it says $X_b \cap X_c = X_a$. Individual injectivity of every arrow does not imply this equality.

For a complete failure, take $X_a = \varnothing$ and $X_b = X_c = X_d = \{*\}$, with the maps into X_d the identity. Every structure map is injective. The latching map at d is the fold $\{b, c\} \to \{*\}$, which is not. The open $K = \{a, b, c\}$ has colimit a two-element set, and its map to X_d identifies the two branches. Thus the extra open-set tests detect the precise identification that ordinary pointwise cofibrancy misses.

The topological adjective in Corollary 2.5 also needs its order convention. $\mathrm{Esp}(I)$ has the lower sets as its opens. Noetherianity means that no strictly increasing infinite sequence of lower sets

12. et réciproquement, caractérise les objets C-cofibrants.

exists. The process on page 30 adds a principal lower set whenever the current open is proper; in a noetherian space this process must stop after finitely many additions. The argument therefore uses only finitely many pushouts and compositions, even when the chosen principal opens themselves are infinite. This removes the transfinite *closure* assumption; it does not by itself remove the need for the colimits occurring inside those opens.

There is a useful simplification when noetherianity is combined with artinianity. Under the usual choice principles, an artinian poset with noetherian lower-set topology is finite. Indeed, if I were infinite, choose a minimal element of I, then a minimal element of what remains, and continue. After n choices the chosen finite set J_n is lower: when an element was chosen, every strict predecessor had already been chosen. The sequence $J_0 \subsetneq J_1 \subsetneq \cdots$ contradicts noetherianity. Conversely every finite poset has both properties. This observation explains why finite colimits suffice in the first alternative of Theorem 3.1. Noetherianity alone allows infinite examples, such as $\mathbf{N}^{\mathrm{opp}}$; those examples are not artinian.

Démonstration du théorème 2.1 et du corollaire 2.5.

2.1. 1°) On peut supposer $J = I$, $K \subset I$. On construit une suite transfinie strictement croissante d'ouverts I_α, avec

$$\begin{cases} I_0 &= K, \\ I_{\alpha+1} &= I_\alpha \cup I/s_\alpha \quad \text{où } s_\alpha \in I \backslash I_\alpha \text{ (si } I_\alpha \neq I \text{, sinon, la construction transfinie s'arrête)}, \\ I_\alpha &= \bigcup_{\beta<\alpha} I_\beta \quad \text{si } \alpha \text{ ordinal limite.} \end{cases}$$

Il existe un α_0 tel qu'on ait $I_{\alpha_0} = I$. On voit alors comme au paragraphe 1 que pour tout α, on a [page 31]

$$(*) \qquad u_{I_\alpha, I_{\alpha+1}} \in C,$$

car il est déduit de $u_{(I/s_\alpha)\cap I_\alpha, I/s_\alpha}$ par cochangement de base. Cf. diagramme (6), p. 17, qu'il faudrait dégager en lemme, débarrassé des particularités techniques de la situation, i.e. un lemme sur les homomorphismes de carrés cartésiens :

Commentary · Exposition [ms. 31]

The cube reduces to one universal property

Grothendieck extracts Lemma 2.6 to make the long preliminary cube reusable. The useful invariant of a commutative square is its comparison from the pushout of the first three vertices to the fourth. The lemma says that a suitable pushout of squares transports this comparison by pushout. A calculation with universal properties gives the assertion without relying on the perspective of a three-dimensional drawing.

In the notation of the lemma, suppose the two horizontal squares are pushouts,

$$X_1' = X_1 \amalg_{X_0} X_0', \qquad Y_1' = Y_1 \amalg_{Y_0} Y_0'.$$

Let $Q_0 = Y_0 \amalg_{X_0} X_0'$ and $Q_1 = Y_1 \amalg_{X_1} X_1'$. There is a canonical identification

$$Q_1 \cong Y_1 \amalg_{X_0} X_0', \qquad Q_1 \amalg_{Q_0} Y_0' \cong Y_1 \amalg_{Y_0} Y_0' = Y_1'.$$

To check the second identification, a map from either side to an object T is a pair of maps $Y_1 \to T$, $Y_0' \to T$ agreeing on Y_0. The extra map from X_0' is already supplied through Y_0', and the relations imposed by Q_0 are exactly the stated agreement. Hence the square $Q_0 \to Y_0'$, $Q_1 \to Y_1'$ is cocartesian. This is the claimed pushout of defect maps.

For two lower opens $A, B \subset I$, a cocone over $A \cup B$ is exactly a pair of cocones over A and B agreeing over $A \cap B$. A mixed relation introduces no additional condition: if $a \leq b$ and $b \in B$, lower closure puts a in B. Consequently

$$X_{A\cup B} \cong X_A \amalg_{X_{A\cap B}} X_B,$$

and likewise for Y. Applying the lemma with $A = I_\alpha$ and $B = {\downarrow} s_\alpha$ shows that the attachment from I_α to $I_\alpha \cup {\downarrow} s_\alpha$ is a pushout of the strong local comparison over B. This is the precise connection between the abstract cube and Theorem 2.1.

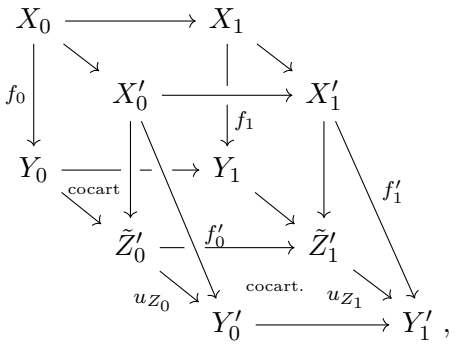
The sentence introducing the lemma says "carrés cartésiens", although the lemma concerns cocartesian squares. The same missing prefix occurs in the final sentence of its proof in the edition. We retain the edition's wording in the source and use the pushout calculation above for its mathematical reading. The diagram's f'_0 is the full map $X'_0 \to Y'_0$, not either horizontal map between intermediate pushouts.

The description of the intermediate cube as "totalement cocartésien" is stronger than the hypotheses justify if it means that all six faces are pushouts. Take all the X-vertices empty, $Y_0 = Y'_0 = \varnothing$, and $Y_1 = Y'_1 = \{*\}$. Both original horizontal squares are pushouts, but the back face with vertices X_0, X_1, Y_0, Y_1 is not. The bottom face of the intermediate cube is nevertheless a pushout, as the calculation proves, and this is the only extra face needed. The lemma is correct; its proof should invoke that face rather than an assertion about every face.

Lemme 2.6. *Soit un homomorphisme de carrés cocartésiens $X_\bullet$, $Y_\bullet$, dans une catégorie $\mathcal{M}$ avec sommes amalgamées (**N.B.** il suffit que les sommes amalgamées intervenant ci-dessus existent) :*

(2.6.1)
$$\begin{array}{ccccc} X_0 & \longrightarrow & X_1 & & \\ \downarrow{\scriptstyle f_0} & \searrow & \downarrow & \searrow & \\ Y_0 & \longrightarrow & X'_0 & \longrightarrow & X'_1 \\ & \searrow & \downarrow{\scriptstyle f'_0} & & \downarrow{\scriptstyle f_1} \\ & & Y_0 & \longrightarrow & Y_1 \\ & & & \searrow & \downarrow{\scriptstyle f'_1} \\ & & & & Y'_0 \longrightarrow Y'_1 \ . \end{array}$$

Soient Z_0, Z_1 les deux carrés latéraux et considérons, pour tout carré commutatif $Z = \begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Y' \end{array}$, la flèche u_Z du diagramme



$$\begin{array}{ccccc} X & \longrightarrow & X' & & \\ \downarrow & \text{cocart.} & \downarrow & & \\ Y & \longrightarrow & \tilde{Z} & \xrightarrow[u_Z]{} & Y' \ . \end{array}$$

Alors la flèche u_{Z_1} se déduit de u_{Z_0} par cochangement de base, de façon plus précise, p. 18 [page 32]
on a un carré cocartésien, où $T = \begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ Y_0 & \longrightarrow & Y_1 \end{array}$ et $T' = \begin{array}{ccc} X'_0 & \longrightarrow & X'_1 \\ \downarrow & & \downarrow \\ Y'_0 & \longrightarrow & Y'_1 \end{array}$ désignent la face postérieure et antérieure du cube (2.6.1) :

(∗)
$$\begin{array}{ccc} \tilde{Z}_0 & \xrightarrow{u_{Z_0}} & Y'_0 \\ \downarrow & \text{cocart.} & \downarrow \\ \tilde{Z}_1 & \xrightarrow{u_{Z_1}} & Y'_1 \ , \end{array}$$

qu'on voit sur la base du diagramme

(∗∗)

dans lequel le cube est un cube totalement cocartésien, déduit du carré cocartésien X en l'"exponentiant" par la flèche $f_0 : X_0 \longrightarrow Y_0$ `[plutôt, par la flèche` (f_0, f_1) `de` $\underline{\mathrm{Fl}}(\mathcal{M})$`]`.

La base du cube, et le carré composé de celui-ci et de (∗) (base du diagramme polyédral (∗∗)) étant cartésien, il en est de même de (∗). [page 33]

Lemme 2.7. *Soit $(I_\alpha)_{\alpha\leq\alpha_0}$ une suite ordinale croissante d'ouverts de I. Alors $u_{I_0,I_{\alpha_0}} : Y_{I_0,I_{\alpha_0}} \longrightarrow Y_{I_{\alpha_0}}$ est composé transfini, indexé par l'ensemble des ordinaux $-1 \leq \alpha < \alpha_0$, d'une suite de flèches v_α, où chaque v_α est déduit de $u_{I_\alpha,I_{\alpha+1}}$ par cochangement de base (et de $u_{I_0} : X_{I_0} \longrightarrow Y_{I_0}$ pour $\alpha = 0$).*

Commentary · Exposition [ms. 33]

The relative transfinite composition starts after the initial attachment

Lemma 2.7 provides the second ingredient in the global argument: once the successive local changes have been understood, they must be assembled into the desired relative map. Its printed statement combines two different starting points and does not state continuity at limit ordinals. Both points can be repaired without changing the filtration actually used in Theorem 2.1.

Fix a continuous increasing filtration of lower opens $(I_\alpha)_{\alpha\leq\lambda}$ with $I_0 = K$ and $I_\lambda = J$, where $I_\delta = \bigcup_{\alpha<\delta} I_\alpha$ at every nonzero limit. Set

$$Z_\alpha = X_J \amalg_{X_{I_\alpha}} Y_{I_\alpha}.$$

Then $Z_0 = Q_f(K, J)$ and $Z_\lambda \cong Y_J$. The universal property of a cocone over a union gives $X_{I_\delta} = \operatorname{colim}_{\alpha<\delta} X_{I_\alpha}$ and the analogous identity for Y. Since colimits commute with colimits, it follows that $Z_\delta = \operatorname{colim}_{\alpha<\delta} Z_\alpha$. At a successor stage the square

$$\begin{array}{ccc} Q_f(I_\alpha, I_{\alpha+1}) & \longrightarrow & Z_\alpha \\ {\scriptstyle d_f(I_\alpha,I_{\alpha+1})}\downarrow & & \downarrow \\ Y_{I_{\alpha+1}} & \longrightarrow & Z_{\alpha+1} \end{array}$$

is a pushout, as follows by substituting the definitions. Thus $d_f(K, J) : Z_0 \to Z_\lambda$ is the continuous transfinite composite of these successor pushouts. There is no additional initial factor involving f_K.

If one wants instead the absolute map $f_J : X_J \to Y_J$, one must first prepend $X_J \to Z_0$, the pushout of f_K, and then take the relative composite. This is the legitimate role of an extra index -1. It cannot be included while the asserted composite still has domain $Q_f(K, J)$. Likewise, the displayed identification $X_J = Z_0$ on page 34 is valid only in the special case $K = \varnothing$, not for the relative assertion as stated.

Continuity cannot be discarded from the lemma. In Set let I have one object, let X be empty, let Y be a singleton, and take $I_n = \varnothing$ for every finite n, but $I_\omega = I$. Every successor attachment below ω is an identity of the empty set, whereas the requested final map is $\varnothing \to \{*\}$. It is therefore not their transfinite composite. The filtration constructed on page 30 is continuous, so this defect of the isolated statement does not invalidate the theorem. The modern terminology makes continuity explicit in the definition of a transfinite composite (Riehl and Verity, 2014, Definition 5.3).

Pour le voir, on introduit la suite transfinie d'objets $Z_\alpha = Y_{I_\alpha,I_{\alpha_0}}$, définis par le diagramme p. 19

$$\begin{array}{ccc} X_{I_\alpha} & \longrightarrow & X_{I_{\alpha_0}} \\ \downarrow & & \downarrow \\ Y_{I_\alpha} & \longrightarrow & Y_{I_\alpha, I_{\alpha_0}} = Z_\alpha \\ & & \downarrow \\ & & Y_{I_{\alpha_0}} \ , \end{array}$$

on a $Z_0 = Y_{I_\alpha, I_{\alpha_0}}$, $Z_{\alpha_0} = Y_{I_\alpha, I_{\alpha_0}}$, $Z_\alpha = \varinjlim_{\beta<\alpha} Z_\beta$ si α ordinal limite. Donc il reste à déterminer [34]
les $v_{\alpha,\alpha+1} : Z_\alpha \longrightarrow Z_{\alpha+1}$ (pour $\alpha < \alpha_0$), ce qu'on voit sur le diagramme

$$\begin{array}{ccccc} X_{I_\alpha} & \longrightarrow & X_{I_{\alpha+1}} & \longrightarrow & X_{I_{\alpha_0}} = Z_0 \\ \downarrow & & \downarrow & & \downarrow \\ Y_{I_\alpha} & \longrightarrow & Y_{I_\alpha, I_{\alpha+1}} & \longrightarrow & Y_{I_\alpha, I_{\alpha_0}} = Z_\alpha \\ & & \downarrow{\scriptstyle u_{I_\alpha, I_{\alpha+1}}} & & \downarrow{\scriptstyle v_{\alpha,\alpha+1}} \\ & & Y_{I_{\alpha+1}} & \longrightarrow & Y_{I_{\alpha+1}, I_{\alpha_0}} = Z_{\alpha+1} \ . \end{array}$$

Reprenons la démonstration de 2.1. On va prouver 1° par les deux lemmes précédents. Notons que lorsque l'espace sous-jacent à I est noethérien, alors la construction transfinie est forcément finie, donc on n'a pas besoin de la stabilité de C par composés transfinis infinis.

Prouvons 2°. On suppose donc que pour tout $i_0 \in I$, on ait $u_{I_{<\alpha_0}, I/i_0} \in C$, on veut en [35]
déduire que $u_\bullet \in C_I$, i.e. $u_{J,I/i_0} \in C$ pour *tout* ouvert.

Lemme 2.8. (Sous hypothèse artinienne sur I.) *Soit $P \subset I$ l'ensemble des $i_0 \in I$ tels que pour $u_\bullet | I/i_0$ soit dans C_{I/i_0}, i.e. que pour tout $i \leq i_0$, et tout ouvert K de I/i, on ait $u_{K,I/i} \in C$. Soit $i_0 \in I$ tel que $I_{<i_0} \subset P$. Alors $i_0 \in P$.*

Démonstration. Il reste à prouver que si $K \subset I/i_0 = J$ est un ouvert, alors $u_{K,J} \in C$. On peut supposer $K \neq I/i_0$, i.e. $K \subset I_{<i_0} \overset{\text{déf}}{=} J'$. Mais alors par hypothèse initiale sur $u_\bullet$, on a $u_{J',J} \in C$, et d'autre part, par hypothèse sur i_0, $u_\bullet | J'$ est dans $C_{J'}$. Donc par le théorème 2.1. 1°, on a $u_{K,J'} \in C$. Donc par transitivité $u_{K,J} \in C$, q.e.d.

Corollaire 2.9. *Si I est artinien, alors $P = I$, i.e. $u_\bullet \in C_I$.*

Cela prouve donc 2.1. 2°. Notons que $\mathrm{Esp}(I)$ est noethérien, il en est de même de tout ouvert (tel J' ci-dessus), donc pour la conclusion du lemme, inutile de supposer C stable par [36]
composition infinie.

Commentary · Exposition [ms. 35]

Well-founded induction turns boundaries into all open tests

Grothendieck now uses artinianity to recover the economical definition with which the chapter began. For a poset, the relevant hypothesis is well-foundedness of the strict relation: every nonempty subset has a minimal element. Under dependent choice this is equivalent to the stated absence of an infinite strictly descending sequence. It is not a finiteness assertion about the predecessor set of an object.

Assume every relative latching map lies in C. Let P consist of those i for which the transformation on $\downarrow i$ satisfies the strong open condition. Suppose all strict predecessors of i lie in P. For a proper lower open $K \subset \downarrow i$, put $J' = I_{<i}$. The restricted transformation on J' has the strong open condition, because this property is tested on the principal lower sets of its objects. Theorem 2.1(1), already proved without artinianity, gives $d_f(K, J') \in C$. By hypothesis $d_f(J', \downarrow i) \in C$. The comparison $d_f(K, \downarrow i)$ factors as a pushout of the first of these maps followed by the second; hence it belongs to C. The case $K = \downarrow i$ is an identity. Well-founded induction proves $P = I$.

The proof is logically independent of Theorem 2.1(3), and uses part (1) only on a smaller lower open. This matters because the induction on the trivial class will repeat the argument with an extra

use of two out of three. The duplicate label "2.9" for the corollary here and the lemma on page 37 should be read by their content, not as a logical back-reference to a later statement.

Modern Reedy theory packages the same boundary calculation as a factorization by degree. For a finite or locally finite artinian poset one can use a degree in $\mathbf{N}$, such as the maximal length of a chain ending at an object. A general artinian poset can require an ordinal rank

$$r(i) = \sup_{j<i}\big(r(j)+1\big).$$

For example $\omega+1$ is artinian but its last element has arbitrarily long finite chains below it, so no strictly increasing $\mathbf{N}$-valued degree exists. Grothendieck's transfinite argument therefore exceeds the finite-degree convention used in many introductions. The relative latching maps themselves are the familiar ones; it is the allowable height and the required colimits that change. The published Reedy account identifies these maps and their cellular presentations explicitly (Riehl and Verity, 2014, Definition 4.14 and Proposition 6.3).

Prouvons 2.1. 3°. On a a) $\Longrightarrow$ b), car par 2.1. 1°, $u_\bullet \in (TC)_I$ implique que pour $i \in I$, $u_i : X_i \longrightarrow Y_i$ est dans TC (cf. cor. 2.1 a). Donc il reste à prouver b) $\Longrightarrow$ a), i.e. si $u_\bullet \in C \cap W_{I^\circ}$, alors $u_\bullet \in (TC)_I$, i.e. les $u_{K,I/i_0}$ sont dans TC. On sait déjà que $u_{K,I/i_0} \in C$ par hypothèse $u_\bullet \in C_I$, donc il faut prouver que c'est dans W. On est ramené à prouver que $u_K \in W$, i.e. $u_K \in TC$, car par le diagramme (où $J = I/i_0$) p. 20

$$\begin{array}{ccc} X_K & \longrightarrow & X_J \\ {\scriptstyle u_K}\downarrow & \text{cocart} & \downarrow{\scriptstyle \tilde{u}_{K,J}} \\ Y_K & \longrightarrow & Y_{K,J} \\ & & {\scriptstyle u_{K,J}}\downarrow \\ & & Y_J \end{array} \qquad u_J \text{ (curved arrow } X_J \to Y_J),$$

$u_K \in TC$ implique $\tilde{u}_{K,J} \in TC$, et comme $u_J \simeq u_{i_0} \in W$ par hypothèse, il en résulte bien $u_{K,J} \in W$ par saturation. Mais on va s'y prendre autrement :

Lemme 2.9. *I ensemble ordonné quelconque, C, W comme dans th.* 2.1, 1° *et* 3°, *$u_\bullet : X_\bullet \longrightarrow Y_\bullet$ dans $C_I \cap W_{I^\circ}$. Soit P l'ensemble des $i_0 \in I$ tels que $u_\bullet | I/i_0$ soit dans $(TC)_{I/i_0}$. Si $i_0 \in I$ est tel que $I_{<i_0} \subset P$, alors $i_0 \in P$.* [37]

En effet, il reste à prouver que pour tout ouvert K de $J = I/i_0$, $K \neq J$, on a $u_{K,J} \in TC$. Mais pour ceci, il suffit de voir que $u_K, u_J \in W$ (comme on venait de le voir). Or $u_J \simeq u_{i_0} \in W$ par hypothèse. D'autre part $u_\bullet | K \in (TC_K)$ puisque $K \subset I_{<i_0} \subset P$, donc par le théorème 2.1, 1°, on conclut que $u_K \in TC$.

Si maintenant on suppose I artinien, il résulte de 3.9 que $P = I$, donc $u_\bullet \in (TC)_I$, q.e.d.

Cela achève la démonstration du théorème 2.1, et aussi du corollaire 2.5, vu que pour la démonstration du lemme 2.9 également, les hypothèses infinies sur C, $C \cap W$ sont inutiles si $\mathrm{Top}(I)$ est noethérien, donc ses ouverts sont aussi noethériens.

Remarques.

1) Dans 2.1. 2°, l'hypothèse I artinien n'est par superflue, comme on voit en prenant $I = \mathbf{N}^{\mathrm{opp}} \simeq \mathbf{Z}^{\leq 0}$, et pour une flèche [38]

$$\emptyset_{\mathcal{M}(I)} \longrightarrow Y_\bullet \ .$$

Dire que cette flèche est dans C_I signifie que les morphismes de transition $Y_i \xrightarrow{u_i} Y_{i+1}$ sont dans C, *et* que les Y_i sont C-cofibrants, i.e. $\emptyset_{\mathcal{M}} \longrightarrow Y_i$ est dans C, pour tout i. Mais la condition envisagée dans 2.1. 1° est seulement que les u_i sont dans C. Donc en prenant pour $Y_\bullet$ un système inductif constant de valeur Y, avec Y non C-cofibrant, i.e. $\emptyset_{\mathcal{M}} \longrightarrow Y$ non dans C, on a un contre-exemple.

Avec le même I, on voit que $u_\bullet : X_\bullet \longrightarrow Y_\bullet$ est dans C si et seulement si

a) les $u_i \in C$, et

b) les $u_{i,i+1} : Y_{i,i+1} \longrightarrow Y_{i+1}$ sont dans C.

Si de plus les u_i sont dans W, donc dans TC, on voit comme ci-dessus que $u_{i,i+1} \in TC$ pour tout i, donc $u_\bullet \in (TC)_I$. Donc ici on a encore p. 21

$$(TC)_I \;=\; C_I \cap W_{I^\circ}\ ,$$

quoique I ne soit pas artinien. J'ignore si l'hypothèse artinienne dans 2.1. 3° est superflue ou non.

2) Soit $u_\bullet \in \mathrm{Fl}(\mathcal{M}(I^\circ))$ [13], donc $u_\bullet$ est un objet de $\underline{\mathrm{Fl}}(\mathcal{M}(I^\circ)) \simeq \mathcal{M}(I^\circ \times \mathbf{\Delta}^1) = \mathcal{M}((I \times (\mathbf{\Delta}^1)^{\mathrm{opp}})^{\mathrm{opp}})$. On vérifie que pour que cet objet soit C-cofibrant, il faut et il suffit que

1°) $X_\bullet$ soit C-cofibrant, et

2°) $u_\bullet \in C_I$ (ce qui implique que $Y_\bullet$ est aussi cofibrant).

[39]

Commentary · Examples [ms. 38]

What the reverse chain does and does not refute

Grothendieck's counterexample separates the local latching tests from cofibrancy of the values. Write $I = \mathbf{Z}^{\leq 0}$ with its usual order. Every strict predecessor set of i has final object $i-1$, so $L_iY = Y_{i-1}$. The latching test for $\varnothing \to Y$ therefore asks only that $Y_{i-1} \to Y_i$ belong to C. By contrast, every nonempty lower open of $\downarrow i$ has a largest element; the strong condition asks for all these transition maps and also for $\varnothing \to Y_i$.

Choose, for instance, $\mathcal{M} = \mathrm{Set}$ and C the isomorphisms. This class contains the isomorphisms and is stable under pushout and transfinite composition. Let Y be the constant singleton diagram. Every latching map is the identity of a singleton, while $\varnothing \to Y_i$ is not an isomorphism. The latching criterion therefore fails to imply the strong criterion. This makes the counterexample completely concrete; it does not require a model category or a choice of W.

For an arbitrary transformation $f : X \to Y$ on this chain, the strong condition is equivalent to $f_i \in C$ and the adjacent relative maps $d_f(\downarrow i, \downarrow (i+1)) \in C$. A larger interval is obtained by finitely many such attachments, and the empty lower open supplies the pointwise condition. If in addition every $f_i \in W$, then every $f_i \in TC$. In the adjacent factorization of f_{i+1}, the first map is a pushout of f_i, hence is in TC, and two out of three puts the adjacent relative map in TC. Finite composition gives all remaining tests. Thus the equality involving TC survives in this example even though the latching characterization does not.

The two issues on page 38 are consequently distinct. The displayed constant diagram disproves omission of artinianity from Theorem 2.1(2). It is not a counterexample to Theorem 2.1(3) without artinianity. The latter is the question Grothendieck leaves undecided here.

Commentary · Development (commentators') [ms. 38]

The trivial-cofibration equality on chains without a first element

Grothendieck's reverse-chain calculation suggests that a missing first element need not obstruct the trivial-cofibration equality. We can extend his example by using cofinality in place of well-foundedness. The statement concerns the strong open definition of C_I throughout. We checked the direct-diagram definitions in Rădulescu-Banu (2009, Sections 9.1–9.2) and the relative latching and cellular presentations in Riehl and Verity (2014, Definition 4.14 and Proposition 6.3); these specified passages do not state the following extension. We record the argument as a continuation of the source, without a claim of priority or a claim to settle arbitrary posets.

Proposition. [ours] Assume $\mathcal{M}$ is cocomplete, C contains isomorphisms and is closed under pushout and small transfinite composition, W contains isomorphisms and satisfies two out of three, and $TC = C \cap W$ has the same closure properties as C. Suppose every principal lower set $\downarrow i$ of I is linearly ordered. Then

$$(TC)_I = C_I \cap W_{I^\circ},$$

13. $I^\circ = I^{\mathrm{opp}}$.

without an artinian hypothesis on I.

Proof. First let K be a nonempty linearly ordered set. It admits a strictly increasing well-ordered cofinal subset. To construct one, choose $s_0 \in K$. At a stage where the previously chosen elements are not cofinal, choose an element strictly greater than all of them; such an element exists because failure of cofinality gives a k above which no earlier choice lies, and linearity then puts all earlier choices below k. Distinct stages give distinct elements of the set K, so the construction stops before an ordinal of cardinality larger than K. At its stopping stage the chosen subset $S = \{s_\alpha \mid \alpha < \lambda\}$ is cofinal. A largest element, if present, simply ends the construction.

Now let $f \in C_I \cap W_{I^\circ}$ and fix a lower open $K \subset\!\downarrow i$. If $K = \varnothing$, then f_K is an identity. Otherwise choose such a cofinal chain $S \subset K$. For each $\alpha < \lambda$ put

$$U_\alpha = \bigcup_{\beta<\alpha} \downarrow s_\beta.$$

The earlier chosen elements are cofinal in U_α, so their X- and Y-colimits are X_{U_α} and Y_{U_α}. This identification follows directly from cocones: every object of U_α maps to an earlier chosen element, and a common later choice compares any two such maps. The relative latching map of $f|_S$ at α is therefore

$$X_{s_\alpha} \amalg_{X_{U_\alpha}} Y_{U_\alpha} \longrightarrow Y_{s_\alpha},$$

namely $d_f(U_\alpha, \downarrow s_\alpha)$, which lies in C by the strong condition. The pointwise maps of $f|_S$ are in W. Proposition 1 and its corollary, applied to the well-ordered set S, give $\operatorname{colim}_S f \in TC$. Cofinality identifies this map with f_K, so $f_K \in TC$.

The composite $X_i \to X_i \amalg_{X_K} Y_K \to Y_i$ is f_i. Its first factor is a pushout of $f_K \in TC$, and its second factor belongs to C. Two out of three makes that second factor a weak equivalence. These are all the strong TC tests at i. The reverse inclusion follows by taking $K = \varnothing$ in the definition. This proves the proposition.

In particular the result covers every linearly ordered small set, including dense chains and chains with no first element. It also covers branching posets in which branching occurs only upwards, so that each individual object's predecessors remain linearly ordered. The proof uses the full transfinite hypotheses; it does not assert that sequential closure alone suffices at arbitrary cofinalities.

Commentary · Exposition [ms. 38]

An arrow is a cofibrant two-layer diagram

The second remark turns a relative assertion into an absolute one. Label the two layers so that the arrow $f : X \to Y$ is the diagram on $I \times [1]$ with X at level 0 and Y at level 1. This fixes the endpoint convention independently of the opposite-category notation in the source. A lower open in this product is determined by lower opens $B \subset A \subset I$, and its colimit is

$$X_A \amalg_{X_B} Y_B.$$

The formula follows because the arrows from level 0 to level 1 impose precisely the relations already imposed over B.

Suppose X is strongly cofibrant and $f \in C_I$. At an object $(i, 0)$ the absolute cofibration test is a test for X. At $(i, 1)$ an arbitrary lower-open test has the form

$$X_A \amalg_{X_B} Y_B \longrightarrow Y_i, \qquad B \subset A \subset\!\downarrow i.$$

It factors through $X_i \amalg_{X_B} Y_B$. The first map is a pushout of $X_A \to X_i$, which belongs to C by cofibrancy of X; the second is the strong comparison for f. Thus the two-layer diagram is cofibrant. Conversely, testing its level-0 objects gives cofibrancy of X, and taking $A =\!\downarrow i$ in the level-1 tests gives all the strong tests for f. Taking the whole level-1 principal lower set also proves cofibrancy of Y.

This calculation explains why the relative construction is natural under iteration. A map of diagrams is itself a diagram with one additional direction, and its relative latching object is the boundary contribution in that direction. The observation is valid for the strong definition without assuming artinianity. Artinianity is needed only when one replaces all these tests by the single latching test at each object.

3 Catégories de modèles à cofibrations

Soit $\mathcal{M}$ une catégorie munie de deux ensembles de flèches

$$W,\ C\ \subset\ \mathrm{Fl}(\mathcal{M})\ .$$

On suppose que $\mathcal{M}$ contient un objet initial, et :

Cof$_0$ W est modérément saturé, i.e. contient les isomorphismes et si f, g sont composables, et si deux parmi f, g, gf sont dans W, le troisième aussi.

Cof$_1$ C contient les isomorphismes, est stable par composition et par cochangement de base.

Cof$_2$ $TC \overset{\text{déf}}{=} C \cap W$ est stable par cochangement de base.

Cof$_3$ Toute flèche f dans $\mathcal{M}$ s'écrit

$$f\ =\ pi$$

avec $i \in C$, $p \in W$.

Ce sont les axiomes de K. S. Brown (forme duale), qui suppose de plus que les objets de $\mathcal{M}$ sont C-cofibrants, i.e. $\emptyset_{\mathcal{M}} \longrightarrow X$ est dans C. Je ne ferai pas cette hypothèse. La sous-catégorie $\mathcal{M}_c$ de $\mathcal{M}$ formée des objets C-cofibrants satisfait aux axiomes de Brown, de plus on prouve [40] que

$$\mathrm{Ho}_W(\mathcal{M}_c) \xrightarrow{\sim} \mathrm{Ho}_W(\mathcal{M})$$

est une équivalence. Ainsi les résultats de Brown relatifs à $\mathcal{M}_c$, muni des ensembles de flèches induits par W, C, sont applicables à $\mathrm{Ho}_W(\mathcal{M})$ et à ses avatars (tels $\mathrm{Ho}_W(S\backslash\mathcal{M})$, $\mathrm{Ho}_W(\mathcal{M}/T)$ et $\mathrm{Ho}_W(S\underset{u_0}{\backslash}\mathcal{M}/T)$, où $u_0 : S \longrightarrow T$ est donné). Il se trouve que pour l'essentiel, les résultats homotopiques standard (notamment suite exacte de cofibrations relatifs aux opérations homotopiques "à droite" (ou faut-il dire à gauche ? il s'agit pourtant de questions d'exactitude à droite, non à gauche)) sont valables. Il me faudra revenir dessus de façon plus circonstanciée par la suite. Notamment, il y a une bonne théorie de carrés W-cocartésiens (et *dans* $\mathcal{M}_c$, il y a assez de W-cofibrations [14], …), et de plus, ceux-ci sont *exacts*. La catégorie p. 22 $\mathrm{Ho}_W(\mathcal{M}) \simeq \mathrm{Ho}_W(\mathcal{M}_c)$ "se calcule" par un calcul de fractions à gauche dans $\pi\mathcal{M}_c$, où $\pi\mathcal{M}_c$ [41] est la catégorie déduite de $\mathcal{M}_c$ en y remplaçant les $\mathrm{Hom}_{\mathcal{M}_c}(X,Y) = \mathrm{Hom}_{\mathcal{M}}(X,Y)$ par le quotient par une relation d'homotopie convenable :

$f, g : X \rightrightarrows Y$ sont QB-homotopes (au sens de *Quillen-Brown*) s'il existe un $X' \xrightarrow{\alpha} X$ dans W (et on peut supposer $X' \in \mathrm{Ob}\,\mathcal{M}_c$ également) tel que $f\alpha \overset{1}{\sim} g\alpha$ au sens de Quillen, i.e. il existe un objet cylindre $\begin{array}{ccc} I_{X'} & \xrightarrow{\in W} & X' \\ {\scriptstyle \in C}\uparrow & \nearrow & \\ X' \vee X' & & \end{array}$ pour X', tel que $(f\alpha, g\alpha)\ :\ X' \vee X' \longrightarrow Y$ se factorise par un $h' : I_{X'} \longrightarrow Y$.

Commentary · Context [ms. 39]

Brown's axioms and the role of noncofibrant objects

Grothendieck introduces cofibrations as auxiliary data for a fixed localization. The weak equivalences are required to satisfy two out of three; the cofibrations supply the pushouts and factorizations needed to construct homotopy colimits. No lifting relation with a class of fibrations is imposed. The historical reference is to the dual of Brown's theory of fibrant objects (Brown, 1973). The broad comparison with Quillen's axioms was treated in the commentary on Chapter VI, manuscript p. 108; the new point here is the systematic inclusion of noncofibrant objects.

The existence convention in "stable par cochangement de base" matters. The Brown interpretation includes existence of the required pushouts of cofibrations. If the words were read as closure only

14. Plus précisément, par K. S. Brown, *dans* $\mathcal{M}_c$, les objets de C sont des W_c-cofibrations.

for pushouts that happened to exist, Cof_0–Cof_3 together with an initial object would not provide the finite constructions used below. The explicit finite-colimit hypothesis of Theorem 3.1 removes this issue there. With the Brown existence convention, the cofibrant objects form a category of cofibrant objects: a pushout of a cofibration between cofibrant objects remains cofibrant, a factorization of a map with cofibrant source has cofibrant middle object, and finite coproducts are pushouts of the cofibrations from the initial object.

In particular, the cylinder needed later is obtained by factoring the fold map

$$X \amalg X \longrightarrow X \quad \text{as} \quad X \amalg X \hookrightarrow IX \xrightarrow{\sim} X.$$

The hook here denotes membership in C, not literal injectivity in an arbitrary category. Each endpoint inclusion $X \to IX$ is a trivial cofibration: it is a composite of cofibrations, and its composite with $IX \to X$ is the identity. Thus cylinders are constructed from Cof_3 rather than introduced as an independent choice of extra structure.

Allowing noncofibrant objects does not enlarge the localized theory. Factoring $\varnothing \to X$ gives a cofibrant replacement $QX \xrightarrow{\sim} X$. This proves essential surjectivity of $\mathrm{Ho}_W(\mathcal{M}_c) \to \mathrm{Ho}_W(\mathcal{M})$ immediately; full faithfulness requires the approximation argument, not just the existence of these replacements. The source returns to it in Lemma 3.4. A precise modern treatment is Rădulescu-Banu (2009, Theorem 6.1.6). We do not replace this argument by a tacit assumption that replacement choices are functorial.

The same construction applies to slices and coslices with their induced weak equivalences and cofibrations. In a coslice $S\backslash\mathcal{M}$, cofibrancy means that the structure map $S \to X$ is a cofibration; it does not mean that X was cofibrant in $\mathcal{M}$. This relative interpretation is what makes the later discussion of exact homotopy pushout squares possible.

C'est de ce critère que résulte l'exactitude (à gauche) des carrés W-cocartésiens.

Je veux voir comment une structure de cofibrations sur $\mathcal{M}$ s'étend aux catégories $\mathcal{M}(I^\circ) = \underline{\mathrm{Hom}}(I, M)$. On a dans $\mathcal{M}(I^\circ)$ l'ensemble W_{I°, et C_I (il vaut mieux sans doute le noter aussi C_{I°) défini au paragraphe précédent. Il s'agit de vérifier les axiomes. L'axiome Cof_0 est immédiat, et bien connu pour I une catégorie quelconque. [42]

Commentary · Exposition [ms. 41]

Fractions, homotopy, and weak pushout exactness

Grothendieck is preparing a calculus of representatives for morphisms in the localization. His QB relation first allows a weak equivalence $\alpha : X' \to X$ in the source, then asks for an ordinary cylinder homotopy between $f\alpha$ and $g\alpha$. That is the formula printed in the edition. It should not be silently replaced by the formula one expects from the dual of a category of fibrant objects.

Every relation of the displayed kind implies equality of f and g in $\mathrm{Ho}_W(\mathcal{M})$. Indeed, for the two endpoint maps $e_0, e_1 : X' \to IX'$ and the cylinder projection q, the equations $qe_0 = qe_1 = 1$ show that $e_0 = e_1$ after localization. A map $h : IX' \to Y$ gives $f\alpha = he_0 = he_1 = g\alpha$ there, and invertibility of α gives $f = g$. This verifies the direction used whenever such an explicit homotopy is supplied.

A useful, separately verified equality criterion is the Brown formulation with enlargement of the target: for cofibrant X, Y, equality in the localization is equivalent to the existence of a trivial cofibration $b : Y \to Y'$ and a cylinder homotopy from bf to bg. This is the convention in Rădulescu-Banu (2009, Section 6.3, diagram (6.1), and Theorem 6.3.1). Its formal cancellation is in the target, whereas the displayed QB definition cancels in the source. The source does not explicitly assert that its quotient $\pi\mathcal{M}_c$ is already the full category of morphisms in the localization: it still localizes by fractions. Therefore the difference between these formulas is not, by itself, a counterexample to his assertion about fractions.

For the applications here one may use this target-enlargement criterion and Brown's homotopy calculus. A morphism is represented by $X \to Z \xleftarrow{\sim} Y$; the denominator may be chosen to be a trivial cofibration (Rădulescu-Banu, 2009, Theorem 6.4.5(1)(a)). This makes both the direction of the denominator and the role of the homotopy quotient explicit.

The square-exactness requirement has a concrete consequence which is useful throughout the construction. Write $\mathcal{H} = \mathrm{Ho}_W(\mathcal{M})$. For a homotopy-cocartesian square completing a span

$B \leftarrow A \to C$ to P, and any test object T, the comparison

$$\mathrm{Hom}_{\mathcal{H}}(P,T) \longrightarrow \mathrm{Hom}_{\mathcal{H}}(B,T) \times_{\mathrm{Hom}_{\mathcal{H}}(A,T)} \mathrm{Hom}_{\mathcal{H}}(C,T)$$

is surjective. Grothendieck explicitly gives the dual Hom-set formulation in Chapter XIV, manuscript page 6, Corollary 2, and introduces its cocartesian dual on page 7 (Grothendieck, 1990–1991r). XVII invokes Brown's calculus for square exactness here and labels the corresponding requirement Dér 6 in Corollary 3.9. We use the verified Hom-surjectivity statement; we do not identify it with every clause of the stronger quadrangulated-category axioms proposed in XIV.

Here is the proof from that calculus. Represent the homotopy pushout by a span of cofibrant objects whose two legs are cofibrations, with ordinary pushout P, and replace T by a cofibrant representative. Suppose classes $b : B \to T$ and $c : C \to T$ agree on A. The fraction theorem represents them by actual maps $b' : B \to T'$ and $c' : C \to T'$ after one common trivial-cofibration enlargement $T \to T'$: push out their two denominators over T to obtain such a common target. The equality criterion gives, after a further trivial-cofibration enlargement if necessary, a cylinder $A \amalg A \to IA \xrightarrow{q} A$ and $h : IA \to T'$ with endpoint values $b'|_A$ and $c'|_A$.

To make the agreement strict, let $d_0, d_1 : A \to IA$ be the endpoints and put

$$B' = B \amalg_{A,d_0} IA, \qquad P' = B' \amalg_{A,d_1} C.$$

The map $B \to B'$ is a trivial cofibration, being a pushout of d_0. The cylinder projection defines a retraction $r : B' \to B$, which is therefore a weak equivalence. The other endpoint $A \to B'$ is a cofibration: the map $B \amalg A \to B'$ is a pushout of $A \amalg A \to IA$, and $A \to B \amalg A$ is a cofibration because B is cofibrant. The maps b' and h glue on B', and their value on the other endpoint agrees with c'. They consequently give $P' \to T'$. The gluing lemma applied to the objectwise weak equivalence of cofibrant spans $(A, B', C) \to (A, B, C)$ gives a weak equivalence $P' \to P$. Thus

$$P \xleftarrow{\sim} P' \longrightarrow T' \xleftarrow{\sim} T$$

defines the desired morphism in $\mathcal{H}$. Its restrictions are b and c because the construction on B' restricts to b' on B, the map $B \to B'$ becomes the inverse of r, and the construction on C is c'.

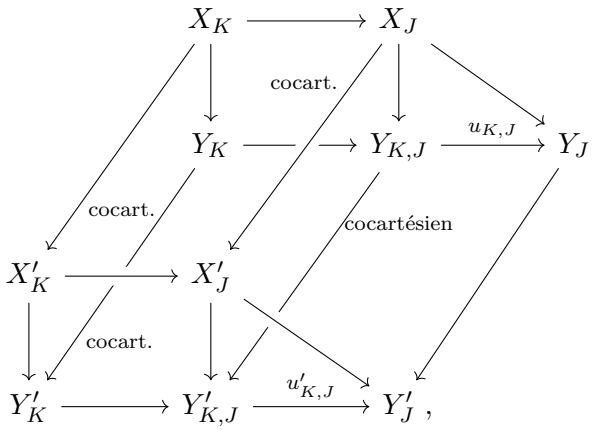
This is a weak pushout property, with no uniqueness assertion. In spaces the homotopy pushout of $* \leftarrow S^0 \to *$ is S^1. Testing against S^1 gives the comparison $\mathbb{Z} \to \{*\}$: self-maps of the circle have all integer degrees, whereas the two point maps and their restrictions have a single unbased homotopy class. Replacing Hom-surjectivity by an ordinary pushout universal property would therefore be false. The proof above applies in a coefficient category as soon as its required cofibration structure has been established.

Cof_1 : C_{I° contient les isomorphismes, c'est clair, parce que C les contient. Stable par composition $X_\bullet \xrightarrow{u} Y_\bullet \xrightarrow{v} Z_\bullet$, regardons $K \subset J$, posons $w = v \circ u$,

$$\begin{array}{ccccccc}
X_K & \longrightarrow & X_J & & & & \\
\downarrow & & \downarrow & & & & \\
Y_K & \longrightarrow & Y_{K,J} & \xrightarrow{u_{K,J}} & Y_J & & \\
\downarrow & & \downarrow & & \downarrow & & \\
Z_K & \longrightarrow & \bullet & \xrightarrow{u'_{K,J}} & Z_{K,J} & \xrightarrow{v_{K,J}} & Z_J \,,
\end{array}$$

with $w_{K,J}$ spanning $\bullet \to Z_J$.

$w_{K,J}$ est composé de $v_{K,J}$, qui est dans C, et $u'_{K,J}$, qui l'est car déduit de $u_{K,J}$ par cochangement de base.



(**N.B.** On a déjà fait le raisonnement avec un seul $u_\bullet$, et *trois* ouverts $J \subset K \subset L$. Il y aurait lieu d'introduire la notion de C-carré $\begin{array}{ccc} X_0 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_3 \end{array}$, comme un carré tel que [43]

$X_1 \amalg_{X_0} X_2 \longrightarrow X_3$ soit dans C (**N.B.** notion symétrique pour les foncteurs de symétrie des carrés), et dire que le composé de deux C-carrés est un C-carré.) p. 23

Cochangement de base

$$\begin{array}{ccc} X_\bullet & \xrightarrow{u} & Y_\bullet \\ \downarrow & & \downarrow \\ X'_\bullet & \xrightarrow{u'} & Y'_\bullet \,. \end{array}$$

Considérons $K \subset J$, on a

où les trois carrés latéraux marqués "cocart." sont cocartésiens, ainsi que le carré en plan incliné. Il en résulte, d'abord que le quatrième carré latéral du cube est lui aussi cocartésien, puis que le carré ayant deux côtés $u_{K,J}$, $u'_{K,J}$ est cocartésien. (**N.B.** comparer le diagramme similaire p. 32 – il y aurait un lemme commun à dégager, distinguant deux cas …) [44]

Commentary · Exposition [ms. 43]

C-squares and the two gluing calculations

Grothendieck's proposed C-square records the same relative defect used throughout the chapter. For a commutative square with vertices A, B, D, E, in that order, its defect is $B \amalg_A D \to E$. Requiring this map to belong to C is symmetric under interchange of the two coordinate directions. It does not require any of the four boundary arrows separately to belong to C.

The composition statement can be proved once in a form that covers both uses in the text. Consider a commutative rectangle with top row $A \to B \to C'$ and bottom row $D \to E \to F$. Its outer defect factors as

$$C' \amalg_A D \longrightarrow C' \amalg_B E \longrightarrow F.$$

The first factor is the pushout of $B \amalg_A D \to E$ along the canonical map to $C' \amalg_A D$; the second is the defect of the right-hand square. If both inner squares are C-squares, pushout closure and composition closure show that the rectangle is one. Transposing gives the corresponding vertical-pasting statement.

There are then two applications. If one holds $K \subset J$ fixed and composes transformations $X \to Y \to Z$, this formula proves closure of C_I under composition. If one holds a transformation fixed and composes inclusions $K \subset J \subset L$, it proves the relative transitivity used in the induction of Theorem 2.1. The pictures differ only in which direction of a diagram is regarded as the variable.

For cobase change, form a pointwise pushout $Y' = Y \amalg_X X'$ of diagrams. Colimits over an open commute with this pushout, so

$$Q_{f'}(K, J) \amalg_{Q_f(K,J)} Y_J \cong Y'_J.$$

The comparison $d_{f'}(K, J)$ is consequently a pushout of $d_f(K, J)$. This is the assertion that the polyhedral diagram on pages 43–44 is designed to show. The proof uses only the universal properties of the displayed colimits and therefore applies equally to C and TC.

These are familiar Leibniz or pushout-product calculations in later terminology. The relative latching map of a composite is explicitly treated in Riehl and Verity (2014, Observation 5.1 and

Example 5.2). The reference identifies a later general organization of the calculation; no lifting axiom, monoidal model structure, or retract closure is needed for the elementary identities just proved.

Cof_2. Pour prouver que $C_{I^\circ} \cap W_{I^\circ}$ est stable par cochangement de base, je ne vois pas de façon de le faire, si je ne sais déjà qu'on a

$$(*) \qquad C_{I^\circ} \cap W_{I^\circ} \;=\; (TC)_{I^\circ} \;,$$

et alors on applique le résultat précédent (où W n'entrait pas) à TC au lieu de C. Mais pour avoir $(*)$, il faut que je suppose qu'on est dans l'un des deux cas suivants (de façon à pouvoir appliquer le théorème 2.1 et son corollaire 2.5).

a) I fini, ou plus généralement I artinien *et* $\mathrm{Top}(I)$ est noethérien.

b) I artinien, et de plus C et TC sont stables par composition transfinie.

Cof_3. L'axiome de facorisation me paraît a priori le plus délicat [15]. Mais cela sort finalement sans trop de mal. Soit donné

$$f \;:\; X_\bullet \longrightarrow Y_\bullet$$

dans $\mathcal{M}(I^\circ)$, considérons les triples p. 24 [45]

$$(J,\; Z,\; i,\; p) \;,$$

où $J \subset I$ est un ouvert, Z un objet de $\mathcal{M}(J^\circ)$, et i, p sont des flèches

$$\begin{cases} X|J \xrightarrow{\;i\;} Z \xleftarrow{\;p\;} Y|J \\ \text{avec } i \in C_{J^\circ},\; p \in W_{J^\circ}. \end{cases}$$

On ordonne les quadruples par prolongement. Si on a un ensemble totalement ordonné, de $(J_\alpha, Z_\alpha, i_\alpha, p_\alpha)$, posant $J = \bigcup I_\alpha$, on trouve de Z, i, p uniques sur J qui prolongent les Z_α, i_α, p_α donnés, de plus on aura $i \in C_{J^\circ}$, $p \in W_{J^\circ}$, car l'appartenance à C_{J° resp. W_{J° est question locale sur J. Donc par Zorn, on est ramené à prouver que si (J, Z, i, p) est maximal, on a $J = I$ – d'ou la factorisation voulue $f = pi$. Donc à prouver que si $J \neq I$, le quadruple n'est pas maximal. Considérons le fermé non vide $I \backslash J$. I est supposé artinien, il y a un *élément minimal* i_0 de $I \backslash J$. Posons [46]

$$J' \;=\; J \cup \{i_0\} \;=\; J \cup I/i_0,$$

et montrons qu'on peut prolonger le triplet Z, i, p en Z', j', p' sur J'. Posant $K' = I/i_0$, $K = J \cap K = I_{<i_0}$, on a donc

$$\begin{array}{ccc} K = J \cap K' & \hookrightarrow & K' = I/i_0 \\ \downarrow & & \downarrow \\ J & \hookrightarrow & J' = J \cup K'. \end{array}$$

On voit alors que les prolongements de (Z, i, p) de J à J' correspondent à ceux de $(Z|K', i|K', p|K')$ à K. Pour ceci, on note que pour une flèche φ d'objets de $\mathcal{M}(J'^\circ)$, cette flèche est dans $C_{J'^\circ}$ resp. $W_{J'^\circ}$, si et seulement si ses restrictions à J et à K' le sont.

15. L'argument qui suit s'applique à d'autres situations de factorisation, par exemple pour un précouple de Quillen donné (Φ, Ψ) dans $\mathcal{M}$.

Commentary · Exposition [ms. 46]

Factorization by adjoining one minimal missing object

Grothendieck's construction is the relative latching factorization, written without a degree function. Its purpose is to preserve all the factorization data already chosen on a lower open. The only new choice at a stage is a factorization in $\mathcal{M}$ of one map from a pushout.

Suppose $f : X \to Y$ has been factored on a lower open J as $X|J \xrightarrow{i} Z \xrightarrow{p} Y|J$, with $i \in C_J$ and p objectwise in W. Choose a minimal element s of $I \setminus J$. Every strict predecessor of s lies in J, so $J \cup \{s\}$ is lower. Put $K = I_{<s}$ and form

$$P_s = X_s \amalg_{X_K} Z_K.$$

The original map f_s and the map $Z_K \xrightarrow{p_K} Y_K \to Y_s$ agree on X_K, hence define $P_s \to Y_s$. Factor it by Cof_3 as

$$P_s \xrightarrow{j_s} Z_s \xrightarrow{p_s} Y_s, \qquad j_s \in C, \quad p_s \in W.$$

The maps from the predecessor values Z_t to Z_s are the composites through Z_K and P_s. They are compatible because they come from a cocone. Define i_s by $X_s \to P_s \to Z_s$. The equality $p_s i_s = f_s$ and the naturality equations follow from the defining pushout. The new relative latching map for i is exactly j_s; all older latching maps are unchanged. Theorem 2.1(2) gives the strong cofibration condition on the enlarged lower open, and p remains a pointwise weak equivalence.

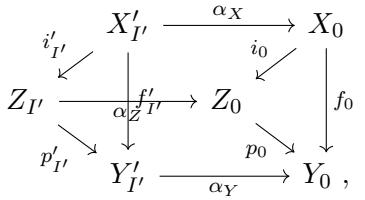
This proves the required extension and also explains the direction of p in the source: it must run from Z to $Y|J$. The backward arrow on page 45 is printed in the edition and is retained as an edition slip. On page 46 the restriction to K must be extended to K', rather than the other way around as the sentence there says.

One may finish with a well-ordered recursion instead of applying Zorn to a possibly large class of partial factorizations. Fix a well-order of the set of objects of I, choose at each successor stage the first minimal missing object, and take the union of the strictly compatible data at a limit stage. This union is an actual diagram: each object, each arrow, and each required naturality equation already occurs at some previous stage. Cofibrancy is local on principal lower sets, so it persists at the union. The recursion stops before more distinct objects have been chosen than I contains. This avoids a size ambiguity in the Zorn wording while preserving the argument. The local factorization choices can be made in the ambient universe; they need not be functorial.

The argument requires the latching colimits X_K, Z_K to exist. In the artinian noetherian alternative the indexing poset is finite, as proved above. In the transfinite alternative suitable small colimits must actually be available. Closure of a class of morphisms under transfinite composition cannot supply a colimit that the ambient category does not have.

On est donc ramené au cas standard d'un ensemble ordonné avec objet final e_0, ensemble ordonné qu'on va noter I, et l'ensemble ordonné I' des objets $i < e_0$, i.e. $I' = I\backslash\{i_0\}$. On a $f : X_\bullet \longrightarrow Y_\bullet$, flèche dans $\mathcal{M}(I^\circ)$, une factorisation de $f|I'$ en $p' \circ i'$ avec $i' \in C_{I'^\circ}$, $p' \in W_{I^\circ}$, et il s'agit de la prolonger en une factorisation similaire de f. On note que la donnée d'un [47]
objet $X_\bullet$ de $\mathcal{M}(I^\circ)$ équivaut à celle d'un objet $X'_\bullet$ de $\mathcal{M}(I'^\circ)$ (la restriction de X à I') et d'une flèche

$$X'_{I'} \xrightarrow{\alpha_X} X_{e_0} = X_0$$



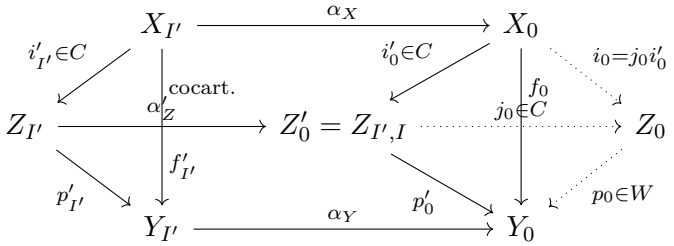
dans $\mathcal{M}$, où $X'_{I'} = \varinjlim_{i' \in I'} X'_{i'}$. Donc la donnée de la flèche $f : X_\bullet \longrightarrow Y_\bullet$ revient à celle de
$f' = f|I' : X'_\bullet \longrightarrow Y'_\bullet$, et d'une flèche $f_0 : X_0 \longrightarrow Y_0$ rendant commutatif le carré p. 25

$$\begin{array}{ccc} X'_{I'} & \xrightarrow{\alpha_X} & X_0 \\ {\scriptstyle f'_{I'}}\downarrow & & \downarrow{\scriptstyle f_0} \\ Y'_{I'} & \xrightarrow{\alpha_Y} & Y_0 \ . \end{array}$$

De même, trouver une factorisation de f en pi, qui prolonge une factorisation donnée

$f' = p'i'$ sur J', revient à la donnée d'un diagramme commutatif

(∗)



où l'objet Z_0, et les trois flèches α_Z, i_0, p_0 sont à déterminer. Si on a $i' \in C_{I'\circ}$, $p \in W_{I'\circ}$, alors on conclut par théorème 2.1. 1° (cor. 2.2) que [48 vide] [49]

$$i'_{I'} \ \in \ C \ ,$$

et si on veut que $i \in C_{I\circ}$, $p \in W_{I\circ}$, il reste seulement à exiger

$$p_0 \in W, \qquad (i'_{I',I} : \underbrace{Z_{I'} \amalg_{X_{I'}} X_0}_{Z'_0} \longrightarrow Z_0) \in C,$$

d'après le théorème 2.1. 2°. On va alors construire le diagramme (∗), à partir du diagramme similaire ci-dessous

(avec Z_0 de (∗) remplacé par $Z'_0 = Z_{I',I}$) en factorisant la flèche canonique $p'_0 : Z'_0 \longrightarrow Y_0$ en

$$p'_0 \ = \ p_0 j_0 \ , \qquad \text{avec } p_0 \in W, \ j_0 \in C \ ,$$

et en posant

$$i_0 \ = \ j_0 i'_0 \ ,$$

ce qui achève la construction.

Commentary · Examples [ms. 49]

A factorization at a branching vertex in chain complexes

The last construction is easiest to see when one can write its new object explicitly. Let $\mathcal{M}$ be chain complexes of vector spaces over a field k, with homological differentials, degreewise injections as cofibrations, and chain homotopy equivalences as weak equivalences. The injections split degree by degree. We use the square poset from the earlier example, with $X = 0$ and with the target diagram $Y_a = 0$, $Y_b = Y_c = Y_d = k[0]$. Both maps into Y_d are the identity. The initial map to this diagram is pointwise a cofibration but fails the diagram cofibration condition at d, where its latching map is the fold $k \oplus k \to k$.

Leave the factorization unchanged at a, b, c. At d the object P_d in the preceding construction is $A = k^2[0]$ and its map to $B = Y_d = k[0]$ is $q(a_1, a_2) = a_1 + a_2$. Define a complex Z_d by

$$(Z_d)_1 = k^2, \qquad (Z_d)_0 = k \oplus k^2, \qquad d(x_1, x_2) = (x_1 + x_2, -x_1, -x_2),$$

and zero in other degrees. Let $j : A \to Z_d$ be $j(a_1, a_2) = (0, a_1, a_2)$ in degree zero, and let $p : Z_d \to B$ be

$$p(b, a_1, a_2) = b + a_1 + a_2$$

in degree zero, with $p = 0$ in degree one. Then $pj = q$, p is a chain map, and j is degreewise injective. The maps from b and c are the two summand inclusions followed by j, so the extended data form a commutative square.

The map p is a homotopy equivalence, not merely a quasi-isomorphism asserted without calculation. Its section sends b to $(b, 0, 0)$. Its kernel in degree zero consists of $(-a_1 - a_2, a_1, a_2)$ and is identified with k^2. Under this identification the differential from degree one is $-1 : k^2 \to k^2$. The homotopy inverse to this differential, with the same minus sign, contracts the kernel. Thus Z_d is the direct sum of B and a contractible complex. The resulting map of diagrams $Z \to Y$ is pointwise in W, and $0 \to Z$ is a diagram cofibration because the new latching map is exactly j.

The construction preserves the homotopy type at the branching vertex while replacing an identification of two branches by an explicit cofibration. Its quotient complex $Z_d/j(A)$ is $k^2 \xrightarrow{(1,1)} k$ in degrees one and zero. Its degree-one homology is $\{(t, -t) \mid t \in k\} \cong k$. This records the relation joining the two branches. The example makes visible why a diagram factorization has more information than choosing independent factorizations of the component maps.

On a ainsi prouvé le

Théorème 3.1. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations (cf. page 39), $\mathcal{M}$ stable par $\varinjlim$ finies. Pour tout ensemble odonné I, considérons le tuple $(\mathcal{M}(I^\circ), W_{I^\circ}, C_{I^\circ})$ correspondant, où C_{I° est défini au paragraphe 2 (cf. à ce sujet le théorème 2.1). Supposons que I soit un ensemble ordonné* artinien *(p.ex. I localement fini, i.e. les I/i finis). Supposons de plus qu'on soit dans l'un des deux cas suivants :* p. 26 [50]

a) *L'espace* $\mathrm{Esp}(I)$ *est noethérien, i.e. toute suite croissante d'ouverts de I est stationnaire (p.ex. I fini).*

b) *C et $TC = C \cap W$ sont stables, non seulement par composition ordinaire, mais aussi par composition transfinie. Dans ce cas, on suppose aussi $\mathcal{M}$ stable par petites $\varinjlim$ filtrantes (donc par petites $\varinjlim$ quelconques).*

Sous ces conditions, $(\mathcal{M}(I^\circ), W_{I^\circ}, C_{I^\circ})$ est également une catégorie à cofibrations.

Commentary · Exposition [ms. 50]

The diagram structure and the size of its indexing category

Grothendieck has now reached the purpose of the preceding combinatorics: a diagram admits a replacement whose ordinary colimit can be trusted homotopically. Write $\mathcal{M}^I = \mathrm{Fun}(I, \mathcal{M})$, remembering that this is his $\mathcal{M}(I^\circ)$. For a well-founded poset the cofibrations of Theorem 3.1 are exactly the maps whose relative latching maps

$$X_i \amalg_{\mathrm{colim}_{j<i} X_j} \mathrm{colim}_{j<i} Y_j \longrightarrow Y_i$$

belong to C. Weak equivalences remain objectwise. The construction at pages 45–49 therefore gives the familiar inductive replacement: after the values below i have been chosen, factor the single map from the relative latching object to the prescribed value at i. The boundary has already encoded every naturality equation involving an incoming arrow. No lifting property between two distinguished classes is needed.

The alternatives in the theorem concern existence of these boundaries as well as preservation of the relevant classes. In case (b), finite colimits and small filtered colimits give all small colimits. Indeed, an arbitrary coproduct is the filtered colimit of its finite subcoproducts, and a general colimit is the coequalizer of the two familiar coproducts indexed by objects and arrows. Transfinite closure of C and $C \cap W$ then supplies precisely the closure needed in the boundary calculations. Merely having ordinary finite composites would not justify a limit stage.

There is a useful simplification of case (a). With the usual choice principles, a well-founded poset whose lower Alexandrov topology is noetherian is finite. If it were infinite, choose successively a minimal element of the remaining poset. After n choices the chosen elements form a lower set: every predecessor of the next chosen element was already chosen. These finite lower sets give an infinite strictly increasing sequence of opens, a contradiction. Consequently the apparent generalization beyond finite I in this branch introduces no additional posets. This observation also explains

why finite colimits suffice here; one must not diagnose an absent infinite-colimit hypothesis in this particular assertion.

The theorem supplies more than an objectwise cofibrant replacement. On the span $a \leftarrow b \rightarrow c$, an objectwise cofibrant diagram can still have a noncofibrant attaching map out of b. A replacement cofibrant for C_I controls those attachments, so its pushout is the model for the homotopy pushout. The distinction is the reason for carrying the relative, rather than just the absolute, latching construction throughout the chapter.

Proposition 3.2. *Soit $u : I \longrightarrow I'$ une application croissante entre ensembles ordonnés, d'où un couple de foncteurs adjoints*

$$\mathcal{M}(I^\circ) \underset{u^*}{\overset{u_!}{\rightleftarrows}} \mathcal{M}(I'^\circ) \quad . \tag{3.2.1}$$

a) *Le foncteur u^* est compatible avec les localiseurs $W_{I'^\circ}$, W_{I°. Si I est discrète, ou u étale, alors u^* applique $C_{I'^\circ}$ dans C_{I°. Il en est encore de même quand u est localement cofiltrant, i.e. si pour tout $i' \in \mathrm{Ob}\, I'$, la catégorie $i'\backslash I$ est localement filtrante, i.e. ses composantes connexes sont cofiltrantes (condition* $\mathrm{PS_g}$ 1 *sur $i'\backslash I$)* [16].* [51]

b) *Dans tous les cas, $u_!$ transforme C_{I° en $C_{I'^\circ}$, TC_{I° en $TC_{I'^\circ}$, enfin $\mathcal{M}(I^\circ)_c$ en $\mathcal{M}(I'^\circ)_c$.*

Commentary · Exposition [ms. 51]

Why restriction needs a condition on the indexing map

Grothendieck wants to know which changes of indices preserve the replacements just constructed. Preservation of weak equivalences is immediate for every restriction functor: the component of u^*f at i is $f_{u(i)}$. Preservation of cofibrations is different, because restriction can change the shape and the connected components of a boundary. Proposition 3.2(a) identifies a condition which prevents this change from changing the relevant colimit.

Here is the poset argument behind the reference to Chapter II. Fix $i \in I$, let $U \subseteq I/i$ be a lower set, and let U' be the lower set of $I'/u(i)$ generated by $u(U)$. For $b \in U'$, the comma category $(b \downarrow u|_U)$ is the poset

$$S_b = \{x \in U \mid b \leq u(x)\}.$$

It is nonempty by the definition of U'. Every object of S_b maps to i in $(b \downarrow u)$, since $x \leq i$ and $b \leq u(i)$. Thus all these objects belong to one connected component of that comma category. If its connected components are cofiltered, any two objects x, y of S_b have a common predecessor z there. Since U is lower, $z \in U$, and hence $z \in S_b$. A poset has no nontrivial parallel-arrow equalization condition, so S_b itself is cofiltered. In particular its underlying undirected graph is connected.

The ordinary final-functor criterion now gives

$$\mathrm{colim}_U\, u^*X' \;\simeq\; \mathrm{colim}_{U'}\, X'.$$

The same holds for Y', and the values at i and $u(i)$ are identical. Consequently the two relative boundary maps in the displayed cube differ only by isomorphisms. This proves the asserted preservation of C_I without introducing any homotopy cofinality theorem. The localizer does not enter this step.

For an étale map of posets the same conclusion is even more direct: the map $I/i \to I'/u(i)$ is an isomorphism. For a discrete source, each boundary is empty, so only the component maps are tested. These are two special ways of making the boundary comparison harmless. The printed phrase "localement filtrante" on page 51 conflicts with the immediately following definition; the proof uses cofiltered connected components, as the statement's initial terminology already indicates. We retain the printed wording and record the slip.

Démonstration. Prouvons a), dans le cas le plus gênant, où on suppose seulement que u est localement faiblement cofiltrant. On applique II 7.4 (p. 92), qui nous dit que $\forall i \in \mathrm{Ob}\, I$, considérant le morphisme induit par u

16. inutile de parler de "faiblement" localement cofiltrant, car il s'agit d'ensembles ordonnés où il n'y a pas à distinguer entre notions forte et faible. [52]

$$I/i \longrightarrow I'/i' \qquad (\text{où } i' = u(i)),$$

celui-ci est *(globalement)* faiblement cofiltrant, et que pour tout ouvert U de I/i, désignant par U' l'ouvert engendré par son image, le morphisme induit $v : U \longrightarrow U'$ est encore faiblement cofiltrant, et a fortiori *cofinal.* Soit alors $f' : X' \longrightarrow Y'$ une flèche dans $C_{I'\circ}$, prouvons que

$$\underbrace{u^*(f')}_{f} \;:\; \underbrace{u^*(X')}_{X} \longrightarrow \underbrace{u^*(Y')}_{Y}$$

est dans $C_{I\circ}$, i.e. que pour tout $i \in I$, et U ouvert de I/i, dans le diagramme canonique p. 27

$$(*) \qquad \begin{array}{ccc} X_U & \longrightarrow & X(i) \\ \downarrow & \text{cocart.} & \downarrow \\ Y_U & \longrightarrow & Y_{U,i} \\ & & \downarrow{\scriptstyle v_{U,i}} \\ & & Y(i)\ , \end{array}$$

la flèche $v_{U,i}$ est dans C. Le diagramme $(*)$ s'envoie dans le diagramme similaire pour [53] $f' : X' \longrightarrow Y'$, $i' = u(i)$, et l'ouvert $U' \subset I'/i'$ engendré par $u(U)$:

$$(**) \qquad \begin{array}{ccccc} X_U & \xrightarrow{\quad} & X(i) & & \\ {\scriptstyle c_U^{X'}}\downarrow & \searrow^{f_U} & \text{cocart.}\downarrow & \searrow & \\ & Y_U & \longrightarrow & Y_{U,i} & \xrightarrow{v_{U,i}} \\ & {\scriptstyle c_U^{Y'}}\downarrow & \text{id}\downarrow & {\scriptstyle c^{f'}_{U,i}}\downarrow & \\ X'_{U'} & \xrightarrow[\text{cocart.}]{} & X'(i') & & Y(i) \\ & \searrow^{f'_{U'}} & \downarrow & \searrow & \downarrow{\scriptstyle \text{id}} \\ & & Y'_{U'} & \longrightarrow & Y'_{U',i'} \\ & & & \searrow^{v_{U',i'}} & Y'(i')\ . \end{array}$$

Par cofinalité, les deux flèches verticales $c_U^{X'}$ et $c_U^{Y'}$ sont des isomorphismes, en plus de $X(i) \xrightarrow{id} X'(i')$, donc la quatrième flèche du cube, $c^{f'}_{U,i}$, est un isomorphisme. Comme $v_{U',i'}$ est dans C, $v_{U,i}$ aussi, on gagne.

Commentary · Examples [ms. 53]

A constant point which is not a cofibrant diagram

The condition on restriction has a visible effect even in sets. Take $\mathcal{M} = \mathsf{Set}$, let C be the injections, and let every map be a weak equivalence. This satisfies the four axioms on page 39: injections are stable under pushout and composition, and any map factors as its source identity followed by a weak equivalence. All objects are cofibrant. The example concerns the cofibration structure; its deliberately indiscriminate weak equivalences play no role in the computation.

Let I have three objects a, b, t, with $a < t$ and $b < t$, and no relation between a and b. For the unique map $q : I \to e$, restrict the one-point set $*$ to the constant diagram. At either minimal object the latching map is $\varnothing \to *$, an injection. At t it is

$$* \amalg * \longrightarrow *,$$

the fold map, which is not injective. Thus q^* does not preserve cofibrant objects. The comma category $(* \downarrow q) = I$ is connected but not cofiltered: a and b have no common predecessor. This is exactly the obstruction detected by the hypothesis of Proposition 3.2(a).

A cofibrant replacement can be written without any choices. Put $Q_a = Q_b = *$, $Q_t = \{a, b\}$, and use the two inclusions as transition maps. The relative boundary at t is the identity of the

two-point set. The obvious map $Q \to \mathrm{const}(*)$ is objectwise a weak equivalence. Its colimit is Q_t, whereas the colimit of the constant diagram is $*$. Those two objects are equivalent for the chosen W, but the two strict diagrams carry different attaching information. The calculation explains why the proof of Theorem 3.7 must work even when ordinary restriction fails to preserve cofibrancy.

For comparison, if $I = [1]$, the boundary at its final vertex is a single copy of $*$. Its map to the final value is the identity, and the constant point is cofibrant. The passage from one predecessor to two disconnected predecessors is already sufficient to destroy preservation. Neither the cardinality of the object values nor a complicated homotopy theory is responsible.

Prouvons b). Soit donc

$$f \ : \ X \longrightarrow Y$$

une flèche dans C_I, et soit

$$f' \ = \ u_!(f) \ : \ u_!(X) = X' \longrightarrow u_!(Y) = Y',$$

prouvons que c'est dans $C_{I'^\circ}$, donc que pour deux ouverts $U' \subset V'$ de I' (où on peut supposer [54]
que $V' = I'/i'$), dans le diagramme-base de $(**)$, $v_{U',V'}$ soit dans C. Soit $U = u^{-1}(U')$, $V = u^{-1}(V')$, et considérons le diagramme similaire à $(**)$, défini par les deux inclusions d'ouverts $U' \subset V'$, $U \subset V$. Cette fois, comme la formation de $u_!$ commute aux restrictions aux ouverts, par transitivité des $\varinjlim$, les trois flèches vertivales $c^X_{U'}$, $c^Y_{U'}$, $c^X_{V'}$ sont des isomorphismes, donc aussi $c^f_{U',V'}$. De même, la flèche $Y_V \longrightarrow Y'_{V'}$ (à la place de $Y(i) \longrightarrow Y'(i')$) est un isomorphisme. Comme $v_{U,V} \in C$, il en est de même de $v_{U',V'}$, ce qui prouve que $f' \in C_{I'^\circ}$. On procède de même pour TC_I. Enfin, l'assertion que $u_!$ applique $\mathcal{M}(I^\circ)_\mathrm{c}$ dans $\mathcal{M}(I'^\circ)_\mathrm{c}$ résulte des définitions et de $u_!(C_{I^\circ}) \subset C_{I'^\circ}$.

Commentary · Exposition [ms. 54]

Left Kan extension transports the whole relative boundary

The asymmetry between the two parts of Proposition 3.2 is deliberate. Restriction changes a boundary, but left Kan extension is designed to preserve the colimit describing that boundary. For any lower set $V' \subseteq I'$ and any diagram $X : I \to \mathcal{M}$, there is a canonical isomorphism

$$\mathrm{colim}_{V'}\, u_!X \ \simeq \ \mathrm{colim}_{u^{-1}V'}\, X,$$

whenever the indicated colimits exist. One can see it directly from cocones. An object contributing to $(u_!X)(b)$ is a pair $(i, u(i) \leq b)$ with $b \in V'$. Since V' is lower, $u(i) \in V'$. Conversely every $i \in u^{-1}V'$ contributes via $b = u(i)$ and the identity arrow. These identity contributions determine every cocone, and their transition relations are exactly those of the restricted diagram on $u^{-1}V'$.

Apply this twice, to $U' \subseteq V'$ and to X, Y. The relative boundary for $u_!f$ is thereby identified with

$$Y_{u^{-1}U'} \amalg_{X_{u^{-1}U'}} X_{u^{-1}V'} \longrightarrow Y_{u^{-1}V'}.$$

Theorem 2.1(1) puts this map in C. Applying the same reasoning to $TC = C \cap W$ puts it in TC if $f \in (TC)_I$. Taking X to be the initial diagram proves preservation of cofibrant objects. This is why the strong definition involving every open subset was convenient before well-foundedness was imposed: the inverse images of the target opens are arbitrary opens of the source, not necessarily single principal ideals.

There is a small logical distinction in the next corollary. The source may be assumed well-founded while the target is not. The equality

$$(TC)_{I'} = C_{I'} \cap W_{I'^\circ}$$

cannot then simply be imported from the artinian part of Theorem 2.1. The proof needs only the inclusion from left to right. This inclusion is automatic for the strong definition: take the empty lower set inside I'/i' to see that each component lies in TC. Thus the unnecessary equality in the proof of Corollary 3.3 can be replaced by this inclusion, with no change to its conclusion. Existence of the ordinary Kan extension remains a separate hypothesis when one leaves the cocomplete setting.

Corollaire 3.3 (de prop. 3.2 et th. 3.1). *Soit $u : I \longrightarrow I'$ comme dans* 3.2. *Supposons de plus I artinien, et qu'on soit pour $\mathcal{M}$, W, C, I dans l'une des conditions* a), b) *du théorème* 3.1. *Alors $u_!$ induit une flèche* p. 28 [55]

$$u_{!\,\mathrm{cof}} \ : \ \mathcal{M}(I^\circ)_\mathrm{c} \longrightarrow \mathcal{M}(I'^\circ)_\mathrm{c} \ \subset \ \mathcal{M}(I'^\circ)$$

qui transforme flèches de $W(I^\circ)$ en flèches de $W(I'^\circ)$ (i.e. compatible avec les localiseurs). Il induit donc un foncteur sur les localisés, d'où un

$$u_!^W \ : \ \mathrm{Ho}_W(I^\circ) \longrightarrow \mathrm{Ho}_W(I'^\circ) \qquad (17). \tag{3.3.1}$$

Démonstration. Par le théorème 3.1, on sait que $\mathcal{M}(I^\circ)$, $W(I^\circ)$, $C(I^\circ)$ est une structure de catégorie de modèles à cofibrations. On sait par ailleurs que $TC_{I^\circ} = C_{I^\circ} \cap W(I^\circ)$, par th. 2.1. 3° (p. 27). Donc par 3.2, $u_!$ applique $C_{I^\circ} \cap W(I^\circ)$ dans $TC_{I'^\circ} = C_{I'^\circ} \cap W(I'^\circ)$, et a fortiori, en des flèches dans $W(I'^\circ)$. Par ailleurs, par la théorie des catégories à cofibrations, on trouve que toute flèche f entre objets cofibrants est composée $f = pi$, où $i \in C_{I^\circ}$, et où p est dans $W(I^\circ)$, et de plus *inverse à gauche* d'une flèche dans $C_{I^\circ} \cap W(I^\circ)$, i.e. d'une flèche de $(TC)_{I^\circ}$. Quand $f \in W(I^\circ)$, alors $i \in W(I^\circ)$, donc $i \in W(I^\circ) \cap C_{I^\circ} = (TC)_{I^\circ}$. Au total, toute [56] flèche $f \in W(I^\circ)_\mathrm{c}$ est composée pi dans $\mathcal{M}(I^\circ)_\mathrm{c}$, où $i \in (TC)_{I^\circ}$, et p est inverse à gauche d'une $j \in (TC)_{I^\circ}$. Comme $u_!$ transforme $(TC)_{I^\circ}$ en $(TC)_{I'^\circ}$, il transforme f en $f' = p'i'$, avec $i' \in (TC)_{I'^\circ} \subset W_{I'^\circ}$, et p' inverse à gauche d'une $j' = u_!(j)$ qui est également dans $W_{I'^\circ}$. Mais alors $i' \in W(I'^\circ)$, donc aussi $f' = p'i' \in W_{I'^\circ}$, ce qui prouve que $u_!(W(I^\circ)_\mathrm{c}) \subset W(I'^\circ)$. La dernière assertion provient du lemme suivant, appliqué à $(\mathcal{M}(I^\circ), W(I^\circ), C_{I^\circ})$ au lieu de $(\mathcal{M}, W, C)$:

Lemme 3.4. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations. Alors l'inclusion $\mathcal{M}_\mathrm{c} \subset \mathcal{M}$ induit une équivalence*

$$\mathcal{M}_\mathrm{c} W_\mathrm{c}^{-1} \xrightarrow{\sim} \mathcal{M} W^{-1} = \mathrm{Ho}_W \ .$$

Nous donnerons la démonstration (par AQT `[âne qui trotte]`) ultérieurement.

Cela achève la démonstration de 3.3.

Commentary · Exposition [ms. 56]

The mapping-cylinder argument behind Corollary 3.3

Grothendieck must now pass from preservation of trivial cofibrations to preservation of all weak equivalences between cofibrant diagrams. The useful fact is a one-sided factorization, stronger than the bare factorization axiom: a map between cofibrant objects factors as a cofibration followed by a weak equivalence which has a trivial-cofibration section. Here is a complete construction in the notation of page 39.

For a cofibrant object A, factor its fold map as

$$A \amalg A \xrightarrow{(d_0,d_1)} IA \xrightarrow{r} A, \qquad (d_0, d_1) \in C, \quad r \in W.$$

Each inclusion $A \to A \amalg A$ is a pushout of $\varnothing \to A$, hence belongs to C. Thus $d_0, d_1 \in C$. The equations $rd_0 = rd_1 = \mathrm{id}_A$ and two-out-of-three show $d_0, d_1 \in TC$. Given $f : A \to B$ with B cofibrant, form

$$M_f = B \amalg_{A,d_0} IA.$$

The inclusion $j : B \to M_f$ is a pushout of d_0, so $j \in TC$. There is a map $p : M_f \to B$ whose restrictions are id_B and fr, and $pj = \mathrm{id}_B$ implies $p \in W$. The other endpoint defines $i : A \to M_f$ with $pi = f$.

To check that i is a cofibration, first observe that $B \amalg A \to M_f$ is the pushout of $(d_0, d_1) : A \amalg A \to IA$ along (f, id_A). The map $A \to B \amalg A$ is a cofibration because B is cofibrant. Their composite is

17. **N.B.** Cette flèche est définie, même sans supposer I' ordonné, car $u_{!\,\mathrm{cof}}$ transforme encore flèches de $W(I^\circ)$ en flèches de $W(I'^\circ)$. Cf. commentaire p. 86.

i. Therefore $f = pi$ has all the claimed properties. If $f \in W$, then $i \in W$ by two-out-of-three, so both i and the section j are trivial cofibrations.

Now let F be any functor carrying trivial cofibrations between cofibrant objects to weak equivalences. Applied to this factorization, $F(j)$ is a weak equivalence and $F(p)F(j) = \mathrm{id}$, so $F(p)$ is one also. If $f \in W$, then $F(i) \in W$, and hence $F(f) = F(p)F(i) \in W$. Taking $F = u_!$ gives the assertion used here. The printed last inference on page 56 repeats $i' \in W$ where the new information is $p' \in W$; the section equation supplies the missing inference. This is a correct argument obscured by a repeated letter, not a failure of Corollary 3.3.

Commentary · Later developments [ms. 56]

What is required of cofibrant replacement

The deferred Lemma 3.4 ensures that the candidate just constructed is defined on the intended homotopy category. Essential surjectivity is immediate: factor $\varnothing \to X$ as $\varnothing \to QX \xrightarrow{q} X$, with QX cofibrant and $q \in W$. Full faithfulness requires more than one such choice for each object. A morphism in a localization is represented by a finite zigzag, and its relations must remain valid after replacing the objects appearing in that zigzag.

The factorization argument of pages 45–49 supplies these compatible replacements on finite direct diagrams. In particular it replaces a span or a composable pair together with its structure maps, rather than replacing its vertices independently. The mapping-cylinder argument in the preceding block compares different choices after passing to homotopy. These are the ingredients of the usual cofibrant-approximation proof. A precise later statement is Rădulescu-Banu (2009, Theorem 6.1.6(1)); its proof passes through the approximation theorem and the comparison lemmas in §6.1. It applies already to precofibration categories, so no infinite-composition hypothesis is needed for Lemma 3.4.

This also clarifies the meaning of the "canonical" functor in (3.3.1). If

$$j_I : \mathcal{M}^I_{\mathrm{c}}[W^{-1}] \longrightarrow \mathcal{M}^I[W^{-1}]$$

is the equivalence and $\overline{u_!}$ is the functor induced on the cofibrant subcategory, then the candidate is $\overline{u_!}\, j_I^{-1}$. Its uniqueness is understood relative to the specified comparison on cofibrant objects. One does not obtain a preferred strict functor before making choices, and one does not obtain an adjunction merely by writing this composite. The next pages are devoted to that second issue.

3.5. Il se pose la question si le foncteur $u_!^W$ de (3.3.1) est bien un adjoint à gauche du foncteur en sens inverse u_W^*, induit par u^*. Notons que c'est le cas si u^* transforme $\mathcal{M}(I'^{\circ})_{\mathrm{c}}$ en $\mathcal{M}(I^{\circ})_{\mathrm{c}}$, et quand on suppose que I' est également artinien et satisfait également à l'une des hypothèses a) b) du théorème 3.1. Car alors $(\mathcal{M}(I^{\circ}), W(I^{\circ}), C_{I^{\circ}})$ est une catégorie à cofibrations par le théorème 3.1, on peut lui appliquer le lemme précédent, donc u_W^* et $u_!^W$ se réalisent à partir d'un couple de foncteurs [57]

$$\mathcal{M}(I^{\circ})_{\mathrm{c}} \underset{u_{\mathrm{c}}^*}{\overset{u_!^{\mathrm{c}}}{\rightleftarrows}} \mathcal{M}(I'^{\circ})_{\mathrm{c}} \quad ,$$

lesquels sont visiblement adjoint l'un de l'autre (puisque induits par un couple de foncteurs adjoints $u_!$, u^*), et de plus compatibles aux localiseurs. Donc on peut appliquer le lemme des foncteurs adjoints pour les localisés. Pour résumer : p. 29

Corollaire 3.5. *Supposons que I, I' soient artiniens, et qu'on soit dans l'un des deux cas suivants :*

a) *Les espaces* $\mathrm{Esp}(I)$, $\mathrm{Esp}(I')$ *sont noethériens (p.ex. I, I' finis).* [page 58]

b) *C et $TC = C \cap W$ sont stables par composition transfinie.*

Supposons de plus que u^* applique $\mathcal{M}(I'^{\circ})_{\mathrm{c}}$ dans $\mathcal{M}(I^{\circ})_{\mathrm{c}}$, ce qui est le cas notamment si u est localement cofiltrant, i.e. les ensembles ordonnés localisés $i'\backslash I$ sont localement cofiltrants. Alors le foncteur $u_!^W$ construit dans (3.3.1) est adjoint à gauche de u_W^*.

Remarque 3.6. Quand on a un couple de foncteurs adjoints

$$\mathcal{C} \underset{u^*}{\overset{u_!}{\rightleftarrows}} \mathcal{C}' \quad ,$$

avec les localiseurs W, W' de $\mathcal{C}$, $\mathcal{C}'$, u^* compatible aux localiseurs, et si de plus on a une sous-catégorie pleine $\mathcal{C}_0$ de $\mathcal{C}$ telle que

a) $u_!|\mathcal{C}_0$ transforme flèches de W en flèches de W', et

b) l'inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ induit une *équivalence* $\mathcal{C}_0 W_0^{-1} \xrightarrow{\sim} \mathcal{C}W^{-1}$ (où $W_0 = W \cap \mathrm{Fl}(\mathcal{C}_0)$),

on trouve deux foncteurs canoniques

$$\mathcal{C}W^{-1} \underset{u_W^*}{\overset{u_!^W}{\rightleftarrows}} \mathcal{C}'W'^{-1} \quad ,$$

où $u_!^W$ est défini seulement à isomorphisme canonique près.

Contrairement à ce que prétend Anderson, il n'est par vrai en général que ces deux foncteurs soient adjoints, sans hypothèses supplémentaires. Voici un contrexemple : on prend $\mathcal{C} = \mathcal{C}'$, $u_! = u^* = \mathrm{id}_{\mathcal{C}}$, $W' = \mathrm{Is}(\mathcal{C})$, $W = \mathrm{Fl}(\mathcal{C})$, donc u_W^* est le foncteur canonique [page 59]

$$\underbrace{\Pi\mathcal{C}}_{\text{groupoïde fondamental}} \longleftarrow \mathcal{C} \ .$$

Supposons que $\mathcal{C}$ soit 1-connexe, i.e. $\Pi\mathcal{C}$ soit équivalente à e. Soit $e \in \mathrm{Ob}\,\mathcal{C}$ tel que $\mathrm{End}_{\mathcal{C}}(e)$ soit le groupe unité, et prenons $\mathcal{C}_0 = \{e\}$. Alors l'hypothèse sur $\mathcal{C}_0$ est satisfaite. Mais si $u_!^W$ était adjoint à gauche de u_W^*, e serait objet initial de $\mathcal{C}$. Par exemple si $\mathcal{C}$ a un objet final e (ce qui implique que $\mathcal{C}$ est 1-connexe et e rigide), cet objet final devrait être initial si Anderson avait raison avec "it is clear that …".

Commentary · Examples [ms. 59]

The two-object test for an alleged derived adjunction

Grothendieck's counterexample isolates a genuine logical error: an equivalence after localization of a chosen subcategory does not by itself make that subcategory a suitable domain for deriving an adjunction. Everything can be computed in the walking arrow $\mathcal{C} = [1] = \{0 \to 1\}$. Put $\mathcal{C}' = \mathcal{C}$, let both ordinary functors be the identity, take W to be all arrows, and take W' to be the isomorphisms. The right-hand identity functor is compatible with these localizers, because it sends an isomorphism to an arrow of W.

Localizing $\mathcal{C}$ at W gives the groupoid with two isomorphic objects and a unique map between any ordered pair; it is equivalent to e. Localizing $\mathcal{C}'$ at W' leaves $[1]$ unchanged. Choose $\mathcal{C}_0 = \{1\}$. Its localization is e, and its inclusion into $\mathcal{C}$ induces an equivalence after localization. The restricted identity functor sends its only arrow to an isomorphism. Thus both hypotheses of Remark 3.6 hold.

After identifying $\mathcal{C}[W^{-1}]$ with e, the constructed candidate $L : e \to [1]$ selects 1, and the localized restriction $R : [1] \to e$ is the unique functor. If $L \dashv R$, then

$$\mathrm{Hom}_{[1]}(1, 0) \simeq \mathrm{Hom}_e(*, *).$$

The left side is empty and the right side has one element. Hence there is no such adjunction. In fact L is right adjoint to R, since 1 is terminal. The defect is the direction in which the chosen representative can map to other objects.

There is a second computation, needed again on page 68. Choose instead $\mathcal{C}_0 = \{0\}$. The candidate now selects the initial object and is indeed left adjoint to R. Nevertheless R is not fully faithful: the map

$$\mathrm{Hom}_{[1]}(1, 0) = \varnothing \longrightarrow \mathrm{Hom}_e(*, *) = \{*\}$$

is not surjective. Before localization the right adjoint was the identity, hence fully faithful; afterwards it has acquired an extra morphism because the two relative structures invert different arrows. This

second version establishes exactly the warning about full faithfulness, without confusing it with the first version's failure of adjunction.

The mathematical counterexample is complete and independent of the historical attribution. We verified the metadata of Anderson (1978), but did not obtain a readable copy of the original argument containing the phrase criticized here. We therefore attribute the criticism to this manuscript and do not attach it to an unverified theorem number in Anderson's publication.

Commentary · Later developments [ms. 59]

The comparison map is part of a derived functor

What the two-point example lacks is the universal comparison carried by a derived functor. If $F : \mathcal{C} \to \mathcal{C}'$ and γ, γ' are the localization functors, a total left derived functor comes with

$$\lambda : (\mathbf{L}F)\gamma \longrightarrow \gamma' F,$$

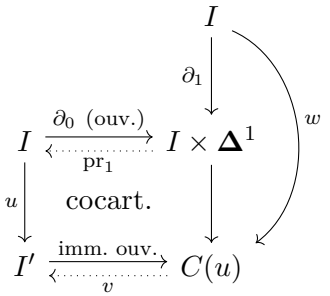
and a universal property for that transformation. A functor obtained by transporting $F|\mathcal{C}_0$ across an equivalence of localizations is not automatically equipped with this universal property. The distinction is substantive even though both constructions are often described informally as "apply F to a replacement."

For an adjunction $F \dashv G$, absolute total derived functors $\mathbf{L}F$ and $\mathbf{R}G$ form an adjunction. The adjective "absolute" means that the defining Kan-extension property survives postcomposition by every functor. Maltsiniotis (2007) proves the adjunction theorem formally from these properties, including compatibility with the original unit and counit; the proof does not require a particular model-category factorization. This is a later precise repair of the general inference under discussion.

In Grothendieck's terminal-object example there cannot even be a comparison λ of the indicated direction. Its component at 0 would have to be a map $1 \to 0$ in [1]. Thus the false assertion is not a counterexample to the modern derived-adjunction theorem. It shows why the comparison and its universal property cannot be suppressed when passing from a homotopically dense subcategory to a derived functor. The following mapping-cone proof constructs the needed adjunction in the geometric situation at hand instead of relying on that suppressed inference.

[page 60]

Néanmoins :



Théorème 3.7. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations stable par $\varinjlim$ finies, et $u : I \longrightarrow I'$ une application croissante entre ensembles ordonnés artiniens. On suppose qu'on est sous l'une des hypothèses suivantes.*

a) $\mathrm{Esp}(I)$, $\mathrm{Esp}(I')$ *sont noethériens, p.ex. I, I' finis.*

b) *C et $TC \overset{déf}{=} C \cap W$ sont stables par composition transfinie, et $\mathcal{M}$ stable par petites $\varinjlim$ filtrantes.* p. 30

Alors le foncteur $u^W_! : \mathrm{Ho}_W(I^\circ) \longrightarrow \mathrm{Ho}_W(I'^\circ)$ construit dans (3.3.1) *est adjoint à gauche du foncteur u^*_W en sens opposé.*

Démonstration. On utilise le diagramme bien connu

pour factoriser u en

$$u \;=\; vw\ ,$$

où w est une *immersion fermée,* et v est déduit de $\mathrm{pr}_1 : I \times \mathbf{\Delta}^1 \longrightarrow I$ par push-out. C'est une rétraction du mapping-cone C(u) sur l'ouvert I', dont le complémentaire fermé s'identifie à I via w.

[page 61]

Le foncteur de recollement entre I', I

$$H \ : \ I'^{\circ} \times I \ \longrightarrow \ \mathrm{Ens}$$

est donné par

$$(*) \qquad \underbrace{H(i',i)}_{=\mathrm{Hom}_{C(u)}(i',i)} \ = \ \mathrm{Hom}_{I'}(i', u(i)) \ .$$

La rétraction v de $C(u)$ dans I' applique i dans $u(i)$, et une flèche $i' \longrightarrow i$ correspondant à $i' \longrightarrow u(i)$ dans I' via $(*)$, est transformé par v en cette même flèche $i' \longrightarrow u(i)$. Calculons, pour i'_0 donné, la catégorie $i'_0\backslash\Big(C(u),\ v : C(u) \longrightarrow I'\Big)$, des couple d'un objet ξ de $C(u)$ et d'une flèche $i'_0 \longrightarrow v(\xi)$ dans I'. On voit que $i'_0\backslash C(u)$ admet l'ouvert $i'_0\backslash I'$, avec le complémentaire fermé $i'_0\backslash I$,

$$\begin{array}{ccccc} & & & & \text{fermé} \\ & & & & \text{complémentaire} \\ & & & & \text{de } I' \\ I' & \underset{\text{ouvert}}{\hookrightarrow} & C(u) & \hookleftarrow & I \\ & & \downarrow & & \\ & & I' \ , & & \end{array}$$

ces deux catégories étant recollées par le bifoncteur

$$\begin{array}{rcl} (i'_0\backslash I')^{\circ} \times (i'_0\backslash I) & \longrightarrow & \mathrm{Ens} \\ \Big((\alpha : i'_0 \longrightarrow i'), (\beta : i'_0 \longrightarrow u(i), i)\Big) & \longmapsto & \mathrm{Hom}_{i'_0\backslash I'}(i', u(i)) \end{array}$$

induit par $(*)$; i.e. les flèches de $(\alpha : i'_0 \longrightarrow i') \in \mathrm{Ob}\,(i'_0\backslash I')$ dans $(\beta : i'_0 \longrightarrow u(i)) \in i'_0\backslash I$ sont les flèches $i' \xrightarrow{\gamma} u(i)$ telles que le triangle

p. 31

$$\begin{array}{ccc} & i'_0 & \\ {\scriptstyle\alpha}\swarrow & & \searrow{\scriptstyle\beta} \\ i' & \xrightarrow{\ \gamma\ } & u(i) \end{array}$$

commute.

[page 62]

Si $i' = i'_0$, $\alpha = \mathrm{id}_{i'_0}$, alors cette commutativité revient à $\gamma = \beta$, ce qui signifie qu'il y a une flèche et une seule de α dans (i, β). Cela montre donc que $(i'_0, \mathrm{id}_{i'_0})$ est un objet initial de $i'_0\backslash C(u)$. On a donc prouvé le lemme :

Lemme 3.8. *Soit $u : I \longrightarrow I'$ une flèche dans* (Cat)*, factorisons-le en*

$$I \xrightarrow{w} C(u) \xrightarrow{v} I' \ ,$$

où $C(u)$ est le mapping-cone défini page 60*, w une immersion fermée de complémentaire I', v la rétraction canonique de $C(u)$ sur I'. Ceci posé, pour tout $i'_0 \in \mathrm{Ob}\, I'$, la catégorie $i'_0\backslash(C(u), v)$ admet un objet initial – donc $v : C(u) \longrightarrow I'$ est (tout ce qu'il y a de) cofiltrante.*

Commentary · Exposition [ms. 62]

The mapping cone as a category of two pieces

Grothendieck's factorization separates two operations for which the adjunction can be controlled. It is useful to describe the category $C(u)$ before reading its comma categories. Its objects are a disjoint copy of the objects of I' and a copy of those of I. Within each copy the old arrows remain. There are no arrows from the I-copy to the I'-copy, and the mixed arrows are

$$\mathrm{Hom}_{C(u)}(i', i) = \mathrm{Hom}_{I'}(i', u(i)).$$

Composition of a mixed arrow with arrows on either side is induced by composition in I' and functoriality of u. This is the collage of the displayed profunctor H. The open–closed language and its profunctor description were developed earlier; the commentary on Chapter XII, manuscript pp. 59–68, explains that construction in its general form.

Let $j : I' \hookrightarrow C(u)$ denote the open inclusion, $w : I \hookrightarrow C(u)$ the closed inclusion, and let $v : C(u) \to I'$ equal the identity on I' and u on I. The mixed-hom formula gives, naturally in $b \in I'$ and $c \in C(u)$,

$$\mathrm{Hom}_{C(u)}(j(b), c) \simeq \mathrm{Hom}_{I'}(b, v(c)).$$

Thus $j \dashv v$, with $vj = \mathrm{id}$. This elementary adjunction is another way to recognize the initial object of each $(b \downarrow v)$: it is $(j(b), \mathrm{id}_b)$. For an object $(c, \beta : b \to v(c))$, the unique arrow from that initial object is the mixed arrow corresponding to β, or the corresponding arrow within I' when $c \in I'$. The same hom-set description proves its uniqueness, including compatibility with every triangle in the comma category.

If I and I' are posets, the collage is a poset: each mixed hom-set is empty or a singleton, and a mixed arrow cannot be followed by an arrow back to the first piece. If both posets are well-founded, so is the collage. A decreasing sequence can cross from the closed piece into the open piece at most once; any infinite decreasing tail would then lie entirely in one of the two original posets. In the finite branch the collage is finite. More generally an increasing chain of lower sets in the collage stabilizes as soon as its intersections with both pieces stabilize, which proves the noetherian-topology assertion directly.

The comma calculation therefore has exactly the strength used in Corollary 3.5. It proves that v is locally cofiltered, so v^* preserves cofibrant diagrams. It is not an invocation of an unspecified homotopy equivalence of the two indexing categories. The original adjunction $j \dashv v$ already identifies the relevant initial objects on the level of categories.

Nous pouvons maintenant prouver 3.7. Tout d'abord, les hypothèses faites sur I, I' se transportent à $C(u)$ (hypothèse artinienne, et éventuellement hypothèse noethérienne sur $\mathrm{Esp}(C(u))$). Donc on peut appliquer les résultats précédents, notamment 3.5, aux flèches v, [page 63]
w. Le lemme précédent montre bien que v satisfait aux conditions de 3.5, donc le foncteur $v_!^W$ construit dans 3.3.1 est adjoint à gauche de v_W^*. Considérons d'autre part le foncteur $w_!^W$ construit dans 3.3.1, je dis que la même conclusion s'applique. Cela provient du fait que w est une immersion fermée. En effet, dans ce cas il est immédiat que

$$w_! \ : \ \mathcal{M}(I^\circ) \ \longrightarrow \ \mathcal{M}(I'^\circ), \qquad \text{où } I = C(u),$$

est compatible avec les localiseurs, puisque l'on a

$$\begin{cases} w_!(X)(j) \ \simeq \ X(j) & \text{si } j \in I, \\ w_!(X)(j) \ \simeq \ \emptyset_{\mathcal{M}} & \text{si } j \in J \backslash I, \end{cases}$$

par le calcul des fibres

$$w_!(X)(j) \ \simeq \ \varinjlim_{i \in I/j} X(i) \ .$$

Donc la définition de $w_!^W$ donnée dans 3.3.1 revient en fait à passer directement aux catégories localisées pour $w_!$, sans avoir à se restreindre à $\mathcal{M}(I^\circ)_{\mathrm{c}}$, et le lemme des foncteurs adjoints p. 32
nous dit que ce foncteur est adjoint à gauche de w_W^*. [page 64]

Comme on a évidemment

$$u_!^W \;\simeq\; v_!^W \circ w_!^W \;, \qquad\qquad u_W^* \;\simeq\; w_W^* \circ v_W^* \;,$$

on en conclut que $u_!^W$ est bien adjoint à gauche de u_W^*, q.e.d.

Commentary · Exposition [ms. 64]

The two adjunctions and their composite

The closed inclusion w supplies the other half of Theorem 3.7 for a particularly transparent reason. A closed full subposet is upward closed. Hence, for $c \notin I$, the comma category $(w \downarrow c)$ is empty: an arrow from an object of the closed piece to c would force c into that piece. For $c \in I$, the same comma category has terminal object (c, id). Therefore

$$(w_! X)(c) = \begin{cases} X(c), & c \in I, \\ \varnothing_{\mathcal{M}}, & c \notin I. \end{cases}$$

This is extension by the initial object, with the unique maps out of that object on mixed arrows. It preserves every objectwise weak equivalence; on the complement its components are identities. Restriction w^* preserves them as well.

Whenever both functors of an ordinary adjunction preserve the relevant weak equivalences, the unit and counit descend to localization. Their naturality continues to hold for formally inverted arrows, and their triangle identities remain identities after applying localization. This proves the localized adjunction in the closed-inclusion case. It also shows that its left adjoint agrees with the candidate defined using cofibrant replacement: $w_!$ already sends the replacement comparison itself to a weak equivalence.

For v, Proposition 3.2 and the preceding comma calculation put both functors on the full cofibrant subcategories. There they remain adjoint, since fullness leaves the old hom-set bijections unchanged. Both are homotopical on these subcategories, so their adjunction descends. Lemma 3.4 transports it to the homotopy categories of all diagrams. This is the restricted adjunction of Corollary 3.5, with its hypotheses now verified.

Finally, ordinary Kan extensions give $(vw)_! \simeq v_! w_!$. On a cofibrant I-diagram, $w_!$ again produces a cofibrant diagram, so no intermediate replacement changes the derived composite. Consequently the candidate $u_!^W$ is canonically isomorphic to $v_!^W w_!^W$. The right adjoints satisfy $u_W^* = w_W^* v_W^*$ simply by restriction. Composing the two established adjunctions gives Theorem 3.7. There is no use of the conclusion to establish this comparison: preservation of cofibrancy supplies the comparison before the final adjunction is deduced.

The symbols in the printed extension-by-initial-object formula require a local repair. Its target is $C(u)$, so the parenthetical "$I = C(u)$" should identify the target, and the subsequent J denotes that same target. The categorical construction above makes both readings unambiguous while leaving the edition's text intact.

Corollaire 3.9. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations. Alors le prédérivateur $\mathbf{D}_W$, restreint à la catégorie* Diag_0 *formée des catégories I* ordonnées *artiniennes et telles que* $\mathrm{Esp}(I)$ *soit noethérien, satisfait aux axiomes* Dér 1 (décomposition), Dér 2 (localisation), Dér 3 (objet final), Dér 4 bis (existence de $u_!$), Dér 5 bis (mode de calcul des $u_!$), Dér 6 (exactitude des carrés W-cocartésiens). *Si C, $TC = C \cap W$ sont stables par composition transfinie, on a le même résultat sur la catégorie* Diag *formée des catégories I ordonnées artiniennes sans plus.*

Commentary · Later developments [ms. 64]

The derivator conclusion and its precise scope

The point of Corollary 3.9 is that homotopy colimits have acquired the two properties that make them usable: an adjunction characterizes them, and a comma-category formula computes their values. In the covariant notation used here the latter is

$$(\mathbf{L}u_! X)_{i'} \simeq \mathrm{hocolim}_{(u \downarrow i')} X.$$

The category $(u \downarrow i')$ records arrows $u(i) \to i'$. For posets it is the lower subposet $u^{-1}(I'/i')$ of I. Restricting a cofibrant diagram to that lower subposet preserves its latching maps. Thus ordinary pointwise Kan extension applied to a cofibrant replacement computes the right-hand side, and the comparison is compatible with the adjunction already proved.

The convention in this formula must be kept visible when the corollary names the historical prederivator. Put

$$H(I) = \mathrm{Fun}(I, \mathcal{M})[W^{-1}], \qquad \mathbf{D}_W(J) = \mathrm{Fun}(J^{\mathrm{op}}, \mathcal{M})[W^{-1}].$$

Then $H(I) = \mathbf{D}_W(I^{\mathrm{op}})$. The preceding induction and the displayed comma formula directly concern H. Expressed for $\mathbf{D}_W$, they concern the opposite indexing categories. This makes no difference to the finite-poset domain, which is closed under opposites. In the infinite branch, the opposite of an artinian poset need not be artinian. Thus the induction as written directly proves the presheaf statement on opposites of artinian posets; it must not simply be relabelled as the same induction on artinian presheaf indices. Under the stated cocomplete and transfinite hypotheses, the later ABC theorem discussed below supplies all small shapes and hence also the asserted artinian domain. This is a qualification of the route of proof, not a counterexample to the corollary. The switch back to presheaves becomes explicit in paragraph 3.11 and determines the final comma square.

The statement retains the assumptions of Theorem 3.7. In particular, the infinite branch needs the indicated small colimits in $\mathcal{M}$ as well as transfinite closure. The abbreviated sentence in Corollary 3.9 must not be read as deriving arbitrary small colimits from the four finite cofibration axioms. The historical list Dér 1–6 also needs its own numbering: Chapter I, manuscript pages 43 and 67–68, keeps Dér 2 as conservativity of evaluations and inserts Dér 3 before moving Kan adjunctions to Dér 4 and their pointwise formulas to Dér 5 (Grothendieck, 1990–1991a).

The “objet final” version of Dér 3 requires constants to be fully faithful when the indexing category has a final object. The final object is in the indexing category. This part has a direct proof for the diagram localizations under discussion. In the source’s presheaf convention, if t is final in J, the constant functor $\mathcal{M} \to \mathrm{Fun}(J^{\mathrm{op}}, \mathcal{M})$ is left adjoint to evaluation at t: a map from a constant diagram to X is uniquely determined by its component into X_t. Its unit is the identity. Both functors preserve the respective weak equivalences, so this adjunction and its identity unit descend to localization. The localized constant functor is therefore fully faithful. This proves precisely the final-object clause independently of the construction of general Kan extensions. The cocartesian exactness clause in Dér 6 invokes the Brown homotopy calculus discussed on pages 40–41; its Hom-surjectivity formulation is proved there by a cylinder-and-gluing construction.

For the finite theory, Cisinski (2010, Corollary 2.24) gives a weak right derivator in his convention from a right derivable category, on finite direct categories, satisfying his additional axiom Der 5. His terminology calls the homotopy-colimit side “right.” For the small-diagram theory, Rădulescu-Banu (2009, Theorems 9.6.3, 9.6.5, and 10.3.2) gives the adjunction, pointwise formula, and strong Heller derivator for ABC cofibration categories. The latter axioms explicitly include the required coproduct and sequential-composition properties. These are precise later realizations of the program, with their hypotheses visible.

The extra ABC closure properties do follow from the stronger transfinite assumptions imposed here. To see the coproduct assertion directly, well-order a small family of maps $f_\alpha : A_\alpha \to B_\alpha$ in C. Start with $\coprod_\alpha A_\alpha$, and replace A_α by B_α one summand at a time. At stage β the object is

$$\coprod_{\alpha<\beta} B_\alpha \amalg \coprod_{\alpha\geq\beta} A_\alpha.$$

Each successor map is a pushout of f_β. At a limit stage the displayed object is the colimit of the preceding stages, as is verified by giving a map from each summand into an arbitrary test object. Transfinite closure therefore puts $\coprod f_\alpha$ in C. The same argument with TC proves the trivial-cofibration assertion. Applied to $\varnothing \to A_\alpha$, it also proves cofibrancy of the coproduct when the summands are cofibrant. The sequential-composition axiom is the countable instance of the assumed transfinite closure. Thus the later theorem applies to the actual cocomplete branch, rather than only to a vaguely similar axiom system. The dual of Cisinski (2010, Corollary 6.21) gives another published arbitrary-small-category result under the corresponding homotopical cocompleteness conditions of his Definition 6.1.

For an ABC cofibration category with all objects cofibrant, Lenz (2018, Theorem 3.33) identifies its homotopy prederivator with that of its quasicategory of frames. The all-cofibrant ABC convention

is explicit in his Definition 1.6 and Warning 1.7; it includes infinite-colimit axioms absent from the four finite axioms here. Corollary 1.41 passes from a general ABC category to its cofibrant subcategory at the level of diagram localizations, and Corollaries 4.1 and 4.5 provide the derivator and strength conclusions. Thus this comparison applies within the preceding ABC framework. It preserves coherent diagrams; it does not identify $\mathcal{M}^I[W^{-1}]$ with $\mathrm{Fun}(I, \mathcal{M}[W^{-1}])$.

3.10. Ainsi, pour avoir un dérivateur au plein sens du terme, soit sur Diag_0, soit sur Diag, il ne manque que Dér 4 (existence des u_*), Dér 5 (calcul des u_*) et Dér 6 (exactitude des carrés W-cartésiens). On va les obtenir en principe à l'aide d'une structure de *catégorie à fibrations* $(\mathcal{M}, F, W)$ associé à $(\mathcal{M}, W)$, i.e. l'espèce de structure duale de celle intro- duite page 39. Ces deux structures n'ont pas à être reliées entre elles d'une façon autre que par le fait qu'elles correspondent au même W. Elles sont considérablement plus faciles à construire que des structures de Quillen (W, C, F), où C, F doivent être reliés de façon extrêmement stricte, avec les propriétés $C \longleftrightarrow \underbrace{TF}_{=F\cap W}$, $\underbrace{TC}_{=C\cap W} \longleftrightarrow F$ (dont il n'est pas question dans l'axiomatique de K. S. Brown), et factorisation pour (C, TF) et (TC, F). [page 65]

Commentary · Context [ms. 65]

Two auxiliary structures over one relative category

Grothendieck's observation on page 65 concerns the economy of the axioms. Once the weak equivalences have been fixed, a cofibration structure may organize homotopy colimits and a fibration structure may organize homotopy limits. Their common object is the relative category $(\mathcal{M}, W)$. A Quillen structure imposes further relations between the two distinguished classes: lifting properties and the two complementary factorizations. None of those relations was used in the mapping-cylinder proof above.

This proposal has a precise later form. Cisinski (2010, Definition 2.25 and Corollary 2.28) defines a derivable category by placing compatible left and right derivability structures over the same weak equivalences, and obtains a derivator on finite direct categories. Compatibility here means the common relative category and the stated axioms; it does not insert Quillen's orthogonality relations. The finite result is the appropriate comparison with Grothendieck's paragraph.

There is an indexing issue in the infinite case which the wording "en principe" leaves to the subsequent development. A proof by well-founded latching induction is not automatically a proof by matching induction on the same infinite poset. The opposite of a well-founded poset need not be well-founded: $\mathbb{N}$ is the basic example. Additional fibration hypotheses, existence of the required limits, and a construction on the relevant opposite shapes must therefore be supplied before a two-sided conclusion on all the stated shapes is justified. We record page 65 as a program, not as an already completed proof of the remaining axioms. The later ABC theory treats the two sides with their respective completeness hypotheses.

Mais revenant à la construction des $u_!^W$, il reste le problème de les construire pour une flèche $u : I' \longrightarrow I$ *quelconque* dans Cat. [page 66]

À vrai dire, la construction du foncteur

$$u_!^W \ : \ \mathrm{Ho}_W(I^\circ) \ \longrightarrow \ \mathrm{Ho}_W(I'^\circ) \tag{3.3.1}$$

est valable sans supposer que I' soit une catégorie ordonnée – ça peut être une catégorie quelconque. Cela provient du fait que le foncteur induit par $u_!$,

$$u_{!\,\mathrm{cof}} \ : \ \mathcal{M}(I^\circ)_{\mathrm{c}} \ \longrightarrow \ \mathcal{M}(I'^\circ)$$

est encore compatible avec les localiseurs, comme on voit par le calcul des fibres

$$u_!(X)(i) \ \simeq \ \varinjlim_{i\in I/i'} X(i) \ .$$

Ainsi, on est ramené aux cas où $I' = e$, quitte à remplacer I par I/i', et en notant que $(I/i' \longrightarrow I$ étant étale) l'image inverse de X sur I/i' est cofibrant (cf. 3.2.a).

Commentary · Development (commentators') [ms. 66]

A finite source can demand an infinite Kan extension

Grothendieck next removes the assumption that the target category is a poset. In the cocomplete branch the pointwise argument survives: the comma category $(u \downarrow i')$ is still a well-founded poset when I is one. Indeed there is at most one arrow between two of its objects because the projection to I is faithful, and a nonidentity decreasing chain projects to a nonidentity decreasing chain in I. The projection is étale in the relevant sense, so restriction preserves cofibrancy. What does not survive automatically is the finite-colimit branch. A finite source can have infinitely many different arrows to a fixed target object.

A finite-colimit obstruction. [ours] There is a category satisfying all four axioms on page 39 and possessing finite colimits, together with a functor from a one-object poset to a small category, for which the desired left adjoint does not exist.

Proof. Take $\mathcal{M} = \mathsf{FinSet}$, W the bijections, and C all maps. Cof_0 is immediate, Cof_1 follows from finite cocompleteness, and Cof_2 says that pushouts of bijections are bijections. For Cof_3, factor $f : A \to B$ as f followed by id_B. All objects are cofibrant. Let $u : e \to B\mathbb{Z}$ be the unique functor to the one-object category of the infinite cyclic group. Restriction is the forgetful functor from finite $\mathbb{Z}$-sets, equivalently finite sets with a permutation, to finite sets. Since W consists of isomorphisms, the localized categories and functors are the same categories and functors.

If this forgetful functor had a left adjoint, let P be its value on the singleton. The adjunction would require

$$\mathrm{Hom}_{\mathbb{Z}}(P, \mathbb{Z}/n) \simeq \mathrm{Hom}_{\mathsf{FinSet}}(*, \mathbb{Z}/n)$$

for every $n \geq 1$. If $P = \varnothing$, the left side has one element, contradicting $n = 2$. Otherwise decompose P into its finitely many nonempty cyclic orbits, of lengths $m_1, \ldots, m_r$. Choose a prime $p > \max_j m_j$. An equivariant map from an orbit of length m_j to the transitive p-cycle would imply $p \mid m_j$: applying the generator m_j times fixes the source point and hence its image. No such map exists. Thus the left side for $n = p$ is empty while the right side has p elements. This contradiction proves the assertion.□

Here $(u \downarrow *)$ is the discrete set $\mathbb{Z}$, so the unavailable pointwise value is the infinite copower $\mathbb{Z} \times *$. The failure occurs before adjunction descent and cannot be repaired by choosing another cofibrant replacement. The example uses $\mathbb{Z}$ specifically; an arbitrary infinite group need not give the same finite-action obstruction.

The corrected scope is to retain the cocomplete and transfinite assumptions, or to require the relevant comma colimits and their homotopical preservation separately. For the construction of the candidate in the finite branch, it suffices, for example, that every $(u \downarrow i')$ be finite: each such poset then admits the finite latching argument. This addresses existence and homotopicality; the adjunction is still a separate assertion. We checked the scope of the arbitrary-index results in Rădulescu-Banu (2009, §9.6) and Cisinski (2010, §2); we did not find this particular FinSet test stated there. The displayed result is supplied as an explicit application of the elementary free-action obstruction, without a claim of priority. The manuscript's footnote on page 55 refers forward to page 86, outside these pages; the audit concerns the assumptions visible here and does not claim that the later manuscript never revisits them.

[page 67]

Mais il se présente à nouveau la perplexité si le foncteur (3.3.1) ainsi construit est bien adjoint à gauche de u_W^*. On peut songer à utiliser encore la même factorisation en $u = vw$, en utilisant le mapping-cone. La difficulté, cependant, c'est qu'à présent $J = C(u)$ n'est plus une p. 33
catégorie ordonnée, donc on n'a pas une définition toute prête de $C_{J^\circ} \subset \mathrm{Fl}(\mathcal{M}(J^\circ))$, donnant lieu à une sous-catégorie $\mathcal{M}(J^\circ)_{\mathrm{c}}$ etc. En fait, il semblerait qu'on soit pratiquement paralysé, tant qu'on n'arrive à construire sur $\mathcal{M}(J^\circ)$ également une structure de catégorie à cofibrations, se comportant bien par rapport au foncteurs $v_!$. La "démonstration" d'Anderson de l'existence de $u_!$ pour *toute* flèche dans Cat, foire totalement (même pour $I \longrightarrow e$, I ensemble ordonné fini – mais là j'ai pu rétablir la situation), car il se ramène au cas où I est ordonné localement fini, et il admet sans plus que *dans ce cas* $u_!^W$ est adjoint à gauche de u_W^*, et *de plus,* que si u [page 68]
est $\mathbf{W}_0$-connexe, donc $u^* : \mathcal{M}(I'^\circ) \longrightarrow \mathcal{M}(I^\circ)$ pleinement fidèle, qu'il en soit de même de u_W^* déduit par passage aux localisés. Or même si on admet que $u_!^W$ est adjoint à gauche de u_*^W, faute de disposer d'un morphisme d'adjonction tout près "en bas" (dans $\mathrm{Ho}_W(I'^\circ)$), déduit du morphisme d'adjonction dans $\mathcal{M}(I^\circ)$, il n'est absolument pas clair que u_W^* soit pleinement

fidèle, i.e. $u_!^W$ un foncteur de localisation. Le contrexemple 3.6 montre bien que, même si on a adjonction (i.e. si e est un objet initial de $\mathcal{C} = \mathcal{C}'$), le foncteur $u^* = \mathrm{id}_{\mathcal{C}}$ a beau être pleinement fidèle (et même une équivalence de catégories), le foncteur localisé n'a aucune raison de l'être : cela pouverait que tout objet de Cat ayant un objet initial est équivalent à e !

Commentary · Exposition [ms. 68]

Full faithfulness is controlled by the derived counit

The remaining warning on page 68 concerns the passage from a left adjoint to a localization functor. For any adjunction $L \dashv R$, the right adjoint is fully faithful exactly when the counit $LR \to \mathrm{id}$ is an isomorphism. To recall the mechanism, an invertible counit identifies the adjunction bijection on $\mathrm{Hom}(RB, RC)$ with the desired bijection $\mathrm{Hom}(B, C)$. Conversely, when R is fully faithful, the counit represents the identity under the same bijections and is invertible. Thus one must control the counit after deriving the functors, not merely the original counit before replacement.

In the second walking-arrow example above, $L : e \to [1]$ selects 0 and R is the projection. The counit at 1 is $0 \to 1$, which is not an isomorphism in the target localization, since that localization inverts only isomorphisms. This locates the entire defect in one component. The original identity adjunction had an identity counit, but its restriction to the chosen replacement subcategory changed the candidate left adjoint. The missing comparison with replacement is precisely what would have been needed to transport full faithfulness.

For actual diagram categories, ordinary finality is likewise weaker than homotopy finality. The strict colimit comparison tests connectedness of comma categories, whereas homotopy colimits can detect their higher homotopy. Here is a finite computation which exhibits the counit itself. Let P be the face poset of the boundary of a triangle: three vertices, three edges, and the six incidence relations from a vertex to an edge. The unique functor $q : P \to e$ is ordinarily final because P is nonempty and connected. Its constant-diagram functor is fully faithful even before localization: naturality along the incidences forces all components of a transformation between constant diagrams to be the same map.

Use simplicial sets with their usual weak homotopy equivalences and monomorphisms. A cofibrant replacement Q of the constant point on P is explicit. Assign Δ^0 to each vertex and Δ^1 to each edge, with the two incident vertices mapping to its distinct endpoints. The latching maps at vertices are $\varnothing \to \Delta^0$; those at edges are $\partial\Delta^1 \to \Delta^1$. All are monomorphisms, so Q is a cofibrant diagram. The unique transformation $Q \to \mathrm{const}(*)$ is an objectwise weak equivalence because every value is contractible. Its ordinary colimit glues three intervals cyclically along their endpoints. Its realization is the triangular circle, and its first integral homology is $\mathbb{Z}$: its cellular boundary sends each oriented edge to the difference of its endpoints, so its kernel is generated by the sum of the three consistently oriented edges, and there are no two-cells.

Consequently the derived counit at the point is represented by this circle mapping to $*$. Integral homology sends weak homotopy equivalences of simplicial sets to isomorphisms, so factors through their homotopy category; its value shows that this counit is not invertible. Thus q^* fails to be fully faithful after localization, despite being fully faithful as an ordinary functor. This calculation uses only the finite cofibrant replacement machinery established here; no appeal to an uncomputed homotopy colimit is hidden in the example.

The objection does not contradict Theorem 3.7. That theorem constructs an adjunction by two controlled factorizations. Full faithfulness of a particular restriction requires the additional counit computation appropriate to that restriction, or a homotopy finality theorem with its actual hypotheses.

[page 69]

3.11. Disons qu'on a une *catégorie à cofibrations stricte,* si dans l'axiome Cof_3 de factorisation (cf. p. 39), la factorisation peut être prise fonctoriellement en f. Il revient ± au même de dire que l'axiome de factorisation reste valable, quand on pense à une catégorie $\mathcal{M}(I)$ pour I dans Cat, en y définissant $W(I)$ et $C(I)$ (à ne pas confondre avec C_I) fibre par fibre. Cela revient au même tout au moins si $\mathcal{M}$ est équivalente à une petite catégorie. Sinon, il faut supposer fonctorialité pour toute *petite* sous-catégorie pleine de $\underline{\mathrm{Fl}}(\mathcal{M})$. Il vaut mieux définir la catégorie à cofibrations stricte par cette propriété de stabilité.

Commentary · Exposition [ms. 69]

Functorial factorization supplies arbitrary parameters

Grothendieck introduces strictness to permit an arbitrary diagram category to serve as the coefficient category in the finite or well-founded construction. A functorial factorization assigns to every arrow $f : X \to Y$ an object $E(f)$ and maps

$$X \xrightarrow{i_f} E(f) \xrightarrow{p_f} Y, \qquad i_f \in C, \quad p_f \in W,$$

and assigns to every commutative square a compatible arrow between the middle objects. Given a natural transformation $f : X \to Y$ of covariant Z-diagrams, apply this assignment to its components. The arrows $E(f_z) \to E(f_{z'})$ coming from the naturality squares satisfy the identity and composition laws because E is a functor on the arrow category. Hence they form a middle Z-diagram and give the required objectwise factorization. Since Z is arbitrary, the same assertion applies to presheaves by replacing Z with Z^{op}.

The converse explains the size qualification. If $\mathcal{M}$ is small, use the covariant index $Z = \mathrm{Fl}(\mathcal{M})$ and the universal natural transformation from its source functor to its target functor. A factorization in $\mathcal{M}^Z$ is exactly a functorial factorization of every arrow of $\mathcal{M}$; in presheaf notation the index is $\mathrm{Fl}(\mathcal{M})^{\mathrm{op}}$. If $\mathcal{M}$ is only essentially small, transport the construction along a small skeleton. For a large category, an assertion quantifying only over small Z yields factorizations on every small diagram of arrows; it does not automatically choose one globally coherent factorization on a proper class. Grothendieck's final preference for stability under small diagram categories keeps that quantification explicit.

Paragraph 3.11 explicitly returns to $\mathbf{D} = \mathbf{D}_{\mathcal{M}}$ and $\mathcal{M}(I)$, hence to the historical presheaf convention. For its parameter category Z, the coefficient category is therefore

$$\mathcal{N} = \mathcal{M}(Z) = \mathrm{Fun}(Z^{\mathrm{op}}, \mathcal{M}), \qquad \mathbf{D}_Z(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{N})[W^{-1}].$$

Equip $\mathcal{N}$ with the pointwise classes $C(Z)$ and $W(Z)$. The first three cofibration axioms hold objectwise, while strictness supplies the fourth. Colimits and the relevant closure properties also pass objectwise. Apply Theorem 3.7 in this coefficient category to $u^{\mathrm{op}} : I^{\mathrm{op}} \to I'^{\mathrm{op}}$. The identification

$$\mathrm{Fun}(I^{\mathrm{op}}, \mathcal{N}) \simeq \mathrm{Fun}((I \times Z)^{\mathrm{op}}, \mathcal{M})$$

identifies its restriction with $(u \times \mathrm{id}_Z)^*$ on the historical $\mathbf{D}$. This proves the parameter assertion directly for finite indices, and in the well-founded branch when I^{op} and I'^{op} are artinian. The infinite-domain qualification explained at Corollary 3.9 applies here as well.

The two cofibration notations must stay distinct. $C(Z)$ tests each arrow component separately. The relative latching class in this application is $C_{I^{\mathrm{op}}}$ inside the coefficient category $\mathcal{N}$: it controls the attachments in the contravariant I direction. Replacing it by pointwise cofibrancy would discard the boundary information that the chapter has established.

Under ABC hypotheses, stability under arbitrary small diagram categories was later established without assuming a globally chosen functorial factorization; see Lenz (2018, Theorem 1.24). That result uses infinite colimits. It therefore completes this program in the stronger setting without making the finite hypotheses sufficient by themselves.

On voit alors que le prédérivateur $\mathbf{D} = \mathbf{D}_{\mathcal{M}}$ sur Cat est un dérivateur *relativement à* $\mathcal{D} = \mathrm{Diag}_0$ défini plus haut (catégories ordonnées I artiniennes, telles que $\mathrm{Esp}(I)$ soit noethérien), ou même relativement à $\mathcal{D} = \mathrm{Diag}$ (catégories ordonnées I artiniennes sans plus) lorsque C et TC sont stables par composition transfinie. J'entends par là que $u_!$ existe quand u est une flèche de $\mathcal{D}$, et que ça reste valable quand on passe à un dérivateur induit $\mathbf{D}_Z$ (Z dans Cat quelconque) ; en d'autre termes, que $v_!$ existe quand v est de la forme $\mathrm{id}_Z \times u$, où $u : I \longrightarrow I'$ est une flèche de $\mathcal{D}$, et que le calcul se fait *au dessus de* I' selon la règle Dér 5 bis. Cela signifie donc que la flèche de changement de base pour les $f_!$ est un isomorphismes dans [page 70]

le cas suivant :

$$\begin{array}{ccc} I \times Z & \longleftarrow & (i'\backslash I) \times Z \\ \downarrow{\scriptstyle u\times \mathrm{id}_Z} & & \downarrow{\scriptstyle \mathrm{pr}_2} \\ I' \times Z & \longleftarrow & \{i'\} \times Z \end{array} \quad ,$$

où i' est un objet quelconque de I'.

Commentary · Examples [ms. 70]

The comma category after returning to presheaves

The final square is correct in the presheaf convention to which paragraph 3.11 has returned. Its slash differs from the earlier covariant formula because the underlying functor is now $I^{\mathrm{op}} \to \mathcal{M}$. For $u : I \to I'$ set

$$A = (i' \downarrow u) = i'\backslash I, \qquad p : A \longrightarrow I.$$

An object of A is a pair $(i, \alpha : i' \to u(i))$. The usual pointwise formula for presheaves derives left Kan extension along u^{op}, and the relevant comma category is canonically

$$(u^{\mathrm{op}} \downarrow i') \simeq A^{\mathrm{op}}.$$

Indeed its objects are the same pairs. An arrow from (i, α) to (j, β) in this opposite comma category is an arrow $j \to i$ in I satisfying $u(j \to i)\beta = \alpha$, exactly the opposite of an arrow in A. Thus for an ordinary presheaf X the formula is

$$(\mathrm{Lan}_{u^{\mathrm{op}}} X)(i') \simeq \mathrm{colim}_{A^{\mathrm{op}}} X p^{\mathrm{op}}.$$

The notation $\mathbf{D}_W(A)$ already supplies this opposite in the index of the coefficient diagram. Replacing A by $u \downarrow i'$ would alter the formula.

The source's parameterwise assertion is therefore

$$(i' \times \mathrm{id}_Z)^* \, \mathbf{L}(u \times \mathrm{id}_Z)_! X \;\simeq\; \mathbf{L}(\mathrm{pr}_Z)_! \, (p \times \mathrm{id}_Z)^* X, \qquad p : (i' \downarrow u) \longrightarrow I,$$

as an isomorphism in $\mathbf{D}_W(Z)$. The arrows $i' \to u(i)$ define the natural transformation from the constant functor at i' to up; after passing to presheaves, its mate is the displayed comparison. The 2-cell is part of the meaning of this comma square.

Here is a direct proof in the range supplied by the preceding construction. Regard X as an I^{op}-diagram in $\mathcal{N} = \mathrm{Fun}(Z^{\mathrm{op}}, \mathcal{M})$ and choose a cofibrant replacement in that coefficient category. If I and I' are posets, A is the upper subposet of elements i for which $i' \leq u(i)$. Consequently A^{op} is a lower subposet of I^{op}, and restriction preserves its latching data. The ordinary pointwise Kan formula then computes both sides from the same restricted cofibrant diagram. Its colimit isomorphism gives the required derived comparison. This proves the finite case, and the well-founded case with I^{op} artinian and the stated coefficient colimits and closure. The later arbitrary-shape ABC theorem removes that indexing restriction under its stronger hypotheses.

A one-arrow computation makes the change of convention visible. Let $u : e \to [1] = \{0 \to 1\}$ select 0, take $i' = 1$, and let $X = *$ in sets with weak equivalences the bijections and cofibrations all maps. For covariant diagrams, $u \downarrow 1$ is a singleton, so $(\mathrm{Lan}_u X)(1) = *$. For presheaves, however, $1 \downarrow u$ is empty. Hence $(\mathrm{Lan}_{u^{\mathrm{op}}} X)(1) = \varnothing$, just as the printed square asserts. At 0 both extensions have value $*$. In particular the presheaf extension is the diagram with values $*$ at 0 and $\varnothing$ at 1, with its unique restriction map $\varnothing \to *$. The covariant extension is the constant point. These are different variance conventions for the same indexing map, not contradictory values of one functor.

Thus the printed $i'\backslash I$ requires no textual correction. The earlier covariant formula remains valid for $H(I) = \mathbf{D}_W(I^{\mathrm{op}})$; the final formula is its correctly reindexed presheaf counterpart.

Overview · XVII-a

Chapter XVII, manuscript pages 1–70: attachments, diagrams, and derived left Kan extensions

Grothendieck is looking for a way to construct the operations of a derivator from a category endowed with weak equivalences and cofibrations (Grothendieck, 1990–1991m). The principal operation in these pages is a left adjoint to restriction of diagrams. Its construction has two logically separate parts. First one must find diagrams on which an ordinary colimit or ordinary left Kan extension respects weak equivalences. Then one must show that the functor obtained after localization has the required adjunction. Much of the force of the chapter lies in its refusal to identify these two tasks. The counterexample in Remark 3.6 makes the distinction precise, and the mapping-cone argument in Theorem 3.7 supplies the missing adjunction for the indexing posets under consideration.

The first twenty-four manuscript pages are a preliminary investigation which the author asks the reader to skip once section 2 has been written. They nevertheless disclose the mathematical problem that determines the stronger definition. Throughout, an open subset of an ordered set is a lower ideal, and $\mathcal{M}(I^\circ)$ denotes covariant I-diagrams. For a map $u : X \to Y$, the elementary test is that

$$X_i \amalg_{\operatorname{colim}_{j<i} X_j} \operatorname*{colim}_{j<i} Y_j \longrightarrow Y_i$$

be a cofibration. This relative latching map measures the attachment at i after all its predecessors have been incorporated. If the indexing order is well founded, one can perform these attachments in a compatible ordinal order. Pushout stability and transfinite-composition stability then put both every component of u and its colimit map in C. Applying the same argument to $TC = C \cap W$, and using two-out-of-three at the next attachment, identifies trivial diagram cofibrations with the diagram cofibrations that are objectwise weak equivalences. The commentary supplies a continuous filtration so that this argument does not tacitly assume continuity of the original diagrams.

The relative statement is more useful than the absolute one. For lower ideals $K \subset J$, write $X_K = \operatorname{colim}_K X$ and similarly for Y, and put

$$r_{K,J}(u) : Y_K \amalg_{X_K} X_J \longrightarrow Y_J.$$

The essential excision identity says that when a new lower ideal B is adjoined to A, the relative map over $A \subset A \cup B$ is a pushout of the relative map over $A \cap B \subset B$. A succession of such comparisons is controlled by a continuous filtration with terms $X_J \amalg_{X_{A_\alpha}} Y_{A_\alpha}$. These two elementary colimit calculations account for the large diagrams of the preliminary section and for Lemmas 2.6–2.7. They also explain the distinction between the relative assertion, which does not require X to be cofibrant, and the assertion $X_K \to X_J \in C$, which does. Footnote 5 overstates the dispensability of this latter hypothesis; footnote 7 already gives the necessary qualification.

Section 2 makes all these relative comparisons part of the definition. A map belongs to the new C_I when $r_{K,I/i}(u) \in C$ for every i and every lower ideal $K \subset I/i$. Theorem 2.1(1) extends that condition to every inclusion of lower ideals, without assuming that I is artinian. Part (2) recovers the single relative-latching test when I is artinian. Part (3) identifies $(TC)_I$ with $C_I \cap W_{I^\circ}$ under the same well-foundedness and closure hypotheses. This change of definition is indispensable: on a poset with an endless descending chain, all relative latching maps can be isomorphisms while the components of a map of diagrams fail even to be injective. The development attached to manuscript page 24 proves that this obstruction detects every failure of well-foundedness, using diagrams of sets extended from the upward closure of a descending chain.

The question left on manuscript pages 38–39 concerns part (3), not part (2): can the artinian hypothesis be removed from the equality involving TC when the stronger definition of C_I is retained? Grothendieck verifies one descending-chain example. The present commentary extends that argument to linearly ordered sets and, more generally, to posets whose principal lower ideals are linearly ordered. A well-ordered cofinal subset of a lower chain reduces its colimit to the established ordinal case. We did not find a resolution of the unrestricted question under exactly the assumptions of Theorem 2.1 in the literature inspected. This is a statement about the scope of our verification, not a claim that the problem is known to remain open. The later theorems on diagram cofibration structures use their own definitions and additional hypotheses, and therefore do not by themselves settle this precise question.

Several corrections concern the formulation of an argument whose conclusion remains valid. Lemma 2.7 must use a chain continuous at limit ordinals; an arbitrary increasing chain can acquire new objects at a limit stage, so its successor comparisons cannot account for the entire relative map. The printed lemma also confuses its initial relative domain with the initial object of an absolute filtration. Both points are repaired explicitly. The description of the intermediate cube in Lemma 2.6 as totally cocartesian is too strong if it means that all six faces are pushouts; pushout associativity proves the needed face without that assertion. These repairs are recorded separately from transcription corrections. The edition's printed slips remain in the source text, while the commentary states and proves the mathematically intended claims.

Section 3 turns the attachment calculus into homotopical algebra. The axioms Cof_0–Cof_3 require two-out-of-three for W, composition and pushout stability for C, pushout stability for TC, and a factorization of every map as a cofibration followed by a weak equivalence. They do not require every object to be cofibrant. The full subcategory of cofibrant objects has the same localization, so Brown's methods can be applied there. The factorization of a diagram is then constructed one index at a time: a factorization already chosen on the predecessors of i produces the map

$$X_i \amalg_{L_iX} L_iZ \longrightarrow Y_i,$$

to which the ambient factorization axiom is applied. This is the direct-diagram form of the Reedy construction. Its later cellular formulation is made explicit in Riehl and Verity (2014, Proposition 6.3 and Lemma 7.1). The source works also with ordinal ranks, which exceed the natural-number degree convention used for many familiar Reedy categories.

The two finiteness branches in Theorem 3.1 deserve to be read literally. In the first, I is artinian and its lower-Alexandrov topology is noetherian. Under the ordinary choice convention used in the argument, their conjunction forces I to be finite: otherwise successive choices of a minimal element of the remaining poset give a strictly increasing sequence of finite lower ideals. The second branch allows arbitrary small artinian posets, requires the necessary small colimits, and imposes transfinite stability on both C and TC. Thus the theorem has a finite construction and a construction with explicit infinitary hypotheses. The commentary keeps these alternatives separate when it discusses the available Kan extensions.

Proposition 3.2 proves that left Kan extension preserves diagram cofibrations, and that restriction preserves them under a suitable local cofilteredness condition. Brown's cylinder factorization then shows that left Kan extension carries weak equivalences between cofibrant diagrams to weak equivalences. Together with the localization equivalence for cofibrant objects, this yields the candidate $u_!^W$. The warning in Remark 3.6 is categorical and complete: choosing a subcategory which computes a localization need not make its inclusion a derived replacement suitable for an adjunction. With the identity adjunction on the walking arrow, different choices of weak equivalences give the stated failure. The related assertion that full faithfulness survives localization also fails without control of the localized counit. These are failures of general inferences, not counterexamples to the properly constructed derived adjunction.

Theorem 3.7 restores the adjunction by factoring $u : I \to I'$ through its categorical mapping cone. One factor is a closed inclusion, whose left Kan extension is extension by the initial object. The other is a retraction whose relevant comma categories have initial objects. Each factor consequently falls under a case where the adjunction can be checked, and their left adjoints compose. The discussion of arbitrary target categories that follows needs a further size qualification in the finite branch. For $u : e \to B\mathbb{Z}$ and $\mathcal{M} = \mathrm{FinSet}$, a left adjoint to the forgetful functor from finite $\mathbb{Z}$-sets would have to provide a free finite $\mathbb{Z}$-set on one generator; finite cycles of unbounded order show that no such object exists. A finite source does not make its comma categories finite. This obstruction disappears when the required small coproducts and colimits are supplied, but that hypothesis must be stated.

The chapter belongs to the program described in *Pursuing Stacks*, section 69, and in the letter to Thomason of 2 April 1991: diagram localizations retain operations that a single homotopy category does not specify, while cofibrations and fibrations are auxiliary means of constructing those operations (Grothendieck, 1983, 1991a). Later work establishes the desired diagram formalism with precise hypotheses. Cisinski (2010, Corollary 2.24) obtains a one-sided derivator on finite direct categories: in his convention, a weak right derivator satisfying the additional axiom Der 5. For ABC cofibration categories, Rădulescu-Banu (2009, Theorems 9.6.3, 9.6.5, and 10.3.2) gives arbitrary small homotopy left Kan extensions, their adjunctions, pointwise formulas, and the resulting derivator. Lenz (2018, Theorem 3.33) identifies the homotopy prederivator of an ABC cofibration category in which every object is cofibrant with that of its quasicategory of frames. These comparisons place the construction in modern homotopy theory while preserving the distinctions in assumptions that matter in this chapter.

The last paragraph introduces strictness in order to apply the same construction to categories of diagrams with an arbitrary additional parameter. Functorial factorization gives objectwise diagram factorizations; the universal arrow diagram gives the converse when the relevant arrow category is small. Here the source returns explicitly to its historical presheaf convention, $\mathbf{D}_W(J) = \mathrm{Fun}(J^{\mathrm{op}}, \mathcal{M})[W^{-1}]$. The preceding covariant construction concerns $H(I) = \mathbf{D}_W(I^{\mathrm{op}})$, so its immediate infinite range must be translated by opposition; the finite range is unchanged. In this presheaf convention the final printed comma category $i'\backslash I = (i' \downarrow u)$ is correct: the colimit computing a left Kan value runs over its opposite. The covariant formula instead uses $(u \downarrow i') = I/i'$. A walking-arrow calculation in both conventions explains the difference and prevents a change of variance from being misdiagnosed as an edition slip. The later ABC theorem supplies the arbitrary-shape extension under the full infinitary hypotheses. The manuscript's own further construction and forward references lie beyond manuscript page 70.

lesquels sont visiblement adjoint l'un de l'autre (puisque induits par un couple de foncteurs adjoints $u_!$, u^*), et de plus compatibles aux localiseurs. Donc on peut appliquer le lemme des foncteurs adjoints pour les localisés. Pour résumer : p. 29

Corollaire 3.5. *Supposons que I, I' soient artiniens, et qu'on soit dans l'un des deux cas suivants :*

a) *Les espaces* $\mathrm{Esp}(I)$, $\mathrm{Esp}(I')$ *sont noethériens (p.ex. I, I' finis).* [page 58]

b) *C et $TC = C \cap W$ sont stables par composition transfinie.*

Supposons de plus que u^* applique $\mathcal{M}(I'^{\circ})_{\mathrm{c}}$ dans $\mathcal{M}(I^{\circ})_{\mathrm{c}}$, ce qui est le cas notamment si u est localement cofiltrant, i.e. les ensembles ordonnés localisés $i'\backslash I$ sont localement cofiltrants. Alors le foncteur $u_!^W$ construit dans (3.3.1) est adjoint à gauche de u_W^*.

Remarque 3.6. Quand on a un couple de foncteurs adjoints

$$\mathcal{C} \underset{u^*}{\overset{u_!}{\rightleftarrows}} \mathcal{C}' \quad ,$$

avec les localiseurs W, W' de $\mathcal{C}$, $\mathcal{C}'$, u^* compatible aux localiseurs, et si de plus on a une sous-catégorie pleine $\mathcal{C}_0$ de $\mathcal{C}$ telle que

a) $u_!|\mathcal{C}_0$ transforme flèches de W en flèches de W', et

b) l'inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ induit une *équivalence* $\mathcal{C}_0 W_0^{-1} \xrightarrow{\sim} \mathcal{C}W^{-1}$ (où $W_0 = W \cap \mathrm{Fl}(\mathcal{C}_0)$),

on trouve deux foncteurs canoniques

$$\mathcal{C}W^{-1} \underset{u_W^*}{\overset{u_!^W}{\rightleftarrows}} \mathcal{C}'W'^{-1} \quad ,$$

où $u_!^W$ est défini seulement à isomorphisme canonique près.

Commentary · Exposition [ms. 58]

The adjunction must survive the choice of resolutions

Grothendieck has constructed the candidate for a left homotopy Kan extension and now asks for the property that makes this candidate useful: maps out of it must correspond to maps into the restricted diagram. The distinction matters because an equivalence between two localized categories remembers neither a preferred direction of replacement nor the comparison maps with the original functor. Corollary 3.5 has enough compatibility to descend an actual adjunction. Remark 3.6 removes that compatibility and exposes what is lost.

Write $F \dashv G$, let $j : \mathcal{C}_0 \hookrightarrow \mathcal{C}$ be the chosen full subcategory, and write γ and δ for localization. If $\mathrm{Ho}(j)$ is an equivalence and Fj preserves weak equivalences, the composite

$$\overline{F} = \mathrm{Ho}(Fj)\,\mathrm{Ho}(j)^{-1}$$

is certainly a functor. Its construction has not supplied a natural transformation $\overline{F}\gamma \to \delta F$. Such a comparison is part of the data of a left derived functor, with a universal property; it cannot be reconstructed from the objectwise choice alone.

The smallest example makes the distinction quite concrete. Let $\mathcal{C}$ be the walking arrow $0 \to 1$, use all arrows as W, only isomorphisms as W', and take $F = G = 1_{\mathcal{C}}$. Inverting the single nonidentity arrow makes $\mathcal{C}[W^{-1}]$ equivalent to the terminal category. Both subcategories $\{0\}$ and $\{1\}$ therefore give localization equivalences. Choosing $\mathcal{C}_0 = \{1\}$ makes $\overline{F}$ select 1, while $\overline{G} : \mathcal{C} \to 1$ is the unique functor. An adjunction would require

$$\mathrm{Hom}_{\mathcal{C}}(1, 0) \simeq \mathrm{Hom}_1(*, *).$$

The first set is empty and the second is a singleton. Choosing $\{0\}$ instead gives an adjunction, since 0 is initial. Even then $\overline{G}$ is not fully faithful: the empty hom-set from 1 to 0 again maps to

a singleton. This also proves the second warning on manuscript p. 68. The two failures concern the formal inferences; they do not disprove a correctly constructed homotopy Kan extension or a correctly justified homotopy-cofinality theorem.

A useful sufficient repair is a functor $Q : \mathcal{C} \to \mathcal{C}_0$ and a natural weak equivalence $q : jQ \to 1_{\mathcal{C}}$, with F homotopical on $\mathcal{C}_0$ and G homotopical on all of its domain. The comparison is then $\delta F q$, rather than an unspecified isomorphism after localization. This is the left-deformation construction of Riehl (2014, Theorems 2.2.8 and 2.2.11). A more intrinsic sufficient condition is that the total derived functors are absolute Kan extensions; their adjunction is the unnumbered theorem of Maltsiniotis (2007).

The direction of q explains the example. The constant choice $Q(X) = 0$ admits $q_X : 0 \to X$; the constant choice $Q(X) = 1$ admits no component $1 \to 0$. Thus the obstruction is visible before any hom-set calculation in the localization. The passage to the categorical mapping cylinder in the next proof is a way of recovering compatible adjunctions without first choosing a functorial resolution of every diagram.

Contrairement à ce que prétend Anderson, il n'est par vrai en général que ces deux foncteurs soient adjoints, sans hypothèses supplémentaires. Voici un contrexemple : on prend $\mathcal{C} = \mathcal{C}'$, $u_! = u^* = \mathrm{id}_{\mathcal{C}}$, $W' = \mathrm{Is}(\mathcal{C})$, $W = \mathrm{Fl}(\mathcal{C})$, donc u^*_W est le foncteur canonique [page 59]

$$\underbrace{\Pi\mathcal{C}}_{\text{groupoïde fondamental}} \qquad\qquad \longleftarrow \mathcal{C}\ .$$

Supposons que $\mathcal{C}$ soit 1-connexe, i.e. $\Pi\mathcal{C}$ soit équivalente à e. Soit $e \in \mathrm{Ob}\,\mathcal{C}$ tel que $\mathrm{End}_{\mathcal{C}}(e)$ soit le groupe unité, et prenons $\mathcal{C}_0 = \{e\}$. Alors l'hypothèse sur $\mathcal{C}_0$ est satisfaite. Mais si $u^W_!$ était adjoint à gauche de u^*_W, e serait objet initial de $\mathcal{C}$. Par exemple si $\mathcal{C}$ a un objet final e (ce qui implique que $\mathcal{C}$ est 1-connexe et e rigide), cet objet final devrait être initial si Anderson avait raison avec "it is clear that …".

Néanmoins :

[page 60]

Commentary · Exposition [ms. 59]

Why the mapping cylinder repairs the argument

Grothendieck replaces the given map of indexing posets by two maps for which the adjunction can be controlled separately. The construction called a mapping-cone here is a categorical mapping cylinder. It is also the collage of the bifunctor $\mathrm{Hom}_{I'}(-, u-)$, the gluing construction already encountered in the commentary on Chapter XII, manuscript pp. 59–61. Here its particular purpose is to make one factor preserve cofibrancy and the other preserve weak equivalences without deriving it.

Keep the convention of Theorem 3.7 explicit: $\mathcal{M}(I^\circ) = \mathrm{Fun}(I, \mathcal{M})$ consists of covariant diagrams. The objects of $C(u)$ are the disjoint union of those of I' and I. Within either piece the original arrows remain; a mixed arrow from $j \in I'$ to $i \in I$ is an arrow $j \to u(i)$ in I'; there are no mixed arrows in the reverse direction. Composition is induced by composition in I' and by u. Thus the inclusion $w : I \hookrightarrow C(u)$ is a cosieve, and the inclusion $s : I' \hookrightarrow C(u)$ is a sieve. The retraction v is the identity on I' and equals u on I.

The essential feature of v can be read directly from its hom-sets:

$$\mathrm{Hom}_{C(u)}(sj, x) \simeq \mathrm{Hom}_{I'}(j, vx).$$

Thus $s \dashv v$, with $vs = 1$. In particular $(j, 1_j)$ is initial in $(j \downarrow v)$. For an object $(x, \beta : j \to vx)$ of this comma category, its unique arrow from $(j, 1_j)$ is the arrow represented by β itself. This proves Lemma 3.8, including uniqueness, for arbitrary categories. An initial object gives a common predecessor for every finite diagram and equalizes each parallel pair; hence the required cofilteredness follows. The result is stronger than a statement that the comma category has contractible nerve.

The other factor is controlled by extension by the initial object. If $j \notin I$, the category $(w \downarrow j)$ is empty, because a cosieve admits no arrow from its objects to an object outside it. If $j \in I$, that category has terminal object $(j, 1_j)$. Consequently

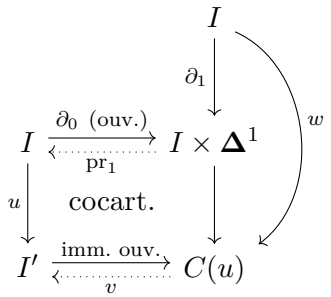
$$(w_! X)_j = \begin{cases} X_j, & j \in I, \\ \varnothing_{\mathcal{M}}, & j \in I'. \end{cases}$$

An objectwise weak equivalence is sent to the same weak equivalence on I and to an identity on I'. Both $w_!$ and w^* are therefore homotopical, and their unit and counit descend. No inference of the kind disproved in Remark 3.6 is needed.

There are two small inheritance checks behind the application of the earlier cofibration theorem. A chain in $C(u)$ can cross from one piece to the other at most once, so artinianity passes from the two pieces to their collage. An increasing chain of open subsets stabilizes once its intersections with the two pieces stabilize, which proves the stated noetherianity assertion. Corollary 3.5 therefore applies to v, while the preceding extension argument applies to w. Compatibility of the already constructed left Kan extensions with composition identifies $u_!^W$ with $v_!^W w_!^W$. Composing the two actual adjunctions proves Theorem 3.7.

For a small worked instance, take I to be two isolated objects and $I' = e$. The cylinder has an initial vertex $*$ and two arrows $* \to a$, $* \to b$. Extending the pair (A, B) along w gives $(\varnothing \to A, \varnothing \to B)$; taking its colimit along v gives $A \amalg B$. Its cocones to Y are exactly the pairs of arrows $A \to Y$, $B \to Y$. With cofibrant replacements $QA \to A$ and $QB \to B$, the same construction gives the derived coproduct $QA \amalg QB$. The proof above, rather than the mere existence of these replacements, supplies its adjunction in the homotopy categories.

Théorème 3.7. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations stable par $\varinjlim$ finies, et $u : I \longrightarrow I'$ une application croissante entre ensembles ordonnés artiniens. On suppose qu'on est sous l'une des hypothèses suivantes.*



a) $\mathrm{Esp}(I)$, $\mathrm{Esp}(I')$ *sont noethériens, p.ex. I, I' finis.*

b) *C et $TC \overset{déf}{=} C \cap W$ sont stables par composition transfinie, et $\mathcal{M}$ stable par petites $\varinjlim$ filtrantes.*

p. 30

Alors le foncteur $u_!^W : \mathrm{Ho}_W(I^\circ) \longrightarrow \mathrm{Ho}_W(I'^\circ)$ construit dans (3.3.1) *est adjoint à gauche du foncteur u_W^* en sens opposé.*

Démonstration. On utilise le diagramme bien connu

pour factoriser u en

$$u \;=\; vw \;,$$

où w est une *immersion fermée,* et v est déduit de $\mathrm{pr}_1 : I \times \mathbf{\Delta}^1 \longrightarrow I$ par push-out. C'est une rétraction du mapping-cone C(u) sur l'ouvert I', dont le complémentaire fermé s'identifie à I via w.

Le foncteur de recollement entre I', I [page 61]

$$H \;:\; I'^\circ \times I \;\longrightarrow\; \mathrm{Ens}$$

est donné par

$$(*) \qquad \underbrace{H(i', i)}_{= \mathrm{Hom}_{C(u)}(i', i)} \;=\; \mathrm{Hom}_{I'}(i', u(i)) \;.$$

La rétraction v de $C(u)$ dans I' applique i dans $u(i)$, et une flèche $i' \longrightarrow i$ correspondant à $i' \longrightarrow u(i)$ dans I' via $(*)$, est transformé par v en cette même flèche $i' \longrightarrow u(i)$. Calculons,

pour i'_0 donné, la catégorie $i'_0\backslash\Big(C(u),\ v : C(u) \longrightarrow I'\Big)$, des couple d'un objet ξ de $C(u)$ et d'une flèche $i'_0 \longrightarrow v(\xi)$ dans I'. On voit que $i'_0\backslash C(u)$ admet l'ouvert $i'_0\backslash I'$, avec le complémentaire fermé $i'_0\backslash I$,

$$\begin{array}{ccccc} & & & & \text{fermé} \\ & & & & \text{complémentaire} \\ & & & & \text{de } I' \\ I' & \xhookrightarrow[\text{ouvert}]{} & C(u) & \hookleftarrow & I \\ & & \Big\downarrow & & \\ & & I' & & \end{array},$$

ces deux catégories étant recollées par le bifoncteur

$$\begin{array}{rcl} (i'_0\backslash I')^\circ \times (i'_0\backslash I) & \longrightarrow & \text{Ens} \\ \Big((\alpha : i'_0 \longrightarrow i'), (\beta : i'_0 \longrightarrow u(i), i)\Big) & \longmapsto & \mathrm{Hom}_{i'_0\backslash I'}(i', u(i)) \end{array}$$

induit par $(*)$; i.e. les flèches de $(\alpha : i'_0 \longrightarrow i') \in \mathrm{Ob}\,(i'_0\backslash I')$ dans $(\beta : i'_0 \longrightarrow u(i)) \in i'_0\backslash I$ sont les flèches $i' \xrightarrow{\gamma} u(i)$ telles que le triangle p. 31

$$\begin{array}{ccc} & i'_0 & \\ {\scriptstyle\alpha}\swarrow & & \searrow{\scriptstyle\beta} \\ i' & \xrightarrow{\ \gamma\ } & u(i) \end{array}$$

commute.

Si $i' = i'_0$, $\alpha = \mathrm{id}_{i'_0}$, alors cette commutativité revient à $\gamma = \beta$, ce qui signifie qu'il y a une flèche et une seule de α dans (i, β). Cela montre donc que $(i'_0, \mathrm{id}_{i'_0})$ est un objet initial de $i'_0\backslash C(u)$. On a donc prouvé le lemme : [page 62]

Lemme 3.8. *Soit $u : I \longrightarrow I'$ une flèche dans* (Cat)*, factorisons-le en*

$$I \xrightarrow{w} C(u) \xrightarrow{v} I' ,$$

où $C(u)$ est le mapping-cone défini page 60*, w une immersion fermée de complémentaire I', v la rétraction canonique de $C(u)$ sur I'. Ceci posé, pour tout $i'_0 \in \mathrm{Ob}\, I'$, la catégorie $i'_0\backslash(C(u), v)$ admet un objet initial – donc $v : C(u) \longrightarrow I'$ est (tout ce qu'il y a de) cofiltrante.*

Nous pouvons maintenant prouver 3.7. Tout d'abord, les hypothèses faites sur I, I' se transportent à $C(u)$ (hypothèse artinienne, et éventuellement hypothèse noethérienne sur $\mathrm{Esp}(C(u))$). Donc on peut appliquer les résultats précédents, notamment 3.5, aux flèches v, w. Le lemme précédent montre bien que v satisfait aux conditions de 3.5, donc le foncteur $v_!^W$ construit dans 3.3.1 est adjoint à gauche de v_W^*. Considérons d'autre part le foncteur $w_!^W$ construit dans 3.3.1, je dis que la même conclusion s'applique. Cela provient du fait que w est une immersion fermée. En effet, dans ce cas il est immédiat que [page 63]

$$w_! \ :\ \mathcal{M}(I^\circ) \ \longrightarrow\ \mathcal{M}(I'^\circ), \qquad \text{où } I = C(u),$$

est compatible avec les localiseurs, puisque l'on a

$$\begin{cases} w_!(X)(j) \ \simeq\ X(j) & \text{si } j \in I, \\ w_!(X)(j) \ \simeq\ \emptyset_{\mathcal{M}} & \text{si } j \in J\backslash I, \end{cases}$$

par le calcul des fibres p. 32

$$w_!(X)(j) \ \simeq\ \varinjlim_{i \in I/j} X(i)\ . \qquad \text{[page 64]}$$

Donc la définition de $w_!^W$ donnée dans 3.3.1 revient en fait à passer directement aux catégories localisées pour $w_!$, sans avoir à se restreindre à $\mathcal{M}(I^\circ)_c$, et le lemme des foncteurs adjoints nous dit que ce foncteur est adjoint à gauche de w_W^*.

Comme on a évidemment

$$u_!^W \simeq v_!^W \circ w_!^W , \qquad u_W^* \simeq w_W^* \circ v_W^* ,$$

on en conclut que $u_!^W$ est bien adjoint à gauche de u_W^*, q.e.d.

Corollaire 3.9. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations. Alors le prédérivateur $\mathbf{D}_W$, restreint à la catégorie* Diag_0 *formée des catégories I* ordonnées *artiniennes et telles que* $\mathrm{Esp}(I)$ *soit noethérien, satisfait aux axiomes* Dér 1 (décomposition), Dér 2 (localisation), Dér 3 (objet final), Dér 4 bis (existence de $u_!$), Dér 5 bis (mode de calcul des $u_!$), Dér 6 (exactitude des carrés W-cocartésiens). *Si C, $TC = C \cap W$ sont stables par composition transfinie, on a le même résultat sur la catégorie* Diag *formée des catégories I ordonnées artiniennes sans plus.*

Commentary · Context [ms. 64]

The invariant theory and the auxiliary structures

The point of Corollary 3.9 is that a one-sided structure on the coefficient category already constructs the corresponding half of the theory of diagrams. Cofibrations organize the calculation of left homotopy Kan extensions. A dual structure of fibrations organizes right homotopy Kan extensions. Grothendieck does not require the two chosen classes to determine one another by lifting properties before recognizing the resulting operations as part of the same homotopy theory.

This viewpoint is stated particularly clearly in the letter to Thomason of 2 April 1991: weak equivalences specify the essential data, while fibrations and cofibrations serve to construct operations and establish their existence (Grothendieck, 1991a, point 1, printed pp. 3–4). Brown's categories of fibrant objects provided a one-sided precedent (Brown, 1973, Section 1); the text here works dually and allows noncofibrant objects before passing to the cofibrant subcategory. A Quillen structure imposes the further agreement of the pairs $(C, F \cap W)$ and $(C \cap W, F)$ through lifting and factorization. That agreement is a powerful construction device, but it is a stronger condition than having two separate ways to calculate the operations attached to W.

Two conventions need attention when reading the corollary. First, its axiom numbers are Grothendieck's. Dér 2 is the localization or evaluation-conservativity assertion. Dér 3 concerns the full faithfulness of the constant-diagram functor when the indexing category has a final object; it does not assert that $\mathbf{D}(e)$ has a final object. Dér 4 bis and Dér 5 bis are the existence and pointwise-computation assertions for left Kan extensions. Dér 6 includes the corresponding exactness of base change on the specified homotopy-cocartesian squares. This older list should not be substituted term by term for a modern list numbered Der1–Der4.

Second, the preceding theorem is about covariant diagrams $\mathcal{M}(I^\circ)$, whereas the usual presheaf notation is $\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})$. Passing to the presheaf prederivator reverses the admissible indexing orders. The artinian condition of Theorem 3.7 becomes a noetherian condition on I; the extra topological condition becomes noetherianity of $\mathrm{Esp}(I^\circ)$. Corollary 3.9 and the corresponding sentence of 3.11 omit this reversal in their wording. Grothendieck gives the corrected presheaf formulation explicitly in Chapter XIX, Proposition 3.2 and the discussion in 3.4 (Grothendieck, 1990–1991j). The finite examples are unaffected, but the infinite indexing convention should be fixed before applying the result.

This also explains why the comma symbols change. For a covariant diagram $X : I \to \mathcal{M}$ the value of $u_!X$ at j is a colimit over $(u \downarrow j) = I/j$. For a presheaf $X : I^{\mathrm{op}} \to \mathcal{M}$ it is a colimit over $(j \downarrow u)^{\mathrm{op}}$. The printed $i'\backslash I$ in the square on manuscript p. 70 is therefore correct in the presheaf convention of 3.11. The square carries its canonical comma natural transformation; it is not meant as an equality of its two composites in the underlying ordinary category of categories.

3.10. Ainsi, pour avoir un dérivateur au plein sens du terme, soit sur Diag_0, soit sur Diag, il ne manque que Dér 4 (existence des u_*), Dér 5 (calcul des u_*) et Dér 6 (exactitude des carrés W-cartésiens). On va les obtenir en principe à l'aide d'une structure de *catégorie à fibrations* $(\mathcal{M}, F, W)$ associé à $(\mathcal{M}, W)$, i.e. l'espèce de structure duale de celle introduite page 39. Ces deux structures n'ont pas à être reliées entre elles d'une façon autre que par le [page 65]

fait qu'elles correspondent au même W. Elles sont considérablement plus faciles à construire que des structures de Quillen (W, C, F), où C, F doivent être reliés de façon extrêmement stricte, avec les propriétés $C \longleftrightarrow \underbrace{TF}_{=F\cap W}$, $\underbrace{TC}_{=C\cap W} \longleftrightarrow F$ (dont il n'est pas question dans l'axiomatique de K. S. Brown), et factorisation pour (C, TF) et (TC, F).

Mais revenant à la construction des $u_!^W$, il reste le problème de les construire pour une flèche $u : I' \longrightarrow I$ *quelconque* dans Cat. [page 66]

À vrai dire, la construction du foncteur

$$u_!^W \ : \ \mathrm{Ho}_W(I^\circ) \ \longrightarrow \ \mathrm{Ho}_W(I'^\circ) \tag{3.3.1}$$

est valable sans supposer que I' soit une catégorie ordonnée – ça peut être une catégorie quelconque. Cela provient du fait que le foncteur induit par $u_!$,

$$u_{!\,\mathrm{cof}} \ : \ \mathcal{M}(I^\circ)_\mathrm{c} \ \longrightarrow \ \mathcal{M}(I'^\circ)$$

est encore compatible avec les localiseurs, comme on voit par le calcul des fibres

$$u_!(X)(i) \ \simeq \ \varinjlim_{i\in I/i'} X(i) \ .$$

Ainsi, on est ramené aux cas où $I' = e$, quitte à remplacer I par I/i', et en notant que ($I/i' \longrightarrow I$ étant étale) l'image inverse de X sur I/i' est cofibrant (cf. 3.2.a).

Commentary · Development (commentators') [ms. 66]

A finite source can require an infinite supply of coefficients

Grothendieck observes that the target of a Kan extension need not itself be ordered: the calculation can be made over comma categories. This is correct in the transfinite setting, but it does not extend the finite-colimit alternative without a further hypothesis. The new comma categories may be much larger than the source. We make the obstruction precise in a case where weak equivalences introduce no additional difficulty.

Take $\mathcal{M} = \mathrm{FinSet}$, let W be the isomorphisms, and let every map be a cofibration. All the finite cofibration axioms hold: finite colimits exist, pushouts preserve isomorphisms, and $f = 1 \circ f$ is a cofibration–weak-equivalence factorization. Every object is cofibrant. For the functor $e \to BG$, covariant restriction is the forgetful functor

$$U : \mathrm{FinSet}^G \longrightarrow \mathrm{FinSet}.$$

The comma category $(e \downarrow *)$ is the discrete set G, so the proposed pointwise formula on a singleton requires $\coprod_G 1$. If G is infinite this colimit is absent from FinSet. There is also a sharper test for whether any left adjoint exists.

Finite-action criterion. [ours]

For a group G, set

$$N = \bigcap_{[G:H]<\infty} H.$$

The forgetful functor U has a left adjoint if and only if $[G : N]$ is finite. When it exists, the left adjoint sends a finite set S to $(G/N) \times S$, with G acting on the first factor.

Proof. Suppose $F \dashv U$, put $P = F(1)$, and let $p \in P$ be the point specified by the unit. Equivariance and the adjunction give a natural bijection

$$\mathrm{Hom}_G(P, A) \longrightarrow U(A), \qquad f \longmapsto f(p).$$

In particular P is nonempty. For the trivial two-element G-set, an equivariant map is precisely a function on the orbit set of P. If P has k orbits, the left side has 2^k elements and the right side has two. Thus $k = 1$ and P is transitive. Write $H = \mathrm{Stab}_G(p)$, so $P \simeq G/H$ and H has finite index.

For every finite-index subgroup $K \subset G$, apply the bijection to $A = G/K$ and the distinguished point K. The required map taking p to K forces $H \subset K$. Hence $H \subset N$. The reverse inclusion follows because H itself occurs in the intersection, so $H = N$ and $[G : N] < \infty$.

Conversely, the intersection defining N is normal, since conjugation permutes the finite-index subgroups. For every finite G-set A and every $a \in A$, its stabilizer has finite index, so N fixes a. All finite actions therefore factor through G/N. If G/N is finite, $(G/N) \times S$ is a finite G-set, and an equivariant map from it to A is uniquely specified by the arbitrary function $s \mapsto f(N, s)$. This is the required adjunction, naturally in both variables. □

For $G = \mathbb{Z}$, the intersection of the subgroups $n\mathbb{Z}$ is zero and has infinite index. Thus U has no left adjoint, even though the source of $e \to B\mathbb{Z}$ has one object and no nonidentity arrows. Equivalently, a hypothetical universal point in a finite $\mathbb{Z}$-set would have a finite orbit of length r, but could not map to the distinguished point in the cycle of length $r + 1$. This disproves the unrestricted finite-colimit reading of the sentence on manuscript p. 66.

The criterion also separates existence of a left adjoint from the pointwise colimit formula. An infinite group with no nontrivial finite quotients has $N = G$, so all its finite actions are trivial and U is an equivalence. Its left adjoint exists although the infinite discrete coproduct appearing in the proposed formula does not. In the general theory, Dér 5 bis is therefore substantive even when Dér 4 bis has been obtained.

We did not find this explicit finite-action criterion in the derived-functor and ABC sources checked here, nor in a targeted search for adjoints of the finite-action forgetful functor. The elementary argument is supplied as a diagnostic continuation of the text, with no claim of priority. The repair needed for Grothendieck's construction is to retain the transfinite colimit hypotheses, or to require that each comma category and its colimit remain within the range of the finite theorem.

Mais il se présente à nouveau la perplexité si le foncteur (3.3.1) ainsi construit est bien [page 67]
adjoint à gauche de u_W^*. On peut songer à utiliser encore la même factorisation en $u = vw$, en
utilisant le mapping-cone. La difficulté, cependant, c'est qu'à présent $J = C(u)$ n'est plus une p. 33
catégorie ordonnée, donc on n'a pas une définition toute prête de $C_{J^\circ} \subset \mathrm{Fl}(\mathcal{M}(J^\circ))$, donnant lieu à une sous-catégorie $\mathcal{M}(J^\circ)_{\mathrm{c}}$ etc. En fait, il semblerait qu'on soit pratiquement paralysé, tant qu'on n'arrive à construire sur $\mathcal{M}(J^\circ)$ également une structure de catégorie à cofibrations, se comportant bien par rapport au foncteurs $v_!$. La "démonstration" d'Anderson de l'existence de $u_!$ pour *toute* flèche dans Cat, foire totalement (même pour $I \longrightarrow e$, I ensemble ordonné fini – mais là j'ai pu rétablir la situation), car il se ramène au cas où I est ordonné localement fini, et il admet sans plus que *dans ce cas* $u_!^W$ est adjoint à gauche de u_W^*, et *de plus,* que si u [page 68]
est $\mathbf{W}_0$-connexe, donc $u^* : \mathcal{M}(I'^\circ) \longrightarrow \mathcal{M}(I^\circ)$ pleinement fidèle, qu'il en soit de même de u_W^* déduit par passage aux localisés. Or même si on admet que $u_!^W$ est adjoint à gauche de u_*^W, faute de disposer d'un morphisme d'adjonction tout près "en bas" (dans $\mathrm{Ho}_W(I'^\circ)$), déduit du morphisme d'adjonction dans $\mathcal{M}(I^\circ)$, il n'est absolument pas clair que u_W^* soit pleinement fidèle, i.e. $u_!^W$ un foncteur de localisation. Le contrexemple 3.6 montre bien que, même si on a adjonction (i.e. si e est un objet initial de $\mathcal{C} = \mathcal{C}'$), le foncteur $u^* = \mathrm{id}_{\mathcal{C}}$ a beau être pleinement fidèle (et même une équivalence de catégories), le foncteur localisé n'a aucune raison de l'être : cela pouverait que tout objet de Cat ayant un objet initial est équivalent à e !

3.11. Disons qu'on a une *catégorie à cofibrations stricte,* si dans l'axiome Cof_3 de factori- [page 69]
sation (cf. p. 39), la factorisation peut être prise fonctoriellement en f. Il revient ± au même de dire que l'axiome de factorisation reste valable, quand on pense à une catégorie $\mathcal{M}(I)$ pour I dans Cat, en y définissant $W(I)$ et $C(I)$ (à ne pas confondre avec C_I) fibre par fibre. Cela revient au même tout au moins si $\mathcal{M}$ est équivalente à une petite catégorie. Sinon, il faut supposer fonctorialité pour toute *petite* sous-catégorie pleine de $\underline{\mathrm{Fl}}(\mathcal{M})$. Il vaut mieux définir la catégorie à cofibrations stricte par cette propriété de stabilité.

On voit alors que le prédérivateur $\mathbf{D} = \mathbf{D}_{\mathcal{M}}$ sur Cat est un dérivateur *relativement à* $\mathcal{D} = \mathrm{Diag}_0$ défini plus haut (catégories ordonnées I artiniennes, telles que $\mathrm{Esp}(I)$ soit noethérien), ou même relativement à $\mathcal{D} = \mathrm{Diag}$ (catégories ordonnées I artiniennes sans plus) lorsque C et TC sont stables par composition transfinie. J'entends par là que $u_!$ existe quand u est une flèche de $\mathcal{D}$, et que ça reste valable quand on passe à un dérivateur induit $\mathbf{D}_Z$ (Z [page 70]
dans Cat quelconque) ; en d'autre termes, que $v_!$ existe quand v est de la forme $\mathrm{id}_Z \times u$, où $u : I \longrightarrow I'$ est une flèche de $\mathcal{D}$, et que le calcul se fait *au dessus de* I' selon la règle Dér 5 bis. Cela signifie donc que la flèche de changement de base pour les $f_!$ est un isomorphismes dans

le cas suivant :

$$\begin{array}{ccc} I \times Z & \longleftarrow & (i'\backslash I) \times Z \\ \downarrow{\scriptstyle u\times \mathrm{id}_Z} & & \downarrow{\scriptstyle \mathrm{pr}_2} \\ I' \times Z & \longleftarrow & \{i'\} \times Z \end{array} ,$$

où i' est un objet quelconque de I'.

L'hypothèse *stricte* pour une catégorie à cofibrations me paraît assez anodine, dans la plupart des cas à ma connaissance, elle est satisfaite. Mais même moyennant cette hypothèse, je ne vois aucun moyen de prouver l'existence de $u_!$ pour *toute* flèche de Cat, et c'est une situation bien sûr très gênante. On voudrait absolument dégager des conditions qui assurent la validité de Dér 4 bis et de Dér 5 bis (existence de $u_!$ pour *toute* flèche de Cat, et mode de calcul des fibres …). p. 34 [page 71]

Commentary · Later developments [ms. 70]

Strict factorization and arbitrary diagram shapes

Grothendieck introduces strictness to make the theorem uniform in an extra parameter. A natural transformation of Z-diagrams is itself a functor $Z \to \mathrm{Arr}(\mathcal{M})$. A functorial factorization on the arrow category factors all its components together and supplies the transition maps between the intermediate objects. Thus the coefficient category $\mathcal{M}^Z$, with weak equivalences and cofibrations tested componentwise, again has the required factorization axiom. Colimits and the stated closure properties are also tested componentwise. Applying the earlier theorem to these new coefficients constructs the extension along $u \times 1_Z$.

There is a converse behind the qualification about size. If $\mathcal{M}$ is small, factor the universal arrow diagram indexed by $\mathrm{Arr}(\mathcal{M})$; its two endpoint functors and their universal natural transformation recover a functorial factorization on all arrows. For an essentially small category, first choose a small equivalent one. In a large category the all-small-diagrams assertion only makes this choice on every small full subcategory of the arrow category, which is the formulation Grothendieck finally adopts. No global choice on a proper class is needed for the application to a particular small Z.

The arbitrary-shape question at the end of 3.11 was subsequently answered under hypotheses appropriate to all small homotopy colimits. In Rădulescu-Banu (2009, Theorems 9.6.3 and 9.6.5), the existence of the left adjoint and its pointwise comma-category formula are proved separately for ABC cofibration categories; Theorem 10.3.2 identifies the resulting strong left Heller derivator. Here we use the numbering of arXiv:math/0610009v4. Its axioms CF5 and CF6 provide small coproduct and sequential-composition control. The theorem therefore does not assert that the finite axioms alone suffice. The construction proceeds through direct simplicial resolutions of arbitrary categories, rather than requiring a projective Quillen structure on every original diagram category.

Cisinski (2010, Theorem 6.11 and Corollary 6.21) gives the corresponding presheaf and derivator statements in a fibration-oriented convention, with the required homotopical completeness assumptions; the dual statements concern cofibrations. These references establish the later affirmative results without turning the source's uncertainty into a present-day open problem. They also explain why strictness and specialness should remain distinct: strictness is a coherent factorization condition, while the next section adds a set of generators and transfinite closure to obtain a particular transfer construction.

4 Catégories à cofibrations spéciales

4.1. Je suppose à présent que

ⓐ $\mathcal{M}$ est stable par $\varinjlim$ filtrantes, et

ⓑ que ses objets sont accessibles,

de sorte qu'on est sous les conditions d'application du théorème de factorisation (XV, §1). On suppose :

ⓒ donné $W, C \subset \mathrm{Fl}(\mathcal{M})$, satisfaisant les conditions Cof_1, Cof_2 de page 39. Pour Cof_3, cf. plus bas.

ⓓ C, $TC \overset{\text{déf}}{=} C \cap W$ *stables par composition transfinie* (c'est le cas si la structure provient d'une structure de Quillen close (W, C, F)).

$$TF \overset{\text{déf}}{=} C_* \ \subset \ \mathrm{Fl}(\mathcal{M}) \ , \tag{4.1}$$

il résulte du théorème de factorisations que toute flèche f de $\mathcal{M}$ se factorise en

$$f \ = \ pi \ , \qquad p \in TF, \ i \in C \ ,$$

pourvu qu'on fasse l'hypothèse

ⓔ

$$\exists\, C_0 \subset C, \ \textit{petite} \text{ partie de } C, \ \text{telle que } C \subset \tilde{C}_0, \ \text{i.e. } TF = (C_0)_*. \tag{4.3}$$

Sous ces conditions, si on suppose

ⓕ

$$TF \subset W \ , \tag{4.4}$$

alors l'axiome de factorisations Cof_3 est satisfait. Inversement, si Cof_3 est satisfait, et si W est stable par facteurs directs, alors on a 4.4. Donc si W est stable par facteurs directs, Cof_3 équivaut à (4.4). [page 72]

Commentary · Exposition [ms. 71]

What the small set of cofibrations contributes

Grothendieck now changes the method. The induction over a well-founded indexing order is replaced by an induction that attaches solutions to lifting problems. A small set of maps can test all the required right lifting properties at once. This is why the set C_0 enters the argument precisely when the indexing category is allowed to have arbitrary arrows and endomorphisms.

For a class S of maps, write

$$S^{\perp} = \{p : s \perp p \text{ for every } s \in S\}, \qquad \widetilde{S} = {}^{\perp}(S^{\perp}).$$

The tilde denotes closure for the lifting relation, not closure under weak equivalence. If $C_0 \subset C \subset \widetilde{C_0}$, then $C^{\perp} = C_0^{\perp}$ by the two inclusions in the lifting relation. Under the smallness hypotheses, $\widetilde{C_0}$ is also the class of retracts of relative C_0-cell maps. These are the two descriptions connected by the small-object argument; they should not be identified without its hypotheses.

Here is the factorization mechanism in the form needed in 4.1. Given $f : X \to Y$, begin with $X_0 = X$. At a successor stage, form the coproduct of all maps $a : A \to B$ in C_0, indexed further by all commutative squares from a to $X_\alpha \to Y$. Push this coproduct out along its maps to X_α, obtaining $X_\alpha \to X_{\alpha+1}$ and an induced map $X_{\alpha+1} \to Y$. At a limit stage take the colimit of the preceding objects. The set of generators and local smallness ensure that each attaching family is a set. Choose a regular cardinal large enough for the domains of all the generators, and carry the construction to a limit ordinal of at least that cofinality. Every map from a generating domain to the final object then factors through some stage, so its associated lifting square is solved at the next stage. The resulting map $p : X_\lambda \to Y$ lies in $C_0^{\perp} = C^{\perp}$.

The left factor $i : X \to X_\lambda$ lies in C. Indeed, a coproduct of cofibrations can be attached one summand at a time: well-order the indexing set, replace one source summand by its target at each step, and take colimits at limits. Each step is a pushout of a map in C, and transfinite closure finishes the argument. The same closure applies to the successive attaching maps and then to their composite. This gives $f = pi$ with $i \in C$ and $p \in C_*$; the extra assumption $C_* \subset W$ supplies the required weak equivalence. For the standard modern formulation, see Riehl (2014, Theorem 12.2.2 and Corollary 12.2.4).

The converse on manuscript p. 72 is a short retract argument. Factor $p \in C_*$ as $p = qi$ with $i \in C$ and $q \in W$. In the square having top map $1_{\mathrm{dom}\, p}$, left map i, right map p, and bottom map q, a lift h satisfies $hi = 1$ and $ph = q$. Therefore p is a retract of q in the arrow category. Retract closure of W gives $p \in W$. This is exactly where that additional hypothesis is used.

The accessibility assumption should also be read at its stated strength. It provides a smallness cardinal for each relevant object, and the set C_0 permits a common bound for the domains occurring in the construction. It does not, by itself, state that the whole category has a set of presentable generators. Thus a special cofibration category is not automatically being identified here with a combinatorial model category. A second lifting/factorization pair and its compatibility with W are still to be constructed.

4.2. Il me semble que ces conditions, en pratique, ne seront guère jamais remplies, que si W (qui est donné en tout premier lieu, satisfaisant Cof_0 [18]), n'est pas stable par $\varinjlim$ filtrantes. À ce moment, pour construire la structure à cofibrations, on part de C_0 petite p. 35
partie de $\mathrm{Fl}(\mathcal{M})$, prise telle que l'on ait

$$(C_0)_* \subset W \ , \tag{4.5}$$

on prend pour C au choix le saturé C_0' de C_0 par cochangement de base et composition transfinie, ou $C = \tilde{C}_0 =$ ensemble des facteurs directs de C_0'. Les conditions Cof_1 (stabilités de C), Cof_3 (factorisation) sont satisfaites automatiquement, et il reste à s'occuper de Cof_2, qui revient à la stabilité de $C \cap W$ par cochangement de base (la stabilité par composition et que ça contienne les isomorphismes, étant immédiates). C'est une condition délicate, et la seule façon standard que je vois pour l'assurer, c'est en supposant

$$C_0 \subset \mathrm{Cof}_W \ ; \tag{4.6}$$

la stabilité de W par $\varinjlim$ filtrantes (donc aussi par facteurs directs) assure alors qu'on a également [page 73]

$$C \subset \mathrm{Cof}_W \ , \tag{4.7}$$

et par suite

$$\begin{cases} C \cap W \subset \mathrm{Cof}_W \cap W = W^{\mathrm{univ}}, \\ \text{d'où } \ TC \overset{\text{déf}}{=} C \cap W = C \cap W^{\mathrm{univ}} \ , \end{cases} \tag{4.8}$$

ce qui assure la stabilité de $C \cap W$ par cochangement de base. La stabilité de TC par composition transfinie résulte de celle de C, et de la stabilité de W par composition transfinie.

4.3. Je reviens aux conditions générales ⓐ à ⓕ de 4.1, sans supposer nécessairement W stable par $\varinjlim$ filtrantes. Je veux à présent étendre la structure à cofibrations aux $\mathcal{M}(I)$, I quelconque dans Cat. Nous n'avons pas pour ceci (je crois) à utiliser les développements des paragraphes 2, 3, mais nous ferons le lien avec ceux-ci par la suite.

Désignons par I_0 la catégorie discrète ayant mêmes objets que I, d'où un foncteur canonique

$$v = v_I \ : \ I_0 \longrightarrow I \ . \tag{4.9}$$

L'idée est de définir la structure de $\mathcal{M}(I)$ via la structure évidente de $\mathcal{M}(I_0) \simeq \mathcal{M}^{I_0}$, en jouant sur le couple de foncteurs adjoints

$$\mathcal{M}(I_0) \underset{\psi = v^*}{\overset{\varphi = v_!}{\rightleftarrows}} \mathcal{M}(I) \quad .$$

Nous allons présenter les choses de façon un peu plus générale.

[page 74]

18. i.e. saturation faible.

Commentary · Exposition [ms. 73]

Why intrinsic cofibrations control the weak equivalences

The difficulty in 4.2 is not producing a large class of cofibrations. Pushouts and transfinite compositions already do that. The problem is keeping those maps that are also weak equivalences stable under arbitrary cobase change. Grothendieck's intrinsic class Cof_W addresses precisely this issue: a map belongs to it when pushout along it preserves weak equivalences between objects under its source. This class is determined by W, while C_0 is a chosen supply of maps with which to construct factorizations.

Suppose W is stable under filtered colimits of diagrams of arrows. Pushout stability of Cof_W follows from the associativity of pushouts. For a transfinite composite of intrinsic cofibrations, push a weak equivalence through the successive stages. At a successor stage it remains a weak equivalence by the defining property; at a limit stage it remains one by filtered-colimit stability. This proves the transfinite closure needed to pass from C_0 to its cellular closure.

The same hypothesis on W also gives retract closure, by a useful elementary argument. If an arrow f is a retract of an arrow $g \in W$, let e be the corresponding idempotent endomorphism of g in the arrow category. The sequence

$$g \xrightarrow{e} g \xrightarrow{e} g \xrightarrow{e} \cdots$$

has colimit f. To see this, compose the retraction and section maps with the defining cocones; the identities for a split idempotent establish both universal properties. All objects of this sequence lie in W, so its colimit does as well. Retracts of intrinsic cofibrations are then intrinsic cofibrations: any pushout comparison for the retract is a retract of the corresponding comparison for the original arrow. This proves the passage from the cellular closure to $\widetilde{C_0}$.

The equality $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$ used in the text relies here on the factorization already obtained, and admits a direct verification. Let $a : A \to B$ be both intrinsic and weakly invertible, and take any map $A \to A'$. Factor the latter as $A \xrightarrow{c} Z \xrightarrow{q} A'$ with $c \in C \subset \mathrm{Cof}_W$ and $q \in W$. Pushing a along c gives a weak equivalence $Z \to B \amalg_A Z$. Since the pushout $Z \to B \amalg_A Z$ of a is itself intrinsic, pushing the weak equivalence q along it gives a weak equivalence

$$B \amalg_A Z \longrightarrow B \amalg_A A'.$$

The commutative square with these two maps and q shows, by two-out-of-three, that $A' \to B \amalg_A A'$ is a weak equivalence. Conversely, if all pushouts of a are weak equivalences, the two horizontal pushouts of a in any cobase-change comparison are in W; two-out-of-three shows that the comparison is in W whenever its input is. Thus a is intrinsic.

Consequently $TC = C \cap W^{\mathrm{univ}}$ is pushout-stable. Its transfinite stability follows from that of C and the limit-stage hypothesis on W. The negative wording "n'est pas stable" at the end of manuscript p. 72 is printed in the edition but conflicts with the positive stability hypothesis used throughout this argument. We retain the wording in the source and record the intended sign in the correction register.

Définition 4.4. J'appelle structure de cofibrations *spéciale* une structure $(\mathcal{M}, W, C)$ satisfaisant les conditions a) à f) de 4.1, que je reformule :

ⓐ $\mathcal{M}$ stable par petites limites inductives, et les objets de $\mathcal{M}$ sont accessibles. p. 36

ⓑ W est faiblement saturé (i.e. Cof_0 de p. 39), C stable par cochangement de base et par composition, $TC \overset{\text{déf}}{=} C \cap W$ stable par cochangement de base (et par composition automatiquement).

ⓑ′ C et TC sont stables même par composition *transfinie.*

ⓒ $\exists$ petite partie $C_0 \subset C$ telle que $C \subset \tilde{C}_0$ ($\Longrightarrow \tilde{C} = \tilde{C}_0$).

ⓓ $TF \overset{\text{déf}}{=} C_* \subset W$ (ce qui implique, joint àⓐ àⓒ, l'axiome de factorisation Cof_3 de page 39).

4.5. Nous allons donner une recette générale d'extension d'une telle structure, quand on

dispose d'un couple de foncteurs adjoints

$$\mathcal{M} \underset{v^*}{\overset{v_!}{\rightleftarrows}} \mathcal{M}' \ ,$$

$\mathcal{M}$ étant muni d'une structure de cofibrations spéciale (W, C), et $\mathcal{M}'$ satisfaisant la condition liminaire ⓐ. On définira alors les parties W', C' de $\mathrm{Fl}(\mathcal{M}')$ par [page 75]

$$(4.5.1) \qquad \begin{cases} W' \ = \ (v^*)^{-1}(W) \\ C' \ = \ \text{clôture stable par cochangement de base} \\ \qquad\quad \text{et composition transfinie de } v_!(C), \end{cases}$$

donc

$$(4.5.2) \qquad v_!(C) \ \subset \ C' \ \subset \ (v_!(C))^{\sim} \ = \ \tilde{C}' \ .$$

Je dis que (W', C'), et au choix $(W', \tilde{C}')$, est une structure de cofibrations spéciale sur $\mathcal{M}'$. On va vérifier les différentes conditions de 4.4. La condition a) est déjà acquise.

Commentary · Exposition [ms. 75]

The transfer proof and its exact hypotheses

The adjunction in 4.5 is meant to reconstruct a diagram from its values at objects. Grothendieck first proves the transfer abstractly so that the construction does not depend on a particular indexing category. Write $L = v_!$ and $U = v^*$. The proposed weak equivalences are detected by U, while the proposed cofibrations are built from the images under L of the old cofibrations. These are different parts of the construction, and the proof must show that their intersection behaves correctly.

Let $C' = \mathrm{cell}(LC)$ denote closure under pushouts and transfinite composition, including isomorphisms, and let $W' = U^{-1}W$. The two substantive assumptions are

$$U \text{ preserves small colimits}, \qquad UL(C) \subset C.$$

Every operation forming C' is then sent to the corresponding operation in the source category. Induction through a cellular construction gives $U(C') \subset C$. Therefore

$$U(C' \cap W') \subset C \cap W = TC.$$

If $a' \in C' \cap W'$ is pushed out in the target, its image under U is a pushout of a trivial cofibration. It remains in TC, so the target pushout lies in W' as well as in C'. For a transfinite composite of maps in $C' \cap W'$, preservation of the relevant colimits gives a transfinite composite in TC; the same conclusion follows. This proves the two closure statements whose compatibility was initially in doubt.

The set of generators is transferred using the left adjoint, not the right one. If $C_0 \subset C \subset \widetilde{C_0}$, then L preserves pushouts and transfinite composites, and every functor preserves retract diagrams. Hence

$$L(C_0) \subset C' \subset \widetilde{L(C_0)}.$$

The target smallness hypothesis permits the small-object argument for this new set. Notice that the assertion is about a generating set for the lifting closure; it does not claim that every map of C' is a cell complex on $L(C_0)$ without taking retracts.

Finally, right lifting properties pass across an adjunction exactly. A commutative square from $L(a)$ to p' corresponds to a square from a to $U(p')$, and diagonal fillers correspond under the same bijection. Since left lifting properties survive pushouts, transfinite compositions and retracts,

$$(C')^{\perp} = (LC)^{\perp} = U^{-1}(C^{\perp}) = U^{-1}(TF) \subset U^{-1}(W) = W'.$$

The small-object factorization therefore has a weakly invertible right factor. These arguments prove Proposition 4.6 without assuming that U preserves all weak equivalences by some separate theorem: that property is part of the definition of W'.

For the optional replacement of C' by $\widetilde{C'}$, the proof needs C to be retract-closed. Then $U(\widetilde{C'}) \subset C$, and the pushout and transfinite arguments apply again to $\widetilde{C'} \cap W'$. This does not require silently adding retract closure of W'. Footnote 20 offers a different route, developed in Proposition 5.1, using additional stability assumptions on W. The announcement in 4.5 should be read with the hypotheses collected in the actual proposition, not as a theorem preceding them.

In the diagram application, U is evaluation on the discrete object set and genuinely does preserve colimits. The composite UL is a coproduct of the old objects indexed by arrows of the indexing category. The stability of C under such coproducts, proved by attaching summands as above, is what makes the abstract assumption $UL(C) \subset C$ usable there. The next question concerns trivial cofibrations and is not answered merely by this cofibration calculation.

b) [19]. La saturation faible de W' résulte de celle de W, via (4.5.1). La stabilité de C' par cochangement de base et par composition (même transfinie) est acquise par définition de C', et itou pour $\tilde{C}'$ (étant Q-close à gauche). Stabilité de $TC' \overset{\text{déf}}{=} C' \cap W'$ par cochangement de base ? Il suffit de voir que si on a un carré cocartésien

$$\begin{array}{ccc} X'_0 & \xrightarrow{i'} & X'_1 \\ \downarrow & \text{cocart.} & \downarrow \\ X'_2 & \xrightarrow{j'} & X'_3 \end{array}$$

dans $\mathcal{M}'$, avec i' dans $TC' = C' \cap W'$, alors $j' \in W'$ (car on sait déjà $j' \in C'$), i.e. $v^*(j') \in W'$. ||
Nous allons supposer que v^* *commute aux sommes amalgamées,* et on est donc ramené à prouver que $v^*(i') \in TC$. Donc on doit prouver le p. 37
[page 76]

Lemme 4.5.2. *Sous les conditions* (4.5.3) *et* (4.5.4) *ci-dessous, on a*

$$v^*(C') \ \subset \ C \ , \qquad v^*(TC') \ \subset \ TC \ ,$$

et si $C = \tilde{C}$, *on a* $v^*(\tilde{C}') \subset C$, $v^*(T\tilde{C}') \subset TC$.

Pour $v^*(C') \subset C$, il faut d'abord prouver

$$v^*(v_!(C)) \ \subset \ C \ , \tag{4.5.3}$$

et je ne vois aucun moyen – il faut le poser comme hypothèse. De plus, que v^* commute aux $\varinjlim$ quelconques (cochangement de base déjà admis – à présent on a besoin des limites inductives filtrantes)

$$v^* \text{ commute aux petites } \varinjlim \text{ quelconques} \tag{4.5.4}$$

pour conclure de (4.5.3) que $v^*(C' = \text{clôture de } v_!(C)$ pour cochangement de base et composition transfinie) est également dans C. Passant à $v^*(TC') \subset TC$, par ce qui précède, $v^*(C') \subset C$, il suffit de prouver $v^*(TC') \subset W$, mais $v^*(TC') \subset v^*(W') \subset W$ par définition de W'.

Supposons $C = \tilde{C}$, i.e. C stable par facteurs directs, et prouvons $v^*(\tilde{C}') \subset C$, $v^*(T\tilde{C}') \subset TC$. Par c) plus bas, $\tilde{C}'$ est formé des facteurs directs d'éléments de C', donc $v^*(C') \subset C$ implique $v^*(\tilde{C}') \subset C$ puisque C stable par facteurs directs. [page 77]

Prouvons enfin $v^*(T\tilde{C}') \subset TC \overset{\text{déf}}{=} C \cap W$. Comme $T\tilde{C}' = \tilde{C}' \cap W'$, cela résulte de $v^*(\tilde{C}') \subset C$, et de $v^*(W') \subset W$.

Prouvons b′). La stabilité de C' et de $\tilde{C}'$ par composition transfinie est acquise, il reste à prouver la stabilité de $TC' = C' \cap W'$ et de $T\tilde{C}' = \tilde{C}' \cap W'$. Il suffit de voir que le composé transfinie f en question est dans W', donc que $v^*(f) \in W$, mais cela résulte du fait que v^* commute à la composition transfinie par (4.5.4), et que v^* transforme TC' et $T\tilde{C}'$ dans TC.

19. **N.B.** Il vaut mieux commencer par prouver c).

Prouvons c) pour C' (donc aussi pour $\tilde{C}'$). Soit C_0 une petite partie de C telle que $C \subset \tilde{C}_0$, i.e. C est contenu dans la clôture de C_0 par les trois opérations de cochangement de base, de composition transfinie, des facteurs directs. On voit alors que $v_!(C)$ est dans la clôture de $v_!(C_0)$ pour les opérations, donc aussi C', et on peut alors prendre $C'_0 = v_!(C_0)$.

Prouvons enfin d), c'est la même assertion pour C' et pour $\tilde{C}'$, puisque

$$C'_* \ = \ \tilde{C}'_* \ (\overset{\text{déf}}{=} \ TF' \ ) \ ,$$

il faut donc prouver [page 78]

$$TF' \overset{\text{déf}}{=} C'_* \ \subset \ W' \ .$$

Cela va résulter du p. 38

Lemme 4.5.3. *On a* $TF' = (v^*)^{-1}(TF)$.

C'est formel par définition de TF' comme

$$TF' \ = \ (v_!(C))_* \ ,$$

de TF comme

$$TF \ = \ C_* \ ,$$

et de l'adjonction de $v_!$, v^*. Comme $TF \subset W$, on en conclut

$$TF' \ = \ (v^*)^{-1}(TF) \ \subset \ (v^*)^{-1}(W) = W' \ ,$$

q.e.d.

Donc on a prouvé ceci :

Proposition 4.6. *Considérons un couple de foncteurs adjoints*

$$\mathcal{M} \underset{v^*}{\overset{v_!}{\rightleftarrows}} \mathcal{M}' \ ,$$

où $\mathcal{M}$ *est muni d'une structure de cofibrations* spéciale (W, C). *On suppose de plus les conditions suivantes satisfaites.*

(4.6.1)
- 1°) $\mathcal{M}'$ *stable par petites* $\varinjlim$ *, ses éléments sont accessibles.*
- 2°) v^* *commute aux petites* $\varinjlim$.
- 3°) $v^*(v_!(C)) \subset C$.

Considérons les parties W', C' *de* $\mathrm{Fl}(\mathcal{M}')$ *définies par* [page 79]

(4.6.2)
$$\begin{cases} W' \ = \ (v^*)^{-1}(W), \\ C' \ = \ \textit{clôture de } v_!(C) \textit{ par cochangement de base et par composition} \\ \qquad \textit{transfinie.} \end{cases}$$

Alors $(\mathcal{M}', W', C')$ *est une structure à cofibrations spéciale. Si de plus* $C = \tilde{C}$, *i.e.* C *est stable par facteurs directs, alors* $(\mathcal{M}', W', \tilde{C}')$ *est également une structure à cofibrations spéciale* [(20)].

4.7. J'aimerais, en vue d'énoncés du type 3.7 (établissant l'existence de foncteurs du type $u_!^W$), avoir une prise sur $TC' = C' \cap W'$, et sur $T\tilde{C}' = \tilde{C}' \cap W'$, de façon précise, j'aimerais avoir la relation

$$v_!(TC) \ \subset TC' \subset v_!(TC)^\sim \ , \tag{4.7.1}$$

voire la relation légèrement plus forte

$$\underbrace{v_!(TC) \ \subset TC'}_{} \ \overset{\text{tautol.}}{\subset} \ \underbrace{T\tilde{C}' \ \subset \ (v_!(TC))^\sim}_{} \ , \tag{4.7.2}$$

p. 39

qui se décompose en deux

$$\left\{\begin{array}{rcl} v_!(TC) & \subset & TC' \\ T\tilde{C}' & \subset & (v_!(TC))^\sim . \end{array}\right. \tag{4.7.3}$$

La moins délicate des deux est la première, $v_!(TC) \subset TC'$, qui revient, en vertu des définitions, impliquant [page 80]

$$v_!(TC) \subset v_!(C) \subset C' ,$$

à

$$v_!(TC) \ \subset \ W' ,$$

i.e. par définition de W', à

$$v^* v_!(TC) \ \subset \ TC , \tag{4.7.4}$$

ce qui est une hypothèse de type (4.6.1) 3°), à joindre aux hypothèses (4.6.1).

Commentary · Exposition [ms. 79]

The remaining comparison is a comparison of lifting classes

Grothendieck has enough structure to factor arrows in the new category, but he needs more to derive arbitrary left Kan extensions in a controlled way. The further issue is whether the transferred trivial cofibrations are generated, for lifting purposes, by the images of the original trivial cofibrations. It is this question, rather than the already established existence of a special cofibration structure, that occupies 4.7.

The forward inclusion is transparent once the hypotheses are separated. Since $L(TC) \subset L(C) \subset C'$, one has

$$L(TC) \subset TC' \quad \Longleftrightarrow \quad UL(TC) \subset W \quad \Longleftrightarrow \quad UL(TC) \subset TC.$$

The last equivalence uses $UL(C) \subset C$. Thus equation (4.7.4) is an additional preservation condition, not a consequence of Proposition 4.6 alone.

Assume it from now on. The inclusion $LC \supset L(TC)$ does not control the reverse comparison $TC' \subset \widetilde{L(TC)}$: a cofibration built from LC may happen to be weakly invertible without presenting itself as an attachment of maps from $L(TC)$. Passing to right lifting classes isolates the exact missing assertion. With $F = (TC)^\perp$ and $F' = (TC')^\perp$, adjunction gives

$$(L(TC))^\perp = U^{-1}(F), \qquad F' \subset U^{-1}(F).$$

The reverse inclusion is equivalent to $TC' \subset {}^\perp((L(TC))^\perp)$, which is precisely the desired Quillen-closure inclusion. The equivalence is a formal Galois calculation and does not assume an unproved identification of a lifting closure with a cellular closure.

The same argument applies after retract completion, replacing TC' by $\widetilde{C'} \cap W'$. Proposition 5.1 will compare these two trivial classes; Proposition 5.8 will provide the stronger transfer theorem with the required factorization hypotheses. The question on manuscript p. 80 should therefore be read as a problem that directs the next section. The later propositions answer it under further hypotheses; they do not assert that every special cofibration structure already satisfies this stronger comparison.

La relation hypothétique

$$(*) \qquad \underbrace{T\tilde{C}'}_{=\tilde{C}'\cap W'} \ \subset \ (v_!(TC))^\sim , \quad \text{ou seulement} \quad TC' \subset (v_!(TC))^\sim ,$$

m'apparaît de nature nettement plus délicate. Comme $T\tilde{C}' \supset TC' \supset v_!(TC)$, elle équivaut à l'*égalité* de $(T\tilde{C}')_*$ resp. $(TC')_*$ et $(v_!(TC))_* = (v^*)^{-1}(TC)_*$. Posons

$$\left\{\begin{array}{rcl} (TC)_* & \overset{\text{déf}}{=} & F \\ (TC')_* & \overset{\text{déf}}{=} & F' \ \supset \ (T\tilde{C}')_* \ = \ F'_\sim . \end{array}\right. \tag{4.7.5}$$

20. **N.B.** C'est là un fait général pour les catégories à cofibrations spéciales, et devrait être explicité plus bas (cf. 5.1). L'hypothèse sur C est inutile ici (ou plutôt, il suffit au lieu de cela que W soit stable par facteurs directs *et* par composition transfinie, ce qui n'est pas une hypothèse plus réjouissante …).

On a donc, en vertu de l'inclusion

$$v_!(TC) \ \subset \ TC' \ (\subset \ T\tilde{C}' \ ) \ ,$$

la relation

$$F'_\sim \ \subset \ F' \ \subset \ (v^*)^{-1}(F) \ , \tag{4.7.6}$$

et la question est donc si on a égalité $F' = (v^*)^{-1}(F)$, voire $F'_\sim = (v^*)^{-1}(F)$ (d'où $F'_\sim = F'$).

En fait, on montre assez facilement qu'on a $F'_\sim = F'$, i.e. $T\tilde{C}' \overset{\text{déf}}{=} \tilde{C}' \cap W' \subset (C' \cap W')^\sim$ – c'est une histoire générale de catégories à cofibrations spéciales [21]. Mais je ne vois guère comment prouver (sous des hypothèses convenables) que $F' = (v^*)^{-1}(F)$. Il me faudra revenir là-dessus au besoin [22]. Pour l'instant, je me bornerai à récolter le fruit de 4.6 dans un cas particulier : [page 81]

Commentary · Exposition [ms. 81]

Free diagrams and the missing coproduct lemma

Grothendieck now has a way to give a diagram its cofibrations without choosing an order in which to construct its objects. The price of this freedom is to begin with a diagram having no relations, then attach relations by pushouts. This is the purpose of the adjunction attached to the inclusion of the objects of I. Write $L = v_!$ and $R = v^*$. Since $\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})$, the free diagram on a family (X_j) is

$$(LX)(i) = \coprod_{j \in \mathrm{Ob}\, I} \mathrm{Hom}_I(i,j) \cdot X_j.$$

Here $S \cdot X = \coprod_{s \in S} X$ is a copower. The exponent in the source denotes this coproduct, not a product or an internal Hom. An arrow $i' \to i$ acts by precomposition on the indexing sets $\mathrm{Hom}_I(i,j)$. Thus an arbitrary collection of maps $X_j \to Y(j)$ extends uniquely to a natural transformation $LX \to Y$: on the summand indexed by $i \to j$, use the corresponding structure map of the contravariant diagram Y. This also verifies the variance of the formula directly.

The assertion that the product category has a special cofibration structure contains a smallness argument worth making explicit. If C_0 is a generating set for the right lifting tests in $\mathcal{M}$, put a map of C_0 in one coordinate and the identity of the initial object in every other coordinate. The union of these sets over $\mathrm{Ob}\, I$ is still a set. A family of maps has the right lifting property against it exactly when every component lies in C_*. This gives the required generating set for the product. Colimits and the stated closure properties are computed componentwise. Likewise, a diagram of accessible objects is accessible: choose a regular cardinal larger than the cardinality of the arrows of I and larger than the smallness bounds for all its components. The naturality equations express its Hom functor as an equalizer of two products of component Hom functors. At this cardinal, the relevant filtered colimits of sets commute with those products and the equalizer. The same argument works with sufficiently long ordinal chains in the small-object formulation of accessibility. No common small generating family for the whole category $\mathcal{M}$ is required by this argument.

The coproduct assertion singled out in footnote 25 follows from precisely the two closure operations already assumed. Suppose $\mathcal{A}$ contains the isomorphisms and is stable under pushout and continuous transfinite composition. Given a set of maps $a_s : A_s \to B_s$ in $\mathcal{A}$, well-order its index set as an ordinal λ and form

$$X_\alpha = \left(\coprod_{s<\alpha} B_s \right) \amalg \left(\coprod_{\alpha \le s < \lambda} A_s \right) \qquad (\alpha \le \lambda).$$

The arrow $X_\alpha \to X_{\alpha+1}$ is the pushout of a_α along its coproduct inclusion. At a limit ordinal the displayed object is the colimit of the previous ones, as follows by specifying a map out of each summand. Therefore $X_0 \to X_\lambda$, which is $\coprod_s a_s$, lies in $\mathcal{A}$. The empty family gives the identity of the initial object. Apply this argument separately to C and to TC. It proves that RL preserves both

21. cf. prop. 5.1 ci-dessous.
22. voir cependant prop. 5.8 ci-dessous.

classes and supplies the lemma requested in the footnote. This is the familiar cellular coproduct argument; compare Hovey (1999a, Lemma 2.1.13).

The outcome of Proposition 4.8 is consequently quite concrete. A freely attached diagram cell is a family of copies of a coefficient cell, one for each incoming arrow at an object. Closing under pushouts and transfinite attachment produces diagram cofibrations; the right lifting tests are pointwise. The first formula (4.8.1) has $TC(I)$ where both occurrences must be $TC(I_0)$, since RL is an endofunctor of the category of families. The proof itself uses the correctly typed assertion.

Proposition 4.8. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations spéciale* (déf. 4.4, page 94). *Soit I objet de* Cat*, I_0 la catégorie discrète associée, considérons $v : I_0 \longrightarrow I$ et* p. 40

$$\mathcal{M}(I_0) \underset{v^*}{\overset{v_!}{\rightleftarrows}} \mathcal{M}(I) \quad ,$$

enfin munissons $\mathcal{M}(I_0) = \mathcal{M}^{I_0}$ de la structure de catégorie à cofibrations, produit *de celles des facteurs, i.e. définissons $W(I_0)$, $C(I_0)$ "fibre à fibre". (Cela coïncide avec la définition générale donnée au paragraphe* 2*, pour I_0 muni de la structure d'ordre discret, et fait de $\mathcal{M}(I_0)$ une catégorie à cofibrations spéciale.) Alors le couple $(v_!, v^*)$ satisfait aux conditions de la* [page 82] *proposition* 4.6*, ainsi qu'à la condition supplémentaire à* (4.6.1)*,*

$$4^\circ) \qquad v^*(v_!(TC(I))) \ \subset \ TC(I) \ . \tag{4.8.1}$$

Donc on trouve une structure de catégorie à cofibrations spéciale sur $\mathcal{M}(I)$, en posant

$$W(I) \ = \ (v^*)^{-1}(W(I_0)) \tag{4.8.2}$$

(c'est en fait équivalent à la définition habituelle de $W(I)$) et

$$C(I) \quad = \quad \text{clôture de } v_!(C(I_0)) \text{ pour les opérations de cochangement de base et composition transfinie.} \tag{4.8.3}$$

On a de plus sous ces conditions :

$$\underbrace{TF(I)}_{\overset{\text{déf}}{=}(C(I))_*} \ = \ (v^*)^{-1}\Big(\ \underbrace{TF(I_0)}_{\substack{\overset{\text{déf}}{=}(C_{I_0})_*, \\ \text{se définit aussi} \\ \text{fibre par fibre}}} \ \Big) \ , \tag{4.8.8}$$

$$\begin{cases} v_!\big(\overbrace{(TC)(I_0)}^{C(I_0)\cap W(I_0)} \big) & \subset \quad TC(I) \\ F(I) \overset{\text{déf}}{=} (TC(I))_* & \subset \quad (v^*)^{-1}(F(I_0)). \end{cases} \tag{4.8.9}$$

(23)

Démonstration. On sait déjà que $\mathcal{M}(I)$ est stable par petites $\varinjlim$, et que tout élément est accessible, comme il résulte aussitôt des propriétés idoines de $\overrightarrow{\mathcal{M}}$. Il est clair aussi que v^* commute aux petites $\varinjlim$. Il reste à prouver (4.6.1. 3°), et 4° dans (4.8.1), i.e. que [page 83] $v^*v_! : \mathcal{M}(I_0) \longrightarrow \mathcal{M}(I_0)$ applique C dans C, TC dans TC. Or on a

$$v_!(F_0)(i) \ = \ \varinjlim_{(\alpha,j)\in i\backslash I_0} F_0(j) \tag{24}$$

et $i\backslash I_0$ est la catégorie discrète au dessus de I_0, dont la fibre en $j \in \mathrm{Ob}\, I_0 \ = \ \mathrm{Ob}\, I$ est $\mathrm{Hom}_I(i,j)$:

$$i\backslash I_0 \ = \ \coprod_{j\in \mathrm{Ob}\, I} (\text{catégorie discrète associée à } \mathrm{Hom}_I(i,j)) \ , \qquad \text{p. 41}$$

donc

$$v_!(F_0)(i) \;=\; \coprod_{j\in \mathrm{Ob}\, I=\mathrm{Ob}\, I_0} \underbrace{F_0(j)^{\mathrm{Hom}_I(i,j)}}_{\substack{\text{somme directe}\\ \text{de } \mathrm{Hom}_I(i,j)\\ \text{copies de } F_0(j)}},$$

donc on trouve

$$v^* v_! F_0(\underbrace{\quad i \quad}_{\in \mathrm{Ob}\, I_0 = \mathrm{Ob}\, I}) \;=\; v_!(F_0)(i) \;=\; \curvearrowright \quad .$$

Comme C et TC sont stables par sommes directes quelconques (l'étant par sommes directes finies, à cause des conditions de stabilité finies sur C et TC, et aussi par somme infinies à cause de l'axiome de stabilité transfinie …[25]), il s'ensuit bien que $v^*v_!$ applique $C(I_0)$ et $TC(I_0)$ en eux-mêmes.

Ainsi, la première assertion de 4.8 résulte de 4.6. De plus, (4.8.8) et (4.8.9) ont été vus dans 4.7, dans les conditions générales de 4.6 et en supposant de plus le 4° de (4.7.4).

Commentary · Examples [ms. 83]

A free cell does not make every cofibration free

The two hoped-for equalities in footnote 23 have different meanings. The equality concerning fibrations is established under the stronger assumptions of Proposition 5.8. The literal equality between $v_!(TC(I_0))$ and $TC(I)$ cannot hold in that generality: the class on the left consists of free maps, whereas the class on the right is allowed to attach them to diagrams that already have relations. A small equivariant example makes the distinction visible without any homotopical calculation.

Give **Set** the model structure in which every map is a weak equivalence, cofibrations are injections, and fibrations are surjections. We work with the usual axiom of choice. Injections lift against surjections by choosing a preimage for each new element. Conversely, lifting against $\varnothing \to \{*\}$ characterizes surjections, and a map lifting against all surjections is injective, by the retract argument after factoring it through the injection

$$A \longrightarrow A \amalg B \longrightarrow B.$$

Here the second map is f on A and the identity on B. Thus both weak factorization systems are the injection–surjection system. It is generated by the single map $\varnothing \to \{*\}$, so this is a special closed triple in Grothendieck's sense.

Let $I = BG$ for the group $G = \mathbb{Z}/2$, viewed as a one-object category. Contravariant diagrams are right G-sets, R forgets the action, and $L(S) = S \times G$ is free. Consider the equivariant inclusion

$$k : \{*\} \longrightarrow \{*\} \amalg G,$$

where $*$ is fixed and G acts regularly on the second summand. This is the pushout of $L(\varnothing \to \{*\})$, so it belongs to $TC(I)$; all maps are weak equivalences in the transferred structure. It also has the requisite lifting property directly. Given a lifting square against an equivariant map whose underlying function is surjective, the image of $*$ is already specified. Choose a preimage of the image of the identity element of the free orbit, and extend that choice equivariantly to G. This defines the diagonal and verifies both triangle identities.

On the other hand, k is not isomorphic in the arrow category to $L(a)$ for any injection $a : S \to T$. The domain of $L(a)$ is the free G-set $S \times G$. A nonempty free G-set has no fixed points, whereas the domain of k has one. Even the identity of the fixed point would already disprove the literal equality. The nonidentity map k shows why the failure belongs to the geometry of attachment rather than to a convention about including identities.

The correct conclusion under the hypotheses of Proposition 5.8 is

$$TC(I) = \widetilde{v_!(TC(I_0))}\,, \qquad F(I) = (v^*)^{-1}(F(I_0)).$$

23. Ces inclusions devraient être des égalités, mais je ne sais pas le prouver sans faire des hypothèses plus fortes, du type *catégorie de Quillen spéciale.*

24. où $j \in \mathrm{Ob}\, I_0 = \mathrm{Ob}\, I$, et $\alpha : i \longrightarrow v(j) = j$.

25. mérite un lemme général …

The tilde in the first equality is indispensable. Theorem 6.1(b) gives exactly this statement. Modern descriptions by representable cells have the same distinction; see Riehl (2014, Theorem 12.3.2). We therefore read the first hope in footnote 23 as needing this closure, and the second as the precise question that the next section resolves.

[page 84]

5 Relation des catégories à cofibrations spéciales avec les catégories de Quillen spéciales

Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations spéciale. J'introduis

$$TF = C_*, \qquad TC = C \cap W, \qquad F = (TC)_* , \tag{5.1}$$

donc on a

$$\begin{array}{ccc} TC & \hookrightarrow & C \\ \downarrow & & \downarrow \\ F & \hookrightarrow & TF \end{array} , \tag{5.2}$$

(C, TF) étant un précouple de Quillen clos à droite. On sait alors (XV 4.2 cor. 1, page 31) que $\tilde{C}$ est formé des facteurs directs d'éléments de C. Posons

$$T\tilde{C} = \tilde{C} \cap W , \tag{5.3}$$

d'où

$$TC \subset T\tilde{C} . \tag{5.4}$$

Proposition 5.1 *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations spéciale. On a $T\tilde{C} \subset (TC)^\sim$ (et même $T\tilde{C} \subset (TC)^\natural$ [26]), ou ce qui revient au même en vertu de (5.4), TC et $T\tilde{C}$ ont même Q-clôture à gauche :*

$$T\tilde{C} = (T\tilde{C})^\sim = (TC)^\sim \qquad \textit{(et même } T\tilde{C} \subset (TC)^\natural\textit{)}, \tag{5.5}$$

d'où p. 42

$$(\tilde{C})_* = C_* (= TF), \qquad (T\tilde{C})_* = (TC)_* (= F) \qquad [27]. \tag{5.6}$$

De plus, si W stable par facteurs directs (ou si seulement tout facteur direct d'une flèche de TC est dans W), et si de plus W est stable par composition transfinie, alors $(\mathcal{M}, W, \tilde{C})$ est une catégorie à cofibrations spéciale. De plus, $T\tilde{C}$ est Q-saturé à gauche, donc (par 5.5)

$$T\tilde{C} = (TC)^\natural . \tag{5.7}$$

[page 85]

Commentary · Exposition [ms. 84]

What the retract argument actually identifies

Grothendieck introduces fibrations here in order to measure the remaining obstruction to constructing a model structure. The cofibration factorization is already available. His task is to decide what happens when the cofibrations are enlarged by retracts and whether the trivial

26. **N.B.** Pour une partie A de $\mathrm{Fl}(\mathcal{M})$, $A^\natural$ désigne l'ensemble des facteurs directs d'éléments de A.
27. Ces relations ne dépendent pas de l'hypothèse W stable par facteurs directs.

cofibrations admit a second factorization. These are separate questions, and the calculation of Proposition 5.1 answers the first without assuming an answer to the second.

For a class A of arrows write $A^{\perp}$ for its right lifting class and ${}^{\perp}A$ for its left lifting class. In this notation Grothendieck's Q-closure is

$$\widetilde{A} = {}^{\perp}(A^{\perp}).$$

It is a closure defined by lifting. By contrast, closure under pushouts, transfinite compositions and retracts is the class now usually called weak saturation. The two coincide for a set of generating maps when the small object argument applies. They must not be identified merely because a class is stable under those three operations. A left lifting class has all three stability properties, but the converse requires an additional argument.

Let $f : A \to B$ lie in $\widetilde{C} \cap W$. Use the available factorization $f = pi$, with $i : A \to E$ in C and $p : E \to B$ in $TF = C^{\perp}$. Since $TF \subset W$, the two-out-of-three property gives $i \in C \cap W = TC$. The definition $f \in \widetilde{C} = {}^{\perp}TF$ supplies a map $s : B \to E$ with

$$ps = \mathrm{id}_B, \qquad sf = i.$$

In the arrow category under A, the maps (id_A, s) and (id_A, p) exhibit f as a retract of i. This proves the strong, correctly qualified conclusion

$$TC \subset \widetilde{C} \cap W \subset \mathrm{Retr}(TC) \subset \widetilde{TC}.$$

Taking Q-closures gives

$$\widetilde{\widetilde{C} \cap W} = \widetilde{TC}, \qquad (\widetilde{C} \cap W)^{\perp} = (TC)^{\perp}.$$

This is all that is needed to identify $F'_{\sim}$ with F' on manuscript p. 81. In the source's proof, the occurrence $f \in C$ and the corresponding diagram label should be read as $f \in \widetilde{C}$. The lifting argument remains valid with exactly that hypothesis. Its modern general form is the retract argument of Riehl (2014, Lemma 11.2.3).

The first equality in (5.5), identifying $\widetilde{C} \cap W$ with its own Q-closure, goes beyond this argument. The preceding prose asserts equality of the two closures, and that is the formulation proved here. Likewise, the equality with $\mathrm{Retr}(TC)$ printed at the start of the proof must at that point be read as the inclusion just established. If retracts of trivial cofibrations belong to W, the reverse inclusion follows: a retract of a map in TC belongs to $\widetilde{C}$ and, by this additional hypothesis, to W. Hence

$$\widetilde{C} \cap W = \mathrm{Retr}(TC).$$

We retain these source displays in the transcription and use their justified forms in the audit. No counterexample to the extra first equality of (5.5) under the full stated assumptions is asserted here.

There is a reason for keeping the retract under its fixed source. Push out the retract diagram in $A \backslash \mathcal{M}$ along $A \to A'$. Functoriality of pushout preserves its two splitting identities, so the new map is a retract of a pushout of $i \in TC$. That pushout still lies in TC. Retract stability of W therefore proves the required weak-equivalence assertion after pushout. Transfinite stability of the enlarged trivial class follows under the further hypothesis used by Grothendieck, namely transfinite stability of W itself. The other conditions for a special cofibration structure pass to $\widetilde{C}$ because its right lifting class and its generating set have not changed. This proves his stated sufficient result without silently adding the missing second factorization.

Démonstration. Prouvons

$$T\tilde{C} \ \subset \ (TC)^{\sim},$$

et plus précisément, que tout élément de $T\tilde{C}$ est facteur direct d'un élément de TC :

$$T\tilde{C} = (TC)^{\natural}.$$

Soit donc $f \in T\tilde{C} \overset{\text{déf}}{=} \tilde{C} \cap W$, considérons leur factorisation de f en pi, avec $i \in C$, $p \in TF$. Comme $TF \subset W$, on a $p \in W$, donc $i \in W$, donc $i \in C \cap W \overset{\text{déf}}{=} TC$. Comme $f \in C$, $p \in TF$,

il existe $q : Y \longrightarrow X'$ tel que $pq = \mathrm{id}_Y$, $qf = i$,

$$\begin{array}{ccc} X & \xrightarrow{f \in C \cap W} & Y \\ & {\scriptstyle i \in C} \searrow \quad \overset{q}{\vdots} \quad \nearrow {\scriptstyle p \in TF} & \\ & X' & \end{array}$$

donc f apparaît comme facteur direct de $i \in TC$, q.e.d.

Prouvons que $(\mathcal{M}, W, \tilde{C})$ est une catégorie à cofibrations spéciale (déf. 4.4, page 74). Condition a) sur $\mathcal{M}$ acquise, condition b), la partie sur W, aussi. La stabilité de $\tilde{C}$ par cochangement de base et par composition OK, aussi (pour b′) la stabilité par composition transfinie. Stabilité de $T\tilde{C} = \tilde{C} \cap W$ par cochangement de base : il reste à prouver que si on a un carré cocartésien

$$\begin{array}{ccc} X & \xrightarrow{\ i\ } & Y \\ \downarrow & \text{cocart.} & \downarrow \\ X' & \xrightarrow{\ i'\ } & Y' \end{array},$$

si $i \in \tilde{C} \cap W$, alors $i' \in W$ (car on sait déjà que $i' \in \tilde{C}$). Mais la démonstration précédente montre que c'est facteur direct *dans* $X \backslash \mathcal{M}$ d'une flèche dans TC, donc i' est facteur direct d'une flèche de $TC \subset W$. Donc si W est stable par facteurs directs, $i' \in W$.

Cela achève de prouver b). Pour b′), il reste à voir que $T\tilde{C}$ est stable par composition transfinie. Je ne vois pas d'autre façon de le voir, qu'en supposant que W lui-même est stable par composition transfinie (ce qui paraît à peine moins exigeant que la stabilité de W par $\varinjlim$ `[filtrantes]`). Cela achève de prouver b, b′). La condition c) sur C implique la même condition sur $\tilde{C}$. Enfin, comme $\tilde{C}_* = C_*$, la condition d) est la même pour C et $\tilde{C}$. Cela achève de prouver que $(\mathcal{M}, W, \tilde{C})$ est une catégorie à cofibrations spéciale. (**N.B.** on avait besoin de deux hypothèses supplémentaires sur W, stabilité par facteurs directs et par composition transfinie, pour établir que $T\tilde{C}$ est stable par cochangement de base et par composition transfinie). Le dernière assertion de 5.1 et la relation (5.7) qui en résulte, revient à dire que $T\tilde{C} = \tilde{C} \cap W$ est stable par facteurs directs, ce qui est évident par la même propriété de $\tilde{C}$, et l'hypothèse faite sur W de stabilité par facteurs directs (ou seulement que les facteurs directs d'éléments de $T\tilde{C}$ sont dans W, donc dans $T\tilde{C}$).

p. 43
[page 86]

Proposition 5.2. *Soit* $(\mathcal{M}, W, C)$ *une catégorie à cofibrations spéciale. Alors avec les notations de* (5.1)*, on a*

[page 87]

$$W = TF \circ TC, \tag{5.8}$$

$$TF = F \cap W. \tag{5.9}$$

Démonstration. Soit $f \in W$, écrivons $f = pi$, avec $i \in C$, $p \in TF$, donc $p \in W$, donc $i \in W$, donc $i \in C \cap W = TC$, d'où (5.8).

Prouvons (5.9). On a $TF \subset F \cap W$, prouvons inversement qu'une $f \in F \cap W$ est dans TF. Écrivons $f = pi$, avec $p \in TF$, $i \in TC$.

$$\begin{array}{ccc} X & \xrightarrow{f \in F \cap W} & Y \\ & {\scriptstyle i \in TC} \searrow \quad \nearrow {\scriptstyle p \in TF} & \\ & X' & \end{array}$$

Comme $f \in F$, $i \in TC$, et $TC \longleftrightarrow F$ par définition de F, $\exists\, r : X' \longrightarrow X$ tel que $ri = \mathrm{id}_X$, $fr = p$. Donc f est facteur direct de $p \in TF$, et comme $TF = C_*$ est stable par facteurs directs, on conclut que $f \in TF$.

[page 88]

Corollaire 5.3. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations spéciale. Pour que (W, C, F), $(F \overset{déf}{=} (TC)_*)$ soit un triple de Quillen dans $\mathcal{M}$, il faut et il suffit que le couple (TC, F) satisfasse à l'axiome de factorisation (i.e. que ce soit un précouple de Quillen). Pour que cette structure de Quillen soit clos, il faut et il suffit que C soit stable par facteurs directs.*

Démonstration. La nécessité de l'axiome de factorisation pour (TC, F), pour avoir un triple de Quillen, est tautologique. Pour la suffisance, ayant déjà les deux précouples de Quillen (C, TF), (TC, F) avec

p. 44

$$\begin{array}{ccc} TC & \hookrightarrow & C \\ \updownarrow & & \updownarrow \\ F & \hookleftarrow & TF \end{array} , \tag{5.2}$$

et $TC = C \cap W$, le fait que (W, C, F) est un triple de Quillen est le corollaire 4 p. 36 de XV : Les conditions $TC = C \cap W$, $TF = F \cap W$, $W = TF \circ TW$ sont équivalentes, et équivalentes au fait que (W, C, F) soit un triple de Quillen.

Par la définition de Quillen des triples *clos,* par les propriétés

$$\underbrace{W = TF \circ TC}_{\substack{\text{vraie pour tous} \\ \text{le triples} \\ \text{de Quillen}}}, \qquad C = (TF)^*, \qquad \underbrace{F = (TC)_*}_{\substack{\text{vraie dans} \\ \text{le cas actuel}}} ,$$

il reste à exprimer que $C = (TF)^*$, ce qui équivaut à C stable par facteurs directs (cf. loc. cit. cor. 1, p. 31), q.e.d.

Remarque 5.4. Les énoncés 5.2 et 5.3, et la relation $T\tilde{C} \subset (TC)^\natural$ dans proposition 5.1, ne font pas appel à la totalité de l'hypothèse que $(\mathcal{M}, W, C)$ soit une catégorie à cofibrations spéciale, mais seulement que l'on ait une catégorie à cofibrations, avec $C \longleftrightarrow \underbrace{TF}_{\overset{\text{déf}}{=} C_*} \subset W$, i.e. une catégorie avec W, C satisfaisant Cof_0, Cof_1, Cof_2 de la page 39, plus $TF \overset{\text{déf}}{=} C_* \subset W$, plus l'axiome de factorisation pour (C, TF) (lequel implique Cof_3).

[page 89]

Commentary · Exposition [ms. 88]

The second factorization is the remaining requirement

Grothendieck's comparison with Quillen theory becomes short once the role of the two factorizations is isolated. The factorization associated with C already determines which fibrations must be trivial, even before a general fibration factorization has been constructed. Proposition 5.2 is the calculation that makes this assertion exact.

Set $F = (TC)^\perp$. If $f \in W$, factor $f = pi$ with $i \in C$ and $p \in TF$. Since $p \in W$, two-out-of-three gives $i \in TC$; conversely, a composite of an arrow in TC and an arrow in TF belongs to W. Thus $W = TF \circ TC$. To identify TF, take $f : A \to B$ in $F \cap W$ and use this factorization again. The lifting property of f against i gives $r : E \to A$ satisfying

$$ri = \mathrm{id}_A, \qquad fr = p.$$

The maps (i, id_B) and (r, id_B) exhibit f as a retract of p. A right lifting class is retract-stable, so $f \in TF$. The reverse inclusion is immediate from $TC \subset C$ and $TF \subset W$. We have proved $TF = F \cap W$ without needing W itself to be retract-stable.

It follows that the new requirement for a Quillen triple is precisely a factorization by (TC, F). If $TC_0 \subset TC$ is a set with $(TC_0)^\perp = (TC)^\perp$, the small object argument factors every map as a relative TC_0-cell map followed by an arrow of F. The left map belongs to TC because this class is stable under pushouts and transfinite compositions; coproducts were accounted for above. This proves Corollary 5.5. The source's formula $W = TF \circ TW$ on p. 88 has TC as its intended second factor.

Once the second factorization exists, W is in fact retract-stable. Here is a proof that does not presuppose this conclusion or retract stability of TC. Let $f : A \to B$ be a retract of $w : C \to D \in W$,

with splitting pairs $(a,b) : f \to w$ and $(r,s) : w \to f$, so $ra = \mathrm{id}_A$ and $sb = \mathrm{id}_B$. First suppose $f \in F$. Factor $w = vu$, with $u : C \to E \in TC$ and $v : E \to D \in TF$. Lifting u against f in the square with top r and bottom sv gives $\ell : E \to A$ such that $\ell u = r$ and $f\ell = sv$. The pairs (ua, b) and (ℓ, s) now exhibit f as a retract of v. Thus $f \in TF \subset W$, because $TF = C^{\perp}$ is retract-stable.

For arbitrary f, use the second factorization $f = hg$, with $g : A \to Z \in TC$ and $h : Z \to B \in F$. Push out g along a, writing $E = C \amalg_A Z$ and $j : C \to E$, $t : Z \to E$ for the structure maps. Pushout stability gives $j \in TC$. The compatible maps w and bh induce $k : E \to D$ with $kj = w$ and $kt = bh$, so two-out-of-three gives $k \in W$. The compatible maps gr and id_Z induce $q : E \to Z$ satisfying

$$qj = gr, \qquad qt = \mathrm{id}_Z, \qquad hq = sk.$$

The last identity can be checked on the two pushout summands. Therefore (t, b) and (q, s) exhibit h as a retract of k. The special case already proved gives $h \in W$, and hence $f = hg \in W$. This is the argument of Riehl (2014, Lemma 11.3.3), observed here to require only the indicated factorization, lifting, and pushout properties.

If C is retract-stable, so is $TC = C \cap W$. Factoring a map of ${}^{\perp}F$ by (TC, F) and retracting its left factor therefore proves $TC = {}^{\perp}F$. The first factorization similarly gives $C = {}^{\perp}TF$. Thus the source's criterion for a closed triple supplies the full modern lifting characterizations as well. The second factorization is essential in this explanation; this argument cannot be inserted earlier into Proposition 5.1 to justify its extra equality.

The terminology "special closed triple" thus points toward cofibrant generation: there is one set of tests for trivial fibrations and another for fibrations. Its smallness assumption is imposed on all coefficient objects. Modern treatments generally impose only the smallness needed for the chosen generators; see Hovey (1999a, Theorem 2.1.14 and Definition 2.1.17). If the underlying category is locally presentable, the resulting model category is combinatorial in the now customary terminology. Grothendieck's condition that each object is accessible does not itself state local presentability, which also requires an appropriate set of objects generating the category by filtered colimits. Corollary 5.7 should therefore not be translated by replacing the word "special" with "combinatorial" without that extra hypothesis.

Corollaire 5.5. *Soit $(\mathcal{M}, W, C)$ une catégorie à cofibrations spéciale, telle qu'il existe une* petite *partie $TC_0 \subset TC = C \cap W$, avec*

$$TC \ \subset \ TC_0^{\sim} \ , \tag{5.5.1}$$

ou ce qui revient au même, $(TC)^{\sim} = (TC_0)^{\sim}$, i.e.

$$\underbrace{F}_{\overset{\text{déf}}{=}(TC)_*} \ = \ (TC_0)_* \ . \tag{5.5.2}$$

Alors (W, C, F) est un triple de Quillen. Ce triple est clos si et seulement si C est stable par facteurs directs.

En effet, le théorème de factorisation dans XV §1 implique que moyennant l'hypothèse faite sur $TC_0 \subset TC$, le couple (TC, F) satisfait à la condition de factorisation. En effet, par les conditions b, b′ de la définition 4.4, TC a les propriétés de stabilité voulues (contient les isomorphismes, est stable par cochangement de base et par composition transfinie).

Définition 5.6. Les triples de Quillen déduits comme dans 5.5 d'une catégorie à cofibrations spéciale sont dits *spéciaux.* Ainsi un triple de Quillen (W, C, F) dans $\mathcal{M}$ est spécial s'il satisfait les conditions a) à d) dans la définition (4.4), concernant (W, C) exclusivement, plus les deux conditions suivantes. [page 90]

p. 45

(c′) $\exists$ petite partie TC_0 de TC, telle que $TC \subset (TC_0)^{\sim}$.

(e) $F = (TC)_*$.

Corollaire 5.7. *Soit (W, C, F) un triple de Quillen* clos *dans $\mathcal{M}$. Pour que ce triple soit spécial, il faut et il suffit qu'il satisfasse les conditions suivantes.*

ⓐ $\mathcal{M}$ *stable par petites* $\varinjlim$*, et ses éléments sont accessibles.*

(c, c′) *Il existe une petite partie* C_0 *de* C*,* TC_0 *de* TC*, telles que l'on ait*

$$C = C_0^{\sim}\ , \qquad TC = (TC_0)^{\sim}\ . \tag{5.7.1}$$

En effet, toutes les autres conditions a) à e), y inclus c′) de 5.6, sont automatiquement satisfaites.

Proposition 5.8. *Considérons un couple de foncteurs adjoints* [page 91]

$$\mathcal{M} \underset{v^*}{\overset{v_!}{\rightleftarrows}} \mathcal{M}'\ , \tag{5.8.1}$$

où $\mathcal{M}$ *est munie d'un triple de Quillen spécial clos* $(W, C, F = (TC)_*)$*, avec* $TC = C \cap W$ (cf. définition 5.6). *On suppose satisfaites les conditions suivantes* (comparer prop. 4.6, relations (4.6.1), et (4.7.4)) :

$$\begin{cases} \text{a)} & \mathcal{M}' \text{ stable par petites } \varinjlim \text{ , ses éléments sont accessibles.} \\ \text{b)} & v^* \text{ commute aux petites } \varinjlim\ . \\ \text{c)} & v^*(v_!(C)) \subset C,\ v^*(v_!(TC)) \subset TC. \end{cases} \tag{5.8.2}$$

Définissons (W', C', F') *dans* $\mathcal{M}'$ (comparer prop. 4.6, notamment 4.6.2) *par*

$$\begin{cases} W' &= (v^*)^{-1}(W) \\ C' &= v_!(C)^{\sim} \\ F' &= (TC')_*\ , \qquad \text{où } TC' \overset{\text{déf}}{=} C' \cap W'\ . \end{cases} \tag{5.8.3}$$

Alors (W', C', F') *est un triple de Quillen clos spécial dans* $\mathcal{M}'$*, et on a de plus*

$$F' = (v^*)^{-1}(F)\ , \qquad TF' = (v^*)^{-1}(TF)\ , \tag{5.8.4}$$

$$TC' = (v_!(TC))^{\sim}\ . \tag{5.8.5}$$

Commentary · Exposition [ms. 91]

The two factorizations meet in the transfer theorem

Grothendieck now returns to the equality of fibrations that had resisted the argument of §4. The extra structure supplied by the second generating set does exactly what is needed: it produces a candidate trivial cofibration factorization in the target, and the previously constructed cofibrations then force that candidate to be the correct one. The proof is a transfer argument, but its decisive step is again a retract under a fixed source.

Write $L = v_!$, $R = v^*$, and choose generating sets $I_0 \subset C$ and $J_0 \subset TC$ in the coefficient category. To avoid the ambiguity between the raw image of a class and its closure, put

$$C' = \mathrm{cof}(LI_0), \qquad K' = \mathrm{cof}(LJ_0), \qquad W' = R^{-1}(W),$$

where cof denotes the class of retracts of relative cell maps. The smallness assumptions ensure that these are also the corresponding left lifting classes. Adjointness transports lifting squares and their diagonals, giving

$$(LI_0)^{\perp} = R^{-1}(TF), \qquad (LJ_0)^{\perp} = R^{-1}(F).$$

The equality for trivial fibrations is therefore formal. The equality for fibrations will follow only after K' has been identified with $C' \cap W'$.

First, $K' \subset C'$ because $J_0 \subset C$. It is also contained in W'. Indeed, $RL(TC) \subset TC$ by hypothesis, while R preserves pushouts and transfinite colimits. It follows by induction along an attachment

that R carries every relative LJ_0-cell map into TC. Functors preserve retract diagrams, and TC is retract-stable in the closed coefficient model structure, so $R(K') \subset TC \subset W$. This proves $K' \subset C' \cap W'$. Notice that preservation of weak equivalences alone would not prove this step: it is the cellular construction and the stronger assertion about $RL(TC)$ that control the entire attachment.

For the converse, let $f : A \to B$ belong to $C' \cap W'$. Factor it by the small object argument for LJ_0 as

$$A \xrightarrow{j} E \xrightarrow{p} B, \qquad j \in K', \quad Rp \in F.$$

The first part of the proof gives $j \in W'$. As $f \in W'$, two-out-of-three gives $p \in W'$, hence $Rp \in F \cap W = TF$. Thus $p \in R^{-1}(TF) = (C')^{\perp}$. The lifting property of $f \in C'$ supplies a section $s : B \to E$ with $ps = \mathrm{id}_B$ and $sf = j$. Consequently f is a retract of j, and K' is retract-stable. This proves

$$C' \cap W' = K', \qquad (C' \cap W')^{\perp} = R^{-1}(F).$$

Both target factorizations, both lifting properties, and the equality of the target weak equivalences with the prescribed inverse image are now established. The generating sets are LI_0 and LJ_0.

This presentation also explains the status of Remark 5.9. If the source triple is not closed, use the pushout–transfinite closure C' of $L(C)$ and the relative LJ_0-cell class for the left factor. Its image under R still lies in TC. The same argument shows that every map in $C' \cap W'$ is a retract of one of these cell maps, which suffices to identify the right lifting class. The cell maps themselves lie in $C' \cap W'$, so their small-object factorization supplies the required factorization for that larger class. One need not first assert that either of these classes is closed under retracts.

In the modern transfer theorem, the condition that the right adjoint preserve all colimits can be replaced by a direct acyclicity condition on the transferred trivial cells, together with the smallness needed to form the two factorizations. This is the form of Hirschhorn (2003, Theorem 11.3.2). Grothendieck's hypotheses give a transparent sufficient test for that acyclicity condition. Their main application here is exceptionally well suited to them: restriction from diagrams to their objects computes colimits pointwise, and the free diagram functor produces coproducts of coefficient cells.

[page 92]

Démonstration. Par 4.6, on sait déjà que $(\mathcal{M}', W', C')$ est une catégorie à cofibrations spéciale. (**N.B.** Ce qui est noté C' ici, était noté $\tilde{C}'$ dans la proposition 4.5. On doit utiliser la dernière assertion de 4.6, où on suppose C stable par facteurs directs, OK car (W, C, F) supposé clos.) Pour prouver que $(W', C', F' \overset{\text{déf}}{=} (TC')_*)$ est un triple de Quillen spécial, il reste, par 5.3 et définition 5.6, à prouver qu'il existe une petite partie TC'_0 de TC', telle que p. 46

$$(\ TC'_0\ \subset\ )\ TC' \ \subset\ (TC'_0)^{\sim}\ . \tag{5.8.6}$$

(Ce triple de Quillen sera de plus clos, puisque C' est Q-clos à gauche par définition.) Soit donc TC_0 une petite partie de TC telle que

$$TC \ \subset\ (TC_0)^{\sim}\ , \tag{5.8.7}$$

qui existe par hypothèse sur (W, C, F). On prendra

$$TC'_0 \ \overset{\text{déf}}{=}\ v_!(TC_0)\ . \tag{5.8.8}$$

On a vu dans 4.7 qu'on a

$$v_!(TC) \ \subset\ TC' \tag{5.8.9}$$

(résulte de l'hypothèse $v^*(v_!(TC)) \subset TC$ dans (5.8.2. c)), a fortiori

$$TC'_0 \ =\ v_!(TC_0) \ \subset\ TC'\ ,$$

il reste à prouver

[page 93]

$$TC' \ \overset{?}{\subset}\ (TC'_0)^{\sim}\ , \tag{5.8.10}$$

ce qui équivaut à $(TC')^{\sim} \subset (TC'_0)^{\sim}$, ou encore à

$$(TC'_0)_* \overset{?}{\subset} (TC')_* \overset{\text{déf}}{=} F' , \tag{5.8.10 bis}$$

alors qu'on a a priori l'inclusion inverse (déduite de $TC'_0 \subset TC'$)

$$F' \subset (TC'_0)_* . \tag{5.8.11}$$

Or par adjonction, on a

$$\begin{aligned} (\underbrace{TC'_0}_{v_!(TC_0)})_* &= (v_!(TC_0))_* \\ &= (v^*)^{-1}(\underbrace{(TC_0)_*}_{=(TC)_* \overset{\text{déf}}{=} F}) \\ &= (v^*)^{-1}(F) , \end{aligned}$$

donc (5.8.11) s'écrit

$$F' \subset (v^*)^{-1}(F) , \qquad \text{i.e. } v^*(F') \subset F \tag{5.8.12}$$

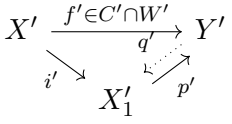
(comparer (4.7.6)), et il faut montrer que cette inclusion est une égalité (sur quoi j'avais buté p. 80, 81 …), ce qui n'est autre que la première des deux relations (5.8.4). Mais c'est sous la forme initiale (5.8.10) (transposée de (5.8.4)) que nous allons prouver la chose, finalement. Notons que l'on a

p. 47
[page 94]

$$(\underbrace{v_!(TC_0)}_{TC'_0})^{\sim} = (v_!(TC))^{\sim} ,$$

puisque TC est la clôture de TC_0 pour les opérations de cochangement de base, de composition transfinie, et de facteurs directs, et que $v_!$ commute à ces opérations. Donc on doit montrer simplement

$$TC' \subset (v_!(TC))^{\sim} \tag{5.8.12 bis}$$



(où il n'est plus question de TC_0). Mais le théorème de factorisation s'applique au couple

$$\Big((v_!(TC))^{\sim},\ (v_!(TC))_* = (v^*)^{-1}(F)\Big) ,$$

puisque $(v_!(TC))^{\sim} = (TC'_0)^{\sim}$, TC'_0 petit. Si donc on a $f' \in TC' = C' \cap W'$, factorisons f' en $p'i'$, avec

$$i' \in (v_!(TC))^{\sim} , \qquad p' \in (v^*)^{-1}(F) . \tag{5.8.13}$$

(∗)

Notons qu'on a

[page 95]

$$(v_!(TC))^{\sim} \subset TC' \ (\overset{\text{déf}}{=} C' \cap W') \tag{5.8.14}$$

car $v_!(TC) \subset TC' \subset C'$, donc $(v_!(TC))^{\sim} \subset \tilde{C}' = C'$, et il reste à prouver que $v_!(TC)^{\sim} \subset W'$, i.e. $v^*((v_!(TC))^{\sim}) \subset W$. Or je dis qu'on a même

$$v^*((v_!(TC))^{\sim}) \subset TC ,$$

i.e.

$$v_!(TC)^\sim \ \subset \ (v^*)^{-1}(TC)\ . \tag{5.8.15}$$

Cela résulte du fait que TC est Q-clos, donc Q-saturé à gauche, ce qui implique, comme v^* commute aux petites $\varinjlim$, que $(v^*)^{-1}(T)$ l'est également. D'autre part, il contient $v_!(TC)$, donc aussi le Q-saturé à gauche de $v_!(TC)$. Mais ce dernier est *égal* à la Q-clôture $(v_!(TC))^\sim$, par le théorème de factorisation, vu que $TC'_0 \subset v_!(TC) \subset (TC'_0)^\sim$, avec TC'_0 petit.

Ainsi, (5.8.13) et (5.8.14) impliquent $i' \in TC' = C' \cap W'$, donc $i' \in W'$, d'où $p' \in W'$, i.e. $v^*(p') \in W$, et comme par hypothèse (5.8.13) on a $v^*(p') \in F$, on a $v^*(p') \in TF$, i.e. p. 48 [page 96]

$$p' \ \in \ (v^*)^{-1}(TF) \ = \ TF' \ (\overset{\text{déf}}{=} \ C' \ )\ ,$$

l'égalité $(v^*)^{-1}(TF) = TF'$, i.e.

$$(v^*)^{-1}(C_*) \ = \ (v_!(C))_*\ ,$$

résultant de l'adjonction de $v_!$, v^*. Au total, on a donc

$$p' \ \in \ TF' \ (\ = \ C'_*\ )\ , \tag{5.8.16}$$

et comme $f' \in C'$, le diagramme $(*)$, page 114, nous montre qu'il existe

$$q' \ : \ Y' \longrightarrow X'_1\ ,$$

avec $p'q' = \mathrm{id}$, $q'f' = i'$. Donc f' est facteur direct de $i' \in v_!(TC)^\sim$, donc on a $f' \in v_!(TC)^\sim$, d'où la relation

$$TC' \ \subset \ v_!(TC)^\sim\ ,$$

ce qui achève de prouver que (W', C', F') est un triple de Quillen spécial et clos.

Les deux relations (5.8.4) ont été prouvées chemin faisant (la deuxième étant essentiellement triviale, et la première représentant la difficulté principale dans la démonstration). Reste à établir (5.8.5). Mais on sait déjà (5.8.9) que

$$v_!(TC) \ \subset \ TC'\ ,$$

d'où [page 97]

$$v_!(TC)^\sim \ \subset \ TC',$$

puisque TC' est Q-clos à gauche (ou parce que ça a été prouvé dans (5.8.14)), on a déjà prouvé l'inclusion en sens inverse (5.8.12 bis), assertion équivalente à (5.8.4) (et qui représentait la principale difficulté).

Remarque 5.9. Si on ne suppose pas que la structure sur $\mathcal{M}$ soit close, alors la démonstration donnée de 5.8 montre qu'on trouve pourtant sur $\mathcal{M}'$ une structure de Quillen spéciale, en définissant cette fois C' comme dans 4.6. Mais je doute qu'on aura jamais à travailler avec des triples de Quillen spéciaux qui ne soient aussi clos. De toute façon, si W est stable par petites $\varinjlim$ filtrantes [28] (et je doute qu'on trouve des triples de Quillen spéciaux en dehors de ce cas), alors si (W, C, F) est un triple de Quillen spécial, il en est de même de $(W, \tilde{C} = C^\natural, F)$, et je présume qu'on a tout intérêt à remplacer le triple initial par celui-ci.

28. ce qui implique la stabilité par facteurs directs, et implique aussi la même propriété pour $W' \overset{\text{déf}}{=} (v^*)^{-1}(W)$.

Commentary · Development (commentators') [ms. 97]

Special triples need not preserve ordinary filtered colimits

Grothendieck closes the section by expressing doubt that special triples occur outside the case where weak equivalences are stable under filtered colimits. The smallness conditions do explain why sufficiently filtered colimits behave well. They do not force the bound to be finite. A countably presented coefficient gives a concrete separation, already in abelian groups.

A special closed triple with a failing sequential colimit. [ours]

Let $A = \mathbb{Z}[1/2]$ and, in **Ab**, define

$$W_A = \{f \mid \mathrm{Hom}(A, f) \text{ is bijective}\},$$
$$I_A = \{0 \longrightarrow A, \quad A \oplus A \xrightarrow{\nabla} A\},$$
$$C_A = {}^{\perp}W_A, \qquad F_A = \mathrm{Mor}(\mathbf{Ab}).$$

Then (W_A, C_A, F_A) is a special closed Quillen triple. Its weak equivalences are not closed under sequential colimits in the arrow category.

Proof. We first identify the right lifting tests. Lifting against $0 \to A$ says that every map $A \to Y$ lifts through $f : X \to Y$; equivalently, $\mathrm{Hom}(A, f)$ is surjective. A lifting square from the fold ∇ to f is a pair of homomorphisms $a, b : A \to X$ with $fa = fb$. A diagonal exists exactly when $a = b$: it must be the common map $A \to X$. The right lifting property against the fold is therefore injectivity of $\mathrm{Hom}(A, f)$. We obtain

$$I_A^{\perp} = W_A.$$

The domains of I_A are small. More explicitly, A has the countable presentation with generators x_n, $n \geq 0$, and relations $2x_{n+1} = x_n$. For a map from this presentation into an $\aleph_1$-filtered colimit, choose representatives of the countably many images of the generators and stages witnessing the countably many relations. Filteredness at $\aleph_1$ provides a common stage at which they define a homomorphism. The same argument applied to the countably many generator equalities proves eventual equality of two such homomorphisms. Thus A, and likewise $A \oplus A$, is $\aleph_1$-presentable. Every abelian group has a presentation of some set cardinality, so the analogous argument supplies the accessibility condition for every object of **Ab**.

The small object argument now gives the weak factorization system (C_A, W_A), with $C_A = \mathrm{cof}(I_A)$. The standard theorem being used is Hovey (1999a, Theorem 2.1.14); all its smallness conditions have just been checked. Since W_A is the inverse image of the isomorphisms of abelian groups under the functor $\mathrm{Hom}(A, -)$, it contains the isomorphisms, satisfies two-out-of-three, and is closed under retracts.

If $f : X \to Y$ lies in both C_A and W_A, apply its left lifting property to the square having f on both vertical sides and identities horizontally. Its diagonal $h : Y \to X$ satisfies $hf = \mathrm{id}_X$ and $fh = \mathrm{id}_Y$. Therefore

$$C_A \cap W_A = \mathrm{Is}(\mathbf{Ab}).$$

The second weak factorization system is consequently $(\mathrm{Is}(\mathbf{Ab}), \mathrm{Mor}(\mathbf{Ab}))$: factor a map as its identity followed by itself, and invert the left map to solve every lifting problem. This verifies all model axioms. Both left classes are defined by lifting and hence are stable under pushout, transfinite composition and retracts. The generating cofibrations are I_A; the generating trivial cofibrations form the empty set, whose right lifting class is all arrows and whose left lifting class is the isomorphisms. Together with cocompleteness and accessibility of the coefficient objects, this verifies every condition of a special closed triple.

To see the failure, consider the sequence in the arrow category whose nth arrow is $0 \to \mathbb{Z}$ and whose transition square is $(\mathrm{id}_0, \times 2)$. Every homomorphism $A \to \mathbb{Z}$ is zero, because the image of each x_n must be divisible by arbitrarily high powers of 2. Thus all these arrows lie in W_A. Their colimit is

$$0 \longrightarrow \mathrm{colim}(\mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{2} \cdots) \cong \mathbb{Z}[1/2] = A.$$

The map $\mathrm{Hom}(A, 0) \to \mathrm{Hom}(A, A)$ is not surjective, since its target contains the nonzero identity. The colimit arrow is not in W_A, as required. □

The example does preserve $\aleph_1$-filtered colimits of weak equivalences, by the presentability calculation in the proof. The general distinction is formalized in Raptis and Rosický (2015, Proposition 4.1): generating cofibrations between κ-presentable objects give stability of weak equivalences under κ-filtered colimits in a combinatorial model category. We checked that result, the standard

small-object and transfer constructions, and searches for this particular $\mathrm{Hom}(\mathbb{Z}[1/2], -)$ example; we did not find this precise illustration in the literature. The construction is a specialization of established methods, and the mark [ours] records the argument assembled here, with no claim of priority.

donc

$$\begin{cases} u^*(\mathcal{M}(I')_{\mathrm{f}}) \ \subset \ \mathcal{M}(I)_{\mathrm{f}} \\ u_{\mathrm{f}}^* : \mathcal{M}(I')_{\mathrm{f}} \longrightarrow \mathcal{M}(I)_{\mathrm{f}} \textit{ est compatible avec les localiseurs.} \end{cases} \tag{6.1.14}$$

Commentary · Exposition [ms. 99]

The projective structure and its free diagrams

Grothendieck has now supplied the structure that was missing from the mapping-cone argument. A diagram can be replaced without discarding its transition maps, and the replacement is good for every left Kan extension. The weak equivalences and fibrations are still tested at individual objects; it is the cofibrations that encode the compatibility needed to make these tests into a theory of diagrams.

We fix the variance before using the theorem. Here

$$\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M}), \qquad (u^*X)(i) = X(u(i)).$$

For $j \in I$, evaluation has a left adjoint F_j, given by

$$(F_jA)(i) = \coprod_{I(i,j)} A.$$

A square from F_jf to a diagram map p is exactly a square from f to $p(j)$; the same correspondence identifies their fillers. Thus, if S and T generate the two lifting systems in $\mathcal{M}$, the sets

$$\{F_js : j \in I,\ s \in S\}, \qquad \{F_jt : j \in I,\ t \in T\}$$

29. C'est le résultat principal dans cette partie XVII des notes.

generate the projective cofibrations and projective trivial cofibrations. The smallness conditions in the preceding sections justify the required factorizations. Formula (6.1.7) is the version using all objectwise cofibrations at once instead of selected generators. This is the modern projective model structure; the construction and its acyclicity check appear in Riehl (2014, Theorem 12.3.2).

The Quillen property of $u_! \dashv u^*$ can also be seen without repeating the cellular construction. If $f \in C(I)$ and $p \in TF(I')$, transpose a lifting square from $u_! f$ to p across the adjunction. Its right side is u^*p, which is still an objectwise trivial fibration. A filler exists by the definition of $C(I)$ and transposes back. Replacing (C, TF) by (TC, F) gives the second preservation statement. In particular, the conclusion does not depend on u preserving the order properties used earlier to construct cofibrant diagrams.

There is a useful economy in (6.1.9). Restriction preserves every weak equivalence, so its functor on homotopy categories is already defined. Only the left adjoint needs to be derived: for a projectively cofibrant replacement $QX \to X$,

$$\mathbf{L}u_!(X) = u_!(QX).$$

The adjunction asserts a natural bijection of morphisms in the localized categories, not merely the existence of this formula on objects. This is the precise additional conclusion that the earlier counterexample made necessary. The elementary lifting criterion for a Quillen adjunction and the preservation of weak equivalences between cofibrant objects are recorded in Riehl (2014, Lemmas 11.3.11 and 11.3.14).

[page 101]

d) *Supposons que I soit une catégorie ordonnée, et considérons l'ensemble $C_I \subset \mathrm{Fl}(\mathcal{M}(I))$ défini dans §2*[30] (cf. page 25, cf. aussi th. 2.1, p. 26, et ses corollaires). *On a alors*

$$\begin{cases} C_I \supset C(I) \\ TC_I \supset TC(I)\,, \end{cases} \tag{6.1.15}$$

et on a égalité quand I est un ensemble ordonné artinien.

Commentary · Development (commentators') [ms. 101]

The order hypothesis follows the variance

The comparison with the earlier order-theoretic cofibrations is meant to show that the new construction recovers the old one. At this point a change of notation matters: the earlier argument used covariant diagrams on an artinian poset, whereas (6.1.1) now uses contravariant diagrams on I. Accordingly, the sufficient condition is that I^{op} be artinian, or that I be noetherian. Corollary 6.3 states exactly this condition. The word *artinien* in 6.1(d), repeated in the sentence preceding 6.3, is printed in the edition and is retained in the source text.

An inverse-sequence counterexample[ours]. The condition printed in 6.1(d) is false in general. We work in sets with the axiom of choice and take

$$W = \mathrm{Mor}(\mathrm{Set}), \qquad C = \{\text{injections}\}, \qquad F = \{\text{surjections}\}.$$

These classes give a closed special Quillen structure. Indeed, injections and surjections are mutually determined by lifting, every map $A \to B$ factors as

$$A \longrightarrow A \amalg B \longrightarrow B,$$

and the single map $\varnothing \to \{*\}$ generates the lifting system. The other specialness conditions hold because sets have all small colimits, each set is small for a sufficiently large regular cardinal, and injections are stable under pushout and transfinite composition. Since every map is in W, the two required factorizations are the same one.

Let $I = \mathbb{N}$ with its usual order. It is artinian but not noetherian. In $\mathcal{M}(I)$ consider $f : \varnothing \to \mathbf{1}$, where $\mathbf{1}$ is the constant singleton inverse sequence. Every nonempty upward closed subset of I is a

30. Au paragraphe 2, c'était noté C_{I° au lieu de C_I.

tail $[n,\infty)$. The colimit of $\mathbf{1}$ over its opposite is a singleton, while the colimit over the empty subset is empty. Therefore every relative-colimit map associated with closed subsets $U \subseteq V$ is one of

$$\varnothing \longrightarrow \varnothing, \qquad \varnothing \longrightarrow \{*\}, \qquad \{*\} \xrightarrow{1} \{*\}.$$

All are injections. In particular $f \in C_I$, whether one uses the defining principal closed-set tests or the equivalent tests for arbitrary closed pairs.

Nevertheless, f is not projectively cofibrant. Define a presheaf E by

$$E(n) = \{k \in \mathbb{N} : k \geq n\}, \qquad E(n+1) \longrightarrow E(n) \quad \text{the inclusion.}$$

The map $E \to \mathbf{1}$ is an objectwise surjection, hence a projective trivial fibration. A filler for the square from $\varnothing \to \mathbf{1}$ to $E \to \mathbf{1}$ would choose compatible elements $k_n \in E(n)$. Compatibility forces all k_n to be the same integer, which would have to belong to every tail. There is no such integer. Thus $C(I) \neq C_I$.

This example isolates the missing hypothesis: the partial-lift argument must start at objects with no predecessors in the direction of the diagram. For inverse sequences indexed by $\mathbb{N}$, that direction has no starting object. We checked the standard projective and Reedy constructions in Riehl (2014, §§12.3 and 14.2) and Riehl and Verity (2014, Observation 4.16); the example is our explicit diagnostic for the printed variance error, with no claim of priority.

Démonstration. L'assertion a) est un cas particulier de 5.8, appliqué au couple de foncteurs adjoints

$$\mathcal{M}(I_0) \underset{v^*}{\overset{v_!}{\rightleftarrows}} \mathcal{M}(I) \quad .$$

Les conditions (5.8.2) sont satisfaites, cela a été vu dans (4.8). La proposition 5.8 nous dit alors l'existence d'une structure de triple de Quillen close sur $\mathcal{M}(I)$, dont l'ensemble des quasi-isomorphismes $W(I)$ et l'ensemble des fibrations $F(I)$, sont donnés par la première formule (5.8.3) et par la première formule (5.8.4), ce qui équivaut aux définitions (6.1.2). (**N.B.** Le fait que $\mathcal{M}(I_0)$, avec la structure $W(I_0)$, $C(I_0)$, $F(I_0)$ évidente (produit), est bien une catégorie de Quillen spéciale close, est ± tautologique.) p. 51 [page 102]

Prouvons b). La relation (6.1.6) est tautologique. Les relations (6.1.7) sont contenues dans 5.8 (cf. deuxième relation dans (5.8.3) pour $C' = v_!(C)^\sim$, i.e. $C(I) = (v_!(C(I_0)))^\sim$, et (5.8.5) pour $TC(I) = (v_!(TC(I_0)))^\sim$).

Prouvons c). La première assertion est, par Quillen, un cas particulier des relations (6.1.10) à (6.1.14), c'est elles qu'il s'agit d'établir. Les relations (6.1.13) et par suite (6.1.14) sont tautologiques en vertu des définitions, donc il s'agit d'établir *(6.1.10)* et (6.1.12).

Pour les formules (6.1.10), j'utilise le diagramme commutatif

$$\begin{array}{ccc} I & \xleftarrow{\ v\ } & I_0 \\ {\scriptstyle u}\downarrow & & \downarrow{\scriptstyle u_0} \\ I' & \xleftarrow{\ v'\ } & I'_0\ , \end{array}$$

et je note que les foncteurs $u_!^{\mathcal{M}}$, $u_{0!}^{\mathcal{M}}$, commutant aux petites limites inductives, se comportent bien pour l'opération [page 103]

$$\Phi \longmapsto \Phi^\sim\ ,$$

quand Φ est une partie de $\mathrm{Fl}(\mathcal{M}(I))$ resp. de $\mathrm{Fl}(\mathcal{M}(I_0))$ qui est Q-accessible, i.e. telle qu'il existe une *petite* partie $\Phi_0 \subset \Phi$ avec $\Phi \subset \tilde{\Phi}_0$, plus précisément, on a

$$u_!(\Phi^\sim) \ \subset\ (u_!(\Phi))^\sim\ .$$

Ceci noté, on a par b)

$$C(I) \ =\ (v_!(C(I_0)))^\sim\ ,$$

d'où

$$u_!(C(I)) \ \subset \ \underbrace{(u_!(v_!(C(I_0))))}_{(uv)_!(C(I_0))}{}^{\sim} ,$$

et le deuxième membre s'écrit aussi

$$(v'_! u_{0\,!}(C(I_0)))^{\sim} \ \overset{?}{\subset} \ (v'_!(I'_0))^{\sim} \ = \ C(I') \ .$$

Donc tout revient à montrer que

$$u_{0\,!}(C(I_0)) \ \subset \ C(I'_0) \ , \tag{6.1.16}$$

ce qui résulte aussitôt du calcul de $u_{0\,!}$ à coups de sommes directes, et du fait que C est stable par sommes directes quelconques. Cela prouve donc $u_!(C(I)) \subset C(I')$, et on prouve de même $u_!(TC(I)) \subset TC(I')$, qui se ramène de même au cas particulier

$$u_{0\,!}(TC(I_0)) \ \subset \ TC(I'_0) \ . \tag{6.1.17}$$

Il reste à prouver (6.1.12), et on procède comme pour 3.3 (p. 54), en utilisant le fait qu'une flèche f dans $\mathcal{M}(I)_{\mathrm{c}}$ qui est dans $W(I)$, s'écrit dans $\mathcal{M}(I)_{\mathrm{c}}$ sous la forme $f = pi$, où $i \in TC(I)$, et où p est inverse à gauche (rétraction) d'une flèche $j \in TC(I)$. On aura donc $u_!(f) = u_!(p)u_!(i)$, et $u_!(i) \in TC(I')$ par (6.1.10), et $u_!(p)$ est inverse à gauche de $u_!(j) \in TC(I')$. On a alors $u_!(i), u_!(j), u_!(p) \in W(I')$, d'où $u_!(f) \in W(I')$, q.e.d. p. 52 [page 104]

Prouvons enfin d). Compte tenu de la définition de C_I, pour établir $C(I) \subset C_I$, il suffit de voir ceci :

Commentary · Exposition [ms. 104]

Relative colimits measure the new attachment

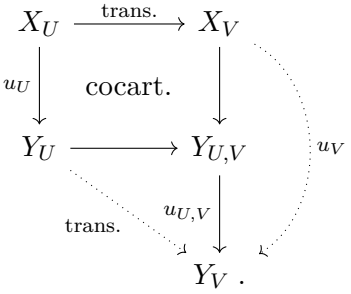
Grothendieck wants a cofibration of diagrams to remain a cofibration when part of the indexing category has already been assembled. The map to inspect is therefore not just the map between two colimits. It is the remaining attachment after the source diagram and the chosen part of the target have been put together:

$$X_V \amalg_{X_U} Y_U \longrightarrow Y_V .$$

For a cosieve $U \subseteq V$ in I, the actual diagram direction is V^{op}, and U^{op} is a sieve. These are exactly the subsets on which a partial covariant diagram can be constructed before its complement. In these formulas X_U means $\mathrm{colim}_{U^{\mathrm{op}}} X$, and similarly for V; the repeated U in the edition's definition of X_V is a slip.

The reduction to an arrow is useful because it separates the categorical bookkeeping from the lifting argument. After restricting to V, take the characteristic map $V \to [1]$ whose fibre at 1 is U. Left Kan extension turns the pair of colimits into the arrow $X_U \to X_V$, and turns a map of diagrams into its square of colimits. The relative map of that square is then the displayed attachment. Only the preservation of projective cofibrations by left Kan extension and the arrow-category calculation remain to be checked.

The restriction step is explicitly deferred in the source. It is justified by 6.4(c) and 6.5: a cosieve inclusion is a discrete opfibration, and its right Kan extension is given objectwise by either evaluation or an empty product. Thus restriction preserves the two projective left classes by adjunction. The temporary assumption in the proof of 6.2 is discharged within these pages.



Corollaire 6.2.[31] *Soit I quelconque dans* Cat*, soient $U \subset V$ deux fermés dans I (i.e. des ouverts dans I°), et soit $f : X_\bullet \longrightarrow Y_\bullet$ une flèche dans $C(I)$ (resp. dans $TC(I)$). Posons encore* [page 105]

$$X_U \ = \ \varinjlim_{i \in U} X(i), \qquad X_V \ = \ \varinjlim_{i \in U} X(i) \ ,$$

31. **N.B.** Ce résultat se généralise, sous les conditions générales dans 6.2.5.

et de même pour Y, et considérons le diagramme

(6.2.1)

Alors la flèche $u_{U,V}$ est dans C (resp. TC).

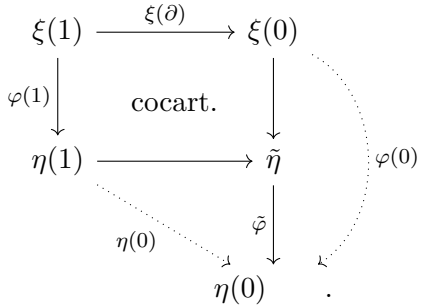
Démonstration de 6.2. Admettons que la restriction d'une flèche de $C(I)$ resp. $TC(I)$ à un fermé V de I est dans $C(V)$ resp. $TC(V)$ (cf. … ci-dessous). Cela nous permet de supposer $V = I$. La donnée de U, qui est un ouvert de I°, équivaut à la donnée d'une flèche $v : I^\circ \longrightarrow \mathbf{\Delta}^1$ (en prenant la fibre en 0), ou encore à la donnée d'une flèche $u : I \longrightarrow (\mathbf{\Delta}^1)^\circ \simeq \mathbf{\Delta}^1$ (en prenant le fibre en 1). Or

$$u \,:\, I \longrightarrow \mathbf{\Delta}^1\,, \qquad U \;=\; I_1 \overset{\text{déf}}{=} u^{-1}(\{1\})\,. \tag{6.2.2}$$

On a alors [page 106]

$$X_U \;=\; u_!(X)(1), \quad X_I \;=\; u_!(X)(0)\,,$$

et le morphisme de transition $X_U \longrightarrow X_I$ est déduit de la flèche $0 \xrightarrow{\partial} 1$ dans $\mathbf{\Delta}^1$, et de même pour Y. Soit



$$\xi \;=\; u_!(X), \qquad \eta \;=\; u_!(Y)\,,$$

donc le diagramme (6.2.1) s'identifie au diagramme déduit de p. 53

$$\varphi \,:\, \xi \longrightarrow \eta\,, \qquad \varphi \;=\; u_!(f)\,,$$

comme

(6.2.3)

Or par 6.1.10 appliqué à $u : I \longrightarrow \mathbf{\Delta}^1$, la relation $f \in C(I)$ resp. $f \in TC(I)$ implique $\varphi \in C(\mathbf{\Delta}^1)$ resp. $\varphi \in TC(\mathbf{\Delta}^1)$. Donc pour établir 6.1, on est ramené au cas particulier où $I = \mathbf{\Delta}^1$, $U = \{1\}$, $V = I$, donc à prouver le

Lemme 6.2.4. *Soit $\varphi : \xi \longrightarrow \eta$ une flèche dans $\mathcal{M}(\mathbf{\Delta}^1)$. Si $\varphi \in C(\mathbf{\Delta}^1)$ (resp. $\varphi \in TC(\mathbf{\Delta}^1)$), alors la flèche $\tilde{\varphi}$ dans le diagramme* (6.2.3) *est dans C (resp. TC).* [page 107]

Plus généralement, et plus précisément :

Lemme 6.2.5. *Soit $\mathcal{M}$ une catégorie stable par sommes amalgamées, et Φ une partie Q-close à gauche* (on prendra $\Phi = C$, et $\Phi = TC$, dans le cas du lemme 6.2.4). *Soit $\Psi = \Phi_*$, et considérons, pour toute I dans* Cat, *$\Phi(I)$, $\Psi\langle I\rangle$ dans $\mathcal{M}(I)$, définis par :*

$$\begin{aligned} &u : X \longrightarrow Y \text{ dans } \mathcal{M}(I) \text{ est dans } \Psi\langle I\rangle \text{ si et seulement si } \forall\, i \in \operatorname{Ob} I,\\ &u(i) : X(i) \longrightarrow Y(i) \text{ est dans } \Psi, \end{aligned} \tag{6.2.5.1}$$

$$\Phi(I) \;=\; \Psi\langle I\rangle^{*}. \tag{6.2.5.2}$$

Prenons le cas $I = \mathbf{\Delta}^1 = \{0 \xrightarrow{\partial} 1\}$, et soit $u : X \longrightarrow Y$ une flèche dans $\mathcal{M}(\mathbf{\Delta}^1)$, correspondant à un carré commutatif

$$\begin{array}{ccc} X(1) & \xrightarrow{X(\partial)} & X(0) \\ {\scriptstyle u(1)}\downarrow & & \downarrow{\scriptstyle u(0)} \\ Y(1) & \xrightarrow{Y(\partial)} & Y(0)\,. \end{array} \tag{6.2.5.3}$$

Considérons le diagramme correspondant

p. 54
[page 108]

$$\begin{array}{ccccc} X(1) & \xrightarrow{X(\partial)} & X(0) & & \\ {\scriptstyle u(1)}\downarrow & \text{cocart.} & \downarrow & \searrow & \\ Y(1) & \longrightarrow & \tilde{Y} & & u(0) \\ & {\scriptstyle Y(\partial)}\searrow & \downarrow{\scriptstyle \tilde{u}} & \swarrow & \\ & & Y(0) & & \end{array} \qquad . \tag{6.2.5.4}$$

Pour qu'on ait $u \in \Phi(\mathbf{\Delta}^1)$, il faut et il suffit que l'on ait

$$u(0),\; u(1),\; \tilde{u} \;\in\; \Phi\;. \tag{6.2.5.5}$$

J'ai déjà vérifié la chose (sous forme duale), mais ne retrouve plus l'endroit (peut-être n'ai-je pas pris des notes). Je n'ai pas envie de rechercher la démonstration ici.

Commentary · Exposition [ms. 108]

The omitted arrow-category calculation

The short lemma that Grothendieck leaves unwritten is the local lifting step used throughout the remainder of the proof. We give it with precisely the pushout hypothesis he states. This also explains why the three maps in (6.2.5.5) are slightly more than one needs to test.

Let $\Phi = {}^{\perp}\Psi$ and $\Psi = \Phi^{\perp}$. Write a map of arrows as

$$\begin{array}{ccc} A_1 & \longrightarrow & A_0 \\ {\scriptstyle f_1}\downarrow & & \downarrow{\scriptstyle f_0} \\ B_1 & \longrightarrow & B_0, \end{array} \qquad P = A_0 \amalg_{A_1} B_1, \qquad t : P \longrightarrow B_0.$$

Then $f \in {}^{\perp}(\Psi\langle[1]\rangle)$ if and only if $f_1, t \in \Phi$. When these conditions hold, $f_0 \in \Phi$ as well.

For sufficiency, take a square from f to a map of arrows $p : (E_1 \to E_0) \to (F_1 \to F_0)$ whose two components belong to Ψ. First choose a filler $h_1 : B_1 \to E_1$ against f_1 and p_1. The given map $A_0 \to E_0$ and the composite $B_1 \xrightarrow{h_1} E_1 \to E_0$ agree on A_1. They define $P \to E_0$. Together with $B_0 \to F_0$, this is a square from t to p_0. A filler $h_0 : B_0 \to E_0$ solves it. Its restriction to B_1 is the prescribed composite, so (h_1, h_0) is a natural filler of the original square.

For necessity of the relative condition, take any square from t to $q : E \to F$ in Ψ, with upper map $a : P \to E$ and lower map $b : B_0 \to F$. Consider the map of arrows

$$(B_1 \xrightarrow{a|_{B_1}} E) \longrightarrow (B_1 \xrightarrow{b|_{B_1}} F)$$

with components $(1_{B_1}, q)$. The maps $(f_1, a|_{A_0})$ and $(1_{B_1}, b)$ define a square from f to this map. A filler has first component 1_{B_1}; its second component is exactly a filler for the prescribed square from t to q. Thus $t \in \Phi$.

To test f_1, one must make an arbitrary square at the first vertex into a square of arrows. Suppose that square has maps $a : A_1 \to E$, $b : B_1 \to F$ and right side $q : E \to F$ in Ψ. Form

$$K = F \amalg_{B_1} B_0.$$

There is a map of arrows $(E \to K) \to (F \to K)$ with components $(q, 1_K)$. The given maps at vertex 1, together with $A_0 \to B_0 \to K$ and $B_0 \to K$ at vertex 0, form a square from f. A filler supplies the desired map $B_1 \to E$. Hence $f_1 \in \Phi$. This construction uses a pushout in place of any terminal-object argument.

Finally, $A_0 \to P$ is the pushout of f_1, and f_0 is its composite with t. A left lifting class is closed under pushout and composition, so $f_0 \in \Phi$. This proves the printed criterion, including its redundant component condition. The same two-stage construction is the direct-category case of the relative-latching lifting argument of Riehl and Verity (2014, Observation 4.16); no model structure or factorization axiom is used here.

Pour achever de prouver 6.1. d), i.e. l'égalité $C(I) = C_I$ pour I artinien, j'ai envie de prouver encore quelque chose de plus générale que voici :

Corollaire 6.3. *Soient* $(\mathcal{M}, \Phi, \Psi)$ *et* $I \longmapsto \Phi(I) \subset \mathrm{Fl}(\mathcal{M}(I))$ *comme dans* 6.2.5. *Soit* I *un ensemble ordonné, et considérons aussi* Φ_I *défini (dans la situation duale) page* 25 (2.2) *(mais avec des notations duales …). Je dis que l'on a*

$$\Phi_I \supset \Phi(I) , \tag{6.3.1}$$

et on a égalité si I *est noethérien, i.e.* I° *est artinien.* [page 109]

Démonstration. La démonstration de $\Phi(I) \subset \Phi_I$ est celle qu'on vient de donner. Il reste à prouver que si I est noethérien, on a $\Phi_I \subset \Phi(I)$. Étant donnée $i : A \longrightarrow B$ dans Φ_I, il faut prouver que $u \in \Phi(I)$, i.e. que pour un diagramme commutatif dans $\mathcal{M}(I)$,

$$\begin{array}{ccc} A & \xrightarrow{\alpha} & X \\ {\scriptstyle i}\downarrow & \overset{h}{\nearrow} & \downarrow{\scriptstyle p} \\ B & \xrightarrow[\beta]{} & Y \end{array} \tag{6.3.2}$$

avec $p \in \Psi\langle I\rangle$, i.e. $p(i) : X(i) \longrightarrow Y(i)$ dans Ψ pour tout i, $\exists\, h : B \longrightarrow X$ laissant le diagramme commutatif. On va revenir aux notations duales, en travaillant dans $\mathcal{M}(I^\circ)$, avec I artinien. On considère l'ensemble $\mathcal{H}$ des couple (U, h_U) d'un ouvert U de I et d'un $h_U : B|U \longrightarrow X|U$, rendant commutatif la restriction à U de (6.3.2). On ordonne $\mathcal{H}$ par prolongement, on note que toute partie totalement ordonnée (U_α, h_{U_α}) dans $\mathcal{H}$ a une borne supérieure, savoir $U = \bigcup_\alpha U_\alpha$, h_U défini par les h_{U_α} sur les U_α.

Commentary · Exposition [ms. 109]

The lift is built in the direction of the arrows

The long cube calculation has a simple purpose: when a new vertex is added, its lift must extend the lifts already chosen on all incoming arrows. The relative latching map incorporates that compatibility in a single lifting problem. We formulate the argument in a fixed covariant convention so that its order hypothesis is visible throughout.

Let J be a small artinian poset, let $A, B, X, Y : J \to \mathcal{M}$, and suppose $p : X \to Y$ is objectwise in Ψ. Assume that the relevant colimits exist. For $j \in J$, put

$$L_j A = \mathrm{colim}_{k<j} A_k, \qquad L_j B = \mathrm{colim}_{k<j} B_k, \qquad \ell_j(f) : A_j \amalg_{L_j A} L_j B \longrightarrow B_j.$$

If every $\ell_j(f)$ belongs to Φ, any square from $f : A \to B$ to p has a natural filler.

Indeed, order partial fillers on downward closed subsets by extension. The empty subset supports a filler, and a chain has an upper bound obtained by taking the union of its domains and its compatible component maps. Zorn's lemma gives a maximal partial filler h_U. If $U \neq J$, choose

a minimal element j of $J \setminus U$. Every $k < j$ lies in U, so the partial filler gives a map $L_jB \to X_j$. Together with $A_j \to X_j$ it induces

$$A_j \amalg_{L_jA} L_jB \longrightarrow X_j.$$

The original square and the naturality of the maps make this a square with lower map $B_j \to Y_j$ and right side p_j. The lifting relation $\Phi \perp \Psi$ supplies $h_j : B_j \to X_j$. Its restriction along $L_jB \to B_j$ is the map already prescribed by h_U, hence it is compatible with every incoming arrow. There are no arrows from j to an old object of U, since U is downward closed. The result is a filler on $U \cup \{j\}$, contradicting maximality. Therefore $U = J$.

This proves the difficult inclusion in 6.3 without shortening any of its mathematical content. Grothendieck's $\widetilde{B}$, $\widetilde{i}$ and $\widetilde{h}_0$ are the pushout, relative latching map and upper arrow just displayed. The identities on pp. 113–116 verify that the proposed upper arrow and lower arrow make the required square commute; they hold by the pushout universal property. The sentence at the end must use the given hypothesis $i \in \Phi_I$, not the printed $i \in \Phi(I)$, which is the conclusion.

The passage from J back to the source's contravariant notation is $J = I^{\mathrm{op}}$. Thus I must be noetherian. The colimit assumption is inherited from the use of the classes defined in §2; pushouts alone, the hypothesis of the arrow lemma, do not ensure that arbitrary L_jA exist. No small-object argument enters this proof. Its induction is legitimate for any small well-founded poset, including those whose ranks are transfinite.

(**N.B.** L'ensemble $\mathcal{H}$ n'est pas vide, car $(\emptyset, h_\emptyset)$ est dans $\mathcal{H}$ – mais c'est contenu dans l'énoncé précédent que toute partie totalement ordonnée de $\mathcal{H}$ y a une borne supérieure …). Par Zorn, il existe un élément maximal (U, h_U). À prouver que $U = I$, et on aura terminé. Ou encore que si (U, h_U) tel que $U \neq I$, ce n'est *pas* maximal. Soit $F = I \backslash U \neq \emptyset$ le fermé complémentaire. Par l'hypothèse artinienne sur I, F a un élément minimal i_0. Soit

p. 55
[page 110]

$$U' \;=\; U \cup \overbrace{I/i_0}^{V} \;=\; U \cup \{i_0\}\ ,$$

on va prolonger h_U en $h_{U'}$ sur U', on aura terminé. Pour ceci, soit $V_0 = V \cap U = V \backslash \{i_0\}$, on est ramené à prolonger la restriction h_{V_0} de h_U à V_0, de V_0 à V. Au total, on peut supposer $I = I/i_0$ muni d'un élément final i_0, $U = I \backslash \{i_0\}$, et montrer qu'une $(U, h_U) \in \mathcal{H}$ se prolonge à I. Soient A', B', X', Y' les restrictions de A, B, X, Y à U (qu'on pourra aussi noter I'). La donné de A équivaut à celle de A', celle de $A_0 = A(i_0) \in \mathrm{Ob}\,\mathcal{M}$, et d'une flèche de

$$A'_{I'} \overset{\text{déf}}{=} \varinjlim_{i' \in I'} A'(i') \xrightarrow{\lambda_A} A_0 \ (\simeq A_I)\ ,$$

et de même pour B, X, Y. Plus précisément, la catégorie $\mathcal{M}(I^\circ)$ s'interprète comme celle des triples $X = (X', X_0, \lambda_X)$, où $X' \in \mathcal{M}(I'^\circ)$, $X_0 \in \mathcal{M}$, et $\lambda_X : X'_{I'} \longrightarrow X_0$. À ce compte, la donnée du diagramme (6.3.2) équivaut à celle d'un diagramme carré similaire [page 111]

(6.3.3)
$$\begin{array}{ccc} A' & \xrightarrow{\alpha'} & X' \\ {\scriptstyle i'}\downarrow & \overset{h'}{\nearrow} & \downarrow{\scriptstyle p'} \\ B' & \xrightarrow[\beta']{} & Y' \end{array}$$

dans $\mathcal{M}(I'^\circ)$, d'où un diagramme dans $\mathcal{M}$

(6.3.4)
$$\begin{array}{ccc} A'_{I'} & \xrightarrow{\alpha'_{I'}} & X'_{I'} \\ {\scriptstyle i'_{I'}}\downarrow & \overset{h'_{I'}}{\nearrow} & \downarrow{\scriptstyle p'_{I'}} \\ B'_{I'} & \xrightarrow[\beta'_{I'}]{} & Y'_{I'}\ , \end{array}$$

d'un autre diagramme carré *dans* $\mathcal{M}$

$$\begin{array}{ccc} A_0 & \xrightarrow{\alpha_0} & X_0 \\ {\scriptstyle i_0}\downarrow & & \downarrow{\scriptstyle p_0} \\ B_0 & \xrightarrow[\beta_0]{} & Y_0\ , \end{array} \tag{6.3.5}$$

et enfin d'un homomorphisme $\lambda = (\lambda_A, \lambda_B, \lambda_X, \lambda_Y)$ du carré (6.3.4) dans le carré (6.3.5) : p. 56 [page 112]

$$\begin{array}{ccccc} A'_{I'} & & \xrightarrow{\alpha'_{I'}} & & X'_{I'} \\ & \searrow^{i'_{I'}} & \nearrow_{h'_{I'}} & & \downarrow{\scriptstyle \lambda_X} \quad \searrow^{p'_{I'}} \\ \downarrow{\scriptstyle \lambda_A} & & B'_{I'} & \xrightarrow{\beta'_{I'}} & Y'_{I'} \\ & & \downarrow{\scriptstyle \lambda_B} & & \downarrow \\ A_0 & \xrightarrow{\alpha_0} & X_0 & & \downarrow{\scriptstyle \lambda_Y} \\ & \searrow^{i_0} & \nearrow_{h_0} & \searrow^{p_0} & \\ & & B_0 & \xrightarrow[\beta_0]{} & Y_0 \end{array} \tag{6.3.6}$$

32

D'autre part, la question de prolonger $(I', h') \in \mathcal{H}$ en (I, h), revient à celle de trouver $h_0 : B_0 \longrightarrow X_0$ dans $\mathcal{M}$, de façon qu'avec $h'_{I'}$ cela fasse encore un diagramme commutatif de (6.3.6), ce qui revient à dire que d'une part les deux triangles formés dans le carré de base sont commutatifs :

$$p_0 h_0 \ = \ \beta_0, \qquad h_0 i_0 \ = \ \alpha_0\ , \tag{6.3.7}$$

et d'autre part le carré diagonal défini par $h'_{I'}$, h_0 soit commutatif (ce qui exprime qu'on a une flèche h de B dans X) :

$$\lambda_X h'_{X'} \ = \ h_0 \lambda_B\ . \tag{6.3.8}$$

Mais le diagramme (6.3.6), où la flèche en traits pointillés denses $h'_{I'}$ est déjà acquise, et h_0 en pointillés espacés reste à trouver, donne naissance au diagramme, dans lequel est mis en évidence la flèche $\tilde{i} \in \Phi$ qui exprime l'hypothèse $i \in C(i)$, compte tenu de $i' \in C(I')$: [page 113]

$$\begin{array}{ccccc} A'_{I'} & & \xrightarrow{\alpha'_{I'}} & & X'_{I'} \\ & \searrow^{i'_{I'}} & \nearrow_{h'_{I'}} & & \downarrow{\scriptstyle \lambda_X} \quad \searrow^{p'_{I'}} \\ \downarrow{\scriptstyle \lambda_A} & & B'_{I'} & \xrightarrow{\beta'_{I'}} & Y'_{I'} \\ & \text{cocart.} & \downarrow{\scriptstyle s} & & \downarrow \\ A_0 & \xrightarrow{\alpha_0} & & & X_0 \quad \downarrow{\scriptstyle \lambda_Y} \\ & \searrow^{r} & \nearrow_{\tilde{h}_0} & & \searrow^{p_0 \in \Psi} \\ & & \tilde{B} & \xrightarrow{\tilde{\beta}_0} & Y_0 \\ & \searrow^{i_0} & \downarrow{\scriptstyle \tilde{i} \in \Phi} & \nearrow_{h_0} & \\ & & B_0\ , & \xrightarrow[\beta_0]{} & \end{array} \tag{6.3.9}$$

où la flèche $\tilde{h}_0$ en traits pointillés denses de $\tilde{B} \overset{\text{déf}}{=} A_0 \amalg_{A'_{I'}} B'_{I'}$ dans X_0, est définie par les p. 57

32. **N.B.** La condition $p \in \Psi\langle I \rangle$ s'exprime par $p' \in \Psi\langle I' \rangle$ et $\boxed{p_0 \in \Psi.}$

conditions de commutativité

$$\tilde{h}_0 r \;=\; \alpha_0, \qquad \tilde{h}_0 s \;=\; \lambda_X h'_{I'} \;, \tag{6.3.10}$$

ce qui est licite, vu que

$$\begin{aligned} \alpha_0\lambda_A &= (\lambda_X h'_{I'})i'_{I'} \\ &= \lambda_X(h'_{I'}i'_{I'}) \\ &= \lambda_X\alpha'_{I'}. \end{aligned}$$

Quant à la flèche $\tilde{\beta}_0 : \tilde{B} \longrightarrow Y_0$, elle est donnée par la condition de commutativité [page 114]

$$\tilde{\beta}_0 r \;=\; p_0\alpha_0, \qquad \tilde{\beta}_0 s \;=\; \lambda_Y \beta'_{I'} \;, \tag{6.3.11}$$

ce qui est encore licite, puisque

$$(p_0\alpha_0)\lambda_A \;=\; (\lambda_Y\beta'_{I'})i'_{I'}$$

en vertu de la commutativité du cube (6.3.6). Pour établir la commutativité totale du diagramme (6.3.9) (traits pleins, et traits pointillés denses pour $h'_{I'}$, $\tilde{h}_0$ et $\tilde{\beta}_0$ – à l'exclusion de h_0 pas encore construit), il faut encore vérifier d'une part les relation

$$\begin{cases} \tilde{h}_0 r \;=\; \alpha_0, \quad p_0\tilde{h}_0 \;=\; \tilde{\beta}_0, \\ \lambda_X h'_{I'} \;=\; \tilde{h}_0 s \end{cases} \qquad {}^{33}, \tag{6.3.12}$$

établissant la commutativité du cube supérieur avec le carré diagonal (diagramme du type (6.3.6), la flèche pointillée h_0 y incluse), d'autre part les relations

$$\begin{cases} \tilde{i} r \;=\; i_0 \qquad (\text{et } \tilde{i}s = \lambda_B \text{ pour mémoire}) \\ \beta_0\tilde{i} \;=\; \tilde{\beta}_0 \;, \end{cases} \tag{6.3.13}$$

où la première ligne est déjà connue par définition de $\tilde{B}$ et de $\tilde{i}$. La deuxième se ramène aux deux relations [page 115]

$$\begin{aligned} (\beta_0\tilde{i})r &= \beta_0(\tilde{i}r) \\ &= \beta_0 i_0 \\ &= p_0\alpha_0 \\ &= \tilde{\beta}_0 r \;, \end{aligned}$$

OK par commutativité du carré de base de (6.3.5),

$$\begin{aligned} (\beta_0\tilde{i})s &= \beta_0(\tilde{i}s) \\ &= \beta_0\lambda_B \\ &= \lambda_Y\beta'_{I'} \\ &= \tilde{\beta}_0 s \;, \end{aligned}$$

OK par commutativité du carré antérieur dans (6.3.6). p. 58

Commentary · Examples [ms. 113]

A diamond and the compatibility at its last vertex

Grothendieck's cube records information that an objectwise cofibration test would miss. A finite example makes the attachment visible. Work in simplicial sets, whose cofibrations are the monomorphisms (Riehl, 2014, Example 11.3.5), and let J be the poset with objects a, b, c, d and

33. **N.B.** la première et la troisième de ces relations sont déjà connues, cf. (6.3.10).

relations $a < b < d$ and $a < c < d$. We use covariant diagrams, or equivalently the source's notation $\mathcal{M}(J^{\mathrm{op}})$.

Define a diagram B by

$$B_a = \Delta^0, \qquad B_b = B_c = \Delta^1, \qquad B_d = \Delta^1 \amalg_{\Delta^0} \Delta^1,$$

where the maps out of B_a choose the initial endpoint of each interval, and the maps into B_d are the two inclusions. The latching objects are

$$L_a B = \varnothing, \qquad L_b B = L_c B = \Delta^0, \qquad L_d B = \Delta^1 \amalg_{\Delta^0} \Delta^1.$$

Every latching map is a simplicial monomorphism: at d it is the identity. Consequently B is projectively cofibrant by the lifting argument just given. Its colimit is B_d, since d is terminal in J; its realization is two intervals joined at an endpoint. A compatible map out of B_b and B_c is exactly a pair of paths with the same value at their initial endpoints. The pushout in the latching object expresses precisely this requirement.

Now retain the first three values but replace B_d by Δ^0, with both maps from the intervals collapsing them. All four values remain cofibrant simplicial sets. However, the last latching map becomes

$$\Delta^1 \amalg_{\Delta^0} \Delta^1 \longrightarrow \Delta^0,$$

which is not a monomorphism, since it identifies distinct vertices. The diagram is therefore not projectively cofibrant. A choice of lifts at its four objects need not be compatible along the two paths through the diamond. This is why the proof asks for $\widetilde{i} \in \Phi$, rather than merely the component map $i_0 \in \Phi$.

Donc il reste à vérifier la deuxième relation (6.3.12),

$$p_0 \tilde{h}_0 \;=\; \tilde{\beta}_0 \ ,$$

ce qui se ramène à

$$\begin{aligned} (p_0 \tilde{h}_0) r \;&=\; p_0 (\tilde{h}_0 r) \\ &=\; p_0 \alpha_0 \\ &=\; \tilde{\beta}_0 r \ , \end{aligned}$$

OK par (6.3.11),

$$\begin{aligned} (p_0 \tilde{h}_0) s \;&=\; p_0 (\tilde{h}_0 s) \\ &=\; p_0 (\lambda_X h'_{I'}) \\ &=\; (p_0 \lambda_X) h'_{I'} \\ &=\; (\lambda_Y p'_{I'}) h'_{I'} \\ &=\; \lambda_Y (p'_{I'} h'_{I'}) \\ &=\; \lambda_Y \beta'_{I'} \\ &=\; \tilde{\beta}_0 s \ , \end{aligned}$$

OK.

Ceci posé, je dis que les contraintes (6.3.7), (6.3.8) sur h_0 reviennent à la commutativité des deux triangles dans les carré

(6.3.14)
$$\begin{array}{ccc} \tilde{B} & \xrightarrow{\tilde{h}_0} & X_0 \\ {\scriptstyle \tilde{i} \in \Phi}\downarrow & \overset{h_0}{\nearrow} & \downarrow{\scriptstyle p_0 \in \Psi} \\ B_0 & \xrightarrow[\beta_0]{} & Y_0 \ , \end{array}$$

i.e. aux deux relations

[page 116]

(6.3.15)
$$h_0 \tilde{i} \;=\; \tilde{h}_0 \ , \qquad p_0 h_0 \;=\; \beta_0 \ .$$

La deuxième de ces relations n'est autre que la première relation (6.3.7), et il reste à voir que la première relation (6.3.15) équivaut à l'ensemble des deux relations restantes dans (6.3.7), (6.3.8) :

$$h_0 i_0 \;=\; \alpha_0\ , \qquad \lambda_X h'_{I'} \;=\; h_0 \underbrace{\lambda_B}_{\tilde{i}s} \tag{6.3.16}$$

Or la relation en question $h_0\tilde{i} = \tilde{h}_0$ équivaut à l'ensemble des deux relations p. 59

$$\begin{aligned}(h_0\tilde{i})r &= h_0(\tilde{i}r)\\ &= h_0 i_0\\ &\overset{?}{=} \alpha_0\\ &= \tilde{h}_0 r,\end{aligned}$$

équivalent à $h_0 i_0 = \alpha_0$,

$$\begin{aligned}(h_0\tilde{i})s &= h_0(\tilde{i}s)\\ &= h_0\lambda_B\\ &\overset{?}{=} \lambda_X h'_{I'}\\ &= \tilde{h}_0 s,\end{aligned}$$

équivalent à $h_0\lambda_B = \lambda_X h'_{I'}$, c'est OK.

Ceci posé, dans le carré (6.3.14), les hypothèses $i \in \Phi(I)$, $p \in \Psi\langle I\rangle$ impliquent $\tilde{i}_0 \in \Phi$, $p_o \in \Psi$. Donc la flèche cherchée h_0 existe, q.e.d.

Cela achève la démonstration du corollaire 6.3, et par là aussi, celle de la dernière partie, d), de 6.1. On est heureux !

[page 117]

Commentary · Later developments [ms. 116]

The direct part of Reedy theory

The proof just completed has become the direct part of Reedy theory. For a category with degrees and unique direct–inverse factorizations, a new vertex has both incoming and outgoing constraints. Relative latching maps encode the former and relative matching maps the latter. In a direct category the inverse part has only identities, so matching objects are terminal and Reedy fibrations are objectwise fibrations. Whenever the projective structure exists, the two model structures then agree because their fibrations and weak equivalences agree.

Riehl and Verity (2014, Definition 4.14, Observation 4.16 and Theorem 4.18) give the relative maps, the lifting construction and the resulting model structure; their Lemma 7.1 also identifies trivial Reedy cofibrations by trivial relative latching maps. The familiar natural-number degree convention in that treatment is sufficient for finite posets. Grothendieck's well-founded-poset argument allows transfinite rank directly, without requiring a uniform finite bound on the lengths of chains entering a vertex. The equality in 6.3 concerns this direct situation, after the variance has been fixed; it is not an equality of the projective and arbitrary Reedy structures on every diagram category.

Commentary · Exposition [ms. 118]

Why terminal comma components preserve cofibrations

The final proposition asks when restriction can serve on the left of a Quillen adjunction as well as on the right. The distinction is useful in applying the construction to a subdiagram. Restriction always preserves the objectwise right classes. To preserve the left classes as well, its right adjoint must preserve the corresponding objectwise right classes. The commentary on Chapter XII, manuscript p. 114 ("A terminal fibre controls all the ordinary direct images"), discusses terminal fibres and ordinary direct images; the additional point here is the product stability of right lifting classes.

Here is the formal detail behind the equivalence in 6.4(b). With all required copowers available, one has

$$\Psi\langle I\rangle = \Phi(I)^{\perp}.$$

One inclusion follows from the definition $\Phi(I) = {}^{\perp}(\Psi\langle I\rangle)$. For the other, use the free evaluation diagrams $F_i A = I(-, i) \cdot A$. If $a \in \Phi$, then $F_i a \in \Phi(I)$ by adjunction. A map right-orthogonal to $\Phi(I)$ therefore has each component right-orthogonal to Φ, hence in Ψ. Transposing lifting problems across $u^* \dashv u_*$ now proves both directions of (6.4.2). Factorizations are not needed.

The geometric hypothesis makes right Kan extension particularly simple. Its actual pointwise formula for presheaves is

$$(u_*X)(i') = \lim_{(I/i')^{\mathrm{op}}} X.$$

If each connected component of I/i' has a terminal object e_α, that object is initial in the opposite indexing category. A cone on the restricted diagram is then determined by its map into $X(e_\alpha)$. Splitting the index into its components gives

$$(u_*X)(i') \cong \prod_{\alpha} X(e_\alpha).$$

For a morphism of diagrams the same formula gives a product of its components. Right lifting classes are closed under products: solve a square against the product by projecting to each factor, choosing the factorwise fillers, and using the universal property of the product. The empty product gives an identity map of a terminal object. Thus the displayed formula proves the required preservation.

For completeness, if u is a discrete opfibration and $(i, \gamma : u(i) \to i')$ is an object of I/i', lift γ uniquely to $i \to \gamma_! i$. Its target lies over i', and (i, γ) has a unique map to $(\gamma_! i, 1_{i'})$. A morphism in the comma category leaves this target unchanged by uniqueness of lifting. Consequently the comma category is a disjoint union of components, each with one of these terminal objects. If I is discrete, the comma category itself is discrete and the assertion is immediate. These facts prove the two implications that the source abbreviates as $1° \Rightarrow 3°$ and $2° \Rightarrow 3°$.

Démonstration de 6.4. Les assertions ⓐ , ⓑ sont ± tautologiques, par adjonction, comparer XIII, prop. 2, et cor., page 46. Pour prouver c), il suffit de traiter le cas 3°), car 1° $\Longrightarrow$ 3°, 2° $\Longrightarrow$ 3°. Mais le calcul de

$$u_*(X)(i') \ \simeq \ \varprojlim_{i \in I/i'} X(i)$$

montre que si les composantes connexes $(I/i')_\alpha$ de I/i' ont chacune un objet final e_α, alors

$$u_*(X)(i') \;\simeq\; \prod_\alpha X(e_\alpha)\ .$$

Or Ψ, étant clos à droite, est stable par produits quelconques, donc $X \in \Psi\langle I\rangle$ implique que les $u_*(X)(i')$ sont dans Ψ, donc u_* est dans $\Psi\langle I'\rangle$, q.e.d.

Commentary · Development (commentators') [ms. 118]

A converse when the source is a poset

Grothendieck's terminal-component condition is sufficient for every Q-dual pair. The elementary model of sets used above shows that, for a poset source, it is also a necessary condition if one wants such preservation even in this one test theory. This identifies exactly how much of the comma category the assertion detects.

Proposition [ours]. Let $u : I \to I'$ be a functor between small categories, with I a poset. Give sets the model structure with all maps weak equivalences, injections cofibrations and surjections fibrations, and give presheaf categories their projective structures. The following conditions are equivalent:

1. Every connected component of every I/i' has a terminal object.
2. u^* preserves projective cofibrations.
3. u^* takes every representable presheaf on I' to a projective presheaf on I.

Here projective means having the lifting property against objectwise surjections, and the axiom of choice is understood.

We first establish the elementary description of projectives needed for the converse. If P is a presheaf on a small poset I, form the canonical objectwise surjection

$$q : \coprod_{(i,x),\ x\in P(i)} I(-,i) \longrightarrow P.$$

It is surjective at j because the summand indexed by (j,z) sends 1_j to every given $z \in P(j)$. If P is projective, choose a section s of q. The induced map of categories of elements takes each connected component of $\int P$ into a single representable summand, say the summand indexed by (i,x). For any element (j,z) in that component, $qs = 1$ says that the arrow selected by s has the form $j \to i$ and sends x to z. Hence (j,z) has an arrow to (i,x) in $\int P$, so (i,x) belongs to the same component. Because I is a poset there is at most one such arrow. Thus (i,x) is terminal in that component.

Conversely, if every component of $\int P$ has a terminal element (i_α, x_α), the maps represented by these elements give an isomorphism

$$\coprod_\alpha I(-,i_\alpha) \xrightarrow{\ \sim\ } P.$$

At j, existence and uniqueness of the arrow to the appropriate terminal element give respectively surjectivity and injectivity. A representable is projective by evaluation, and a coproduct of representables is projective by choosing a lift in each summand. We have proved that projective presheaves on a poset are exactly coproducts of representables, equivalently presheaves whose categories of elements have terminal connected components. The general background is the description of indecomposable projectives as retracts of representables and its Cauchy-complete refinement in van Oosten (2021, Proposition 0.7 and Theorem 0.8); the poset case eliminates nonidentity idempotents.

Condition 1 implies condition 2 by 6.4 and 6.5. Condition 2 implies condition 3 because $\varnothing \to I'(-,i')$ is a projective cofibration: any lifting problem against an objectwise surjection is a lifting problem for an element at i'. Restriction preserves the initial presheaf. Finally,

$$\int \big(u^* I'(-,i')\big) = I/i',$$

including both its objects and its morphisms. The description of projectives just proved therefore makes condition 3 imply condition 1, completing the proof.

The poset hypothesis has a precise role. In a general category a projective presheaf may be a proper retract of a representable, controlled by a nontrivial idempotent; a terminal object in its

category of elements need not exist. We checked the projective-presheaf results just cited and the projective diagram construction in Riehl (2014, §12.3). We did not locate this exact formulation of the converse to 6.4(c) in those sources. The proposition is an elementary application of those established results, developed here to clarify the scope of Grothendieck's criterion, not a claim of priority.

Commentary · Later developments [ms. 118]

The pointwise formula and the derivator theorem

Grothendieck has now constructed enough compatible diagram structures to return to the purpose of the chapter: computing a homotopy Kan extension at one object. The last restriction criterion is the bridge. We spell out this application because the printed chapter stops immediately after the criterion, before drawing the conclusion in these terms.

We keep the convention of §6, so that $\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})$. Given $u : I \to I'$ and $i' \in I'$, put $S = i'\backslash I$, with objects $(i, \alpha : i' \to u(i))$, and let $q : S \to I$ and $p : S \to e$ be the projections. An arrow of S over $a : i \to j$ is forced by the equation $\beta = u(a)\alpha$. Thus q is a discrete opfibration. More explicitly, for each $j \in I$, the category S/j splits according to the composite $i' \to u(i) \to u(j)$; the part indexed by $\gamma : i' \to u(j)$ has terminal object $((j, \gamma), \mathrm{id}_j)$. This verifies exactly condition 3 of Proposition 6.4, with no claim that arbitrary restrictions preserve projective cofibrations.

There is also a direct check of the required preservation of cofibrations which uses only coproducts, and therefore does not import the right Kan extension existence proviso in Proposition 6.4. Write $F_i(A)(j) = \coprod_{I(j,i)} A$ for the free presheaf at i. Unique outgoing lifts along q give

$$q^* F_i(A) \cong \coprod_{s \in q^{-1}(i)} F_s(A).$$

Restriction preserves colimits and retracts. This formula and the generating descriptions in Theorem 6.1(b) show that it preserves projective cofibrations and trivial cofibrations. Choose a projectively cofibrant replacement $QX \to X$; then q^*QX is projectively cofibrant on S. Ordinary left Kan extension gives

$$(u_! QX)(i') \cong p_! q^* QX = \operatorname*{colim}_{S^{\mathrm{op}}} q^* QX.$$

The first expression computes the value of $\mathbf{L}u_! X$, and the second computes $\mathbf{L}p_!(q^*X)$. Evaluation and restriction preserve all objectwise weak equivalences, so the replacement maps identify this comparison independently of the chosen cofibrant representative. We obtain the canonical pointwise formula

$$i'^* \mathbf{L}u_! X \cong \operatorname*{hocolim}_{(i'\backslash I)^{\mathrm{op}}} q^* X.$$

Here the opposite on the comma category is essential. In the covariant convention of §3 the corresponding indexing category is I/i', without this opposite. The formula is the content of the left Kan extension axiom, not merely an objectwise recipe unrelated to the adjunction.

The other elementary properties can also be read directly from the diagram model structures. Diagrams on a disjoint union form a product of diagram categories; cofibrant and fibrant representatives show that their homotopy categories decompose accordingly. Evaluations jointly detect isomorphisms: represent a homotopy-category morphism between cofibrant–fibrant objects, and use saturation of weak equivalences in a closed model category in each component. If I has a terminal object t, the constant-presheaf functor is left adjoint to evaluation at t, with identity unit; both functors preserve weak equivalences, so constant diagrams remain fully faithful after localization. These are the precise elementary assertions behind the older axiom names.

The full, two-sided existence theorem is now available without the chapter's special-generation hypotheses, for a model category admitting all small limits and colimits. Cisinski (2003, Theorem 6.11 and its dual) establishes the homotopy Kan extension and pointwise assertions; his "left" terminology there is attached to the right Kan extension convention. For combinatorial model categories, Groth (2013, Theorem 1.28, Proposition 1.30, and Theorem 1.32) presents the projective–injective argument and records the general theorem. The present chapter provides the projective, colimit side; existence of all ordinary right Kan extensions is not part of its cocompleteness assumption.

Commentary · Later developments [ms. 118]

What the coherent diagram remembers

Grothendieck's decision to localize the category of whole diagrams has a precise counterpart in the language of higher categories. Suppose, for a direct comparison, that $\mathcal{M}$ is a combinatorial simplicial model category, and let $\mathcal{C}_\infty$ be the coherent nerve of its simplicial subcategory of cofibrant–fibrant objects, with universes fixed as usual. Rectification identifies

$$\mathrm{Ho}\big(\mathcal{M}^{I^{\mathrm{op}}}\big) \simeq h\,\mathrm{Fun}\big(N(I^{\mathrm{op}}), \mathcal{C}_\infty\big).$$

One precise reference is Lurie (2009, Proposition 4.2.4.4, Remark 4.2.4.5, and Corollary 4.2.4.8); the statement is made there with size-controlled subcategories, which give the displayed comparison after choosing an ambient universe. Projective and injective presentations have the same weak equivalences. The homotopy Kan extensions above present the corresponding higher categorical Kan extensions.

The comparison is with the homotopy category of a coherent diagram category. It does not identify that category with $\mathrm{Fun}(I^{\mathrm{op}}, h\mathcal{C}_\infty)$. Passing to the homotopy category before forming diagrams discards the compatibility of homotopies. The latching maps in the proof of Corollary 6.3 provide a concrete model-level account of precisely this compatibility: each new lift must extend the lifts already chosen, and its domain is a pushout recording those earlier choices.

Overview · XVII-b

From cofibrant diagrams to a calculus of homotopy Kan extensions

The second half of Chapter XVII supplies a construction that the preceding discussions have repeatedly needed: a homotopy theory of diagrams in a category of coefficients, compatible with changing the category of indices. Grothendieck begins with the economical axioms of a category with cofibrations and ends with projective model structures on arbitrary small diagram categories. The intervening work explains why the latter are useful. They provide a uniform source of derived adjunctions, while the earlier constructions on ordered sets explain how the resulting cofibrations can be recognized locally. The text therefore moves between two kinds of argument: a formal calculus of lifting and adjunction, and an inductive construction in which the part of a diagram already built controls the next attachment.

This is one concrete realization of the programme described in Grothendieck (1983, §69, opening discussion). A single derived category does not retain enough information about compatible constructions on complexes or spaces. One must also retain the localized categories of diagrams, together with restriction and the operations adjoint to restriction. The letter to Thomason of 2 April 1991 explains the role of the auxiliary model structures in this programme: the weak equivalences specify the homotopy theory; cofibrations and fibrations make its operations constructible (Grothendieck, 1991a, point 1, printed pp. 3–4). Chapter XVII shows both the reach of this principle and the difficulty of implementing it with a minimal axiom system.

A convention must remain visible throughout. In §3 the diagrams under construction are covariant, written $\mathcal{M}(I^\circ) = \mathrm{Fun}(I, \mathcal{M})$. In §§4–6 the notation returns to $\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})$. A left Kan extension therefore uses I/i' in the first convention and $(i'\backslash I)^{\mathrm{op}}$ in the second. Likewise, well-founded induction concerns an artinian poset in the covariant convention and a noetherian poset in the presheaf convention. The corrections and commentary preserve the printed text where it slips between these formulations, but do not treat a legitimate change of convention as a transcription error.

The adjunction must survive the construction

The first obstruction is already present in ordinary localization. An adjunction $L \dashv R$ does not automatically yield an adjunction between a functor obtained by restricting L to a convenient subcategory and the localization of R. An equivalence between the localized subcategory and the whole localization is insufficient. Grothendieck's counterexample in Remark 3.6 is decisive: localizing all arrows in a contractible category can identify it with the terminal category, while selecting a terminal object of the original category does not make that object initial. A left adjoint from the terminal category would have to select an initial object. The defect concerns the universal property of the constructed functor, not its existence as a functor.

Theorem 3.7 repairs the argument for the allowed ordered index categories. A functor is factored through its categorical mapping cylinder, or collage. One part is a closed inclusion; its left extension is extension by the initial object. The other part is a retraction with an initial object in every relevant comma category. Each part admits the localized adjunction already justified by the earlier cofibration arguments. Their composite therefore has the desired adjoint property. This is a proof, not an appeal to a general principle that localization preserves adjunctions without hypotheses.

The subsequent attempt to allow arbitrary targets exposes a separate size issue. Finite colimits do not provide the coproduct indexed by every hom-set of an arbitrary target. For example, finite sets admit the finite-branch cofibration axioms with every map a cofibration and only isomorphisms weak equivalences, but restriction from finite $\mathbb{Z}$-sets to finite sets has no free-action left adjoint. The commentary gives the argument and states precisely which additional colimits repair the construction. Later results for cocomplete cofibration categories

require corresponding infinite coproduct and sequential-colimit axioms; they should not be read back into the finite axioms of these pages.

Small generation and transfer

Sections 4 and 5 organize a second route. A special cofibration structure has enough colimits, individually accessible objects, a small family generating its cofibrations in the lifting sense, and the inclusion $C^{\square} \subseteq W$. The accessibility condition is used to run the small object argument. It does not by itself assert that the category has a small generating family of presentable objects; identifying it without qualification with local presentability would strengthen the source's hypotheses.

Given $L \dashv R$, the candidate weak equivalences in the target are detected by R, while the candidate cofibrations are built from $L(C)$ by pushouts and transfinite compositions. The central calculation is the lifting identity

$$(L(C))^{\square} = R^{-1}(C^{\square}).$$

To make this into a cofibration structure, the source requires R to preserve the relevant colimits and RL to preserve cofibrations. Preservation of trivial cofibrations is a distinct condition. This distinction explains the difficulty of identifying the transferred fibrations: they are initially defined by lifting against the transferred trivial cofibrations, whose description is the very point at issue.

The free-diagram adjunction is particularly favourable. If I_0 is the discrete category of objects of I, the left adjoint to restriction along $I_0 \to I$ sends a family (A_j) to

$$i \longmapsto \coprod_{j \in I} I(i,j) \cdot A_j.$$

For a map of families, every component of its free-diagram image is a coproduct of coefficient maps. Pushout stability and transfinite closure give the needed coproduct stability. The commentary supplies both the cardinal argument for accessibility of an entire diagram and the elementary transfinite construction of these coproducts.

Section 5 then isolates the remaining model-category problem. Put $TC = C \cap W$, $TF = C^{\square}$ and $F = (TC)^{\square}$. The established factorization gives $W = TF \circ TC$; a retract argument gives $TF = F \cap W$. To obtain a Quillen triple one needs the second factorization, into a trivial cofibration followed by a fibration. A small generating family for TC supplies it. With this second factorization, a pushout and retract argument also proves retract stability of W, justifying the later comparison with closed model categories. Under the corresponding preservation hypotheses on RL, Proposition 5.8 identifies transferred trivial cofibrations as the lifting closure of $L(TC)$ and transferred fibrations as $R^{-1}(F)$.

The distinction between a generating image, its cellular closure, its retract closure, and its double-orthogonal closure matters here. The equality suggested in footnote 23 cannot be true for the raw image of the free-diagram functor; a worked equivariant example shows why pushouts are indispensable. Proposition 5.1 also contains a displayed equality stronger than the argument preceding the additional hypotheses establishes. The audit records the precise inclusions proved and separates this unresolved strengthening from the later, correctly proved transfer theorem. We do not infer falsity merely from an incomplete justification.

The local structure of a projective cofibration

Theorem 6.1 constructs, for every small I, the model structure on $\mathcal{M}(I)$ whose weak equivalences and fibrations are objectwise. Thus every left Kan extension is a left Quillen functor and its derived functor is left adjoint to restriction. Its cofibrations are generally more restrictive than objectwise cofibrations. The rest of the chapter explains what their compatibility condition says.

For a map of arrows, the decisive map is the relative latching map

$$X_0 \amalg_{X_1} Y_1 \longrightarrow Y_0.$$

Along with the cofibration at the source of the arrow, it characterizes the projective lifting condition. Lemma 6.2.5 states this criterion but leaves its proof unwritten. The commentary proves both directions under exactly the stated pushout hypothesis. No terminal object or model-category factorization is needed for that lemma.

For a well-founded diagram, the same pushout occurs every time one extends an already constructed lift to a new object. Grothendieck uses Zorn's lemma to organize the extensions and writes out the final compatibility cube in detail. The mathematical content of that cube is that one lift from a relative latching object enforces both the pointwise lifting equation and naturality with all previous components. Corollary 6.3 correctly places the noetherian hypothesis on I in the presheaf convention. The contrary word in Theorem 6.1(d) is a genuine printed variance slip: the inverse sequence of nonempty tails of $\mathbb{N}$, with empty inverse limit, gives a counterexample to the literal artinian version. Chapter XIX, Proposition 3.2 and §3.4, subsequently uses the corrected noetherian formulation (Grothendieck, 1990–1991j).

The final proposition identifies restrictions that preserve projective cofibrations. When the connected components of each I/i' have terminal objects, right Kan extension is a product of evaluations. Right lifting classes are closed under products, and adjunction gives the preservation assertion. The commentary also develops a converse test with set-valued presheaves on a poset, making precise how much the terminal-component condition can detect.

What is settled, and what the commentary adds

The arbitrary-shape derivator construction is no longer an open problem for model categories with small limits and colimits. Cisinski proves the required homotopy Kan extension theorem without the special-generation restriction (Cisinski, 2003, Theorem 6.11 and its dual); Groth gives a projective–injective treatment in the combinatorial case (Groth, 2013, Proposition 1.30 and Theorem 1.32). For a combinatorial simplicial presentation, rectification identifies the localized diagram categories with $h\,\mathrm{Fun}(N(I^{\mathrm{op}}), \mathcal{C}_\infty)$ (Lurie, 2009, Proposition 4.2.4.4). These results concern coherent diagrams, retaining the compatibility which the latching construction makes explicit.

The developments marked [ours] are proved in the accompanying blocks and make no claim of priority. In particular, a special closed model structure on abelian groups detected by $\mathrm{Hom}(\mathbb{Z}[1/2], -)$ shows that weak equivalences need not be closed under all filtered colimits. The counterexample addresses the expectation expressed on manuscript p. 97 while respecting the chapter's generation and accessibility hypotheses. Together with the poset restriction criterion and the complete missing arrow-category proof, it turns the commentary into a mathematical continuation of the arguments at the points where a reader needs one.

4 Paratopos et l'opération $\mathcal{M} \boxtimes \mathcal{N}$

p. 1
[page 50]

4.1 Pseudo-topos. Problème du produit.

J'appelle *catégorie pseudo-$\mathfrak{U}$-topos*, ou simplement *pseudo-topos*, une $\mathfrak{U}$-catégorie $\mathcal{M}$ stable par $\mathfrak{U}$-limites inductives, et qui admet une *petite* sous-catégorie $\mathcal{M}_0$ *strictement génératrice* (i.e. génératrice par épimorphismes stricts). Alors $\mathcal{M}$ admet aussi des $\mathfrak{U}$-limites projectives (SGA 4 I 8.12.7). (Mais l'exemple de (Gr), cf. loc. cit. 8.12.9, montre que $\mathcal{M}^\circ$ n'est par forcément, pour autant, un pseudo-$\mathfrak{U}$-topos, faute à $\mathcal{M}$ d'admettre une petite sous-catégorie strictement *co*génératrice. Mais le théorème 2.6 `[du chapitre XIX]` donne des conditions sur $\mathcal{M}$ (surtout du type exactitude) pour que $\mathcal{M}$ admette assez d'injectifs – ce qui impliquera alors [page 51] l'existence d'une petite sous-catégorie strictement cogénératrice, donc que $\mathcal{M}^\circ$ est également un pseudo-topos ([1]).

Commentary · Context [ms. 50]

Why the theory of coefficients leads to cardinal arithmetic

Grothendieck is looking for categories of coefficients in which constructions on diagrams can be made uniformly. The first sentence already contains the two ingredients that will govern the chapter: arbitrary small colimits, which make extensions possible, and a small family of objects, which makes those extensions controllable. His geometrical language is deliberate. Calling a category a category of sheaves encourages us to regard a colimit-preserving functor as an inverse image, even when no topology and no left exactness have been supplied. The subsequent tensor problem will test how much of this geometrical picture survives.

There is unusually direct historical evidence for the place of this digression. In the opening paragraph of the letter of 2 April 1991 to Thomason, Grothendieck describes work on accessible categories as a return to SGA 4, I, 9, needed for his broader homotopical project; the editor identifies Chapter XVIII explicitly (Grothendieck, 1991a, opening paragraph, printed p. 2). Thus the relevance of the present pages does not have to be inferred from a modern theory of derivators. The connection to factorization methods is also internal to the manuscript: Chapter XIX, Theorem 2.6, uses accessibility, cardinal filtrations, and exactness assumptions to construct the required lifting factorizations (Grothendieck, 1990–1991j, ms. pp. 25–26).

We keep the universe fixed. "Small" means small relative to $\mathfrak{U}$, and a $\mathfrak{U}$-category has $\mathfrak{U}$-small hom-sets. The whole category need not be small. A small full subcategory $S \subset \mathcal{M}$ is strictly generating in the sense used here when its canonical families of maps reconstruct objects and their morphisms; equivalently in this cocomplete setting, the restricted Yoneda functor

$$\rho_S : \mathcal{M} \longrightarrow [S^{\mathrm{op}}, \mathrm{Ens}], \qquad x \longmapsto \mathcal{M}(-, x)|_S$$

is fully faithful. Such a subcategory is called dense in current terminology. In particular,

$$x \simeq \operatorname*{colim}_{(s \to x) \in S/x} s.$$

The category S/x is small: its objects form a small union of hom-sets and its arrows a small union of subsets of hom-sets of S. This observation is where the size of the generating family first does mathematical work.

A pseudo-topos category here is consequently a cocomplete category with a small dense subcategory. It is not assumed accessible in the modern sense, and the adjective does not assert the exactness axioms of a topos. Later, the paratopos condition adds a uniform presentability bound on a small generating family; the resulting categories are the locally presentable categories. We establish that identification in the commentary to Section 4.3, with the cardinal convention made explicit. It should not be read back into the first definition.

For the diagram-theoretic motivation, the commentary on Chapter I, manuscript p. 4 ("From derived coefficients to diagram categories"), and on Chapter XII, manuscript p. 225 ("Smoothness and properness depend on a coefficient theory"), provides the appropriate continuity. Here we develop the additional size arguments, rather than repeating the construction of a derivator from a relative category.

1. C'est le cas notamment si $\mathcal{M}$ est un topos.

Je visualise les catégories pseudo-topos comme étant la catégorie des "faisceaux" sur un objet $\mathcal{X}$, visualisé comme une sorte d'"espace" que je distingue de la catégorie $\mathcal{M} = \mathrm{Fais}(\mathcal{X})$ des faisceaux sur $\mathcal{X}$. C'est $\mathcal{X}$ qui sera pour ceci le "pseudo-topos". Les pseudo-topos forment une 2-catégorie, la variance dans $\mathcal{X}$ étant opposée de celle dans $\mathrm{Fais}(\mathcal{X}) = \mathcal{M}$. De façon précise, si $\mathcal{X}$ correspond à $\mathcal{M}$, $\mathcal{Y}$ à $\mathcal{N}$, un morphisme f de $\mathcal{X}$ dans $\mathcal{Y}$ sera donné par un foncteur

$$f^* \ : \ \mathcal{N} \longrightarrow \mathcal{M} \tag{4.1.1}$$

en sens inverse, commutant aux $\varinjlim$ inductives quelconques ([2]). (**N.B.** si $\mathcal{X}$, $\mathcal{Y}$ sont même des topos, i.e. $\mathcal{M}$, $\mathcal{N}$ des catégories-topos, et si on veut que f soit un morphisme de topos, on exigera de plus que f^* soit de plus *exact à gauche*. On dira qu'un *morphisme de pseudo-topos est exact* si de plus f^* est exact à gauche.)

En vertu du dual de loc. cit. 8.12.7, cela équivaut au fait que f^* admette un adjoint à droite f_*, [page 52]

$$f_* \ : \ \mathcal{M} \longrightarrow \mathcal{N} \ , \tag{4.1.2}$$

lequel commute donc aux petites $\varprojlim$. La donnée de f_* satisfaisant à cette propriété détermine donc f^* à isomorphisme unique près. Mais en général, il ne suffit pas de se donner un tel f_*, pour pouvoir affirmer qu'il corresponde à un f^*, i.e. qu'il admette un adjoint à droite ; pour ceci, il faudrait qu'on sache que les foncteurs $\mathcal{M} \longrightarrow \mathrm{Ens}$ qui commutent aux petites $\varprojlim$ sont représentables, ce qui sera le cas si $\mathcal{M}$ admet une petite sous-catégorie *co*génératrice, i.e. si $\mathcal{M}^\circ$ est également une catégorie pseudo-topos.

2. Dire ici que les objets de $\mathcal{M}$ sont visualisés comme des "ouverts" généralisés de $\mathcal{X}$. On a $\mathcal{M} \xrightarrow{\sim} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ, \mathrm{Ens})$, i.e. $\mathcal{M}$ s'interprète bel et bien comme les "faisceaux" sur cette catégorie $\mathcal{M}$ d'ouverts …

Il est sans doute judicieux de procéder comme dans le cas des topos, et d'appeler *morphisme de pseudo-topos* $f : \mathcal{X} \longrightarrow \mathcal{Y}$ un quadruple p. 2

$$(f^*, f_*, \alpha, \beta) \tag{4.1.3}$$

de deux foncteurs adjoints (f^*, f_*), et des morphismes d'adjonction. Quand f^* est une équivalence, ce qui équivaut à f_* une équivalence, ou α et β des isomorphismes, on dira qu'on a une *équivalence de pseudo-topos*, et à toutes fins pratiques, on pourra alors regarder $\mathcal{X}$ et $\mathcal{Y}$ comme des objets essentiellement identiques. [page 53]

Commentary · Exposition [ms. 52]

Adjoints, representability, and the direction of a morphism

Grothendieck wants to recover the direct image from the inverse image, just as for a geometric morphism of topoi. The relevant existence theorem is the dual special adjoint functor theorem. In the present situation it says that a colimit-preserving functor out of a pseudo-topos category has a right adjoint. The representability statement used is SGA 4, I, Corollaries 8.12.7–8.12.8, applied to the opposite category (Artin et al., 1972).

Here is the application with its variance exposed. If $L : \mathcal{N} \to \mathcal{M}$ preserves small colimits and $m \in \mathcal{M}$, then

$$n \longmapsto \mathcal{M}(Ln, m) : \mathcal{N}^{\mathrm{op}} \longrightarrow \mathrm{Ens}$$

sends colimits in $\mathcal{N}$ to limits of sets. Representability provides an object Rm and bijections

$$\mathcal{M}(Ln, m) \simeq \mathcal{N}(n, Rm).$$

Yoneda makes these choices functorial in m and gives $L \dashv R$. Applying the same argument to the diagonal $\mathcal{M} \to \mathcal{M}^I$, which preserves colimits, supplies all small limits in $\mathcal{M}$. No assertion that $\mathcal{M}^{\mathrm{op}}$ is another pseudo-topos is needed for either step.

The converse problem starts with R, not with L. Preservation of limits alone does not give a left adjoint on an arbitrary complete category. The small cogenerating hypothesis on $\mathcal{M}$ is a sufficient condition; it permits the undualized representability theorem to be applied to $m \mapsto \mathcal{N}(n, Rm)$. The printed phrase "un adjoint à droite" at the end of manuscript p. 52 has the wrong direction: the missing adjoint to f_* is the left adjoint f^*. This is an edition slip, retained in the source and registered separately.

The asymmetry can already be seen in groups. There are arbitrarily large simple groups, for example the finitary alternating groups on sufficiently large infinite sets. Given a small family of groups (G_i), choose a simple group H whose cardinal exceeds every $|G_i|$. Every homomorphism $H \to G_i$ is trivial, since a nontrivial map from a simple group is injective. Such maps cannot separate the identity endomorphism of H from the trivial endomorphism. Thus no small family cogenerates groups, although finite free groups give a small generating supply. This independently explains the obstruction invoked in SGA 4, I, 8.12.9; it is not an objection to the existence of right adjoints to colimit-preserving functors out of groups.

Finally, an adjunction includes its unit and counit. The equivalence between descriptions by left and right adjoints reverses natural transformations: a transformation $L \Rightarrow L'$ corresponds to a transformation $R' \Rightarrow R$. This is the reason for the opposite category in (4.1.5). Invertible unit and counit characterize an adjoint equivalence. Requiring f^* also to preserve finite limits gives the usual extra condition for a geometric morphism when the coefficient categories are topoi; it is an additional requirement, not a consequence of having an adjoint.

Pour deux pseudo-topos $\mathcal{X}$, $\mathcal{Y}$, j'ai envie d'introduire (comme dans le cas des topos) un pseudo-topos produit

$$\mathcal{X} \times \mathcal{Y}\,, \tag{4.1.4}$$

qui ait les propriétés d'un 2-produit dans la 2-catégorie des pseudo-topos ([3]). Je devrais

3. Il apparaît finalement que ce qu'on construit n'est *pas* un 2-produit dans la 2-catégorie envisagée, donc il vaut mieux le noter par un signe tel que $\mathcal{X} \boxtimes \mathcal{Y}$. Mais si $\mathcal{X}$, $\mathcal{Y}$ sont deux topos, $\mathcal{X} \boxtimes \mathcal{Y}$ est un 2-produit dans la 2-catégorie des topos.

préciser que par définition

$$\begin{aligned}\underline{\mathrm{Hom}}_{\mathrm{pstop}}(\mathcal{X},\mathcal{Y}) &\simeq \underline{\mathrm{Hom}}_{!}(\mathcal{F}(\mathcal{Y}),\mathcal{F}(\mathcal{X}))^{\circ}\\ &\simeq \underline{\mathrm{Hom}}^{!'}(\mathcal{F}(\mathcal{X}),\mathcal{F}(\mathcal{Y})),\end{aligned} \tag{4.1.5}$$

où l'indice ! (resp. l'exposant !) indique la sous-catégorie pleine dans la catégorie $\underline{\mathrm{Hom}}$ envisagée formée des foncteurs qui commutent aux petites $\varinjlim$ (resp. aux petites $\varprojlim$), et l'accent dans le $\underline{\mathrm{Hom}}^{!'}$ dans le dernier membre indique qu'on exige de plus que le foncteur en question ait un adjoint à gauche. [page 54]

Soient donc

$$\mathcal{M} = \mathcal{F}(\mathcal{X}), \qquad \mathcal{N} = \mathcal{F}(\mathcal{Y}), \tag{4.1.6}$$

et soit $\mathcal{Z}$ un troisième pseudo-topos, décrit par

$$\mathcal{P} = \mathcal{F}(\mathcal{Z}). \tag{4.1.7}$$

On veut expliciter, à équivalence près, la catégorie produit $\underline{\mathrm{Hom}}_{\mathrm{pstop}}(\mathcal{Z},\mathcal{X}) \times \underline{\mathrm{Hom}}_{\mathrm{pstop}}(\mathcal{Z},\mathcal{Y})$, i.e.

$$\underline{\mathrm{Hom}}_{!}(\mathcal{M},\mathcal{P})^{\circ} \times \underline{\mathrm{Hom}}_{!}(\mathcal{N},\mathcal{Q})^{\circ}. \tag{4.1.8}$$

Je vais introduire pour cela une catégorie p. 3 [page 55]

$$\mathcal{M}\boxtimes\mathcal{N} \tag{4.1.9}$$

par la formule

$$\mathcal{M}\boxtimes\mathcal{N} \simeq \underline{\mathrm{Hom}}^{!!}(\mathcal{M}^{\circ}\times\mathcal{N}^{\circ},\mathrm{Ens}), \tag{4.1.10}$$

où le signe $\underline{\mathrm{Hom}}^{!!}$ désigne la sous-catégorie pleine de la catégorie $\underline{\mathrm{Hom}}$, formée des bi-contrafoncteurs

$$F : \mathcal{M}^{\circ}\times\mathcal{N}^{\circ} \longrightarrow \mathrm{Ens}, \tag{4.1.10.1}$$

tels que pour tout x dans $\mathcal{M}$, le foncteur

$$y \longmapsto F(x,y) : \mathcal{N}^{\circ} \longrightarrow \mathrm{Ens} \tag{4.1.10.2}$$

soit dans $\underline{\mathrm{Hom}}^{!}(\mathcal{N}^{\circ},\mathrm{Ens})$, i.e. transforme petites $\varinjlim$ en $\varprojlim$, et que, symétriquement, pour tout y dans $\mathcal{N}$, le foncteur

$$x \longmapsto F(x,y) : \mathcal{M}^{\circ} \longrightarrow \mathrm{Ens} \tag{4.1.10.3}$$

soit dans $\underline{\mathrm{Hom}}^{!}(\mathcal{M}^{\circ},\mathrm{Ens})$. Mais cela signifie aussi que ces foncteurs sont *représentables*; donc on trouve aussi

$$\mathcal{M}\boxtimes\mathcal{N} \xleftarrow{\sim} \underline{\mathrm{Hom}}^{!}(\mathcal{N}^{\circ},\mathcal{M}) \tag{4.1.11}$$

et

$$\mathcal{M}\boxtimes\mathcal{N} \xleftarrow{\sim} \underline{\mathrm{Hom}}^{!}(\mathcal{M}^{\circ},\mathcal{N}) \tag{4.1.12}$$

en utilisant (dans chacune de ces formules) dans deux côtés les équivalences de catégories [page 56]

$$\begin{cases}\mathcal{M} & \xrightarrow{\sim} \underline{\mathrm{Hom}}^{!}(\mathcal{M}^{\circ},\mathrm{Ens})\\ \mathcal{N} & \xrightarrow{\sim} \underline{\mathrm{Hom}}^{!}(\mathcal{N}^{\circ},\mathrm{Ens}).\end{cases} \tag{4.1.13}$$

On peut dire aussi que la catégorie $\mathcal{M} \boxtimes \mathcal{N}$ est équivalente à celle des *couples* de foncteurs

$$\begin{cases} \varphi & : & \mathcal{M}^\circ & \longrightarrow & \mathcal{N} \\ \psi & : & \mathcal{N}^\circ & \longrightarrow & \mathcal{M}\,, \end{cases} \tag{4.1.14}$$

munis de deux morphismes d'adjonction

$$\begin{cases} \psi\varphi^\circ & \overset{\alpha}{\longleftarrow} & \mathrm{id}_{\mathcal{M}} \\ \varphi\psi^\circ & \overset{\beta}{\longleftarrow} & \mathrm{id}_{\mathcal{N}} \end{cases} \tag{4.1.15}$$

satisfaisant les deux compatibilités habituelles exprimant l'adjonction de φ° et de ψ (ou, de façon équivalente, de ψ° et de φ). Le foncteur

$$(\varphi, \psi) \longmapsto \varphi \qquad (\text{resp. } (\varphi, \psi) \longmapsto \psi)$$

donne une équivalence de la catégorie de ces couples avec $\underline{\mathrm{Hom}}^!(\mathcal{M}^\circ, \mathcal{N})$ (resp. avec $\underline{\mathrm{Hom}}^!(\mathcal{N}^\circ, \mathcal{M})$), de sorte qu'on a un carré commutatif d'équivalences canoniques de foncteurs :

Commentary · Exposition [ms. 54]

The actual product and the proposed tensor

The attempted product is useful because it makes Grothendieck identify the universal property he really needs. Two inverse-image functors into a coefficient category and one functor preserving colimits separately in two variables carry different information. The former already have a simple representing category.

Let $\mathcal{M}, \mathcal{N}, \mathcal{P}$ be pseudo-topos categories, and denote by $\mathrm{Cocont}(\mathcal{A}, \mathcal{B})$ the category of colimit-preserving functors and natural transformations. There is an equivalence

$$\mathrm{Cocont}(\mathcal{M} \times \mathcal{N}, \mathcal{P}) \simeq \mathrm{Cocont}(\mathcal{M}, \mathcal{P}) \times \mathrm{Cocont}(\mathcal{N}, \mathcal{P}).$$

To prove it, write 0 for initial objects and use the two inclusions $m \mapsto (m, 0)$ and $n \mapsto (0, n)$. Every pair (m, n) is canonically the coproduct of $(m, 0)$ and $(0, n)$. A cocontinuous F therefore satisfies

$$F(m, n) \simeq F(m, 0) \amalg F(0, n).$$

Conversely, two cocontinuous functors G, H determine $F(m, n) = G(m) \amalg H(n)$; interchange of colimits shows that F is cocontinuous. A natural transformation between two such functors is uniquely the coproduct of its restrictions. These constructions are mutually inverse up to the indicated canonical isomorphisms. Moreover, $\mathcal{M} \times \mathcal{N}$ is a pseudo-topos category: colimits are coordinatewise, and the union of the two small strictly generating families $(s, 0)$ and $(0, t)$ is strictly generating.

After reversing the variance and the two-cells as in (4.1.5), this is precisely the bicategorical product of pseudo-topoi. The tensor category which the text is about to define solves a different universal problem, once its existence has been established:

$$\mathrm{Cocont}(\mathcal{M} \boxtimes \mathcal{N}, \mathcal{P}) \simeq \mathrm{Cocont}_2(\mathcal{M} \times \mathcal{N}, \mathcal{P}),$$

where the subscript 2 means preservation of colimits in each variable separately. We will use this formula only in the accessible setting or in the explicit examples where it is proved.

The difference is visible without large categories of coefficients. For sets, separate continuity of the contravariant bifunctor gives

$$F(X, Y) \simeq F(1, 1)^{X \times Y},$$

since X and Y are coproducts of singleton sets. Hence $\mathrm{Ens} \boxtimes \mathrm{Ens} \simeq \mathrm{Ens}$, whereas the category representing the first displayed universal property is $\mathrm{Ens} \times \mathrm{Ens}$. These categories are not equivalent: the terminal object of Ens has two subobjects, while the terminal object of $\mathrm{Ens} \times \mathrm{Ens}$ has four. The footnote on manuscript p. 53 correctly retracts the product interpretation. Within the smaller bicategory of topoi and geometric morphisms, imposing left exactness changes the problem and recovers the geometrical product; the two bicategories must not be interchanged. p. 4 [page 57]

Commentary · Exposition [ms. 56]

Birepresentability and contravariant adjunctions

Grothendieck's definition packages a candidate coefficient object by all of its pairings with objects in the two factors. This is why a bifunctor, rather than a pair of functors, is the natural starting point. Fix $F : \mathcal{M}^{\mathrm{op}} \times \mathcal{N}^{\mathrm{op}} \to \mathrm{Ens}$ preserving limits separately. Representability in the first variable gives objects $\psi(y) \in \mathcal{M}$ such that

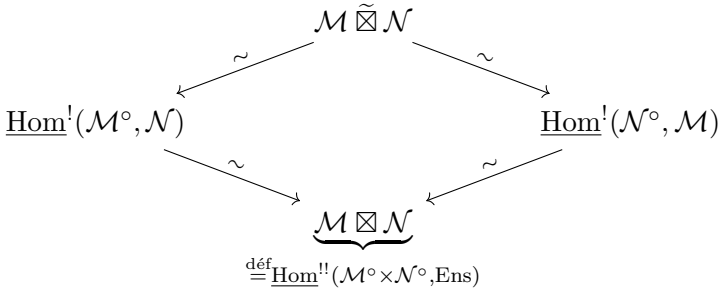
$$F(x, y) \simeq \mathcal{M}(x, \psi(y)).$$

An arrow $y' \to y$ in $\mathcal{N}$ induces a transformation $F(-, y) \to F(-, y')$ and therefore an arrow $\psi(y) \to \psi(y')$. This determines a functor $\psi : \mathcal{N}^{\mathrm{op}} \to \mathcal{M}$. It preserves limits because each representable $\mathcal{M}(x, -)$ does, and the family of all representables detects a limiting cone. Representing in the other variable gives $\varphi : \mathcal{M}^{\mathrm{op}} \to \mathcal{N}$ and the natural bijection

$$\mathcal{N}(y, \varphi(x)) \simeq F(x, y) \simeq \mathcal{M}(x, \psi(y)).$$

Thus $\varphi^{\mathrm{op}} : \mathcal{M} \to \mathcal{N}^{\mathrm{op}}$ is left adjoint to ψ. The apparent two units in (4.1.15) are the unit and the opposite of the counit of this ordinary adjunction. Their triangular identities, not just the existence of two comparison arrows, are required.

The argument also works on morphisms. A transformation $F \to F'$ gives compatible transformations $\psi \to \psi'$ and $\varphi \to \varphi'$ by Yoneda. Conversely, either transformation determines the bifunctor transformation. This proves the equivalences (4.1.11)–(4.1.16), including their two-cell content. An object of the tensor is therefore a contravariant adjunction, not a cocontinuous functor from $\mathcal{M}$ to $\mathcal{N}$.



Small limits of such bifunctors are calculated pointwise. Indeed, if (F_i) is a diagram and (x_j) a colimit diagram in $\mathcal{M}$, then

$$\left(\lim_i F_i\right)(\mathrm{colim}_j x_j, y) \simeq \lim_i \lim_j F_i(x_j, y) \simeq \lim_j \lim_i F_i(x_j, y).$$

The interchange is the universal property of limits in sets, with no filteredness assumption. The same argument treats the other variable. This establishes completeness. It does not construct coproducts or a left adjoint to the forthcoming inclusion in a presheaf category. The sentence on p. 57 announcing that the tensor is a pseudo-topos is a proposed conclusion; the questions immediately following it and the later footnote to Lemma 4.2.3 show that it is not yet proved.

There is also a precise size benefit to restricting both variables to small dense subcategories. Once Corollary 4.2.2 is established, transformations between two candidate tensors form a subset of a product indexed by $\mathrm{Ob}(S \times T)$ of small sets. This proves local smallness of the candidate tensor before cocompleteness is known. The restriction theorem addresses the size of hom-sets; accessibility will address the size of constructions.

(4.1.16)

[où $\mathcal{M} \widetilde{\boxtimes} \mathcal{N}$ est la catégorie des couples définie dans la page précédente.]

Je dis que $\mathcal{M} \boxtimes \mathcal{N}$ *est une catégorie pseudo-topos*. Il est clair, [en] outre, qu'elle admet des petites $\varprojlim$, qui se calculent argument par argument dans $\underline{\mathrm{Hom}}(\mathcal{M}^\circ \times \mathcal{N}^\circ, \mathrm{Ens})$, ou au choix dans $\underline{\mathrm{Hom}}^!(\mathcal{M}^\circ, \mathcal{N})$, ou $\underline{\mathrm{Hom}}^!(\mathcal{N}^\circ, \mathcal{M})$. Comment construire des petites $\varinjlim$? Il n'est pas question d'invoquer un argument de cogénérateurs. Il faut d'ailleurs trouver aussi une

petite sous-catégorie strictement génératrice. Visiblement, il y a quelque chose de non trivial à démontrer !

4.2 Cafouillages sur $\mathcal{M} \boxtimes \mathcal{N}$

Revenons à la situation générale d'un pseudo-topos $\mathcal{X}$, décrit par la catégorie pseudo-topos $\mathcal{M}$. Si $\mathcal{N}$ est une catégorie quelconque, on définit la catégorie [page 58]

$$\mathrm{Fais}(\mathcal{X},\mathcal{N}) \qquad \text{ou} \qquad \mathcal{F}(\mathcal{X},\mathcal{N})$$

des faisceaux sur $\mathcal{X}$, à valeurs dans $\mathcal{N}$, par

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathcal{N}) \ . \tag{4.2.1}$$

On a donc un foncteur pleinement fidèle

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathcal{N}) \hookrightarrow \mathrm{Hom}^!(\mathcal{N}^\circ,\overline{\mathcal{M}}) \ , \tag{4.2.2}$$

où $\overline{\mathcal{M}}$ désigne la sous-catégorie de $\mathcal{M}^\wedge$ (**N.B.** $\mathcal{M}^\wedge$ n'est pas en général une $\mathcal{U}$-catégorie qu'à cela ne tienne) formée des foncteurs *représentables* $\mathcal{M}^\circ \longrightarrow \mathrm{Ens}$ (laquelle est une $\mathfrak{U}$-catégorie, équivalente à $\mathcal{M}$ par l'inclusion canonique $\mathcal{M} \hookrightarrow \overline{\mathcal{M}}$). Donc on a à isomorphisme unique près une factorisation de (4.2.2) en

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{pl. fid.}}{\hookrightarrow} \underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,\mathcal{M}) \ , \tag{4.2.3}$$

l'image essentielle étant formée des foncteurs

$$\psi \ : \ \mathcal{N}^\circ \longrightarrow \mathcal{M}$$

tels que pour tout x dans $\mathcal{M}$,

$$y \longmapsto \mathrm{Hom}(y,\psi(x)) \ : \ \mathcal{N}^\circ \longrightarrow \mathrm{Ens}$$

soit représentable, i.e. des foncteurs qui admettent un *adjoint à gauche*. Quand $\mathcal{N}$ lui-même est une catégorie pseudo-topos, cette condition est automatique (elle résulte de l'hypothèse p. 5
que ψ commute aux petites $\varprojlim$). Donc dans ce cas, (4.2.3) est une équivalence de catégories. [page 59]

Soit maintenant S (S comme "site") une *petite* sous-catégorie de $\mathcal{M}$, génératrice par épimorphismes stricts. On sait que cela signifie que le foncteur composé

$$\mathcal{M} \overset{\sim}{\longrightarrow} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathrm{Ens}) \xrightarrow{\text{restriction à } S} S^\wedge \ (\overset{\text{déf}}{=} \underline{\mathrm{Hom}}(S^\circ,\mathrm{Ens})) \tag{4.2.4}$$

est pleinement fidèle, et ceci implique plus généralement, que pour toute catégorie $\mathcal{N}$, le foncteur restriction

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathcal{N}) \overset{\text{pl. fid.}}{\hookrightarrow} \underline{\mathrm{Hom}}(S^\circ,\mathcal{N}) \tag{4.2.5}$$

est pleinement fidèle. En effet, le deuxième membre, via le plongement pleinement fidèle

$$\mathcal{N} \overset{\text{pl. fid.}}{\hookrightarrow} \underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,\mathrm{Ens}) \hookrightarrow \mathcal{N}^\wedge \ ,$$

se plonge dans

$$\underline{\mathrm{Hom}}(S^\circ,\underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,\mathrm{Ens})) \simeq \mathrm{Hom}^!(\mathcal{N}^\circ,S^\wedge) \ ,$$

et la pleine fidélité de (4.2.5) équivaut donc à celle du foncteur composé

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathcal{N}) \longrightarrow \underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,S^\wedge) \simeq \underline{\mathrm{Hom}}(S^\circ,\underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,\mathrm{Ens})) \ . \tag{4.2.6}$$ [page 60]

Or on a commutativité dans le carré

$$\begin{array}{ccc} \mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathcal{N}) & \xrightarrow{(4.2.5)} & \underline{\mathrm{Hom}}(S^\circ,\mathcal{N}) \\ {\scriptstyle (4.2.3)}\big\downarrow \text{pleinement fidèle} & & \big\downarrow \text{pleinement fidèle} \\ \underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,\mathcal{M}) & \xrightarrow[\text{pleinement fidèle}]{(4.2.4)} & \underbrace{\underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,S^\wedge)}_{\simeq \underline{\mathrm{Hom}}(S^\circ,\underline{\mathrm{Hom}}^!(\mathcal{N}^\circ,\mathrm{Ens}))} \end{array} \tag{4.2.7}$$

(où les flèches verticales sont des équivalences, si $\mathcal{N}$ est lui-même une catégorie pseudo-topos). Notons d'autre part que l'on a une équivalence

$$\underline{\mathrm{Hom}}(S^\circ,\mathcal{N}) \xleftarrow{\sim} \underline{\mathrm{Hom}}^!(S^{\wedge\circ},\mathcal{N}) \overset{\text{déf}}{=} \mathcal{F}(\mathrm{Top}(S),\mathcal{N}) , \tag{4.2.8}$$

où $\mathrm{Top}(S)$ est le pseudo-topos (en fait, un topos) défini par la catégorie pseudo-topos $S^\wedge$. Pour ceci, notons qu'on a

$$\underline{\mathrm{Hom}}^!(S^{\wedge\circ},\mathcal{N}) \xrightarrow{\sim} \underline{\mathrm{Hom}}_!(S^\wedge,\mathcal{N}^\circ)^\circ ,$$

et d'autre part le foncteur restriction à $S \hookrightarrow S^\wedge$ donne

$$\underline{\mathrm{Hom}}_!(S^\wedge,\mathcal{N}^\circ) \xrightarrow{\sim} \underline{\mathrm{Hom}}(S,\mathcal{N}^\circ) ,$$

d'où

$$\underline{\mathrm{Hom}}(S^{\wedge\circ},\mathcal{N}) \xrightarrow{\sim} (\underline{\mathrm{Hom}}(S,\mathcal{N}^\circ))^\circ \xrightarrow{\sim} \underline{\mathrm{Hom}}(S^\circ,\mathcal{N}) ,$$

p. 6
[page 61]

ce qui n'est autre que (4.2.8). Ainsi :

Commentary · Exposition [ms. 59]

Density reconstructs a continuous functor

The move to a small site is the first effective reduction in the tensor problem. Grothendieck needs to remember a limit-preserving functor on a small collection of test objects, and density supplies exactly that reconstruction. It is helpful to prove full faithfulness directly, so that no completeness of an arbitrary target is silently inserted.

Let $S \subset \mathcal{M}$ be small and dense, and let $F, G : \mathcal{M}^{\mathrm{op}} \to \mathcal{N}$ preserve all small limits of $\mathcal{M}^{\mathrm{op}}$. This formulation includes the requirement that the relevant image cones have limits in $\mathcal{N}$. For each x, density gives $x = \mathrm{colim}_{S/x} s$, hence

$$F(x) \simeq \lim_{(S/x)^{\mathrm{op}}} F(s), \qquad G(x) \simeq \lim_{(S/x)^{\mathrm{op}}} G(s).$$

Given a transformation $\eta : F|_{S^{\mathrm{op}}} \to G|_{S^{\mathrm{op}}}$, compose the projections from $F(x)$ with the maps η_s. They form a cone to the diagram defining $G(x)$, and therefore give a unique map $\eta_x : F(x) \to G(x)$. If $u : x \to x'$ is an arrow in $\mathcal{M}$, both composites from $F(x')$ to $G(x)$ have the same projections to every $G(s)$ indexed by $s \to x$; they are equal. Thus η_x is natural in x. Uniqueness follows from the same limiting projections. This proves (4.2.5) for any $\mathcal{N}$ in which the functors under consideration exist.

The symmetry construction has an equally transparent formula. Given F, represent in $\mathcal{M}$ the functor

$$x \longmapsto \mathcal{N}(y, Fx),$$

for each $y \in \mathcal{N}$. The resulting $\psi : \mathcal{N}^{\mathrm{op}} \to \mathcal{M}$ lies in the image exactly when, for every x, the presheaf

$$y \longmapsto \mathcal{M}(x, \psi(y))$$

is representable in $\mathcal{N}$. This is the well-typed formula intended on manuscript p. 58. The printed $\mathrm{Hom}(y, \psi(x))$ interchanges the variables and cannot be evaluated with the stated types. In terms of adjunctions, ψ must have a left adjoint $\mathcal{M} \to \mathcal{N}^{\mathrm{op}}$.

Now take both coefficient categories to be pseudo-topos categories. Restrict first along $S \subset \mathcal{M}$ and then along $T \subset \mathcal{N}$. The argument just given proves

$$\mathcal{M} \boxtimes \mathcal{N} \longhookrightarrow [(S \times T)^{\mathrm{op}}, \mathrm{Ens}]$$

fully faithful. It also explains why the construction respects natural transformations, an issue that cannot be settled merely by asserting that every object is a colimit of generators. The functors being reconstructed must carry those presentations to the appropriate limits. This qualification will reappear in the proof of Theorem 4.4.16.

Proposition 4.2.1. *Soient $\mathcal{M} = \mathcal{F}(\mathcal{X})$ une catégorie pseudo-topos, munie d'une sous-catégorie pleine strictement génératrice S, $\mathcal{N}$ une $\mathfrak{U}$-catégorie quelconque, alors le foncteur "restriction à S" suivant est pleinement fidèle.*

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^{!}(\mathcal{M}^{\circ},\mathcal{N}) \longrightarrow \underline{\mathrm{Hom}}(S^{\circ},\mathcal{N}) \xleftarrow{\sim} \underbrace{\underline{\mathrm{Hom}}(S^{\wedge\circ},\mathcal{N})}_{\overset{\text{déf}}{=}\mathcal{F}(\mathrm{Top}(S),\mathcal{N})} , \tag{4.2.1.1}$$

et il s'insère dans le carré commutatif (4.2.7) de foncteurs pleinement fidèles.

Corollaire 4.2.2. *Supposons que $\mathcal{N} = \mathcal{F}(\mathcal{Y})$ soit également une catégorie pseudo-topos, munie d'une sous-catégorie pleine T strictement génératrice. Alors*

$$\mathcal{F}(\mathcal{X},\mathcal{N}) \simeq \mathcal{F}(\mathcal{Y},\mathcal{M}) \simeq \underbrace{\underline{\mathrm{Hom}}^{!!}(\mathcal{M}^{\circ} \times \mathcal{N}^{\circ}, \mathrm{Ens})}_{=\mathcal{M}\boxtimes\mathcal{N}} ,$$

et le foncteur restriction

$$\begin{aligned} \mathcal{M} \boxtimes \mathcal{N} \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^{!!}(\mathcal{M}^{\circ} \times \mathcal{N}^{\circ}, \mathrm{Ens}) &\longrightarrow \underline{\mathrm{Hom}}(S^{\circ} \times T^{\circ}, \mathrm{Ens}) \\ &\simeq (S \times T)^{\wedge} \\ &\overset{\text{déf}}{=} \mathcal{F}(\mathrm{Top}(S \times T)) \end{aligned} \tag{4.2.2.1}$$

est pleinement fidèle.

La première assertion a été vue dans 4.1. Pour la pleine fidélité de (4.2.2.1), on note que ce foncteur s'interprète, à équivalence de catégories près, comme le composé du foncteur pleinement fidèle (4.2.1.1), et du foncteur similaire relatif à $\mathcal{N}$ (donc lui aussi pleinement fidèle)

[page 62]

$$\mathcal{F}(\mathcal{Y}, S^{\wedge}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^{!}(\mathcal{N}^{\wedge}, S^{\wedge}) \xrightarrow{\text{restr. à } T} \underbrace{\underline{\mathrm{Hom}}(T^{\circ}, S^{\wedge})}_{\underline{\mathrm{Hom}}(S^{\circ}\times T^{\circ},\mathrm{Ens})} , \tag{4.2.2.2}$$

compte tenu de l'équivalence de symétrie

$$\mathcal{F}(\mathcal{Y}, S^{\wedge}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}^{!}(\mathcal{N}^{\circ}, S^{\wedge}) \simeq \underline{\mathrm{Hom}}^{!}(S^{\wedge\circ}, \mathcal{N}) . \tag{4.2.2.3}$$

Commentary · Examples [ms. 61]

The missing completeness hypothesis in the presheaf equivalence

The restriction theorem is sound, but the displayed equivalence (4.2.8) asks for more: every functor $S^{\mathrm{op}} \to \mathcal{N}$ is supposed to extend continuously to $\widehat{S}^{\mathrm{op}}$. For an arbitrary $\mathcal{N}$ this is false. The free-cocompletion argument in the text is being applied with target $\mathcal{N}^{\mathrm{op}}$, which needs the colimits used by that argument.

Take S to be the category with one object and only its identity, so that $\widehat{S} = \mathrm{Ens}$, and take $\mathcal{N} = \mathrm{FinSet}$. A functor $S^{\mathrm{op}} \to \mathcal{N}$ can select the two-element set 2. If it extended to a continuous $F : \mathrm{Ens}^{\mathrm{op}} \to \mathrm{FinSet}$, the countable coproduct decomposition $\mathbb{N} = \coprod_{n\in\mathbb{N}} 1$ would force

$$F(\mathbb{N}) \simeq \prod_{n\in\mathbb{N}} 2.$$

No finite set represents this product in FinSet: testing the product universal property on 1 would give a bijection from a finite set to the infinite set $2^{\mathbb{N}}$. Thus restriction is not essentially surjective. This counterexample concerns the claimed equivalence, not the already proved full faithfulness of restriction.

Here is the sufficient hypothesis and its proof. Suppose $\mathcal{N}$ has all small limits and let $A : S^{\mathrm{op}} \to \mathcal{N}$. For a presheaf P, define

$$\overline{A}(P) = \lim_{(S/P)^{\mathrm{op}}} A(s).$$

The category of elements S/P is small. For $n \in \mathcal{N}$, the universal property gives

$$\mathcal{N}(n, \overline{A}(P)) \simeq \mathrm{Nat}\big(P, \mathcal{N}(n, A(-))\big).$$

The right-hand side carries colimits in P to limits of sets. Since representables detect limits, $\overline{A}$ carries colimits of presheaves to limits in $\mathcal{N}$. For $P = h_s$, Yoneda identifies $\overline{A}(h_s)$ with $A(s)$. The density argument of the preceding block gives uniqueness on objects and on transformations. Therefore

$$[S^{\mathrm{op}}, \mathcal{N}] \simeq \mathrm{Cont}(\widehat{S}^{\mathrm{op}}, \mathcal{N})$$

under the completeness hypothesis.

There are also two missing superscripts in the printed formulas on p. 61: the initial equivalence and the final term of (4.2.1.1) use unrestricted $\underline{\mathrm{Hom}}(\widehat{S}^{\mathrm{op}}, \mathcal{N})$ where the continuous functors $\underline{\mathrm{Hom}}^!$ are intended. Adding these superscripts repairs the notation but does not repair the missing hypothesis on $\mathcal{N}$. Corollary 4.2.2 takes $\mathcal{N}$ to be a pseudo-topos category, which is complete, so the corollary survives intact.

Au total, quand $\mathcal{M}$, $\mathcal{N}$ sont tous deux des catégories pseudo-topos, munies de sous-catégories strictement génératrices S resp. T, on a un plongement pleinement fidèle canonique

$$\mathcal{M} \boxtimes \mathcal{N} \xhookrightarrow{\ \rho\ } (S \times T)^{\wedge} , \tag{4.2.9}$$

qu'on interprète par la suite comme $(f_S^{\mathcal{M}} \times f_T^{\mathcal{N}})_*$, où

$$\begin{cases} f_S^{\mathcal{M}} \ : \ \mathcal{X} \longrightarrow \mathrm{Top}S \\ f_T^{\mathcal{N}} \ : \ \mathcal{Y} \longrightarrow \mathrm{Top}T \end{cases} \tag{4.2.10}$$

p. 7

sont les morphismes de pseudo-topos, donnés par les plongements pleinement fidèles (foncteurs image directe)

$$\begin{cases} (f_S^{\mathcal{M}})_* \ : \ \mathcal{M} \longrightarrow S^{\wedge} \\ (f_T^{\mathcal{N}})_* \ : \ \mathcal{N} \longrightarrow T^{\wedge} , \end{cases} \tag{4.2.11}$$

lesquels admettent bel et bien des adjoints à gauche

$$\begin{cases} (f_S^{\mathcal{M}})^* \ : \ S^{\wedge} \longrightarrow \mathcal{M} \\ (f_T^{\mathcal{N}})^* \ : \ T^{\wedge} \longrightarrow \mathcal{N} , \end{cases} \tag{4.2.12}$$

[page 63]

à savoir les prolongements canoniques (par commutativité aux petites $\varinjlim$) des foncteurs d'inclusion $S \hookrightarrow \mathcal{M}$, $T \hookrightarrow \mathcal{N}$.

La question essentielle, à présent, c'est visiblement de construire un adjoint à gauche pour le foncteur (4.2.9). Il revient au même, pour (s,t) dans $S \times T$, de définir un objet

$$s \boxtimes t \ \in \ \mathrm{Ob}\, \mathcal{M} \boxtimes \mathcal{N} , \tag{4.2.13}$$

tel que l'on ait, pour F variable dans $\mathcal{M} \boxtimes \mathcal{N}$, un isomorphisme fonctoriel en F,

$$\underbrace{\rho(F)(s,t)}_{\overset{\text{déf}}{=} F(s,t)} \ \simeq \ \mathrm{Hom}(s \boxtimes t, F) .$$

Donc il faut prouver ceci :

Lemme 4.2.3 ([4]). *Soient $\mathcal{M}$, $\mathcal{N}$ deux catégories pseudo-topos, et $s \in \mathrm{Ob}\,\mathcal{M}$, $t \in \mathrm{Ob}\,\mathcal{N}$,*

4. Pas prouvé ; peut-être faux !

et considérons sur $\mathcal{M}\boxtimes\mathcal{N} \overset{déf}{=} \underline{\mathrm{Hom}}^{!!}(\mathcal{M}^\circ\times\mathcal{N}^\circ, \mathrm{Ens})$ *le foncteur* $F \longmapsto F(s,t)$*. Ce foncteur est* représentable *(par un objet que je note* $s\boxtimes t$*).*

L'idée naturelle serait de définir $s\boxtimes t$ par

$$(s\boxtimes t)(x,y) \;=\; s(x)\times t(y) \;=\; \mathrm{Hom}_{\mathcal{M}}(x,s)\times\mathrm{Hom}_{\mathcal{N}}(y,t)\ ,$$

ce qui définit bien un foncteur [page 64]

$$\mathcal{M}^\circ\times\mathcal{N}^\circ \longrightarrow \mathrm{Ens}\ .$$

Malheureusement, pour un des arguments fixé, disons pour y fixé, ce foncteur n'est *pas* compatible aux limites projectives, p.ex. il ne transforme pas l'objet final de $\mathcal{M}^\circ$ correspondant à l'objet initial de $\mathcal{M}$) en objet final de Ens, mais en $t(y)=\mathrm{Hom}_{\mathcal{N}}(y,t)$. Néanmoins, je pense que $s\boxtimes t$ doit bel et bien se définir comme produit de deux objets de $\mathcal{M}\boxtimes\mathcal{N}$, dépendant fonctoriellement de s resp. de t ([5]). On est donc amené dès à présent, qu'on le veuille ou non, à essayer de définir des foncteurs canoniques, commutant aux petites $\varinjlim$, p. 8

$$\mathcal{M}\longrightarrow\mathcal{M}\boxtimes\mathcal{N}\longleftarrow\mathcal{N} \tag{4.2.13}$$

(lesquels seront les foncteurs image inverse pour les projections canoniques $\mathcal{X}\times\mathcal{Y}\to\mathcal{X}$, $\mathcal{X}\times\mathcal{Y}\to\mathcal{Y}$)

([6]).

Commentary · Exposition [ms. 63]

The reflector is the actual existence problem

At this point the tensor has a faithful realization as a category of presheaves. Grothendieck wants to build colimits in it by first building ordinary presheaf colimits and then reflecting them. The individual coefficient categories already illustrate this procedure without any accessibility assumption.

For the restricted nerve $\rho_S:\mathcal{M}\to\widehat{S}$, define

$$L_S(P)=\operatorname*{colim}_{(s,a)\in S/P} s.$$

For each $x\in\mathcal{M}$, a map from this colimit to x is a compatible family of maps $s\to x$, one for each element $a\in P(s)$. Equivalently, it is a natural transformation $P\to\rho_S x$. Thus $L_S\dashv\rho_S$. Density says that the counit $L_S\rho_S x\to x$ is invertible. This constructs the morphisms (4.2.10)–(4.2.12) and shows exactly where cocompleteness of $\mathcal{M}$ enters.

For $\rho:\mathcal{E}=\mathcal{M}\boxtimes\mathcal{N}\hookrightarrow\widehat{S\times T}$ the same formula would require the colimits one is trying to prove exist. If a reflector L exists, then

$$s\boxtimes t=L(h_{(s,t)}),\qquad \mathcal{E}(s\boxtimes t,F)\simeq F(s,t),$$

and arbitrary colimits in $\mathcal{E}$ are L applied to the corresponding colimits of nerves. This is a consequence of the adjunction, not a prior recipe for constructing L.

The restriction to generator pairs in Lemma 4.2.3 is therefore natural. Their evaluation functors are the coordinate functions of the embedding. If $\mathcal{E}$ were already cocomplete and these evaluations representable, their representing objects could be extended from $S\times T$ to all presheaves by the displayed colimit construction. At the present stage cocompleteness is not available. The wording "Pas prouvé; peut-être faux!" should be retained as a genuine record of the state of the argument. The accessible case will have a positive answer; the general case needs a separate existence theorem and is not settled by the formal Yoneda calculations.

5. également faux, cf. plus bas.

6. Le cas où $\mathcal{M}$, $\mathcal{N}$ sont des catégories-topos, nous montre que ces foncteurs devraient être décrits comme $x\longmapsto x\boxtimes e_{\mathcal{N}}$, $y\longmapsto e_{\mathcal{M}}\boxtimes y$. Mais il n'est pas clair qu'on ait en dehors du cas des topos, et même en admettant l'existence du $x\boxtimes y$, la formule (valable pour un topos) $x\boxtimes y\simeq(x\boxtimes e_{\mathcal{N}})\times(e_{\mathcal{M}}\boxtimes y)$.

4.3 L'opération $\mathcal{M} \boxtimes \mathcal{N}$ et l'axiome d'accessibilité

J'ai passé la journée hier, essayant d'établir l'existence des $x \boxtimes y$ dans $\mathcal{M} \boxtimes \mathcal{N}$, sans y parvenir – du moins pas sans faire une hypothèse supplémentaire d'accessibilité, dont il devient évident à présent qu'il faut la faire de toutes façons. Je vais quand même énoncer le positif de mes perplexités. [page 65]

Commentary · Development (commentators') [ms. 64]

Why the naive formula fails, and the abelian calculation

Grothendieck has reached a useful obstruction: the external product of two representable presheaves need not be a separately continuous bifunctor. We can sharpen the obstruction to an exact criterion and then calculate an example in which the proposed product decomposition is impossible. These are elementary consequences of the definitions, developed here to locate the failed geometrical intuition. We checked the tensor constructions in Kelly (1982, Section 6.5) and the algebraic examples in Freyd (1966, p. 95); the latter already contains the tensor calculus for module theories. We make no priority claim for the following formulations or proofs.

The external-product criterion. [ours] Let $\mathcal{M}, \mathcal{N}$ be pseudo-topos categories. The bifunctor

$$H_{s,t}(x, y) = \mathcal{M}(x, s) \times \mathcal{N}(y, t)$$

belongs to $\mathcal{M} \boxtimes \mathcal{N}$ if and only if s and t are terminal in their respective categories.

Proof. If $H_{s,t}$ preserves the empty limit in the first variable, evaluate at the initial object $0_{\mathcal{M}}$. For every y we obtain

$$1 \simeq H_{s,t}(0_{\mathcal{M}}, y) \simeq \mathcal{N}(y, t).$$

This says exactly that t is terminal. Interchanging the variables proves that s is terminal. Conversely, if both are terminal, $H_{s,t}$ is the constant singleton bifunctor and preserves every limit separately. This proves both directions, including the degenerate case of a one-object coefficient category. □

For the tensor itself, there is a particularly instructive classical calculation:

$$\mathrm{Ab} \boxtimes \mathrm{Ab} \simeq \mathrm{Ab}, \qquad A \boxtimes B \longleftrightarrow A \otimes_{\mathbb{Z}} B.$$

We give the full argument because it identifies the universal elements, rather than only the ambient category. Under (4.1.11), an object is a continuous $\psi : \mathrm{Ab}^{\mathrm{op}} \to \mathrm{Ab}$. Composing with the forgetful functor to sets gives a continuous contravariant set-valued functor, hence $U\psi(B) \simeq \mathrm{Ab}(B, C)$ for some C. The group structure on these sets is natural in B. By Yoneda, its multiplication is a morphism $\mu : C \times C \to C$ in Ab, with an internal unit. That unit is necessarily zero; since μ is a group homomorphism and has zero as its unit,

$$\mu(c, d) = \mu(c, 0) + \mu(0, d) = c + d.$$

The inverse is consequently the usual negative. Thus the internal abelian group structure is forced, and

$$\psi(B) = \mathrm{Ab}(B, C)$$

with its ordinary pointwise group structure. Natural transformations between two such functors are exactly homomorphisms between their representing groups; they automatically preserve these structures. Under the tensor description, the associated bifunctor is

$$F_C(A, B) = \mathrm{Ab}\big(A, \mathrm{Ab}(B, C)\big) \simeq \mathrm{Ab}(A \otimes_{\mathbb{Z}} B, C).$$

The last bijection follows directly by sending a homomorphism $A \to \mathrm{Ab}(B, C)$ to its bilinear evaluation map $(a, b) \mapsto f(a)(b)$, and then using the defining generators and bilinear relations of $A \otimes_{\mathbb{Z}} B$. It proves that evaluation at (A, B) is represented by $A \otimes_{\mathbb{Z}} B$.

Now the terminal object of Ab is 0. The proposed formula involving terminal coefficients would give

$$(A \boxtimes 0) \times (0 \boxtimes B) = 0,$$

whereas $\mathbb{Z} \boxtimes \mathbb{Z}$ corresponds to $\mathbb{Z}$. This is a complete counterexample to the proposed decomposition outside topoi. The failure has no size-theoretic cause: abelian groups are locally finitely presentable and their tensor exists. What fails is the identification of a bilinear operation with a cartesian product operation.

Commentary · Later developments [ms. 64]

The modern tensor comparison and its precise scope

The construction becomes a well-behaved tensor on locally presentable categories. Its universal property involves functors preserving colimits separately; its objects can be realized by the separately continuous bifunctors used in (4.1.10). Kelly's construction of tensors for small categories with prescribed colimits supplies an earlier categorical framework for this operation (Kelly, 1982, Section 6.5, equation (6.24)). Thus this part of the comparison predates the manuscript. The accessible presentation developed below connects the small presentation with the large category of coefficients.

The ordinary topos assertion also has a precise predecessor: Pitts (1985, Theorem 2.3, pp. 50–52) proves that the product of Grothendieck topoi is their tensor as cocomplete categories, in a more general indexed setting. The construction uses the topology on a product of sites generated by covers in each variable. Specializing the base to sets gives the assertion in Grothendieck's footnote on p. 53 and the external-product formula in the footnote on p. 64. Pitts's Definition 2.2 explicitly separates this theorem from an unrestricted existence claim for arbitrary locally small cocomplete categories.

The higher analogue is especially close in its formulas. For presentable ∞-categories, Lurie (2017, Proposition 4.8.1.15, Lemma 4.8.1.16, and Proposition 4.8.1.17) constructs the tensor and identifies it with the category of limit-preserving functors $\mathcal{C}^{\mathrm{op}} \to \mathcal{D}$. Examples 4.8.1.19–4.8.1.20 identify its restriction to ∞-topoi with their product and identify spaces as the tensor unit. These are structural analogues of the present formulas, with mapping spaces in place of hom-sets.

There is no implication here that replacing sets by spaces converts every assertion in these pages into a correct higher assertion. Ordinary filtered colimits, strict categories of elements, and cardinal estimates on actual hom-sets all have to be replaced by their appropriate higher versions. Conversely, the derivator formalism by itself does not establish an accessibility bound on an arbitrary coefficient category. The present chapter is supplying such bounds before the homotopical constructions are made. The unconditional pseudo-topos tensor problem and the positive accessible tensor theorem must therefore remain separate entries in the audit.

Commentary · Exposition [ms. 65]

The representability problem behind the tensor

Grothendieck has found the right category of bilinear coefficients; what is missing is the ability to make objects in it. A separately continuous bifunctor is easy to recognize, and limits of such bifunctors remain separately continuous. Colimits are different: their pointwise values generally destroy the continuity conditions. The proposed object $x \boxtimes y$ would solve this problem at its smallest visible scale, by representing the operation which reads a coefficient at (x, y).

Write $\mathcal{E} = \mathcal{M} \boxtimes \mathcal{N}$ and $P = (S \times T)^{\wedge}$, and let $\alpha : \mathcal{E} \hookrightarrow P$ be restriction. If a reflection $L \dashv \alpha$ exists, then

$$\mathcal{E}\big(Lh_{(s,t)}, F\big) \cong P(h_{(s,t)}, \alpha F) \cong F(s,t).$$

Thus $s \boxtimes t = Lh_{(s,t)}$. The same adjunction supplies every small colimit:

$$\operatorname*{\overset{\mathcal{E}}{colim}}_{i \in I} F_i \cong L\left(\operatorname*{\overset{P}{colim}}_{i \in I} \alpha F_i\right).$$

The images of representables generate $\mathcal{E}$ densely, because every presheaf is the colimit of its representables and L preserves that colimit. These are the sound implications $c \Rightarrow b'$ and $c \Rightarrow a$ in Proposition 4.3.1. No left exactness of L is needed.

There is a genuine difficulty in the reverse implication as written. Lemma 4.3.2 assumes that $\mathcal{E}$ has small *limits*, although its proof constructs a *colimit* of representing objects. The printed variance $\mathcal{E}^{\circ} \to$ Ens is also reversed: $\xi \mapsto \alpha(\xi)(x)$ is covariant. These readings occur in the edition, not only in the transcription. The valid elementary lemma says that if $\mathcal{E}$ is cocomplete and each evaluation is corepresented by $r(x)$, then

$$LF = \operatorname*{colim}_{(x,u) \in X/F} r(x) \quad \text{satisfies} \quad \mathcal{E}(LF, e) \cong P(F, \alpha e).$$

Indeed, applying $\mathcal{E}(-, e)$ turns this colimit into the limit of the evaluations $\alpha(e)(x)$ over the category of elements of F, which is precisely the set of natural transformations $F \to \alpha(e)$. The representing

objects form a functor $r : X \to \mathcal{E}$ by Yoneda, so the displayed colimit has the required coherent transition maps.

Completeness alone cannot replace cocompleteness in that elementary lemma. Let $\mathcal{E}$ be the opposite of the ordered category of ordinals belonging to the fixed universe. It has every small limit, since a small family of ordinals has a supremum, but it has no initial object. Take $X = \{*\}$ and $\alpha(e) = \mathcal{E}(0, e)$. Its only evaluation is corepresentable. A left adjoint would nevertheless have to send the empty set to an initial object of $\mathcal{E}$, which does not exist. This example concerns the lemma's generality; it is not a counterexample to the tensor construction, where α has additional properties. The written argument for $b' \Rightarrow c$ therefore needs an existence theorem beyond this lemma. The accessibility hypothesis introduced next provides one, as we prove below.

Proposition-perplexité 4.3.1. *Soient $\mathcal{M}$, $\mathcal{N}$ deux catégories pseudo-topos, d'où $\mathcal{M} \boxtimes \mathcal{N}$ comme dans 4.1. Soient $S \subset \mathcal{M}$, $T \subset \mathcal{N}$ deux petites sous-catégories strictement génératrices, et considérons l'inclusion pleinement fidèle correspondante :*

$$\underbrace{\mathcal{M} \boxtimes \mathcal{N}}_{\overset{\text{déf}}{=} \underline{\mathrm{Hom}}^{!!}(\mathcal{M}^\circ \times \mathcal{N}^\circ, \mathrm{Ens})} \overset{\varphi\,?}{\hookleftarrow} \xrightarrow[\alpha]{} S^\wedge \boxtimes T^\wedge \;\simeq\; (S \times T)^\wedge . \tag{4.3.1.1}$$

Considérons les conditions suivantes :

a) $\mathcal{M} \boxtimes \mathcal{N}$ est un pseudo-topos.

b) Pour $x \in \mathrm{Ob}\,\mathcal{M}$, $y \in \mathrm{Ob}\,\mathcal{N}$, $x \boxtimes y \in \mathrm{Ob}\,\mathcal{M} \boxtimes \mathcal{N}$ existe, i.e. le foncteur (commutant aux petites $\varprojlim$)

$$F \longmapsto F(x, y)\ , \qquad \mathcal{M} \boxtimes \mathcal{N} \longrightarrow \mathrm{Ens} \tag{4.3.1.2}$$

est représentable.

b′) Comme b), avec $x \in \mathrm{Ob}\,S$, $y \in \mathrm{Ob}\,T$.

c) Le foncteur α (lequel commute aux petites $\varprojlim$) admet un adjoint à gauche

$$\varphi \;:\; (S \times T)^\wedge \longrightarrow \mathcal{M} \boxtimes \mathcal{N}\ .$$

On a alors les implications

$$b \implies b' \iff c \implies a\ . \tag{4.3.1.3}$$

De plus, si c est satisfait, on a ceci : pour $s \in S$, $t \in T$, considérons p. 9

$$(s, t) \;\in\; (S \times T) \;\subset\; (S \times T)^\wedge \;\simeq\; S^\wedge \boxtimes T^\wedge\ ,$$

qui s'explicite aussi comme

$$\begin{cases} (s,t) \;=\; \mathrm{pr}_1^*(s) \times \mathrm{pr}_2^*(t) \;\simeq\; s \overset{S^\wedge, T^\wedge}{\boxtimes} t \in \mathrm{Ob}\ (S \times T)^\wedge\ , \\ \textit{i.e. } (s,t)(s',t') \;=\; s(s') \times t(t') \;=\; \mathrm{Hom}_S(s', s) \times \mathrm{Hom}_T(t', t) \\ \qquad\qquad\qquad\qquad\quad \;=\; \mathrm{Hom}_{S \times T}((s', t'), (s, t))\ , \end{cases} \tag{4.3.1.4}$$

$$\begin{array}{ccc} S \times T & \xrightarrow{\mathrm{pr}_2} & T \\ \downarrow{\scriptstyle \mathrm{pr}_1} & & \\ S\ , & & \end{array}$$

on a [page 66]

$$s \overset{\mathcal{M},\mathcal{N}}{\boxtimes} t \simeq \varphi(s,t)\ , \tag{4.3.1.4}$$

et $\varphi(S\times T)=\{s\boxtimes t \mid s\in S,\ t\in T\}$ est une partie strictement génératrice de $\mathcal{M}\boxtimes\mathcal{N}$ ([7]).
N.B. Je ne connais pas d'exemple où les conditions envisagées ne soient satisfaites, mais doute pourtant à présent que même la plus faible le soit toujours, i.e. que $\mathcal{M}\boxtimes\mathcal{N}$ soit un pseudo-topos dès que $\mathcal{M}$ et $\mathcal{N}$ le sont.
Démonstration de 4.3.1. L'implication b $\Longrightarrow$ b′ est tautologique. L'implication b′ $\Longleftrightarrow$ c résulte du
Lemme 4.3.2. *Soient $\mathcal{E}$, X des $\mathfrak{U}$-catégories avec X petite, $\mathcal{E}$ stable par petites $\varinjlim$,*

$$\alpha\ :\ \mathcal{E}\longrightarrow X^\wedge$$

un foncteur. Pour que α admette un adjoint à gauche φ, il faut et il suffit que pour tout $x\in \mathrm{Ob}\,X$, le foncteur

$$\begin{cases} \xi & \longmapsto & \mathrm{Hom}_{X^\wedge}(x,\alpha(\xi)) \ =\ \alpha(\xi)(x) \\ \mathcal{E}^\circ & \longrightarrow & \mathrm{Ens} \end{cases}$$

soit représentable.
C'est évidemment nécessaire. La suffisance résulte du fait que $X\subset X^\wedge$ est strictement génératrice dans $X^\wedge$, i.e. que tout objet F de $X^\wedge$ est limite inductive $F=\varinjlim_I F_i$, les F_i dans X (on prend $I=X/F$), d'où p. 10 [page 67]

$$\begin{aligned}\mathrm{Hom}(F,\alpha(\xi)) &\simeq \varprojlim_I \underbrace{\mathrm{Hom}(F_i,\alpha(\xi))}_{\mathrm{Hom}(\rho(F_i),\xi)} \\ &\simeq \mathrm{Hom}(\varinjlim_I(\rho(F_i),\xi))\ ,\end{aligned}$$

donc le foncteur $\xi\longmapsto\mathrm{Hom}(F,\alpha(\xi))$ est représenté par $\rho(F)\overset{\text{déf}}{=}\varinjlim_I \rho(F_i)$.
Prouvons c $\Longrightarrow$ a. Pour l'existence des petites $\varinjlim$ dans $\mathcal{M}\boxtimes\mathcal{N}$, et l'existence d'une partie strictement génératrice, on invoque le lemme général :
Lemme 4.3.3. *Soit $\alpha:\mathcal{E}\hookrightarrow\mathcal{F}$ un foncteur pleinement fidèle admettant un adjoint à gauche ρ.*

ⓐ *Si les $\varinjlim$ d'un type donné I existent dans $\mathcal{F}$, elles existent dans $\mathcal{E}$, et se calculent comme*

$$\varinjlim_I{}_{\mathcal{E}}\,\xi_i \ =\ \rho(\varinjlim_I{}_{\mathcal{F}}\,\alpha(\xi_i))\ . \tag{4.3.3.1}$$

ⓑ *Si U est une petite partie strictement génératrice de $\mathcal{F}$, $\rho(U)$ est une petite partie strictement génératrice dans $\mathcal{F}$.*

En effet, si ξ désigne le deuxième membre [de l'égalité 4.3.3.1], et η un objet variable de $\mathcal{E}$, on aura

$$\begin{aligned}\mathrm{Hom}_{\mathcal{E}}(\xi,\eta) &\overset{\text{adj.}}{\simeq} \mathrm{Hom}_{\mathcal{F}}(\varinjlim_I \alpha(\xi_i),\alpha(\eta)) \\ &\simeq \varprojlim_I \underbrace{\mathrm{Hom}_{\mathcal{F}}(\alpha(\xi_i),\alpha(\eta))}_{\simeq \mathrm{Hom}_{\mathcal{E}}(\xi_i,\eta)\ \text{ car } \alpha \text{ pleinement fidèle}}\ . \\ &\simeq \varprojlim_I \mathrm{Hom}_{\mathcal{E}}(\xi_i,\eta)\ ,\end{aligned}$$

[page 68]

7. **N.B.** On a bien sûr $(s,t)=s\overset{S^\wedge,T^\wedge}{\boxtimes}t$.

ce qui prouve que ξ est une limite inductive des ξ_i dans $\mathcal{E}$ ([8]).
Ceci prouve que (moyennant c)) $\mathcal{M} \boxtimes \mathcal{N}$ est stable par petites $\varinjlim$, donc il reste à prouver que $\mathcal{M} \boxtimes \mathcal{N}$ admet une petite famille strictement génératrice. Cela résultera du b) dans le lemme, puisque $S \times T$ engendre strictement $(S \times T)^\wedge$. Cela prouve en même temps la dernière assertion de la proposition, sous réserve de prouver la formule (4.1.3.4). Il faut donc prouver un isomorphisme fonctoriel en $F \in \mathrm{Ob}\, \mathcal{M} \boxtimes \mathcal{N}$,

$$\mathrm{Hom}(\rho(s,t), F) \;\simeq\; F(s,t)\ ,$$

mais par adjonction on a

$$\mathrm{Hom}(\rho(s,t), F) \;\simeq\; \mathrm{Hom}((s,t), \alpha(F)) \;=\; \alpha(F)(s,t) \;=\; F(s,t)\ ,$$

OK.

Proposition 4.3.4. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie. Les conditions suivantes sont équivalentes.* p. 11 [page 69]

a) $\mathcal{M}$ est une catégorie $\mathfrak{U}$-pseudo-topos, i.e. elle est stable par $\mathfrak{U}$-limites inductives, et admet une $\mathfrak{U}$-petite sous-catégorie S strictement génératrice.

b) Il existe une $\mathfrak{U}$-petite catégorie S, et un foncteur $i : \mathcal{M} \hookrightarrow S^\wedge$ pleinement fidèle, *ayant un adjoint à gauche.*

Démonstration. On a a) $\Longrightarrow$ b), car il suffit de prendre pour S dans b) celui spécifié dans a), l'hypothèse sur S implique que le foncteur canonique

$$\mathcal{M} \;\longrightarrow\; S^\wedge\ , \qquad \text{composé de } \mathcal{M} \hookrightarrow\; \mathcal{M}^\wedge \;\xrightarrow{\text{restriction}}\; S^\wedge$$

est pleinement fidèle. Qu'il admette un adjoint à gauche résulte du lemme 4.3.2. L'implication b) $\Longrightarrow$ a) résulte du lemme 4.3.3.

Commentary · Exposition [ms. 69]

A reflective presentation and its generators

Grothendieck now moves from the particular tensor problem to the presentation of its possible factors. The useful feature of a pseudo-topos is that its objects can be reconstructed from a fixed small category of probes. This is the precise content of the restricted Yoneda embedding; it is stronger than asking the probes merely to distinguish parallel arrows.

For a small full strictly generating subcategory $S \subset \mathcal{M}$, put

$$N(x)(s) = \mathcal{M}(s,x), \qquad L(F) = \operatorname*{colim}_{(s,u)\in S/F} s.$$

The colimit exists because $\mathcal{M}$ is cocomplete. The universal property of a colimit and Yoneda give $\mathcal{M}(LF, x) \cong \mathrm{Nat}(F, Nx)$. Strict generation says that the canonical diagram $S/x \to \mathcal{M}$ has colimit x; equivalently, the counit $LNx \to x$ is an isomorphism. Hence N is fully faithful. This proves Proposition 4.3.4 directly, without the incorrect completeness hypothesis of Lemma 4.3.2. The density statement is the one formulated in Artin et al. (1972, Exposé I, Proposition 7.2(i)).

Conversely, suppose $L : P(S) \rightleftarrows \mathcal{M} : N$ is a reflection. If $D : I \to \mathcal{M}$ is a small diagram, then $L\,\mathrm{colim}_I ND$ represents its cocones, by adjunction and full faithfulness. Thus $\mathcal{M}$ is cocomplete. For $x \in \mathcal{M}$, apply L to the category-of-elements presentation of Nx:

$$x \cong LNx \cong \operatorname*{colim}_{(s,u)\in S/Nx} Lh_s.$$

This presentation is natural in x and exhibits the family Lh_s as dense. The target of this family is $\mathcal{M}$; correspondingly, the last $\mathcal{F}$ in the printed Lemma 4.3.3(b) must be read mathematically as $\mathcal{E}$. The source wording is retained in the text and recorded in the corrections register.

8. Pour prouver b), on note que la pleine fidélité de α implique que ρ est essentiellement surjectif ; comme ρ commute aux petites $\varinjlim$ et que tout objet de $\mathcal{F}$ est de la forme $\varprojlim_I x_i$, les x_i dans U, on aura $\rho(x) = \varinjlim_I \rho(x_i)$, les $\rho(x_i)$ dans $\rho(U)$, on gagne.

The adjunction also explains the accessibility assertion in Corollary 4.3.5. Suppose all Lh_s preserve sufficiently filtered colimits under their Hom functors. Since S is small, choose one regular cardinal κ which works for every s. Colimits in a presheaf category are pointwise, so

$$N \operatorname{colim}_I x_i \cong \operatorname{colim}_I Nx_i \quad \text{for every } \kappa\text{-filtered } I$$

is equivalent to the same assertion after evaluating at each s, hence to κ-presentability of all Lh_s. Every x is a small colimit of these objects. Choose a larger regular cardinal λ than κ and than the number of arrows in one such presentation of x. In sets, λ-filtered colimits commute with limits of fewer than λ arrows. Applying this to the Hom formula for that presentation proves that x is λ-presentable. Thus each object has a rank, although the ranks of all objects need not share one bound.

Corollaire 4.3.5. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie. Pour que $\mathcal{M}$ soit un $\mathfrak{U}$-pseudo-topos* accessible *(i.e. dont tous les objets sont accessibles), il faut et il suffit qu'il existe S dans* Cat *et un foncteur pleinement fidèle et* accessible $\mathcal{M} \overset{\alpha}{\hookrightarrow} S^\wedge$*, admettant un adjoint à gauche ρ.*

Démonstration. Il suffit de noter que si S, α sont comme dans 4.3.4 b), alors α est accessible si et seulement si les $\rho(S)$ sont formées d'objets accessibles dans $\mathcal{M}$; comme cette partie est strictement génératrice, on sait que cela implique que *tout* objet de $\mathcal{M}$ est accessible. (Cf. SGA 4 I 9.9.) [page 70]

Commentary · Exposition [ms. 70]

From accessible probes to an ind-presentation

Theorem 4.3.6 seeks an intrinsic description of the categories for which the tensor construction should work. In contemporary terminology its main conditions describe a locally presentable category. The indexing convention needs care: throughout these pages, "grand devant π" permits simultaneous solutions to diagrams with at most π arrows. With π infinite, this is modern κ-filteredness for $\kappa = \pi^+$. An object called π-accessible here is therefore π^+-presentable, not generally π-presentable. The implication from a cocomplete category with a small strong generator of presentable objects to local presentability is also stated in Adámek and Rosický (1994, Theorem 1.20). For the dense generator used here, a direct proof clarifies the role of the ranks.

Assume $\mathcal{M}$ is cocomplete and has a small full dense subcategory S of accessible objects. Choose an infinite regular κ such that every object of S is κ-presentable. Enlarge S to a small full subcategory C closed, up to isomorphism, under colimits of diagrams with fewer than κ arrows. Here is a construction which also proves the required smallness. Start with S; at each successor stage choose colimits of every such diagram in the preceding stage, and take the full subcategory on the resulting set of objects. At a limit stage take the union of the preceding object sets. Carry out κ stages. All sets used remain in the universe. By regularity, a diagram with fewer than κ arrows in the union appears at some earlier stage, so its chosen colimit also belongs to the union.

All objects of C remain κ-presentable. For a diagram $D : K \to \mathcal{M}$ of that size, the formula

$$\mathcal{M}(\operatorname{colim}_K D, -) \cong \lim_{K^{\mathrm{op}}} \mathcal{M}(D(-), -)$$

and the corresponding interchange theorem in sets prove closure of presentable objects under these colimits. At every stage this applies to the objects just constructed.

For any $x \in \mathcal{M}$, the category C/x is κ-filtered. Given a diagram of fewer than κ arrows in C/x, take the colimit of its underlying diagram in C. Its structure maps to x induce a map from this colimit to x, giving a cocone in C/x. This includes the empty diagram, because C contains an initial object. Moreover

$$x \cong \operatorname*{colim}_{(c,u)\in C/x} c.$$

To see density after enlarging S, a cocone from C/x to y restricts to one from S/x, hence to a unique map $x \to y$. For each $c \to x$, its agreement with the given map $c \to y$ can be tested after every map $s \to c$, and density of S gives that agreement. Thus the restriction has neither lost nor added cocones.

The functor which takes a κ-filtered diagram of objects of C to its colimit in $\mathcal{M}$ is now essentially surjective. It is fully faithful because, for diagrams $(c_i)_{i\in I}$ and $(d_j)_{j\in J}$, presentability gives

$$\mathcal{M}(\operatorname{colim}_I c_i, \operatorname{colim}_J d_j) \cong \lim_{i\in I^{\mathrm{op}}} \operatorname*{colim}_{j\in J} \mathcal{M}(c_i, d_j),$$

the defining Hom formula for ind-objects. Consequently $\mathcal{M} \simeq \mathrm{Ind}_\kappa C$, with the subscript here in the modern convention. When $\kappa = \pi^+$ this is Grothendieck's $\mathrm{Ind}_\pi C$.

This argument proves the structural part of the theorem without asserting that the particular slice-cardinality filtration chosen on page 72 already satisfies all the axioms of a cardinal filtration. That stronger numerical statement is exactly where the subsequent attempted proof encounters difficulty. The converse structural implication uses the cocompleteness of $\mathrm{Ind}_\kappa C$ when C has the indicated small colimits; Section 4.4 supplies it. No inaccessible cardinal beyond the standing universe is required for this passage.

Commentary · Exposition [ms. 70]

Why accessibility supplies the tensor reflector

The accessible presentation gives a concrete answer to the existence problem which opened Section 4.3. It replaces a class of continuity requirements by a set of requirements on a small category. We give the construction, because that change of size is the mathematical reason the added axiom works.

Take a common regular cardinal κ and small full subcategories $C \subset \mathcal{M}$, $D \subset \mathcal{N}$ of κ-presentable objects, closed under colimits of fewer than κ arrows, with $\mathcal{M} \simeq \mathrm{Ind}_\kappa C$ and $\mathcal{N} \simeq \mathrm{Ind}_\kappa D$. Write $P = (C \times D)^\wedge$. In P consider the set Σ of maps

$$\operatorname*{colim}_{i \in K}{}^{P} h_{(c_i,d)} \longrightarrow h_{(\operatorname{colim}_K^C c_i,d)}$$

for all diagrams in C of fewer than κ arrows and all $d \in D$, together with the analogous maps in the second variable. There is a set of such maps, since the categories are small and one may choose a set of representatives of all indexing shapes of the stated size. A presheaf F is orthogonal to Σ exactly when it takes those colimits to limits separately: orthogonality means that precomposition with each displayed map induces a bijection into F.

The orthogonal subcategory $\Sigma^\perp \subset P$ is reflective. To see the size control explicitly, choose a regular μ such that all domains and codomains in Σ are μ-presentable presheaves. This is possible by writing each as a small colimit of representables and taking one bound for the set Σ. Starting with $X_0 \in P$, perform the following two operations at every successor stage. First push out the coproduct of all maps $s : A \to B$ in Σ along all maps $A \to X_\alpha$, thus adjoining every required extension. Then coequalize every pair of maps $B \rightrightarrows Y$ into that new object Y which agree on A, for every $s \in \Sigma$. At limit stages take the colimit. Continue for μ stages.

For an orthogonal object Z, each operation induces a bijection from maps out of the new stage into Z to maps out of the preceding stage into Z. The pushout operation does so because extensions into Z exist uniquely; the coequalizer operation does so because those extensions agree whenever they agree on A. The same holds at limits. Thus $X_0 \to X_\mu$ is already universal for maps into orthogonal objects. The endpoint is itself orthogonal: a map $A \to X_\mu$ factors through one stage by presentability and is extended at the next; two maps $B \rightrightarrows X_\mu$ agreeing on A factor through a common stage, their equality on A holds at a later stage, and the coequalizer step then makes them equal. The ordinal μ is μ-filtered, which justifies each factorization. Hence this construction is the reflector $L : P \to \Sigma^\perp$.

To identify this category with Grothendieck's tensor, first recall a useful description of the restricted ind-completion. A presheaf H on a small κ-cocomplete category C belongs to $\mathrm{Ind}_\kappa C$ if and only if it carries the indicated colimits in C to limits of sets. In one direction, representables have that property, and κ-filtered colimits commute with those limits. In the other, a diagram of fewer than κ arrows in C/H has a cocone: take its underlying colimit in C and use the compatible elements to obtain the element of H at the colimit. The canonical category-of-elements presentation then proves the assertion.

Each factor is complete, and its reflective presheaf embedding computes limits. Indeed, objects in a full reflective subcategory are precisely those orthogonal to every reflection unit. A limit of such objects remains orthogonal to every unit, since Hom into a limit is a limit; orthogonality to its own unit then makes that unit invertible. Thus the presheaf limit belongs to the reflective subcategory.

It follows that a separately continuous $F \in \Sigma^\perp$ gives a functor $D^{\mathrm{op}} \to \mathcal{M}$ preserving limits of fewer than κ arrows. The dual functor $D \to \mathcal{M}^{\mathrm{op}}$ therefore preserves the corresponding colimits.

By the ind-completion universal property proved in Section 4.4, it extends uniquely to a colimit-preserving functor $\mathcal{N} \to \mathcal{M}^{\mathrm{op}}$. Dualizing and applying the Hom pairing recovers a separately continuous bifunctor on $\mathcal{M}^{\mathrm{op}} \times \mathcal{N}^{\mathrm{op}}$. Conversely, restriction of such a bifunctor lies in $\Sigma^{\perp}$, and its values on general objects are determined by their ind-presentations. These constructions are inverse, including natural transformations.

Thus $\mathcal{M} \boxtimes \mathcal{N} \simeq \Sigma^{\perp}$ is a reflective subcategory of P. It is cocomplete, with colimits obtained by reflection, and has the small dense family $Lh_{(c,d)}$. Its inclusion preserves μ-filtered colimits, since orthogonality to maps with μ-presentable endpoints is preserved by those colimits. Accordingly the reflected representables are μ-presentable, and the tensor is again locally presentable. Finally every evaluation $F \mapsto F(x, y)$ has a representing object: it preserves all limits and is accessible, or, equivalently, it is obtained from the small evaluation objects using the cocontinuity in x and y and the now-established colimits. For the latter explicit construction, choose presentations $x = \mathrm{colim}_{C/x}\, c$, $y = \mathrm{colim}_{D/y}\, d$ and take

$$x \boxtimes y = \operatorname*{colim}_{(c \to x, d \to y) \in (C/x) \times (D/y)} Lh_{(c,d)}.$$

Applying $\mathrm{Hom}(-, F)$ verifies the representing property directly. This proves all the existence assertions of Proposition 4.3.1 under the accessibility hypothesis, without using the disputed general implication $b' \Rightarrow c$.

Je vais essayer de donner un énoncé plus complet :

Théorème 4.3.6. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie. Conditions équivalentes :*

a) $\mathcal{M}$ stable par petites $\varinjlim$, et elle admet une petite sous-catégorie pleine S, strictement génératrice, et formée d'objets accessibles de $\mathcal{M}$.

a′) $\mathcal{M}$ est une catégorie $\mathfrak{U}$-pseudo-topos faiblement accessible, i.e. satisfait a), avec en plus tout *élément de $\mathcal{M}$ (pas seulement ceux de S) accessible dans $\mathcal{M}$.*

b) Il existe une petite catégorie S, et un foncteur $\alpha : \mathcal{M} \hookrightarrow S^{\wedge}$ pleinement fidèle et accessible, *tel que α admette un adjoint à gauche.*

c) $\mathcal{M}$ est stable par petites $\varinjlim$, est accessible, et admet une filtration cardinale [page 71] $(\mathrm{Filt}^{\pi}\, \mathcal{M})_{\pi \geqslant \pi_0}$.

d) Il existe un cardinal π_1, une petite catégorie $\mathcal{M}_{\pi_1}$, stable par limites inductives de cardinal $\leqslant \pi_1$, tels qu'on ait une équivalence de catégories

$$\mathcal{M} \xleftarrow{\sim} \mathrm{Ind}_{\pi_1}\, \mathcal{M}_{\pi_1}\ , \tag{4.3.6.1}$$

où le deuxième membre désigne la sous-catégorie pleine de $\mathrm{Ind}(\mathcal{M}_{\pi_1})$ *formée des ind-objets $(X_i)_{i \in I}$ de $\mathcal{M}_{\pi_1}$ tels que I soit grand devant π_1.*

Démonstration de 4.3.6 ([9]). On a déjà vu a′ $\Longrightarrow$ a $\Longrightarrow$ b $\Longrightarrow$ a′, i.e. l'équivalence de a, a′, b, soit PTA cette condition. Nous allons prouver les implications

$$\mathrm{PTA} \implies \mathrm{c} \implies \mathrm{d} \implies \mathrm{PTA}\ ,$$

ce qui établira le théorème.

Prouvons PTA $\Longrightarrow$ c. Soit S une petite sous-catégorie pleine strictement génératrice. Ainsi, p. 12 pour tout x dans $\mathcal{M}$ on a [page 72]

$$x \;=\; \varinjlim_{s \in S/x} s \tag{4.3.6.2}$$

(cf. SGA 4 I 7.2 (i)). Soit $\pi_0 = \mathrm{card}\, \mathrm{Fl}(S)$, et pour tout cardinal $\pi \geqslant \pi_0$, soit

$$\mathrm{Filt}^{\pi}\, \mathcal{M} \;=\; \text{sous-catégorie pleine de } \mathcal{M} \text{ formée des objets } x \text{ tels que } \mathrm{card}\,(\mathrm{Fl}(S/x)) \leqslant \pi\ . \tag{4.3.6.3}$$

9. Pour une démonstration complète (celle donnée ici canule à partir d'un certain moment), cf. §4.6 (p. 139-148).

Je veux prouver que l'on trouve ainsi une filtration cardinale sur $\mathcal{M}$, i.e. que les conditions a) b) c) de SGA 4 I 9.12 sont satisfaites. C'est prouvé dans loc. cit. 9.13 sous des hypothèses légèrement différentes, la condition d'accessibilité de $\mathcal{M}$ étant remplacée par celle (beaucoup moins sympathique!) que les familles de flèches épimorphiques strictes dans $\mathcal{M}$ sont épimorphiques strictes universelles. Cette condition n'est utilisée que dans la démonstration de la condition b), à savoir la stabilité de $\mathrm{Filt}^{\pi}\mathcal{M}$ par $\varinjlim_{I}$ de cardinal $\leqslant \pi$ (sans avoir d'ailleurs à supposer I filtrante, ni a fortiori grand devant π_0). Il faut d'ailleurs dire que la définition de $\mathrm{Filt}^{\pi}\mathcal{M}$ donnée dans loc. cit. n'est pas tout à fait la même que (4.3.6.3), mais c'est [page 73]

(4.3.6.3′) $\mathrm{Filt}'^{\pi}\mathcal{M}$ = sous-catégorie pleine de $\mathcal{M}$ formée des objets x tels qu'il existe une famille épimorphique stricte $x_i \xrightarrow{\alpha_i} x$ de cardinal $\leqslant \pi$, avec $x_i \in S \ \forall\ i \in I$.

Ainsi on a

$$\mathrm{Filt}^{\pi}\mathcal{M} \ \subset\ \mathrm{Filt}'^{\pi}\mathcal{M}\ ,$$

mais dans loc. cit. on prouve que pour x dans $\mathrm{Filt}'^{\pi}\mathcal{M}$, on a

$$\operatorname{card}\mathrm{Fl}(S/x)\ \leqslant\ \pi^{\pi_0}\ ,$$

d'où

$$\mathrm{Filt}^{\pi}\mathcal{M}\ \subset\ \mathrm{Filt}'^{\pi}\mathcal{M}\ \subset\ \mathrm{Filt}^{\pi^{\pi_0}}\mathcal{M}\ ,$$

donc si $\pi = \pi^{\pi_0}$, p.ex. $\pi = 2^c$ avec $c \geqslant \pi_0$, alors on trouve

$$\mathrm{Filt}^{\pi}\mathcal{M}\ =\ \mathrm{Filt}'^{\pi}\mathcal{M}\ .$$

Donc les deux filtrations on l'air ± équivalentes. Mais la démonstration donnée de la stabilité de Filt'^{π} semble vraiment faire appel de façon essentielle à la condition d'universalité des familles épimorphiques strictes (donc épimorphiques effectives, avec les hypothèses faites impliquant l'existence de petites $\varprojlim$). Donc il me faut bon gré, mal gré, refaire le travail!

Condition a) : Filt^{π} équivalente à une petite catégorie. C'est immédiat, puisque par (4.3.6.2), Filt^{π} est formée de $\varprojlim_{I}$ dans $\mathcal{M}$ d'objets de S (petite catégorie), avec I telle que $\operatorname{card}\mathrm{Fl}\,I \leqslant \pi$. p. 13 [page 74]

Condition b) : Filt^{π} stable par $\varprojlim_{I}$, quand $\operatorname{card}\mathrm{Fl}\,I \leqslant \pi$ ([10]). Soit donc $(x_i)_{i\in I}$, où

$$\begin{array}{ccc} I & \longrightarrow & \mathcal{M} \\ i & \longmapsto & x_i \end{array}$$

un système inductif dans $\mathcal{M}$, avec des x_i dans Filt^{π}. Considérons le produit fibré

(4.3.6.4)
$$\begin{array}{ccccc} I & \xleftarrow{\text{cofibré}} & S/I = J & & \\ {\scriptstyle\varphi}\downarrow & & \downarrow & \searrow^{\psi} & \\ \mathcal{M} & \xleftarrow[\text{Cat-cofibré}]{\text{but}} & S/\mathcal{M} & \xrightarrow{\text{source}} & S \hookrightarrow \mathcal{M}\ , \end{array}$$

où J est Cat-cofibré sur I, sa fibre en $i \in \mathrm{Ob}\,I$ étant isomorphe à S/x_i, donc $\operatorname{card}\mathrm{Fl}\,J_i \leqslant \pi$. Comme par hypothèse $\operatorname{card}\mathrm{Fl}\,I \leqslant \pi$, on en conclut que $\operatorname{card}\mathrm{Fl}\,J \leqslant \pi^3 = \pi$. (**N.B.** L'ensemble des flèches $v : j_0 \longrightarrow j_1$ de J au dessus d'une flèche $u : i_0 \longrightarrow i_1$ de I est "contenu" dans l'ensemble produit $\mathrm{Ob}\,J_{i_0} \times \mathrm{Fl}\,J_{i_1}$, par l'application

$$v \longmapsto (\operatorname{source} v, v' : u_*(j_0) \longrightarrow j_1)\ ,$$

donc de cardinal majoré par π^2.) On a alors

10. quand I filtrante et grande devant π_0 – je ne le prouve que dans ce cas, hélas! [page 75]

$$x \overset{\text{déf}}{=} \varinjlim_{I} x_i = \varinjlim_{J} \underbrace{\xi_j}_{=\psi(j)} \qquad ([11]),$$

où cette fois la limite est une limite d'objets de S, prise dans $\mathcal{M}$. Il s'ensuit que $x \in \mathrm{Filt}'^{\pi}$, ce n'est pas tout à fait $x \in \mathrm{Filt}^{\pi}$. (Ça implique $x \in \mathrm{Filt}^{\pi^{\pi_0}}$, donc $x \in \mathrm{Filt}^{\pi}$ si $\pi = \pi^{\pi_0}$, p.ex. $\pi = 2^c$ avec $c \geqslant \pi_0$.) Mais c'est le moment d'utiliser le fait que les objets de S sont accessibles, et on prendra π_0 tel que les objets de S soient π_0-accessibles, et cette fois on prendra quand même I filtrante et grande devant π_0 (pour nous borner à ce qui est exigé dans la condition b) de loc. cit.). On doit prouver que $\mathrm{card}\,(\mathrm{Fl}(S/x)) \leqslant \pi$ (ce qui signifie $x \in \mathrm{Filt}^{\pi}$). Mais comme les objets de S sont π_0-accessibles et I grande devant π_0, on voit aussitôt que

$$S/x \simeq \varinjlim_{i} S/x_i ,$$

d'où p. 14

$$\mathrm{Fl}\ S/x \simeq \varinjlim_{i} \mathrm{Fl}\ S/x_i ,$$

donc

$$\mathrm{card}\,\mathrm{Fl}(S/x) \leqslant \underbrace{(\mathrm{card}\, I)}_{\leqslant \pi}\ \underbrace{(\sup_i \mathrm{card}\,\mathrm{Fl}(S/x_i))}_{\leqslant \pi} \leqslant \pi^2 = \pi ,$$

q.e.d.

Prouvons c) ([12]), i.e. que pour tout $\pi' > \pi \geqslant \pi_0$ et tout $x \in \mathrm{Ob}\ \mathrm{Filt}^{\pi'}$, on peut écrire [page 76]

(4.3.6.5) $\qquad x = \varinjlim_{I} x_i \qquad I$ grande devant π, les x_i dans Filt^{π}, $\mathrm{card}\, I \leqslant \pi'^{\pi}$.

La démonstration se fait comme dans loc. cit. (p. 151-152), en changeant légèrement la définition de I, comme désignant l'ensemble des sous-catégories pleines i de S/x qui sont filtrantes, de cardinal $\leqslant \pi$ *et de plus grandes devant* π_0 ([13]). (On pourra supposer S/x filtrante en augmentant S de façon à ce que S soit stable dans $\mathcal{M}$ par petites $\varinjlim$ finies, donc les catégories S/x aussi, ce qui implique qu'elles sont filtrantes. Il est `[phrase incomplète]`)

On a donc prouvé PTA $\Longrightarrow$ c).

Commentary · Exposition [ms. 76]

Why the first filtration argument stops

Grothendieck wants a presentation which controls not only the existence of small pieces but also their number. The two proposed measurements record different information. The condition $|\mathrm{Fl}(S/x)| \leq \pi$ counts *all* maps from probes and their relations. The primed condition asks for one strictly epimorphic family from at most π probes. The first implies the second, but a family which covers x need not furnish lifts of every map from a probe into x.

This distinction matters already on page 73. The estimate $|\mathrm{Fl}(S/x)| \leq \pi^{\pi_0}$ cited from SGA 4 is proved there for a universally epimorphic, pullbackable covering family; see Artin et al. (1972, Exposé I, Proposition 7.6 and Proposition 9.13). That hypothesis allows a map into x to be pulled back to a covering family and then encoded by maps among the probes. Accessibility alone is not the hypothesis of that estimate. Its use in the present argument is therefore not justified by the

11. On utilise la propriété de distributivité des $\varinjlim$, relative à un foncteur Cat-cofibrant

$$\begin{array}{ccc} J & \longrightarrow & I \\ & \searrow & \\ & & \mathcal{M} \end{array} ,$$

explicitée dessus.

12. *Démonstration canulée*, ne marche que si $\pi^{\pi_0} = \pi$!!

13. Il n'est pas sûr que I soit grande devant π, sauf si on suppose $\pi^{\pi_0} = \pi$!

cited result. This identifies a missing inference, rather than a counterexample to every possible version of the estimate.

Several parts of the argument do work. There are only a small set of presheaves on S whose categories of elements have at most π arrows, up to isomorphism, so the unprimed layer is essentially small. If I is κ-filtered, the objects of S are κ-presentable, $|\operatorname{Fl} I| \le \pi$, and $|\operatorname{Fl}(S/x_i)| \le \pi$, then

$$|\operatorname{Ob}(S/\operatorname{colim}_I x_i)| \le \sum_{i\in I} |\operatorname{Ob}(S/x_i)| \le \pi.$$

For a fixed arrow $s \to t$ in S, the arrows over it are determined by a map $t \to \operatorname{colim}_I x_i$. Thus the number of all arrows is at most $|\operatorname{Fl} S| \cdot \pi \le \pi$. This is a precise version of the calculation on pages 74–75. It uses filtered colimits of the relevant size, not arbitrary colimits. The two projective-limit signs on page 74 are source slips; the argument concerns colimits.

The proposed proof of the decomposition axiom on page 76 requires more. Starting with at most π arrows of S/x, one must close the resulting subcategory under simultaneous cocones for at most π_0 constraints. The number of constraints can be π^{π_0}, so closure need not stay within π. A fixed-point hypothesis such as $\pi^{\pi_0} = \pi$ permits the familiar closure construction: adjoin chosen cocones for all these constraints, iterate through an ordinal of cofinality greater than π_0, and keep cardinality π. Without a bound of this kind, the ordered collection of proposed small subcategories has not been shown to be large enough in the required sense. The manuscript explicitly retracts this step in its footnotes; the sentence claiming that PTA implies condition (c) is not supported by the preceding proof.

The failure can be seen without uncertain cardinal arithmetic. Take $\mathcal{M} = \mathbf{Set}$, let S be a skeleton of finite sets, and put $\pi_0 = \pi = \aleph_0$. Let x be an infinite set. The proposed poset I consists of countable full subcategories of S/x which are $\aleph_1$-filtered. For each $t \in x$, the singleton subcategory on the map $1 \to x$ with value t is such a subcategory. If countably many distinct such singleton subcategories had an upper bound $K \in I$, $\aleph_1$-filteredness would give a common cocone for their countable family of objects. Its vertex would be a finite set mapping to x whose image contains all those distinct values, which is impossible. Thus this particular I is not grand devant $\aleph_0$. Sets still have the desired decompositions, for instance by their countable subsets; the failed part is the proposed indexing construction.

The repair should preserve that distinction. The direct construction in the preceding block proves an ind-presentation from accessible probes. It does not identify the provisional filtration with the later intrinsic filtration by presentability ranks. The latter comparison is the subject of Section 4.5, and the manuscript itself points forward to Section 4.6 for a corrected proof of the theorem. An audit can therefore retain the theorem's structural content while recording that this particular numerical proof is abandoned.

Prouvons c) $\Longrightarrow$ d). Soit

$$\pi_1 \;=\; 2^c \qquad \text{avec} \qquad c \;\geqslant\; \pi_0\ .$$

On sait alors que

$$\operatorname{Filt}^{\pi_1}\mathcal{M} \;=\; \mathcal{M}_{\pi_1} \overset{\text{déf}}{=} \text{ sous-catégorie pleine de } \mathcal{M} \text{ des objets } \pi_1\text{-accessibles de } \mathcal{M}$$

(loc. cit. 9.16), ce qui implique notamment que $\mathcal{M}_{\pi_1}$ est stable par $\varinjlim$ de cardinal $\leqslant \pi_1$, en vertu de loc. cit. 9.9 (page 145). De plus, par loc. cit. 9.18 b) (p. 156), on a

[page 77]

$$\operatorname{Ind}_{\pi_1}(\mathcal{M}_{\pi_1}) \xrightarrow{\sim} \mathcal{M}\ ,$$

ce qui prouve d).

Prouvons d) $\Longrightarrow$ PTA. Par loc. cit. 9.18 a) (p. 156), on voit que les objets de $\mathcal{M}_{\pi_1}$ sont π_1-accessibles dans $\operatorname{Ind}_{\pi_1}(\mathcal{M}_{\pi_1})$, d'autre part il est clair que $\mathcal{M}_{\pi_1}$ est une sous-catégorie pleine strictement génératrice de $\operatorname{Ind}_{\pi_1}(\mathcal{M}_{\pi_1})$, donc il reste à voir que $\operatorname{Ind}_{\pi_1}(\mathcal{M}_{\pi_1})$ est stable par petites $\varinjlim$, i.e. le

Lemme 4.3.7. *Soit $\mathcal{M}_\pi$ une $\mathfrak{U}$-catégorie stable par limites inductives de cardinal $\leqslant \pi$, où π est un cardinal infini donné. Alors $\operatorname{Ind}_\pi \mathcal{M}_\pi$ est stable par petites limites inductives. De* p. 15

plus, $\mathcal{M} = \mathrm{Ind}_\pi \mathcal{M}_\pi$, munie de $\mathcal{M}_\pi \longrightarrow \mathcal{M}$, est solution d'un problème 2-universel, à savoir que pour toute catégorie $\mathcal{N}$ stable par petites limites inductives, le foncteur restriction induit une équivalence

$$\underline{\mathrm{Hom}}_!(\mathcal{M},\mathcal{N}) \xrightarrow{\sim} \underline{\mathrm{Hom}}_{!\,\pi}(\mathcal{M}_\pi,\mathcal{N}) \ , \tag{4.3.7.1}$$

où le signe ! (resp. $!\,\pi$) désigne la sous-catégorie pleine de la catégorie Hom*, formée des foncteurs qui commutent aux petites* $\varinjlim$ *(resp. aux limites inductives de cardinal $\leqslant \pi$).*

Prouvons d'abord que les $\varinjlim$ de cardinal $\leqslant \pi$ *dans* $\mathcal{M}_\pi$ sont aussi des $\varinjlim$ *dans* $\mathcal{M} = \mathrm{Ind}_\pi \mathcal{M}_\pi$ ([14]). On a donc [page 78]

$$x \xleftarrow{\sim} \varinjlim_I x_i \qquad \textit{dans } \mathcal{M}_\pi \ ,$$

i.e.

$$(*) \qquad \mathrm{Hom}(x,y) \xrightarrow{\sim} \varprojlim_I \mathrm{Hom}(x_i,y) \qquad \text{si } y \in \mathrm{Ob}\,\mathcal{M}_\pi \ ,$$

prouvons que cela reste vrai pour y dans $\mathcal{M}$, i.e. y de la forme

$$y \ = \ \varinjlim_J y_j \ , \qquad J \text{ grande devant } \pi, \text{ les } y_j \text{ dans } \mathcal{M}_\pi.$$

On a en effet

$$\begin{aligned} \mathrm{Hom}(x,y) \ &\simeq \ \varinjlim_J \mathrm{Hom}(x,y_j) \\ &\overset{(*)}{\simeq} \ \varinjlim_J \varprojlim_I \mathrm{Hom}(x_i,y_j) \\ &\overset{\text{SGA 4 I 9.8}}{\simeq} \ \varprojlim_I \varinjlim_J \mathrm{Hom}(x_i,y_j) \\ &\simeq \ \varprojlim_I \mathrm{Hom}(x_i,y) \ , \end{aligned}$$

au total

$$\mathrm{Hom}(x,y) \ \simeq \ \varprojlim_I \mathrm{Hom}(x_i,y),$$

q.e.d.

Pour prouver que les petites $\varinjlim$ sont représentables dans $\mathcal{M} = \mathrm{Ind}_\pi(\mathcal{M}_\pi)$, comme elles le sont dans $\mathrm{Ind}(\mathcal{M}_\pi)$ (SGA 4 I 8.9.5 b, on utilise l'hypothèse que les $\varinjlim$ *finies* sont représentables dans $\mathcal{M}_\pi$), il reste à voir que $\mathrm{Ind}_\pi(\mathcal{M}_\pi)$ est stable dans $\mathcal{M}_\pi$ par ces limites.

Commentary · Examples [ms. 78]

Which colimits the ind-completion remembers

Grothendieck's warning on page 78 is essential to the next section. An ind-completion always remembers the original category fully faithfully, but it remembers a colimit *as a colimit* only when the objects allowed as targets impose the appropriate continuity condition. Here the large filtering condition supplies precisely that condition.

Let $\kappa = \pi^+$, suppose C has colimits of diagrams with fewer than κ arrows, and let $x = \mathrm{colim}_{i\in I}\, x_i$ be such a colimit in C. If $Y = \mathrm{colim}_{j\in J}\, h_{y_j}$ is a κ-filtered colimit of representables, then

$$\begin{aligned} \mathrm{Hom}(h_x, Y) &\cong \mathrm{colim}_{j\in J}\, C(x,y_j) \\ &\cong \mathrm{colim}_{j\in J}\, \lim_{i\in I^{\mathrm{op}}} C(x_i,y_j) \\ &\cong \lim_{i\in I^{\mathrm{op}}} \mathrm{colim}_{j\in J}\, C(x_i,y_j) \cong \lim_{i\in I^{\mathrm{op}}} \mathrm{Hom}(h_{x_i}, Y). \end{aligned}$$

The middle interchange is justified because there are fewer than κ simultaneous representatives and compatibility equations to choose. First choose a common upper stage for the representatives; then

14. Mais *attention*, $\mathcal{M}_\pi \longrightarrow \mathrm{Ind}(\mathcal{M}_\pi)$ ne commute *pas* à ces $\varinjlim$!

choose a common upper stage where the equations hold. Injectivity follows by doing the same for the equations expressing equality. Thus $C \to \mathrm{Ind}_\kappa C$ preserves the indicated colimit. Notice that the colimit need not be the pointwise colimit in $C^\wedge$.

One explicit example separates the two completions. Let C be a skeleton of the category of countable sets, let $\pi = \aleph_0$, and put $\kappa = \aleph_1$. Countable colimits of countable sets are countable. Every set X is the $\aleph_1$-filtered union of its countable subsets, since a countable collection of countable subsets has countable union. A map from a countable set into such a union factors through one stage, and two maps which become equal agree at a later stage. It follows that the restricted Yoneda functor identifies

$$\mathrm{Ind}_{\aleph_1} C \simeq \mathbf{Set}.$$

In particular, the countable coproduct of the singleton objects is represented by the countable set $\mathbb{N}$.

In the ordinary filtered completion $\mathrm{Ind}_{\aleph_0} C$, however, consider the filtered diagram of finite subsets $A \subset \mathbb{N}$. Its colimit is the presheaf

$$F(c) = \mathrm{colim}_{A \subset \mathbb{N} \text{ finite}} C(c, A) = \{f : c \to \mathbb{N} \mid f(c) \text{ is finite}\}.$$

This is not $h_{\mathbb{N}}$: evaluating at $c = \mathbb{N}$ misses the identity map. Since finite coproducts of representables agree with those in C, this F is the countable coproduct of the singleton in the ordinary ind-completion. The inclusion of C therefore does not preserve this countable coproduct there.

The proposed final sentence of page 78 cannot establish closure of $\mathrm{Ind}_\pi C$ under colimits *inside* ordinary $\mathrm{Ind}\, C$ either. In this example its countable coproduct would be F, which is not $\aleph_1$-continuous on C°: $F(\mathbb{N})$ consists only of finite-image maps, whereas the product of countably many copies of $F(1) = \mathbb{N}$ contains every sequence. Section 4.4 correctly turns instead to constructing colimits intrinsically in the restricted completion.

[page 79]

4.4 Étude de $\mathrm{Ind}_\pi(C)$ (pour C petite catégorie stable par $\varinjlim$ de cardinal $\leqslant \pi$)

4.4.1. Finalement, la démonstration du lemme 4.3.7 n'est pas tellement évidente que je l'anticipais, et il me faut lui consacrer des préliminaires techniques, que je vais réunir ici. Dans toute la suite, C représente une $\mathfrak{U}$-catégorie équivalente à une petite catégorie.

Proposition 4.4.2. *Soit $F \in C^\wedge$ un foncteur ind-représentable, i.e. tel que C/F soit filtrante. Soit d'autre part $i \longmapsto x_i$ un foncteur $I \longrightarrow C$, où I est une petite catégorie filtrante, et soit* p. 16

$$\alpha \;:\; x \;=\; \varinjlim_I {}^{C^\wedge} x_i \longrightarrow F \qquad (4.4.2.1)$$

[15]

*un système projectif de flèches $x_i \longrightarrow F$ (**N.B.** la limite inductive x est prise dans $C^\wedge$, et est calculée argument par argument), ce qui équivaut à une factorisation $\varphi_\alpha : I \longrightarrow C/F$ de $I \longrightarrow C$ en*

$$I \xrightarrow{\varphi_\alpha} C/F \underset{\psi}{\xleftarrow{can.}} C\ .$$

Ceci dit, pour que α (4.4.2.1) soit un isomorphisme dans $\mathrm{Ind}'(C) \subset C^\wedge$ (sous-catégorie pleine des foncteurs ind-représentables sur C), il faut et il suffit que φ_α soit cofinal*, ou ce qui revient au même, I étant filtrante, qu'il satisfasse les deux conditions habituelles :*

F 1) *$\forall\, \xi \in \mathrm{Ob}\, C/F$, $\exists\, i \in \mathrm{Ob}\, I$ et une flèche $\xi \longrightarrow \varphi_\alpha(i)$.*

F 2) *$\forall\, \xi \in \mathrm{Ob}\, C/F$, et $i \in \mathrm{Ob}\, I$, et toute double-flèche*

$$\xi \rightrightarrows \varphi_\alpha(i)\ ,$$

[page 80]

il existe une flèche $i \xrightarrow{u} j$ dans I telle que $\varphi_\alpha(u)$ égalise la double-flèche.

15. La donnée de α équivaut aussi à celle d'un homomorphisme d'ind-objets $(x_i)_{i \in I} \longrightarrow F$, F étant considéré comme ind-objet (généralisé) indexé par C/F.

Démonstration. Si φ_α est cofinal, on en conclut par définition que $\varinjlim \varphi_\alpha \longrightarrow \varinjlim \psi\varphi_\alpha$ est un isomorphisme, or cette flèche n'est autre que α. Inversement, supposons que cette flèche soit un isomorphisme, donc $C/F \xleftarrow{\sim} C/\varinjlim x_i$, et il reste à voir que le foncteur canonique

$$I \longrightarrow C/\varinjlim_{C^\wedge} x_i$$

est cofinal, i.e. satisfait F 1) et F 2). La vérification est ± tautologique, en utilisant le fait que pour tout y dans C, on a

$$\mathrm{Hom}(y, \varinjlim_{C^\wedge} x_i) \xleftarrow{\sim} \varinjlim_{\mathrm{Ens}} \mathrm{Hom}(y, x_i),$$

et du "calcul" des limites inductives filtrantes dans Ens.

Commentary · Exposition [ms. 80]

Cofinality as an elementwise presentation criterion

The point of Proposition 4.4.2 is to replace a statement about equality of ind-objects by a statement about the category indexing their elements. That change makes later simultaneous constructions possible: one can arrange factorization and equality at stages, rather than manipulate abstract maps out of a completed category.

Let $F : C^{\mathrm{op}} \to \mathbf{Set}$, and write C/F for its category of elements. An object is a pair (c, u) with $u \in F(c)$; a morphism $(c, u) \to (d, v)$ is a map $a : c \to d$ satisfying $F(a)(v) = u$. There is always a canonical presentation

$$F \cong \operatorname*{colim}_{(c,u)\in C/F} h_c \qquad \text{in } C^\wedge.$$

A map $\alpha : \mathrm{colim}_{i\in I} h_{x_i} \to F$ is consequently the same as compatible choices $u_i \in F(x_i)$, hence a functor $q : I \to C/F$ over C.

If q is final, replacing C/F by I in the canonical presentation gives α as an isomorphism. Conversely, suppose I is filtered and α is an isomorphism. For any $(c, u) \in C/F$, the identity

$$F(c) \cong \mathrm{colim}_{i\in I} C(c, x_i)$$

represents u by some arrow $c \to x_i$. This is F1. If two arrows $(c, u) \rightrightarrows q(i)$ are given, their underlying maps $c \rightrightarrows x_i$ have the same image in that colimit of sets. Filteredness supplies a later arrow $i \to j$ at which the two composites agree. This is F2. These conditions make every comma category $(c, u) \downarrow q$ nonempty and connected: two objects can first be moved to a common index of I, and their remaining discrepancy can then be equalized. Thus q is final.

For $\kappa = \pi^+$, the same observation yields the clean formulation of Corollary 4.4.5:

$$F \in \mathrm{Ind}_\kappa C \quad \Longleftrightarrow \quad C/F \text{ is } \kappa\text{-filtered.}$$

One implication follows by the presentation criterion and the stability of κ-filteredness under a final functor from a κ-filtered category. For the other, the canonical presentation itself is a κ-filtered presentation. If ind-objects are required to use ordered indexing sets, the replacement by a final κ-directed poset is justified in the next block. What is not required is that each bounded collection of arrows of C/F lie inside a subcategory with an actual terminal object. The distinction is exactly the one exposed by the editors' idempotent example.

Corollaire 4.4.3. *Soit π un ordinal infini. Pour que F soit dans $\mathrm{Ind}'_\pi(C)$ (image essentielle de $\mathrm{Ind}_\pi(C)$ dans $C^\wedge$), il faut et il suffit qu'il existe une catégorie ordonnée grande devant π I, et un foncteur cofinal $I \longrightarrow C/F$.*

Il nous faut donc donner des conditions, sur une catégorie J $(= C/F)$, pour qu'il existe une catégorie ordonnée I grande devant π, et un foncteur cofinal $I \longrightarrow J$.

Une telle catégorie s'appellera *grande devant π*. (Il est immédiat que dans le cas où J est elle-même ordonnée, cette terminologie est cohérente avec celle déjà adoptée pour les ensembles ordonnés, i.e. que s'il existe une application croissante cofinale $\varphi : I \longrightarrow J$, avec I grand devant π, alors J est lui-même grand devant π.) Une telle catégorie est automatiquement [page 81] p. 17

filtrante (SGA 4 I 8.1.3 b)). Notons aussi que si on a un foncteur cofinal $J \longrightarrow J'$, si J est grande devant π, J' l'est aussi (par transitivité de la cofinalité).

Proposition 4.4.4. *Soient J une $\mathfrak{U}$-catégorie, π un cardinal infini. Conditions équivalentes :*

a) J est grande devant π, i.e. il existe un ensemble ordonné grand devant π et un foncteur cofinal $\varphi : I \longrightarrow J$.

b) J satisfait les deux conditions suivantes :

PF$_\pi$ 1 *$\operatorname{Ord} J$ est grande devant π, i.e. pour toute famille $(y_\alpha)_{\alpha\in A}$ d'objets de J, avec $\operatorname{card} A \leqslant \pi$, il existe un majorant y dans J (i.e. un y et des flèches $y_\alpha \xrightarrow{v_\alpha} y$).*

PF$_\pi$ 2 *Pour y_0, y_1 dans J et tout ensemble $(u_\alpha)_{\alpha\in A}$ de flèches $y_0 \xrightarrow{u_\alpha} y_1$ avec $\operatorname{card} A \leqslant \pi$, il existe une flèche $y_1 \xrightarrow{u'} y_2$ qui les égalise, i.e. telle que $u'u_\alpha = u'u_\beta \;\forall\, \alpha, \beta \in A$. (Il suffit de l'exiger quand $\operatorname{card} A \geqslant 2$.)*

c) Pour toute partie A de $\operatorname{Fl} J$, avec $\operatorname{card} A \leqslant \pi$, existe une sous-catégorie J' de J, avec $\operatorname{card} \operatorname{Fl} J' \leqslant \pi$, telle que $A \subset \operatorname{Fl} J'$ et que J' admette un objet final.

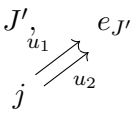
d) Soit I l'ensemble des sous-catégories J' de J telles que $\operatorname{card} J' \leqslant \pi$ et ayant un objet final

et ordonnons I par inclusion. Alors I est grand devant π, de plus le foncteur canonique [page 82]
$I \longrightarrow J$ ($J' \longmapsto e_{J'}$ = objet final de J') est cofinal ([16], [17], [18]).

([19])

Démonstration.

a $\Longrightarrow$ b vérification immédiate, en utilisant le critère F 1, F 2 de la cofinalité pour I filtrante.



b $\Longrightarrow$ c par AQT [âne qui trotte].

c $\Longrightarrow$ d par AQT [âne qui trotte].

d $\Longrightarrow$ a Considérons l'ensemble ordonné grand devant π construit dans l'énoncé de d), et le *foncteur* p. 18

$$I \longrightarrow J$$

donné par $J' \longmapsto e_{J'}$ = objet final de J'. (Vérification que c'est un foncteur immédiate.) Ce foncteur est surjectif, donc satisfait la condition F 1 de cofinalité. La condition F 2 résulte aussi de d) en regardant les trois objets J', $j \xrightarrow{u_1} e_{J'}$, $j \xrightarrow{u_2} e_{J'}$ de I,

16. Introduire $I(J)$ avant l'énoncé de la proposition. **N.B.** La condition de cofinalité $I(J) \longrightarrow J$ n'est pas automatique, comme on voit en prenant $J = B_G$, $G = \{\pm 1\}$.

17. **N.B.** L'hypothèse de cofinalité est superflue si J est rigide, i.e. tout endomorphisme d'un objet de J est identique.

18. N. Éd. Dans cette condition (d), le "*de plus le foncteur … est cofinal*" est ajouté par Grothendieck *a posteriori*, ce qui explique sa vaine tentative de l'établir dans l'implication d $\Longrightarrow$ a ci-dessous, implication qui devient évidente après cet ajout. Par ailleurs, les conditions (c) et (d) ne sont *pas* impliquées par les conditions équivalentes (a) et (b). Par exemple, si J est la catégorie ayant un seul objet et un seul morphisme non identique p tel que $p^2 = p$, alors J satisfait aux conditions (a) et (b), mais *pas* aux conditions (c) et (d).

19. Autres conditions :

e) Pour tout ensemble A avec $\operatorname{card} A \leqslant \pi$, $\operatorname{diag}_J : J \longrightarrow J^A$ est cofinal.

e′) (Si A_0 est un ensemble donné, de cardinal $= \pi$.) $J \longrightarrow J^{A_0}$ est cofinal.

Voir aussi 4.9.6.9.1 et 4.9.6.9.2, pages 237, 238.

et en prenant un J'' qui les majore tous trois, alors $e_{J'} \longrightarrow e_{J''}$ égalise u_1, u_2 ([20]).

Corollaire 4.4.5. *Soit $F \in \mathrm{Ob}\, C^\wedge$. Pour que F appartienne à $\mathrm{Ind}'_\pi(C)$, il faut et il suffit que C/F satisfasse à l'ensemble des quatre conditions équivalentes de 4.4.4.*

Corollaire 4.4.6. *Soit J une catégorie stable par $\varinjlim$ de cardinal $\leqslant \pi$. Alors J est grande devant π.*

En effet, les conditions $\mathrm{PF}_\pi 1$, $\mathrm{PF}_\pi 2$ sont visiblement vérifiées.

Commentary · Development (commentators') [ms. 82]

A corrected terminal-subcategory criterion

Grothendieck is trying to turn simultaneous solvability of equations into a particularly concrete indexing poset: its elements would be small subcategories already possessing a final object. The editors explain why this construction is too restrictive. We first give the correct general replacement, then show precisely when his proposed one works. The filtered-category argument is classical; the second statement isolates and proves the repair suggested by his rigidity footnote. We checked the formulation in SGA 4 I, Section 8.1, the present edition's note 18, and the later product criterion cited below; we did not find this exact bounded rigid formulation there. The label on the second result records our proof of that formulation, not a claim of priority.

For a small category J and an infinite cardinal π, put $\kappa = \pi^+$. Conditions $\mathrm{PF}_\pi 1$ and $\mathrm{PF}_\pi 2$ are equivalent to saying that every diagram with fewer than κ arrows has a cocone. To prove the nontrivial direction, first choose a common target for all objects in the diagram. For each arrow $a : i \to j$ there are then two maps from its source to that target, namely the chosen map at i and the composite through j. Use $\mathrm{PF}_\pi 2$ to choose a map from the common target to an object z_a equalizing that individual pair, then choose a common target z of all the z_a. The resulting maps from the original common target to z need not coincide; apply $\mathrm{PF}_\pi 2$ to this family. Their common composite equalizes every required pair. If there are no compatibility pairs, the first common target suffices. The empty diagram is included in $\mathrm{PF}_\pi 1$.

Such a small J admits a final functor from a κ-directed poset. Here is a construction which does not presume the false terminal-subcategory condition. Begin with a discrete poset P_0 having a vertex over each object of J. Inductively maintain a functor $q_\alpha : P_\alpha \to J$ such that every principal downset in P_α has fewer than κ elements. At the next stage, for every subset $A \subset P_\alpha$ of size less than κ, adjoin a new vertex above its downward closure. That closure has size less than κ by regularity, so a chosen cocone of its image defines the new vertex and all arrows into it. Also, for every $p \in P_\alpha$ and every parallel pair $u, v : j \rightrightarrows q_\alpha(p)$, adjoin a vertex above the downset of p whose transition map equalizes u, v. This is possible by applying the cocone condition to that downset with a new formal source and those two arrows. Distinct new vertices are left incomparable. At limit stages take unions.

After κ stages the union P is a set, all its principal downsets remain of size less than κ, and any subset of P of size less than κ occurs at one earlier stage and hence has an upper bound. Thus P is κ-directed. The functor $q : P \to J$ satisfies F1 because of P_0, and F2 because every parallel-pair requirement is addressed at a successor stage. The preceding presentation criterion proves that q is final. This supplies the implication $b \Rightarrow a$ of Proposition 4.4.4 in the small case needed for $J = C/F$.

Proposition (the rigid repair). [ours] Suppose J is small and every endomorphism of every object of J is an identity. Then J is κ-filtered if and only if every set of at most π arrows of J is contained in a subcategory with at most π arrows and a terminal object. In that event, the poset of these terminal subcategories is κ-directed, and the functor choosing their terminal objects is final.

Proof. Let A be the prescribed set of arrows. Close it under identities and finite composition to obtain a subcategory K with at most π arrows. Choose a cocone $\eta : K \to j$ in J. Adjoin j, the arrows $\eta_k : k \to j$, and the identity of j. If j was not in K, the generated subcategory has no nonidentity arrow leaving j, and every path ending at j equals the appropriate η_k by naturality. Hence j is terminal. If j already belongs to K, rigidity forces $\eta_j = 1_j$. For an old arrow $a : k \to j$, naturality gives $a = \eta_j a = \eta_k$. All newly generated paths ending at j reduce to the same arrow, again by naturality. Thus j is terminal in this case too. The enlarged subcategory still has at most π arrows.

20. Un peu bref, le cas où $e_{J'} = j$ échappe à cet argument, et demande qu'on `[phrase incomplète]`

Conversely, the arrow set of a diagram of at most π arrows is contained in such a terminal subcategory, whose terminal object gives a cocone. For directedness, take at most π terminal subcategories, form the union of their arrow sets, and apply the proved condition. Their union has at most π arrows. To prove finality of the terminal-object functor, every object of J occurs in its singleton subcategory, giving F1. Given a terminal subcategory K and two maps $j \rightrightarrows e_K$, enlarge the arrow set of K by this pair and choose a terminal subcategory containing it. The unique map from e_K to the new terminal object equalizes the pair, giving F2. This completes the proof.

The rigidity hypothesis addresses the precise obstruction. In the one-object category with arrows $1, p$ and $p^2 = p \neq 1$, every family of parallel arrows is equalized by postcomposition with p, so the category is κ-filtered for every infinite κ. A subcategory containing p cannot have a terminal object: its only object has two endomorphisms. Its only terminal subcategory is therefore the identity-only subcategory. The resulting functor from the singleton indexing poset is not final, since the relevant comma category has two disconnected objects. This proves the editors' failure of both (c) and (d), and explains why Corollary 4.4.5 must refer to (a) or (b), rather than to all four printed conditions.

Commentary · Later developments [ms. 82]

The infinite-product criterion

The diagonal conditions in note 19 point toward a valid alternative. For a small J, finality of $J \to J^A$ for every $|A| \leq \pi$, including $A = \varnothing$, means that J-colimits of sets commute with these products. Since π is infinite, Adámek et al. (2000, Theorem 3.1) identifies this condition with π^+-filteredness. The restriction to infinite π matters: finite-product commutation alone is the weaker condition of siftedness.

The single-power condition (e′) needs a nonemptiness clause. For $J = \varnothing$ and a nonempty set A_0, both J and J^{A_0} are empty, so the diagonal is final vacuously. For nonempty J, finality of the indicated diagonal first forces connectedness. Padding a smaller family with constant singleton diagrams then reduces its product comparison to the A_0 comparison. Thus (e′) recovers (e) with that clause added.

[page 83]

4.4.6. Je me donne un foncteur

$$J \xrightarrow{\varphi} \operatorname{Ind}'_\pi C\ , \tag{4.4.6.1}$$

J une petite catégorie, et on cherche une $\varinjlim$ dans $\operatorname{Ind}'_\pi C$, en postulant au besoin l'existence des $\varinjlim$ de cardinal $\leqslant \pi$ dans C, et l'hypothèse $\operatorname{card} \operatorname{Fl} J \leqslant \pi$. Le procédé le plus naturel pour ramener la question de l'existence des $\varinjlim$ dans $\operatorname{Ind}'_\pi C$, à la question similaire dans C, est explicité dans SGA 4 I 8.8.3. On considère l'inclusion pleinement fidèle

$$C \xhookrightarrow{\alpha} \operatorname{Ind}'_\pi C\ , \tag{4.4.6.2}$$

laquelle commute aux $\varinjlim$ de cardinal $\leqslant \pi$ (celles qui sont représentables dans C, cf. p. 78 et référence à SGA 4 I 9.8), d'où

$$\underline{\operatorname{Hom}}(J, C) \xhookrightarrow{\alpha} \underline{\operatorname{Hom}}(J, \operatorname{Ind}'_\pi C) \tag{4.4.6.3}$$

également pleinement fidèle, et commutant aux $\varinjlim$ de cardinal $\leqslant \pi$ (représentables dans le premier membre). Cette flèche s'insère dans le carré commutatif relatif à la donnée d'un $j \in \operatorname{Ob} J$, et des foncteurs d'inclusion

$$e \xrightarrow{\varepsilon_j} J\ , \qquad e_j(e) \ = \ j\ ; \tag{4.4.6.4}$$

p. 19
[page 84]

$$\begin{array}{ccc} \underline{\operatorname{Hom}}(J, C) & \xrightarrow{\alpha^J} & \underline{\operatorname{Hom}}(J, \operatorname{Ind}'_\pi C) \\ \downarrow{\scriptstyle \varepsilon_j^*} & & \downarrow{\scriptstyle \varepsilon_j^{*\prime}} \\ C & \xrightarrow{\alpha} & \operatorname{Ind}'_\pi(C) \end{array} \qquad \begin{array}{c} \ni \varphi \\ \downarrow \\ \ni \varphi(j)\ , \end{array} \tag{4.4.6.2}$$

([21])

lequel induit un foncteur

$$\underbrace{\underline{\mathrm{Hom}}(J/C)/\varphi}_{\overset{\text{déf}}{=} I} \xrightarrow{\varepsilon_j^{\varphi}} C/\varphi(j)\ . \tag{4.4.6.3}$$

Si C est stable par $\varinjlim$ relatives à un ensemble K du type de conditions $\leqslant \pi$ (p.ex. $\varinjlim$ finies), il en est de même de $\underline{\mathrm{Hom}}(J,C)$, et aussi de $\underline{\mathrm{Hom}}(J,C)/\varphi$, et de $C/\varphi(j)$, en vertu du fait que α^J et α commutent aux $\varinjlim$ du type envisagé, de plus (4.4.6.3) commute aux limites en question. Supposons donc C stable tout au moins par $\varinjlim$ finies, donc les catégories source et but dans (4.4.6.3) sont filtrantes. (Le fait que le foncteur commute aux $\varinjlim$ finies ne semble pas utile dans le contexte présent.) Cela nous servira pour avoir le critère commode de cofinalité SGA 4 I 8.1.3 b) par F 1, F 2.

Commentary · Exposition [ms. 84]

One index category for an entire diagram

The next difficulty is coherence. An individual ind-object has many filtered presentations, but presentations chosen separately at the vertices of a diagram need not carry its arrows and relations. Grothendieck uses the category of all coherent approximations at once:

$$I = \mathrm{Fun}(J, C)/\varphi.$$

An object of I consists of a C-valued diagram D and a natural transformation $\alpha D \to \varphi$, where $\alpha : C \to \mathrm{Ind}_\pi C$. A morphism is a natural transformation over φ. Evaluating at j gives $\varepsilon_j^{\varphi} : I \to C/\varphi(j)$. In general I is a category, not an ordered set; the phrase calling it an ordered set on page 85 is not needed by the argument.

The purpose of Lemma 4.4.9 is to show that each evaluation is final. We can prove its stronger assertion directly and avoid the temporary dependency on coproducts of arbitrary ind-objects. Assume that C admits the copowers indexed by the sets $J(j, j')$, all of cardinality at most π. Define

$$(L_j c)(j') = \coprod_{a \in J(j,j')} c.$$

An arrow $b : j' \to j''$ carries the summand indexed by a to the summand indexed by ba. This makes $L_j c$ a diagram in C. A natural transformation $L_j c \to D$ is uniquely determined by the map from the identity summand $c \to D(j)$; its component on the a-summand must be $D(a)$ composed with that map. Hence L_j is left adjoint to evaluation on C-valued diagrams.

Page 78 proves that α preserves these particular coproducts. Therefore, for any $\varphi : J \to \mathrm{Ind}_\pi C$, the same calculation gives

$$\mathrm{Nat}(\alpha L_j c, \varphi) \cong \mathrm{Hom}(\alpha c, \varphi(j)).$$

This calculation uses coproducts of copies of the representable object c only. It does not require the still-pending existence of coproducts of arbitrary objects of $\mathrm{Ind}_\pi C$.

For an object $(c, f : \alpha c \to \varphi(j))$ of $C/\varphi(j)$, let $\widetilde{f} : \alpha L_j c \to \varphi$ be the corresponding natural transformation. Set

$$R_j(c, f) = (L_j c, \widetilde{f}) \in I.$$

A map from $R_j(c, f)$ to (D, η) in I is a transformation $\theta : L_j c \to D$ with $\eta\alpha\theta = \widetilde{f}$. By the preceding calculation, this is exactly a map $g : c \to D(j)$ with $\eta_j \alpha(g) = f$, which is a map $(c, f) \to \varepsilon_j^{\varphi}(D, \eta)$ in the slice. These bijections are natural, proving $R_j \dashv \varepsilon_j^{\varphi}$. Every comma category $(c, f) \downarrow \varepsilon_j^{\varphi}$ has the resulting universal object as an initial object, so evaluation is final.

If C has all colimits of cardinality at most π, then so does I: take a colimit of approximating diagrams pointwise in C, use preservation by α, and form the induced map to φ. Thus I is π^+-filtered. Finality of each evaluation gives

$$\varphi(j) \cong \operatorname*{colim}_{i \in I} \alpha D_i(j).$$

21. Les foncteurs ε_j^*, $\varepsilon_j^{*\prime}$ sont les foncteurs évaluation en j.

If $|\operatorname{Fl} J| \leq \pi$, form $c_i = \operatorname{colim}_{j\in J} D_i(j)$ in C. Testing against any target Z and interchanging two limits of Hom sets gives

$$\operatorname{Hom}(\operatorname{colim}_{i\in I} \alpha c_i, Z) \cong \lim_{j\in J^{\mathrm{op}}} \operatorname{Hom}(\varphi(j), Z).$$

The left colimit exists by its π^+-filtered presentation. It therefore supplies the desired J-colimit in $\operatorname{Ind}_\pi C$. This proves the content of Lemma 4.4.7 and Corollary 4.4.8 after their explicitly stated cofinality reservation has been discharged.

[page 85]

Rappelons que la cofinalité des foncteurs (4.4.6.3), quand elle a lieu (?), implique le fait que φ est une limite inductive du foncteur composé

(4.4.6.4)
$$\begin{array}{ccccc} I & \xrightarrow{\psi_J} & \underline{\mathrm{Hom}}(J,C) & \xrightarrow{\alpha^J} & \underline{\mathrm{Hom}}(J,\mathrm{Ind}'_\pi(C)) \\ \| & & \vdots{\scriptstyle \varepsilon_j^*} & & \vdots{\scriptstyle \varepsilon_j^{*\prime}} \\ \underline{\mathrm{Hom}}(J,C)/\varphi & & & & \\ {\scriptstyle \varepsilon_j^\varphi}\downarrow & & & & \\ C/\varphi(j) & \xrightarrow{\psi_j} & C & \xrightarrow{\alpha} & \mathrm{Ind}'_\pi(C)\ , \end{array}$$

suivant l'ensemble ordonné filtrant I, plus précisément que φ est la $\varinjlim$ "argument par argument en j", ce qui signifie que pour tout $j \in \operatorname{Ob} J$, $\varphi(j) = \varepsilon_j^*(\varphi)$ est limite inductive de $\varepsilon_j^*(\alpha^J\psi) = (\alpha\psi_j)\varepsilon_j^\varphi$. (Or on sait en effet que $\varphi(j)$ est la limite de $\alpha\psi$, puisque $\varphi(j) \in \operatorname{Ob} C^\wedge$ est ind-représentable, donc aussi celle de $(\alpha\psi_j)\varepsilon_j^\varphi$ si ε_j^φ est cofinal.)

Ainsi, admettant la cofinalité de (4.4.6.3) et interprétant ψ_J dans (4.4.6.4)

[page 86]

$$\psi_J \ :\ I \longrightarrow \underline{\mathrm{Hom}}(J,C)$$

comme un foncteur

$$I \times J \xrightarrow{\Psi} C\ ,$$

on trouve la "représentation indicielle" de φ

$$\varphi(j) \ = \ \underbrace{\varinjlim_{i\in I} \psi(i,j)}_{\substack{\text{limite inductive}\\ \text{prise dans } \mathrm{Ind}'_\pi(C)\\ \text{d'objets de } C\hookrightarrow \mathrm{Ind}'_\pi(C)}} \quad ,$$

d'où

p. 20

$$\begin{aligned} \underbrace{\varinjlim_{j\in J} {}_{\mathrm{Ind}'_\pi C}\varphi(j)}_{\text{sous réserve d'existence}} &= \varinjlim_{j\in J} \varinjlim_{i\in I} \psi(i,j) \\ &= \varinjlim_{i\in I} \varinjlim_{j\in J} \psi(i,j)\ , \end{aligned}$$

toutes les limites inductives étant prises dans $\mathrm{Ind}'_\pi(C)$. Mais si les $\varinjlim$ de type J sont représentables dans C, et $\operatorname{card} J \leqslant \pi$, on sait que la $\varinjlim_{j\in J} \psi(i,j)$ *dans* C est aussi leur $\varinjlim$ dans $\mathrm{Ind}'_\pi C$, et on trouve donc que $\varinjlim_{j\in J} \varphi(j)$ existe dans $\mathrm{Ind}'_\pi(C)$ si et seulement si $\varinjlim_{i\in I} \Psi(i)$ existe dans $\mathrm{Ind}'_\pi(C)$, où pour $i \in I$, on pose

$$\Psi(i) \ = \ \varinjlim_{j\in J} \psi(i,j) \qquad \textit{dans } C.$$

Résumons ce que nous avons obtenu :

[page 87]

Lemme 4.4.7. *Soit C une petite catégorie, π un cardinal infini, J une catégorie telle que* $\operatorname{card} \operatorname{Fl} J \leqslant \pi$, *$\varphi : J \longrightarrow \mathrm{Ind}'_\pi(C)$ un foncteur. Supposons les $\varinjlim$ de type J existant dans C, et*

que les foncteurs ε_j^{φ} ($j \in \mathrm{Ob}\, J$) de (4.4.6.3) soient cofinaux *(ce qui s'explicite de façon simple surtout si source et but sont filtrants, chose acquise si C est stable par $\varinjlim$ finies). Alors φ a une "représentation indicielle canonique"*

$$\psi \ : \ I \times J \longrightarrow C \tag{4.4.7.1}$$

avec

$$I \ = \ \underline{\mathrm{Hom}}(J, C)/\varphi \ , \tag{4.4.7.2}$$

i.e. on a l'isomorphisme fonctoriel en $j \in \mathrm{Ob}\, J$

$$\varphi(j) \ \simeq \ \varinjlim_{I} \psi(i, j) \qquad ([22]) \ . \tag{4.4.7.3}$$

Posons pour tout $i \in \mathrm{Ob}\, I$

$$\Psi(i) \ = \ \varinjlim_{J} \psi(i, j) \qquad ([23]) \ . \tag{4.4.7.4}$$

Alors $\varinjlim_{j \in J} \varphi(j)$ (dans $\mathrm{Ind}'_\pi\, C$) existe si et seulement si la $\varinjlim_{i \in I} \Psi(i)$ existe (dans $\mathrm{Ind}'_\pi\, C$ également), et les deux sont égales. [page 88]

Corollaire 4.4.8. *Supposons que C soit stable par $\varinjlim$ de cardinal $\leqslant \pi$ (pas seulement par celles de type J). Alors $\underline{\mathrm{Hom}}(J, C)$ et $I = \underline{\mathrm{Hom}}(J, C)/\varphi$ ont la même propriété, I est grande devant π, et $\varinjlim_{j \in J} \varphi(j) \ = \ \varinjlim_{i \in I} \Psi(i)$ existe dans $\mathrm{Ind}'_\pi(C)$, sous réserve de cofinalité des foncteurs (4.4.6.3).*

Il suffit en effet de vérifier ce

Lemme 4.4.8.1. *Soit I une catégorie grande devant π, et $\Psi : I \longrightarrow C$ un foncteur. Alors $\varinjlim_i \Psi(i)$ existe dans $\mathrm{Ind}'_\pi(C)$, et c'est la limite inductive dans $C^\wedge$, ou encore "c'est" l'ind-objet grand devant π représenté par Ψ.* (En d'autres termes ([24]), $\mathrm{Ind}'_\pi(C) \subset C^\wedge$ est une sous-catégorie strictement pleine *stable* par $\varinjlim$ grandes devant π.) p. 21

Ce lemme est une tautologie : si F désigne la limite inductive dans $C^\wedge$, il est clair par définition (en prenant un foncteur $I_0 \longrightarrow I$ cofinal, avec I_0 *ordonnée* grande devant π, de sorte que la $\varinjlim$ peut être prise suivant I_0) que F est dans $\mathrm{Ind}'_\pi(C)$, et alors c'est a fortiori une $\varinjlim$ dans $\mathrm{Ind}'_\pi\, C$. [page 89]

Pour vérifier l'existence des $\varinjlim$ de cardinal $\leqslant \pi$ dans $\mathrm{Ind}'_\pi\, C$, dans le cas où C lui-même est stable par lesdites limites, il suffit donc, grâce au corollaire 4.4.8, de prouver la cofinalité des foncteurs (4.4.6.3). Cela va résulter du

Lemme 4.4.9. *Soient C une petite catégorie, π un cardinal infini, J une petite catégorie telle que pour tous $j, j' \in \mathrm{Ob}\, J$, on ait* $\mathrm{card}\, \mathrm{Hom}(j, j') \leqslant \pi$. *Sous ces conditions, pour tout $j \in \mathrm{Ob}\, J$, le foncteur (4.4.6.3)* admet un adjoint à gauche, *donc a fortiori il est cofinal (car les catégories colocalisées au dessus de $C/\varphi(j)$ ont un objet initial, a fortiori elles sont* 0*-connexes).*

Démonstration de 4.4.8. Revenons au diagramme (4.4.6.2), dont on déduit (4.4.6.3), nous allons le réécrire de façon simplifiée : [page 90]

$$\begin{array}{ccc} B & \xrightarrow{\beta} & B' \qquad \ni y'_0 \\ {\scriptstyle\lambda}\uparrow\downarrow{\scriptstyle\varepsilon} & & {\scriptstyle\lambda'}\uparrow\downarrow{\scriptstyle\varepsilon'} \qquad \downarrow \\ C & \xrightarrow{\gamma} & C' \qquad \ni z'_0 \ . \end{array} \tag{4.4.9.1}$$

22. limite inductive dans Ind'_π d'objets de C.
23. limite inductive prise dans C, mais valable aussi dans $\mathrm{Ind}'_\pi\, C$.
24. C'est abusif, cette stabilité est un énoncé nettement plus fort! Je le prouve page 99.

Je dis que ε, ε' ont *des adjoints à gauche* λ resp. λ', et que l'homomorphisme canonique de "changement de base"

$$\lambda'\gamma \longrightarrow \beta\lambda \tag{4.4.9.2}$$

est un *isomorphisme.* En effet, l'existence des adjoints de ε, ε', à savoir des foncteurs $\varepsilon_{j\,!}$ et $\varepsilon'_{j\,!}$ relatifs à l'inclusion

$$\varepsilon_j \ : \ e \longrightarrow J$$

et aux catégories de foncteurs $\underline{\mathrm{Hom}}(J, C)$ resp. $\underline{\mathrm{Hom}}(J, \mathrm{Ind}'_\pi C)$, résultant de l'existence des sommes de type $\mathrm{Hom}(j, j')$ ($j' \in \mathrm{Ob}\, J$) dans C (déjà acquise), *et dans* $\mathrm{Ind}'_\pi C$ *;* et le fait que le foncteur $C \longrightarrow \mathrm{Ind}'_\pi C$ commute auxdites sommes (chose également déjà acquise, puisque card $(\mathrm{Hom}(j, j')) \leqslant \pi$) implique alors que (4.4.4.2) est un isomorphisme. Moyennant la vérification en suspens (l'existence des sommes de cardinal $\leqslant \pi$ dans $\mathrm{Ind}'_\pi(C)$), le lemme 4.4.9 résultera du résultat plus général : [page 91] p. 22

Lemme 4.4.10. *Considérons un carré commutatif (4.4.9.1) (traits pleins) de catégories, où ε admet un adjoint à gauche λ, ε' un adjoint à gauche λ', et la flèche de changement de base (4.4.9.2) est un isomorphisme. Alors pour tout y'_0 dans B', posant $\varepsilon'(y'_0) = z'_0$, le foncteur induit par $(\varepsilon, \varepsilon')$,*

$$\overline{B} \ = \ B/y'_0 \xrightarrow{\bar{\varepsilon}} \overline{C} = C/z'_0 \ ,$$

admet un adjoint à gauche $\overline{\lambda}$, donné par

$$\overline{\lambda}(\gamma(z) \xrightarrow{v} z'_0) \quad = \quad \Big(\lambda'\gamma(z) \simeq \beta(\lambda(z)) \xrightarrow{\lambda'(v)} \lambda'(z'_0) \Big\| \ \lambda'\varepsilon'(y'_0) \Big\downarrow \mathrm{adj.} \ y'_0\Big) \ .$$

($\overline{\lambda}(v) = $ composé adj$\circ\lambda'(v)$)

La démonstration se fait par un AQT `[âne qui trotte]` fastidieux (j'avoue ne pas avoir poussé jusqu'au dernier détail …). [page 92]

Commentary · Exposition [ms. 92]

The adjunction on categories of presentations

Grothendieck needs to present an entire diagram by objects of C, while keeping the prescribed value of that diagram at a chosen vertex. The passage to comma categories in Lemma 4.4.10 is what makes these two requirements compatible. Its proof is indeed formal, but the formal statement includes the invertibility of the specified mate, not merely the existence of four functors making a square commute.

Write the square as $\varepsilon'\beta = \gamma\varepsilon$, and write η, ϵ and η', ϵ' for the units and counits of $\lambda \dashv \varepsilon$ and $\lambda' \dashv \varepsilon'$. Let

$$\chi : \lambda'\gamma \longrightarrow \beta\lambda$$

be the invertible mate used in the source. Fix $y' \in B'$. An object of $(\gamma \downarrow \varepsilon' y')$ is a pair (c, v) with $v : \gamma c \to \varepsilon' y'$. Define

$$q_v = \epsilon'_{y'}\, \lambda'(v)\, \chi_c^{-1} : \beta\lambda c \longrightarrow y'.$$

Thus the proposed left adjoint sends (c, v) to $(\lambda c, q_v)$. On a morphism $a : (c, v) \to (d, w)$, the equation $w\gamma a = v$ and naturality of χ show that λa is a morphism of the required comma category. This already supplies the functor whose existence the displayed formula asserts.

We check the adjunction by retaining the equation defining a morphism in the comma category. Given (b, u) with $u : \beta b \to y'$, an arrow from $(\lambda c, q_v)$ to (b, u) is an arrow $f : \lambda c \to b$ such that $u\beta f = q_v$. Its transpose under $\lambda \dashv \varepsilon$ is

$$k = \varepsilon(f)\eta_c : c \longrightarrow \varepsilon b.$$

The definition of the mate gives

$$\varepsilon'(\chi_c)\eta'_{\gamma c} = \gamma(\eta_c).$$

Consequently the transpose, under $\lambda' \dashv \varepsilon'$, of $u\beta f\chi_c$ is $\varepsilon'(u)\gamma(k)$. The transpose of $q_v\chi_c$ is v. Since transposition is a bijection, the required equation on f is equivalent to

$$\varepsilon'(u)\gamma(k) = v.$$

This is exactly the condition that k be a morphism from (c, v) to the image of (b, u) in $(\gamma \downarrow \varepsilon' y')$. Both transposition bijections are natural in the objects, so this proves the comma-category adjunction, including its action on morphisms.

In the application, ε is evaluation at j. Its left adjoint sends c to the diagram $j' \mapsto \coprod_{J(j,j')} c$. The comparison χ is invertible because the embedding of C preserves these coproducts. Lemmas 4.4.11 and 4.4.12 establish their existence in the completion without presupposing general cocompleteness. A functor with a left adjoint is final: for each object in its target, the unit exhibits an initial object in the corresponding comma category. This explains why the adjunction provides precisely the cofinality needed for the simultaneous presentation.

Pour terminer la démonstration de 4.4.9, il reste à prouver un dernier (?)

Lemme 4.4.11. *Soit C une petite catégorie, stable par sommes de cardinal $\leqslant \pi$. Alors $\mathrm{Ind}'_\pi C$ est stable par sommes de cardinal $\leqslant \pi$ (et, pour mémoire, le foncteur $\alpha : C \longrightarrow \mathrm{Ind}'_\pi C$ y commute).*

Appliquant le corollaire 4.4.8 au lemme 4.4.7, on est ramené à prouver la cofinalité de (4.4.6.3) quand J est discrète, plus le fait que $\underline{\mathrm{Hom}}(J, C)/\varphi$ est grande devant π, dans ce cas. Mais la donnée de φ revient à celle d'une famille $(\varphi_j)_{j\in J}$ d'objets de $\mathrm{Ind}'_\pi(C)$, et le foncteur (4.4.6.3) s'explicite comme la projection

$$\prod_{j\in J}(C/\varphi_j) \longrightarrow C/\varphi_j$$

du produit total sur un des facteurs. Donc on est ramené à ceci :

Lemme 4.4.12. *Soit $(C_j)_{j\in J}$ une famille de petites catégories grandes devant π, indexée par un petit ensemble J. Alors $\prod C_j$ est grande devant π, et les projections (pour $j_0 \in J$) $\prod C_j \longrightarrow C_{j_0}$ sont cofinales.* [page 93]

Prouvons d'abord la cofinalité, qui est le plus important pour nous. C'est évident si $J = \{j_0\}$, sinon on a $J = J' \cup \{j_0\}$, et $\prod_{j\in J} C_j \simeq C' \times C_{j_0}$, où $C' = \prod_{j\in J'} C_j$, donc il faut voir que $C' \times C_{j_0} \longrightarrow C_{j_0}$ est cofinal, i.e. que toute catégorie $\xi\backslash(C' \times C_{j_0})$ (pour $\xi \in \mathrm{Ob}\, C_{j_0}$) est 0-connexe, or elle est isomorphe à $C' \times (\xi\backslash C_{j_0})$, et $\xi\backslash C_{j_0}$ étant 0-connexe, il reste à voir que C' est 0-connexe. On fera attention à cet égard qu'un produit *infini* de catégories 0-connexes n'est pas forcément 0-connexe, donc la cofinalité n'est pas totalement tautologique! Mais si on prouve que la catégorie $\prod_{j\in J} C_j$ est grande devant π, donc filtrante, cela implique qu'elle est 0-connexe, et on peut appliquer ce même résultat à $C' = \prod_{j\in J'} C_j$, et on gagne. p. 23 [page 94]

Donc on est ramené à prouver que $\prod C_j$ est grande devant π. Ceci se voit soit sur le critère $\mathrm{PF}_\pi\, 1$, $\mathrm{PF}_\pi\, 2$ de 4.4.4 b, soit en se ramenant au cas où les C_j sont ordonnées, mais cela a l'air plus long. Notons que l'on prouve de même qu'un (petit) produit de catégories filtrantes est encore une catégorie filtrante.

Commentary · Exposition [ms. 94]

Products of indexing categories and the first coproducts

The coproduct argument isolates the part of the construction that can be done before arbitrary colimits have been established. Put $\kappa = \pi^+$. A category called "grande devant π" here is κ-filtered. If $(D_j)_{j\in J}$ is any small family of such categories, a diagram with fewer than κ arrows in $\prod_j D_j$ projects to such a diagram in every factor. Choose a cocone in each factor and take their product. This proves that the product is κ-filtered, including its nonemptiness; the usual axiom of choice is being used in making these simultaneous choices.

The projection to D_{j_0} is final for a similarly concrete reason. For $d \in D_{j_0}$ its comma category is

$$(d \downarrow \mathrm{pr}_{j_0}) \simeq (d \downarrow D_{j_0}) \times \prod_{j \neq j_0} D_j.$$

The first factor is filtered and nonempty, and the remaining product is filtered and nonempty by the argument just given. Their product is therefore connected. The finality criterion follows. This proof also explains the warning about products of connected categories. Connectedness alone supplies zigzags of possibly unbounded length; filteredness supplies compatible cocones of one fixed shape.

For a literal example of that distinction, let P_n be the poset on $0, 1, \ldots, n$, with each even vertex below its adjacent odd vertices and no further nonidentity comparisons. Every P_n is connected. In $\prod_{n \geq 1} P_n$, however, the tuples $(0)_n$ and $(n)_n$ cannot be joined by a finite zigzag. A zigzag of length r projects to one of length r in every factor, whereas the distance from 0 to n in the underlying undirected graph of P_n is n. Choosing $n > r$ gives a contradiction. Thus the source's caution is a real one, even for a product of finite posets.

Now let $|J| \leq \pi$ and $F_j \in \mathrm{Ind}'_\pi C$, assuming only that C has coproducts with at most π summands. Set $I = \prod_j (C/F_j)$. For $i \in I$, write $c_{i,j} \to F_j$ for its jth component and put $s_i = \coprod_j c_{i,j}$ in C. The object

$$H = \varinjlim_{i \in I} y(s_i)$$

belongs to $\mathrm{Ind}'_\pi C$, because I is κ-filtered. Here y denotes the Yoneda embedding, and this colimit is taken in the presheaf category. To identify H, take $G \in \mathrm{Ind}'_\pi C$. Such a G sends the given coproducts in C to products of sets: it is a κ-filtered colimit of representables, and these colimits commute with products having fewer than κ factors. Hence

$$\begin{aligned} \mathrm{Hom}(H, G) &\simeq \varprojlim_i G(s_i) \simeq \varprojlim_i \prod_j G(c_{i,j}) \\ &\simeq \prod_j \varprojlim_i G(c_{i,j}) \simeq \prod_j \mathrm{Hom}(F_j, G). \end{aligned}$$

The last isomorphism uses the finality of the projections just proved. All the maps are induced by the evident coproduct cocone, so this proves the required universal property. For an empty family, I is terminal and s_i is the initial object of C; the same calculation includes the empty coproduct. There is therefore no circular use of the cocompleteness theorem in Lemma 4.4.11.

Remarques.

1. Cet argument ne montre nullement (même si C est stable par $\varinjlim$ de cardinal $\leqslant \pi$) que pour tout $\varphi \in \underline{\mathrm{Hom}}(J, \mathrm{Ind}(C))$, le foncteur similaire à (4.4.6.3)

$$\underline{\mathrm{Hom}}(J, C)/\varphi \longrightarrow C/\varphi(j)$$

soit cofinal, et je doute qu'il le soit toujours. La difficulté provient du fait que $C \longrightarrow \mathrm{Ind}\, C$ ne commute pas aux sommes de cardinal $\leqslant \pi$, seulement aux sommes finies, donc le lemme [page 95] 4.4.10 ne peut être invoqué.

2. Nous venons de prouver, via 4.4.8 et 4.4.9 (dont la démonstration est achevée avec 4.4.12), que si C est une petite catégorie stable par $\varinjlim$ de cardinal $\leqslant \pi$, alors $\mathrm{Ind}_\pi C$ est également stable par ces limites. De plus, les systèmes inductifs de ce type J dans $\mathrm{Ind}_\pi C$ admettent une représentation indicielle

$$\psi \ : \ I \times J \longrightarrow C \ ,$$

avec I grande devant π. Et on peut toujours supposer, quitte à prendre $I' \longrightarrow I$ cofinal avec I' ensemble ordonné grand devant π, que I est de plus un ensemble ordonné.

Commentary · Examples [ms. 94]

An ordinary ind-object whose action has no stage

The doubt on page 94 concerns the loss of a cardinal bound when $\mathrm{Ind}_\pi(C)$ is replaced by the ordinary ind-completion. It has a concrete negative answer. Fix a small skeleton C of the category of at most countable sets. This category has all countable colimits, so it satisfies the hypothesis under discussion with $\pi = \aleph_0$. In $\widehat{C}$, define

$$F(c) = \{f : c \longrightarrow \mathbb{Z} \mid f(c) \text{ is finite}\}.$$

The presheaf F is an ordinary ind-object. Indeed, the finite subsets $T \subset \mathbb{Z}$ form a filtered poset, and

$$F = \varinjlim_{T \subset \mathbb{Z},\ T \text{ finite}} y(T)$$

pointwise: a map lies in the displayed colimit exactly when its image is contained in one finite T. Translation on $\mathbb{Z}$ defines an action on F, hence a diagram $\varphi : B\mathbb{Z} \to \mathrm{Ind}'(C)$.

An object of $C^{B\mathbb{Z}}/\varphi$ consists of a countable $\mathbb{Z}$-set c and an equivariant map of presheaves $y(c) \to F$. By Yoneda, the map corresponds to a function $f : c \to \mathbb{Z}$ with finite image. Equivariance says

$$f(n \cdot x) = n + f(x) \qquad (n \in \mathbb{Z}).$$

If c were nonempty, the image of f would therefore be a nonempty finite subset of $\mathbb{Z}$ invariant under every translation. Taking any element in that image produces all its translates, a contradiction. Thus every such c is empty.

Evaluation at the unique object of $B\mathbb{Z}$ consequently has image only the initial presentation $y(\varnothing) \to F$. In C/F, the element $0 \in F(1)$ defines a presentation $y(1) \to F$, and there is no morphism from this presentation to $y(\varnothing) \to F$. The corresponding comma category for evaluation is empty. Evaluation is therefore not final, exactly as Grothendieck suspected.

The example also locates the obstruction. At $c = \mathbb{N}$, the identity-shaped enumeration of an infinite set cannot be represented at a finite stage. Accordingly, F does not send a countable coproduct of singletons to the corresponding product: its value there consists of finite-image sequences. It is not an object of $\mathrm{Ind}'_{\aleph_0} C$. The stronger filteredness in the positive theorem is what prevents this failure of simultaneous realization. The distinction between a formal ind-object and the colimit of its values already appeared in the commentary on Chapter VII, manuscript p. 123 ("A colimit need not be the same ind-object"); here it obstructs a specific comparison of diagram categories.

Commentary · Later developments [ms. 94]

The modern comparison for diagram categories

Grothendieck's simultaneous presentation is the essential-surjectivity part of a familiar modern comparison. With $\kappa = \pi^+$ and J having fewer than κ arrows, it gives

$$\mathrm{Ind}_\kappa(C^J) \longrightarrow \mathrm{Ind}_\kappa(C)^J$$

when C has κ-small colimits. Here Ind_κ uses the modern regular-cardinal convention, so it is Grothendieck's Ind_π, not his ordinary Ind.

Henry (2025a, Theorem 1.2 and Corollary 2.2) proves that this comparison is an equivalence under precisely these hypotheses, and characterizes the diagram shapes for which the statement holds uniformly in C. The paper also shows why removing the colimit hypothesis on C requires additional restrictions on J; its Theorem 1.3 treats the corresponding well-founded shapes. These are results about the chosen presentability rank and about realizing diagrams by stages. They should be distinguished from the mere existence of some accessibility rank for a functor category. We use the theorem numbering of the checked arXiv version 2, dated 9 October 2024; the published article appeared in 2025 under the title cited in the bibliography.

C'est là le moyen donc, pour la démonstration du

Théorème 4.4.13. *Soit C une catégorie équivalente à une petite catégorie, et stable par $\varinjlim$ de cardinal $\leqslant \pi$, où π est un cardinal infini donné. Alors :* [page 96]

a) (Pour mémoire.) Le foncteur canonique

$$C \longrightarrow \mathrm{Ind}_\pi(C) \xrightarrow{\sim} \mathrm{Ind}'_\pi(C)$$

commute aux $\varinjlim$ *de cardinal* $\leqslant \pi$.

b) (Pour mémoire.) Les systèmes inductifs de cardinal $\leqslant \pi$ *dans* $\mathrm{Ind}_\pi(C)$ *(i.e. les foncteurs* $\varphi : J \longrightarrow \mathrm{Ind}_\pi(C)$*, avec* $\mathrm{card}\,\mathrm{Fl}(J) \leqslant \pi$*) admettent une représentation indicielle*

$$\psi \ : \ I \times J \longrightarrow C \ ,$$

avec I *ensemble ordonné grand devant* π*, et admettent une limite inductive dans* $\mathrm{Ind}_\pi C$ *qui se calculent par*

$$\underbrace{\varinjlim_{j\in J} \varphi(j)}_{\text{dans } \mathrm{Ind}_\pi(C)} \quad \simeq \quad \text{“} \varinjlim_{i\in I} \text{”}\Psi(i)$$

avec

$$\Psi(i) \ = \ \varinjlim_{j\in J}{}_C \, \psi(i,j) \ .$$

p. 24

c) $\mathrm{Ind}_\pi C$ *est stable par petites limites inductives* ([21]).

Il reste à établir ce dernier point. Comme on a déjà les $\varinjlim$ finies par b, il reste à prouver l'existence des petites $\varinjlim$ filtrantes, ou au choix des sommes infinies, ce qui sera plus joli en fait. Mais on pourra aussi bien traiter le cas général d'une $\varinjlim$ de type J quelconque (J petite). Pour ceci, soit [page 97]

$$I \ = \ I(J) \ = \ \text{ensemble des sous-catégories } J' \text{ de } J \text{ telles que } \mathrm{card}\,\mathrm{Fl}(J') \leqslant \pi,$$

ordonnons I par inclusion. Il est évident que $I \neq \emptyset$ (car $\emptyset \in I$), et même que I *est grand devant* π, car si $(J'_\alpha)_{\alpha\in A}$ avec $\mathrm{card}(A) \leqslant \pi$ est une famille d'éléments de I, alors la sous-catégorie de J engendrée par les J'_α est encore dans I (vérification immédiate), et majore les J'_α. En fait, la considération de $I(J)$ associée à J va nous permettre de prouver ceci, qui généralise 4.4.13 c), compte tenu de b) :

Corollaire 4.4.14 ([22]). *Soit* $\mathcal{M}$ *une catégorie,* π *un cardinal infini tel que*

a) $\mathcal{M}$ *est stable par* $\varinjlim$ *de cardinal* $\leqslant \pi$*, et*

b) $\mathcal{M}$ *est stable par* $\varinjlim$ *sur les ensembles ordonnés* I *grands devant* π. [page 98]

Alors $\mathcal{M}$ *est stable par petites* $\varinjlim$.

([23]).

En effet, si $\varphi : J \longrightarrow \mathcal{M}$ est donné, on en construit

$$\psi \ : \ I \ = \ I(J) \ \longrightarrow \ \mathcal{M}$$

par

$$\psi(J') \ = \ \varinjlim_{J'} \varphi(J') \ ,$$

qui existe par hypothèse sur $\mathcal{M}$. Il est alors immédiat que $\varinjlim_J \varphi$ existe si et seulement si $\varinjlim_I \psi$ existe, or cette existence est assurée du fait que I est grand devant π, et l'hypothèse sur $\mathcal{M}$.

---

21. rajouter aussi, en d), le corollaire 4.4.16, page 101.

22. Comparer aussi 4.11.3, page 270.

23. **Corollaire 4.4.14.1.** $\mathcal{M}$ étant comme dans 4.4.14, et $f : \mathcal{M} \longrightarrow \mathcal{E}$ étant un foncteur qui commute aux $\varinjlim$ de cardinal $\leqslant \pi$, et aux petites $\varinjlim$ grandes devant π, alors f commute aux petites $\varinjlim$.

Commentary · Exposition [ms. 98]

Why bounded colimits suffice for cocompleteness

The passage from bounded colimits to arbitrary small colimits is the structural conclusion of this section. Its proof uses a directed family of portions of the indexing category, so it concerns the diagram and its relations together. A family of subsets of objects would not retain the equations imposed by its arrows.

For a small category J, let $\mathcal{I}_\pi(J)$ be the poset of its subcategories with at most π arrows, with the empty subcategory included. A union of at most π such arrow sets still has size at most π. Closing it under identities and finite compositions does not increase this bound, because π is infinite. The resulting subcategory is an upper bound. Thus $\mathcal{I}_\pi(J)$ is π^+-directed.

Given $X : J \to \mathcal{M}$, suppose that the colimit $X_K = \varinjlim_K X$ exists for every $K \in \mathcal{I}_\pi(J)$. These objects form a diagram indexed by $\mathcal{I}_\pi(J)$. We verify directly that its colimit is the colimit of X. A compatible family of maps $X_K \to Z$ gives a map $X(j) \to Z$ by using the subcategory containing only the identity of j. For an arrow $a : j \to j'$, choose a subcategory containing a and its two objects. Its cocone forces the required equality between the two maps to Z. Conversely, a cocone on X restricts to every K, hence factors uniquely through every X_K, and the resulting maps are compatible with inclusions. These two constructions are inverse and natural in Z. Therefore

$$\varinjlim_J X \simeq \varinjlim_{K \in \mathcal{I}_\pi(J)} \left(\varinjlim_K X \right)$$

whenever the right side exists. This proves Corollary 4.4.14 without an interchange of limits whose existence has not yet been established.

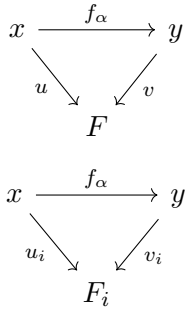
The same cocone argument proves the preservation statement in footnote 27. If a functor preserves the inner colimits and the outer directed colimit, it preserves the colimit of X. No hypothesis about exactness, generators or representability is used. This makes the result useful beyond the particular ind-completion being constructed.

There is a size distinction that becomes consequential on page 110. If $|\operatorname{Fl} J| \leq \rho$, then the set $\mathcal{I}_\pi(J)$ can have size ρ^π, rather than ρ. Thus the same decomposition proves a bound-preserving assertion only if this extra exponent has been controlled, or if a different argument supplies a smaller final indexing family. The unbounded cocompleteness theorem is sound; it does not by itself establish the later assertion that a pointwise cardinal bound survives every bounded colimit.

Pour achever de prouver le théorème 4.4.13, on est donc ramené au cas particulier des limites inductives $\varinjlim_J \varphi(j)$, quand $\varphi : J \longrightarrow \operatorname{Ind}'_\pi C$ est donné, avec J ensemble ordonné grand devant π. Mais ceci va résulter du résultat plus précis : p. 25 [page 99]

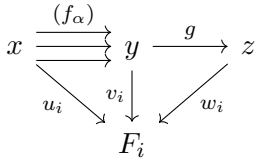
Corollaire 4.4.15 ([24]). *Soit C une petite catégorie. Alors la sous-catégorie strictement pleine $\operatorname{Ind}'_\pi C$ de $C^\wedge$ est stable dans $C^\wedge$ par $\varinjlim$ grandes devant π, en d'autres termes, ces $\varinjlim$ existent dans $\operatorname{Ind}'_\pi(C)$, et le foncteur d'inclusion y commute.*

Démonstration. Soit I ensemble ordonné, grand devant π, et $i \longmapsto F_i$ un foncteur $I \longrightarrow \operatorname{Ind}'_\pi(C)$, $F = \varinjlim_I F_i$ dans $C^\wedge$, prouvons que $F \in \operatorname{Ob} \operatorname{Ind}'_\pi(C)$, i.e. (4.4.3) que C/F est grande devant π. J'utilise le critère b) de 4.4.4, il faut vérifier $\mathrm{PF}_\pi 1$, $\mathrm{PF}_\pi 2$. Soient



$$x_\alpha \xrightarrow{u_\alpha} F = \varinjlim F_i$$

des objets de C/F indexés par A avec $\operatorname{card} A \leqslant \pi$. Chaque u_α provient de $x_\alpha \longrightarrow F_{i_\alpha}$, et en prenant un majorant commun des i_α (I grand devant π), on trouve un $i \in I$ et des $v_\alpha : x_\alpha \longrightarrow F_i$. Comme F_i est dans $\operatorname{Ind}'_\pi(C)$, i.e. C/F_i grande devant π, considérant les v_α comme des objets de C/F_i, ils sont majorés par un objet $x \longrightarrow F_i$ de C/F_i. On a donc



$$\begin{array}{ccccc} x_\alpha & \longrightarrow & F_{i_\alpha} & & \\ \downarrow & & \downarrow & \searrow & \\ x & \longrightarrow & F_i & \longrightarrow & F\,, \end{array}$$

24. comparer à 4.7.3.1, qu'il y aurait lieu d'expliciter ici.

qui montre que les $x_\alpha \longrightarrow F$ sont majorés par $x \longrightarrow F$, ce qui prouve $\mathrm{PF}_\pi\, 1$. Prouvons $\mathrm{PF}_\pi\, 2$, [page 100]
i.e. soient $x \xrightarrow{u} F$, $y \xrightarrow{v} F$ deux objets de C/F, et $(f_\alpha)_{\alpha\in A}$ une famille de cardinal $\leqslant \pi$ de flèches de u dans v. On sait que u, v proviennent de $u_i : x \longrightarrow F_i$, $v_i : y \longrightarrow F_i$ pour i assez grand.

Pour tout α, on peut choisir $i_\alpha \geqslant i$ tel que $v_i f_\alpha$ et u_i deviennent égaux en composant avec $F_i \longrightarrow F_{i_\alpha}$, et comme $\operatorname{card} A \leqslant \pi$ et I grand devant π, il existe un majorant i' des i_α. Au total, on peut supposer (remplaçant i par i') que $v_i f_\alpha = u_i$ pour tout α. Alors u_i, v_i étant considérés comme objets de C/F_i, les f_α sont des flèches de C/F_i de u_i dans v_i. Comme C/F_i est grand devant π (par l'hypothèse $F_i \in \mathrm{Ob}\, \mathrm{Ind}'_\pi(C)$), on trouve qu'il existe un égalisateur $(y, v_i) \xrightarrow{g} (z, w_i)$. p. 26

Alors l'image de g dans C/F (via $F_i \longrightarrow F$) égalise les flèches f_α, en tant que flèches de C/F, ce qui prouve $\mathrm{PF}_\pi\, 2$ et achève la démonstration de 4.4.14, et par là aussi celle du théorème 4.4.13, et du lemme 4.3. Par là est aussi achevée la démonstration de la première assertion du lemme 4.3.7 (p. 77), ce qui achève la démonstration du théorème 4.3.6 (p. 70-71). [page 101]
Il reste à établir la propriété universelle énoncée dans 4.3.7, que je vais rappeler :

Commentary · Exposition [ms. 100]

Filtered closure and its exact strength

Grothendieck now proves the closure property that footnote 24 had correctly distinguished from the definition of an ind-object. A single κ-filtered colimit of representables belongs to $\mathrm{Ind}_\kappa C$ by definition. The closure assertion says that a κ-filtered colimit of objects already in this category belongs to it again. It is this second assertion that allows arbitrary cocompleteness to be deduced from the preceding decomposition.

Here is the argument in a form that displays the two uses of the same cardinal. Let $\kappa = \pi^+$, let I be κ-filtered, and let $F = \varinjlim_i F_i$ in $\widehat{C}$, with every category of elements C/F_i κ-filtered. Replace I by a final κ-directed poset if desired. Given fewer than κ objects of C/F, choose representatives of their defining elements at stages of I. A common upper bound places all of them in one C/F_i. Filteredness of that category supplies a common target, whose image is the desired target in C/F.

For the second filteredness condition, start with fewer than κ parallel arrows between two objects of C/F. Place the two defining elements in one F_i. Each equality saying that an arrow is over F becomes true at some later stage, because equality in a filtered colimit of sets is eventual equality. A common upper bound makes all these equations true together. The corresponding arrows now lie in $C/F_{i'}$, where they can be simultaneously coequalized. Their images coequalize the original arrows. This proves both filteredness conditions and hence $F \in \mathrm{Ind}_\kappa C$.

The word "*égalisateur*" on page 100 denotes a morphism that makes the given arrows equal after composition. No universal coequalizer is asserted or needed. Similarly, no colimits in C are used in this closure proof. The hypothesis that C has κ-small colimits belongs to the cocompleteness theorem, not to Corollary 4.4.15 itself.

The inclusion into $\widehat{C}$ creates these κ-filtered colimits, but generally does not preserve all ordinary filtered colimits. For instance, let C again consist of countable sets and take $\pi = \aleph_0$. The completion

$\mathrm{Ind}'_\pi C$ identifies with sets via $X \mapsto (c \mapsto X^c)$: every set is the $\aleph_1$-filtered union of its countable subsets, and a map out of a countable set factors through one such subset. The increasing union of finite subsets of $\mathbb{N}$ has colimit $\mathbb{N}$ in this completion. Its colimit in $\widehat{C}$, however, contains only finite-image maps $c \to \mathbb{N}$. At $c = \mathbb{N}$ it omits the identity map. This is the precise failure used in the preceding example and the reason the proof of Corollary 4.4.16 must retain the larger filteredness threshold.

Corollaire 4.4.16 ([25]). *Soient C une catégorie équivalente à une petite catégorie, stable par $\varinjlim$ de cardinal $\leqslant \pi$, où π est un cardinal infini donné, et considérons le foncteur d'inclusion canonique*

$$C \xrightarrow{\alpha} \mathrm{Ind}_\pi(C)\ . \tag{4.4.16.1}$$

Ce foncteur est 2-universel pour les foncteurs $f : C \longrightarrow \mathcal{E}$, où $\mathcal{E}$ est une $\mathcal{U}$-catégorie stable par petites $\varinjlim$, et f un foncteur commutant à ces limites inductives. En d'autres termes, on a

1°) α possède les propriétés précédentes, i.e. $\mathrm{Ind}_\pi(C)$ est stable par $\varinjlim$, et le foncteur α commute aux $\varinjlim$ de cardinal $\leqslant \pi$.

2°) Pour toute $\mathfrak{U}$-catégorie $\mathcal{E}$ stable par petites limites inductives, le foncteur

$$\begin{array}{ccc} g & \longmapsto & g \circ \alpha \\ \underline{\mathrm{Hom}}_!(\mathrm{Ind}_\pi C, \mathcal{E}) & \longrightarrow & \underline{\mathrm{Hom}}_{!\,\pi}(C, \mathcal{E}) \end{array} \tag{4.4.16.2}$$

est une équivalence de catégories, où l'indice $!$ (resp. $!\,\pi$) indique la sous-catégorie strictement pleine de la catégorie $\underline{\mathrm{Hom}}$ envisagée, formée des foncteurs qui commutent aux petites $\varinjlim$ (resp. à celles de cardinal $\leqslant \pi$). [page 102]

On peut donc dire aussi que $\mathrm{Ind}_\pi(C)$ joue le rôle d'une "enveloppe" stable par petites $\varinjlim$ de la catégorie C, quand les $\varinjlim$ de cardinal $\leqslant \pi$, lesquelles existent déjà dans C, sont respectées par les plongement de C dans son enveloppe. C'est un résultat nullement tautologique qu'il suffit pour cela d'ajouter à C des $\varinjlim$ *grandes devant* π d'objets de C, et que plus précisément, la catégorie enveloppe est réalisée par $\mathrm{Ind}_\pi C$ (ou, au choix et moins pléthoriquement, par $\mathrm{Ind}'_\pi C \subset C^\wedge$).

Commentary · Exposition [ms. 102]

Density determines the continuous extensions

The universal property is the main result of the construction: the passage from C to $\mathrm{Ind}_\pi C$ freely supplies all small colimits while preserving the colimits of size at most π that were already present. There is a local error in the proof that should be separated from this correct theorem. The unrestricted restriction functor displayed across pages 102–103 is not fully faithful. What is fully faithful is its restriction to functors preserving the canonical presentations by objects of C.

For the required version, write $\mathcal{M} = \mathrm{Ind}'_\pi C$ and use a small skeleton of C. Each $F \in \mathcal{M}$ has its canonical presentation

$$F \simeq \varinjlim_{(c,u) \in C/F} y(c).$$

If $g, h : \mathcal{M} \to \mathcal{E}$ preserve these colimits, a natural transformation $\theta : gy \to hy$ extends at F by taking the colimit of its components along C/F. Naturality for $F \to F'$ follows by postcomposition $C/F \to C/F'$ and the defining cocones. The extension is unique because maps out of the displayed colimit are determined by their composites with its structure maps. On representables it restricts to θ, since $C/y(c)$ has its terminal object (c, id). This proves full faithfulness on the required functor categories. It is the precise density statement of SGA 4, Exposé I, Proposition 7.8 (Artin et al., 1972). Cocontinuous functors satisfy its hypothesis; so do functors preserving the relevant π^+-filtered presentations.

25. Pourrait être incorporé en partie d) au théorème 4.4.13, car c'est un complément important, et pas tellement évident finalement.

The failure without the preservation hypothesis is visible in sets. Let C be a small skeleton of sets of cardinal at most an infinite π, so that $\mathrm{Ind}'_\pi C \simeq \mathrm{Set}$. Define a functor $Q : \mathrm{Set} \to \mathrm{Set}$ by taking $\mathcal{P}(X)$ and identifying all subsets of cardinal at most π to a single distinguished element $*$. Direct image under a function is well-defined on this quotient: the image of a subset of cardinal at most π still has cardinal at most π. For every $X \in C$, $Q(X)$ is a singleton. The identity transformation of Q and the transformation that sends every value to $*$ therefore have identical restrictions to C. They are different on any X with $|X| > \pi$, since the class of X is then different from $*$. Restriction is not even faithful on arbitrary functors.

This example explains why strict generation cannot justify the unrestricted assertion. A generating family detects morphisms of objects; density expresses objects as particular colimits; a functor must respect those colimits for its values and transformations to be reconstructed from the generators. The source uses the correct restricted conclusion throughout the rest of the proof. Replacing the one unrestricted assertion by the density argument above repairs the proof without changing Corollary 4.4.16.

Démonstration. Le 1°) est contenu dans 4.4.13 a) et c). Prouvons donc 2°). Il est évident que α est un foncteur pleinement fidèle dont l'image essentielle engendre strictement $\mathcal{M} = \mathrm{Ind}_\pi C$, d'où résulte que le foncteur (4.4.16.2) est pleinement fidèle, étant induit par le foncteur pleinement fidèle p. 27

$$\alpha^*_{\mathcal{E}} \ : \ \underline{\mathrm{Hom}}(\mathcal{M}, \mathcal{E}) \ \longrightarrow \ \underline{\mathrm{Hom}}(C, \mathcal{E})$$

sur les sous-catégorie pleines envisagées. Il reste donc à montrer que (4.4.16.2) est essentiellement surjectif. Soit donc $f : C \longrightarrow \mathcal{E}$ dans $\underline{\mathrm{Hom}}_{!\,\pi}(C, \mathcal{E})$, considérons son extension canonique [page 103]

$$\text{(4.4.16.3)} \qquad \begin{cases} Lf \ : \ \mathrm{Ind}(C) \ \longrightarrow \ \mathcal{E} \\ Lf((X_i)_{i\in I}) \ = \ \varinjlim_{i\in I} f(X_i) \end{cases}$$

(cf. SGA 4 I 8.7.3), et soit

$$\text{(4.4.16.4)} \qquad \psi(f) \ = \ Lf|\,\mathrm{Ind}_\pi(C) \ .$$

Rappelons que Lf commute aux petites $\varinjlim$ filtrantes, mais comme le foncteur d'inclusion

$$\text{(4.4.16.5)} \qquad \mathrm{Ind}_\pi C \ \longrightarrow \ \mathrm{Ind}(C)$$

ne commute pas à ces $\varinjlim$, il n'est pas clair a priori que $\psi(f)$ commute auxdites limites, ni a fortiori qu'il commute aux petites $\varinjlim$ sans plus. Mais on a vu que (4.4.16.5) commute aux $\varinjlim$ *grandes devant* π, ce qui est contenu dans le corollaire 4.4.15 (vu que les limites inductives *filtrantes* dans $\mathrm{Ind}(C)$ sont les limites *dans* $C^\wedge$) : dire que $\mathrm{Ind}'_\pi(C) \longrightarrow \mathrm{Ind}'(C)$ commute à un certain type de $\varinjlim$ filtrantes, revient à dire qu'il en est ainsi du composé avec $\mathrm{Ind}'_\pi(C) \hookrightarrow C^\wedge$, ce qui est établi par 4.4.15. De ceci résulte que $\psi(f)$ *commute aux* $\varinjlim$ *grandes devant* π. Pour établir que $g = \psi(f)$ commute aux petites $\varinjlim$, il reste donc à voir qu'il commute aux $\varinjlim$ de cardinal $\leqslant \pi$, en vertu de 4.4.14.1 (marge page 98). Pour l'établir, on utilise le théorème 4.4.13 b, en représentant un foncteur $\varphi : J \longrightarrow \mathrm{Ind}_\pi(C)$ (où $\mathrm{card}\,\mathrm{Fl}\,J \leqslant \pi$) sous forme indicielle par [page 104]

$$\text{(4.4.16.6)} \qquad \Phi \ : \ I \times J \ \longrightarrow \ C \ ,$$

I étant un ensemble ordonné grand devant π. On a donc

$$\varphi(j) \ = \ \varinjlim_{i\in I} {}_{\mathrm{Ind}_\pi C}\, \Phi(i, j) \ ,$$

et comme $g = \psi(f)$ commute aux $\varinjlim$ de type I par ce qu'on a vu, on aura

$$g(\varphi(j)) \ = \ \varinjlim_{i\in I} {}_{(\mathcal{E})}\, g(\Phi(i, j)) \ ,$$

d'où

$$(*) \qquad \varinjlim_{j\in J}{}_{(\mathcal{E})}\, g(\varphi(j)) \;=\; \varinjlim_{j\in J} \varinjlim_{i\in I} \underbrace{g(\Phi(i,j))}_{=f(\Phi(i,j))} \qquad \text{(limites dans } \mathcal{E})\,.$$

p. 28

D'autre part, on a

$$\begin{aligned} \varinjlim_{j\in J} \operatorname{Ind}_\pi \varphi(j) \;&\simeq\; \varinjlim_{j\in J} \varinjlim_{i\in I} \Phi(i,j) \\ &\simeq\; \varinjlim_{i\in I} \underbrace{\varinjlim_{j\in J} \Phi(i,j)}_{\substack{\text{peut être calculé}\\ \text{dans } C\text{, soit}\\ \Psi(i)\in \operatorname{Ob} C}}\,, \end{aligned}$$

donc

$$(**) \qquad \varinjlim_{j\in J} \operatorname{Ind}_\pi \varphi(j) \simeq \varinjlim_{i\in I} \Psi(i)\,,$$

d'où en appliquant g, qui commute aux $\varinjlim$ de type I, et se rappelant maintenant que $g|C \simeq f$, [page 105]

$$(***) \qquad g(\varinjlim_{J} \operatorname{Ind}_{\pi\, C} \varphi(j)) \;\simeq\; \varinjlim_{i\in I} f(\Psi(i))\,.$$

On a d'autre part

$$\Psi(i) \overset{\text{déf}}{=} \varinjlim_{j\in J} \Phi(i,j)\,, \qquad\qquad \varinjlim \text{ dans } C\,,$$

et comme f commute aux $\varinjlim$ de type J (car $\operatorname{card}\operatorname{Fl} J \leqslant \pi$), on en conclut

$$f(\Psi(i)) \;\simeq\; \varinjlim_{j\in J} f(\Phi(i,j))\,,$$

donc par $(***)$

$$(****) \qquad g(\varinjlim_{j\in J} \varphi(j)) \;\simeq\; \varinjlim_{i\in I} \varinjlim_{j\in J} f(\Phi(i,j))\,.$$

En composant avec $(*)$ et utilisant à nouveau la commutativité de $\varinjlim_I$ à $\varinjlim_J$, on trouve donc

$$g(\varinjlim \varphi(j)) \;\xleftarrow{\sim}\; \varinjlim g(\varphi(j))\,,$$

ce qui prouve que g commute aux limites inductives de type J, et achève de prouver que g est [dans] $\underline{\operatorname{Hom}}_!(\operatorname{Ind}_\pi(C),\mathcal{E})$. Comme $g|C \simeq f$, on en conclut que le foncteur (4.4.16.2) est essentiellement surjectif, ce qui achève de prouver 4.4.16. De plus, on a construit un foncteur quasi-inverse explicite, ψ, s'insérant dans le diagramme commutatif [page 106]

(4.4.16.6)
$$\begin{array}{ccccc} \underline{\operatorname{Hom}}_{!\,\pi}(C,\mathcal{E}) & \xrightarrow[(\sim)]{\psi} & \underline{\operatorname{Hom}}_!(\operatorname{Ind}_\pi(C),\mathcal{E}) & \longrightarrow & \underline{\operatorname{Hom}}_{!\,\pi}(\operatorname{Ind}_\pi(C),\mathcal{E}) \\ \Big\downarrow{\scriptstyle \text{incl. pl. fid.}} & & \Big\vdots{\scriptstyle \text{pl. fid.}} & \nearrow{\scriptstyle R\ \text{(restriction)}} & \\ \underset{\text{(cf. SGA 4 I 8.7.3)}}{\underline{\operatorname{Hom}}(C,\mathcal{E})} & \xrightarrow[\sim]{L} & \underline{\operatorname{Hom}}_{!\,\operatorname{filt}}(\operatorname{Ind}(C),\mathcal{E}) & & \end{array}\,.$$

Commentary · Exposition [ms. 106]

The extension and the codomain of restriction

The explicit inverse constructed here makes the universal property usable. For a functor $f : C \to \mathcal{E}$ preserving colimits of cardinal at most π, put

$$\overline{f}(F) = \varinjlim_{(c,u)\in C/F} f(c).$$

This is the restriction of the usual extension Lf on the ordinary ind-completion. The latter is characterized by preservation of filtered colimits, as in SGA 4, Exposé I, Proposition 8.7.3 (Artin et al., 1972). It follows from Corollary 4.4.15 that $\overline{f}$ preserves π^+-filtered colimits. The proof on pages 104–105 supplies the remaining preservation property rather than assuming it from the inclusion into $\mathrm{Ind}(C)$.

To see the mechanism, present a diagram $X : J \to \mathrm{Ind}_\pi C$, with $|\operatorname{Fl} J| \le \pi$, by $c : I \times J \to C$, where I is π^+-filtered. Put $s_i = \varinjlim_{j\in J} c(i,j)$ in C. Then all the indicated colimits exist, and the two comparisons are

$$\overline{f}\left(\varinjlim_j X_j\right) \simeq \varinjlim_i f(s_i) \simeq \varinjlim_i \varinjlim_j f(c(i,j)),$$
$$\varinjlim_j \overline{f}(X_j) \simeq \varinjlim_j \varinjlim_i f(c(i,j)).$$

Both are the colimit in $\mathcal{E}$ of the same diagram indexed by $I \times J$. The isomorphism between them is therefore the actual comparison induced by the colimit cocone, not merely an unspecified isomorphism between two objects. Corollary 4.4.14.1 then gives preservation of every small colimit. Natural transformations extend by the same construction, so this proves the asserted equivalence of categories, including its two-dimensional content.

There is a second, independent typing error in the final diagram. Its arrow R, on the whole bottom-middle category, need not land in $\underline{\mathrm{Hom}}_{!\,\pi}(\mathrm{Ind}_\pi C, \mathcal{E})$. A constant singleton functor to sets preserves all nonempty filtered colimits, but it does not preserve the initial object. It is therefore an object of the stated source of R whose restriction is not in the stated target. One may repair the diagram by replacing that target with the full functor category, or by restricting the source of R to the extensions of functors that preserve the specified colimits in C. The dotted downward arrow remains meaningful: it is the fully faithful functor $g \mapsto L(g|_C)$ supplied by the two universal properties. These qualifications preserve the explicit inverse ψ while making every arrow of the diagram well-typed.

p. 29

4.5 Filtration cardinale canonique d'une catégorie $\mathfrak{U}$-paratopos

Définition 4.5.1. On appelle *catégorie* $\mathfrak{U}$*-paratopos* une catégorie $\mathcal{M}$ $\mathfrak{U}$-pseudo-topos et accessible, i.e. qui satisfait aux conditions équivalentes du théorème 4.3.6 (p. 70). On dit que c'est une *catégorie* π-$\mathfrak{U}$*-paratopos*, si elle est π-accessible, i.e. si elle admet une petite sous-catégorie génératrice dont les objets soient π-accessible, ou ce qui revient au même, si $\mathcal{M}$ est équivalente à une catégorie de la forme $\mathrm{Ind}'_\pi(\mathcal{M}_\pi)$, où $\mathcal{M}_\pi$ est une petite catégorie (ou : une catégorie équivalente à une petite catégorie), et stable par $\varinjlim$ de cardinal $\leqslant \pi$. (Et on peut prendre pour $\mathcal{M}_\pi$ la sous-catégorie pleine de $\mathcal{M}$ formée des objets π-accessibles). [page 107]

Dans la suite, nous allons, plus généralement, considérer une catégorie C équivalente à une petite catégorie, stable par $\varinjlim$ de cardinal $\leqslant \pi_0$ ([30]), et la catégorie

$$\mathcal{M} \overset{\text{déf}}{=} \mathrm{Ind}'_{\pi_0} C \ \subset\ C^\wedge\ , \tag{4.5.1}$$

où π_0 est un cardinal infini donné. Je me propose d'introduire sur $\mathcal{M}$ une filtration cardinale canonique :

30. Il n'y a pas lieu de le supposer tout de suite.

Proposition 4.5.2 ([31]). *Soit $F \in \mathrm{Ob}\,\mathcal{M} \subset \mathrm{Ob}\,C^\wedge$, et soit π un cardinal $\geqslant \pi_1 = \sup(\pi_0, \mathrm{card}\,\mathrm{Fl}\,C_0)$, où C_0 est une petite sous-catégorie pleine de C telle que $C_0 \overset{\sim}{\hookrightarrow} C$. Les conditions suivantes sont équivalentes :*

a) $\mathrm{card}\,\mathrm{Fl}(C_0/F) \leqslant \pi$.

a′) $\mathrm{card}\,\mathrm{Ob}\ (C_0/F) \leqslant \pi$.

a″) Pour tout x dans C_0, $\mathrm{card}\,F(x) \leqslant \pi$.

b) Il existe une petite catégorie filtrante I (pas nécessairement ordonnée), grande devant *π_0, avec* $\mathrm{card}\,I \leqslant \pi$, *et un système inductif $(x_i)_{i\in I}$ dans C, tel que l'on ait*

$$F \ \simeq\ \varinjlim_{i\in I} x_i\ , \tag{4.5.2.1}$$

où la $\varinjlim$ est prise dans $\mathcal{M}$, ou ce qui revient au même (en vertu de 4.4.15, I étant grande devant π_0) dans $C^\wedge$, i.e. F est isomorphe au foncteur ind-représentable défini par l'ind-objet $\underline{x} = (x_i)_{i\in I}$ de C.

c) F est π-accessible dans $\mathcal{M}$.

c′) F est π-accessible dans $C^\wedge$.

Démonstration. On a les implications ± tautologiques [page 108]

(∗)
$$\begin{array}{ccccc} & & \mathrm{a}' & \Longrightarrow & \mathrm{a}'' \\ \mathrm{a} & \Longrightarrow & & & \\ & & \mathrm{b} & \Longrightarrow & \mathrm{c}' \Longrightarrow \mathrm{c}\ , \end{array}$$

où $\mathrm{a}' \Longrightarrow \mathrm{a}''$ provient de l'inclusion canonique $F(x) = \mathrm{Hom}_{\mathcal{M}}(x, F) \hookrightarrow \mathrm{Ob}\,C/F$, $\mathrm{a} \Longrightarrow \mathrm{b}$ p. 30 s'obtient en prenant $I = C_0/F$ et notant que I est stable par limites inductives de cardinal $\leqslant \pi_0$ (C l'étant), donc est grande devant π_0 ([32]). On a $\mathrm{b} \Longrightarrow \mathrm{c}'$ en vertu du fait que la sous-catégorie strictement pleine $C^\wedge_\pi$ de $C^\wedge$ définie par

$$\left\{ \begin{array}{lcl} C^\wedge_\pi & = & \text{sous-catégorie strictement pleine de } C^\wedge \text{ formée des} \\ & & F \in \mathcal{M} \text{ qui sont } \pi\text{-accessibles.} \end{array} \right. \tag{4.5.2.2}$$

est stable par $\varinjlim$ de cardinal $\leqslant \pi$ (SGA 4 I 9.9). Enfin $\mathrm{c}' \Longrightarrow \mathrm{c}$ provient du fait que le foncteur d'inclusion $\mathcal{M} \hookrightarrow C^\wedge$ est pleinement fidèle et π_0-accessible, i.e. commute aux limites inductives grandes devant π_0, et a fortiori à celles grandes devant π. Par les implications du diagramme ci-dessus, il suffit donc de prouver qu'on a

$$\mathrm{c} \overset{(33)}{\Longrightarrow} a \qquad \text{et} \qquad \mathrm{a}'' \Longrightarrow \mathrm{a}\ .$$

Commentary · Exposition [ms. 108]

Two meanings of the size of a presheaf

The new section asks whether the intrinsic presentability rank of an object can be read from the size of its canonical presentation. This would turn the generators used to construct a paratopos into an effective cardinal filtration. The potential discrepancy is already visible in Proposition 4.5.2: presentability in $\mathcal{M}$ and presentability in the ambient presheaf category test different colimits.

31. N'est prouvé (et n'est vrai) que si $\pi^{\pi_0} = \pi$, voir rectification 4.5.6, page 116.

32. On n'a pas besoin de cette stabilité, de toutes façons C_0/F est grande devant π_0, en vertu de 4.4.3, p. 80.

33. n'est prouvé (et n'est vrai) que si $\pi^{\pi_0} = \pi$.

Replace C by the small category C_0 in the statement, and put $\theta = \pi_0$, $\mathcal{M} = \mathrm{Ind}_{\theta^+} C$, and $\kappa = \pi^+$, with $\pi \geq \max(\theta, |\operatorname{Fl} C|)$. The following equivalences require no exponentiation hypothesis:

$$|\operatorname{Fl}(C/F)| \leq \pi \iff |\operatorname{Ob}(C/F)| \leq \pi \iff \forall c \in C, |F(c)| \leq \pi,$$
$$\iff F \text{ has a } \theta^+\text{-filtered presentation with at most } \pi \text{ arrows},$$
$$\iff F \text{ is } \kappa\text{-presentable in } \widehat{C}.$$

We give the details, since they isolate the part of the proposition which survives unchanged.

The objects of C/F are pairs (c, a) with $a \in F(c)$, so their number is bounded by π exactly when all the values are bounded by π. A morphism of C/F is determined by a morphism $a : c \to d$ of C and an element of $F(d)$; its source element is then forced. Consequently

$$|\operatorname{Fl}(C/F)| = \sum_{a:c\to d} |F(d)| \leq \pi \cdot \pi = \pi.$$

The reverse bound follows from identity arrows. If these bounds hold, the category C/F itself is the required θ^+-filtered presentation. Conversely, a presentation with at most π arrows has values bounded by π: every representable has that bound, and a colimit of at most π sets of that size again has that size.

Such a presentation also makes F κ-presentable in $\widehat{C}$. Indeed, a colimit of at most π representables represents a limit of at most π evaluation functors, and κ-filtered colimits of sets commute with those limits. For the converse, write any presheaf as the colimit of its partial presentations indexed by the subcategories of C/F with at most π arrows. The preceding small-subcategory argument makes this indexing poset κ-directed. Each partial presentation is pointwise bounded by π. If F is κ-presentable, its identity factors through one of them, making F a retract of a pointwise bounded presheaf. Every value of F then has cardinal at most π. This proves the final equivalence.

The class needed in (4.5.2.2) is the class of all κ-presentable objects of $\widehat{C}$. The printed condition $F \in \mathcal{M}$ in that definition is too restrictive for the assertion of closure under colimits taken in $\widehat{C}$. For example, if C is the terminal category, then $\mathcal{M}$ contains only the singleton presheaf, whereas its empty colimit in $\widehat{C} = \mathrm{Set}$ is empty. The proof is repaired by using the ambient class, as above.

Finally, ambient κ-presentability implies presentability in $\mathcal{M}$, since the inclusion creates κ-filtered colimits. The converse is the unsettled implication $c \Rightarrow a$ in the source. Colimits in $\mathcal{M}$ may enlarge the values of a presheaf; preservation of the colimits that happen to be computed pointwise does not control this enlargement. The condition $\pi^{\pi_0} = \pi$ introduced on page 116 supplies the missing uniform estimate. It is not needed for the five equivalences just proved.

Prouvons a″ $\Longrightarrow$ a. Considérons l'application [page 109]

$$(*) \qquad \operatorname{Fl} C/F \longrightarrow \operatorname{Fl} C$$

induit par le foncteur étale $C' = C/F \longrightarrow C$, alors l'ensemble des flèches au-dessus d'une flèche $\alpha : x \longrightarrow y$ de C est en correspondance biunivoque avec $\operatorname{Ob} C'_y = F(y)$, puisqu'une telle flèche α' est connue quand on connaît son but, qui est un objet quelconque de $F(y)$ ($C' \longrightarrow C$ étant étale, i.e. fibrant à fibres discrètes). Donc le fibre de $(*)$ en α est de cardinal $= \operatorname{card} F(y) \leqslant \pi$, donc on a

$$\operatorname{card} \operatorname{Fl} C/F \leqslant \pi \underbrace{\operatorname{card} \operatorname{Fl} C}_{\leqslant \pi_1} \leqslant \pi \underbrace{\pi_1}_{\leqslant \pi} \leqslant \pi^2 = \pi ,$$

ce qui prouve a.

Prouvons enfin c $\Longrightarrow$ a. Pour ceci, nous allons utiliser la première inclusion $\mathcal{M}_\pi \subset \mathrm{Filt}^\pi \mathcal{M}$ de SGA 4 I 9.16, qui s'applique dès lors que nous prouvons le

Corollaire 4.5.3 ([34]). *Sous les conditions de 4.5.2, soit, pour tout cardinal $\pi \geqslant \pi_1$, $\mathrm{Filt}^\pi(\mathcal{M})$ la sous-catégorie strictement pleine de $\mathcal{M}$ formée des $F \in \operatorname{Ob} \mathcal{M}$ qui satisfont la condition a) de 4.5.2. Alors la famille des $(\mathrm{Filt}^\pi)_{\pi \geqslant \pi_1}$ est une filtration cardinale de $\mathcal{M}$.* [page 110]

34. Pas prouvé, la condition c) des filtrations cardinales peut-être pas satisfaite. Sans doute *faux* en général.

La condition a) de loc. cit. 9.12 (les $\underline{\mathrm{Filt}}^\pi$ sont équivalentes à des petites catégories) est évidente. Prouvons b), i.e. la stabilité de $\underline{\mathrm{Filt}}^\pi$ par $\varinjlim$ filtrantes $F = \varinjlim F_i$ *grandes devant* π_0, de cardinal $\leqslant \pi$. Comme $\mathcal{M} \hookrightarrow C^\wedge$ commute à ces limites, pour x dans C

$$F(x) \;=\; \varinjlim_i F_i(x) \;,$$

d'où $\operatorname{card} F(x) \leqslant \operatorname{card} \operatorname{Ob} I \cdot \pi \leqslant \pi \cdot \pi = \pi$, ce qui (par l'équivalence a $\iff$ a″) implique $F \in \operatorname{Ob} \mathrm{Filt}^\pi$. Prouvons la condition c) de loc. cit. Pour ceci, nous aurons besoin du fait, plus précis que le b), qu'on vient d'établir : p. 31

Corollaire 4.5.4 ([35]). *Pour tout $\pi \geqslant \pi_1$, Filt^π est stable par $\varinjlim$ (dans $\mathcal{M}$) de cardinal $\leqslant \pi$ (pas nécessairement filtrantes, a fortiori pas nécessairement grandes devant π_0).*

Il suffit, en vertu de ce qui est déjà prouvé de du lemme 4.4.14 ([36]), de montrer que Filt^π est stable par $\varinjlim$ *de cardinal* $\leqslant \pi_0$. Si $\varphi : J \longrightarrow \mathrm{Filt}^\pi$ est un foncteur avec $\operatorname{card} J \leqslant \pi_0$, on le met sous forme indicielle

$$\psi \;:\; I \times J \;\longrightarrow\; C \;,$$

grâce à 4.14.3.b, avec I grande devant π_0.

Je rappelle qu'on pouvait prendre [page 111]

$$I \;=\; \underline{\mathrm{Hom}}(J, C)/\varphi \;,$$

où $\underline{\mathrm{Hom}}(J, C) \hookrightarrow \underline{\mathrm{Hom}}(J, \mathcal{M} = \mathrm{Ind}'_\pi C)$, quitte à ne pas exiger que I soit ordonnée. On a envie de prouver que $\operatorname{card} \mathrm{Fl}\, I \leqslant \pi$. L'ennui, c'est qu'on arrive seulement à la majoration

$$\operatorname{card} \mathrm{Fl}\, I \;\leqslant\; \pi^{\pi_0} \;.$$

(Même si J est discrète, on n'a pas mieux, puisqu'alors

$$I \;\simeq\; \prod_{j \in J} C/\varphi(j) \;, \qquad \text{d'où} \quad \mathrm{Fl}\, I = \prod_{j \in J} \mathrm{Fl}\, C/\varphi(j) \;,$$

et si $\operatorname{card} \mathrm{Fl}\, C/\varphi(j) = \pi$ pour tout j, on trouve $\operatorname{card} \mathrm{Fl}\, I = \pi^{\pi_0}$ – il n'y a pas moyen de faire mieux !)

Donc je n'arrive pas à prouver directement 4.5.4, ce qui m'aurait arrangé pour prouver la condition c) de loc. cit. Mais à vrai dire, on a fait ici le travail de la démonstration du théorème 4.3.6, partie b $\Longrightarrow$ c – on y a déjà prouvé que la filtration qu'on vient de construire (par la condition a) de 4.5.2) est une filtration cardinale. La condition c) de SGA 4 I 9.12 est prouvée à la page 76. Mais je vais refaire la démonstration plus sérieusement. [page 112]

Commentary · Exposition [ms. 112]

Counting simultaneous presentations

Grothendieck's obstruction on page 111 is not a failure of the existence theorem for colimits. It concerns the amount of data needed to describe a compatible family of presentations at one time. This distinction is what the initial argument for a cardinal filtration had left uncontrolled.

Suppose $|\mathrm{Fl}\, C| \leq \pi$, $|\mathrm{Fl}\, J| \leq \theta$, and every value $\varphi(j)(c)$ has cardinal at most π. An object of C^J/φ consists of a choice of objects and arrows of C for the diagram, together with at most θ elements defining a compatible transformation to φ. There are at most π^θ such choices. An arrow in this comma category adds at most θ morphisms of C, subject to equations; imposing equations cannot increase the bound. Hence

$$|\mathrm{Fl}(C^J/\varphi)| \leq \pi^\theta.$$

For a discrete J of size exactly θ, the category is $\prod_{j \in J}(C/\varphi(j))$. If each factor has π arrows, its arrow set has size π^θ. Thus the counting argument itself cannot improve this estimate to π. The

35. Prouvé seulement si $\pi^{\pi_0} = \pi$! Sans doute *faux* en général.

36. Il faut une variante du lemme 4.4.14, pour les $\varinjlim$ de cardinal $\leqslant \pi'$, qui se prouve de la même façon.

exact equality in the source's parenthesis tacitly takes $|J| = \pi_0$; for a smaller discrete J, the exponent is $|J|$.

There is a useful positive conclusion that does not require closing the entire argument prematurely. The pointwise bounded objects form an essentially small class: choose standard sets of cardinal at most π at the set of objects of C, and then choose all structure maps satisfying the functor equations. They are also closed under θ^+-filtered colimits indexed by categories with at most π arrows, because those colimits are computed pointwise. These prove the first two estimates used on page 110. They do not prove that every object can be assembled from bounded ones through a π^+-filtered diagram.

To obtain the third property by the method on page 112, one must take a prescribed set of at most π arrows in C/F and enlarge it to a θ^+-filtered subcategory without exceeding π arrows. That is the content of Lemma 4.5.5. It is a genuinely stronger demand than adjoining a cocone to a single small diagram. Closing under all the required cocones may require π^θ simultaneous choices. The original unqualified Corollaries 4.5.3 and 4.5.4 should consequently be read with their retraction notes, not used as completed lemmas while proving Proposition 4.5.2.

Soit donc $F \in \mathrm{Ob}\,\mathcal{M}$, considérons

$$J \;=\; C/F\ ,$$

c'est une catégorie stable par $\varinjlim$ de cardinal $\leqslant \pi_0$, donc grande devant π_0, et on a

$$F \;\simeq\; \varinjlim_{j\in J} x_j \qquad (\varinjlim \text{ dans } \mathcal{M})$$

en désignant par $j \longmapsto x_j$ le foncteur canonique $C/F \longrightarrow C$. Soit alors I l'ensemble des sous-catégories J' de J qui sont *de cardinal $\leqslant \pi$ et grandes devant π_0*, I ordonné par inclusion, et pour tout $J' \in I$, posons p. 32

$$X_{J'} \;=\; \varinjlim_{j\in J'} x_j\ .$$

Comme J' est grande devant π_0, la limite inductive dans $\mathcal{M}$ est aussi une limite dans $C^\wedge$, d'où résulte aussitôt, comme $\mathrm{card}\,\mathrm{Ob}\,J' \leqslant \mathrm{card}\,\mathrm{Fl}\,J' \leqslant \pi$, que $X_{J'}$ est dans Filt^π. Alors

$$J' \;\longmapsto\; X_{J'} \;\in\; \mathrm{Ob}\ \mathrm{Filt}^\pi$$

est un foncteur

$$I \;\longrightarrow\; \mathrm{Filt}^\pi\ ,$$

dont la limite inductive est celle des x_j, donc isomorphe à F. D'autre part, il est immédiat que I est grand devant π, i.e. que si $(J'_\alpha)_{\alpha\in A}$ est une famille d'éléments de I, celle-ci est majorée [page 113] par un $J' \in I$. Ceci résulte du

Lemme 4.5.5 ([37]). *Soient π, π_0, avec $\pi > \pi_0$, des cardinaux infinis, et soit J une catégorie grande devant π_0. Alors pour toute partie Φ de $\mathrm{Fl}\,J$, telle que $\mathrm{card}\,\Phi \leqslant \pi$, il existe une sous-catégorie J' de J* grande devant π_0, *telle que* $\mathrm{card}\,J' \leqslant \pi$ ([38]), *et* $\mathrm{Fl}\,J' \supset \Phi$.

Ce lemme étant admis, on a donc représenté un objet quelconque F de $\mathcal{M}$ comme une $\varinjlim_{i\in I} X_i$, avec I ensemble ordonné grand devant π, les X_i dans Filt^π. Il reste à prouver que si $\pi' > \pi$ et $F \in \mathrm{Filt}^{\pi'}$, alors on peut prendre I tel que $\mathrm{card}\,I \leqslant \pi'^\pi$. Mais $F \in \mathrm{Filt}^{\pi'}$ signifie que $J = C/F$ satisfait $\mathrm{card}\,\mathrm{Fl}\,J \leqslant \pi'$. Alors l'ensemble des parties de cardinal $\leqslant \pi$ de $\mathrm{Fl}\,J$ a un cardinal majoré par π'^π, a fortiori $\mathrm{card}\,I \leqslant \pi'^\pi$, ce qui achève de prouver que $(\mathrm{Filt}^\pi)_{\pi\geqslant\pi_1}$ est une filtration cardinale sur $\mathcal{M}$.

Pour prouver le lemme, on commence par saturer Φ par composition finie, on trouve une [page 114] sous-catégorie J'_0 de J telle que $\mathrm{card}\,\mathrm{Fl}\,J'_0 \leqslant \pi_0$ … Mais je m'aperçois que pour prouver le

37. N'est prouvé *que* si $\pi^{\pi_0} = \pi$! Sans doute faux en général.
38. C'est OK si on exige seulement $\mathrm{card}\,J' \leqslant \pi^{\pi_0}$.

lemme, j'ai encore besoin de $\pi^{\pi_0} = \pi$ – une enveloppe de J' grande devant π_0 va avoir un cardinal majoré (au mieux) par π^{π_0}.

Prenons p.ex.

$$J \;=\; \mathfrak{P}(S) \qquad \text{(ensemble ordonné)}$$

avec $\operatorname{card} S = \pi > \pi_0$, donc J est grand devant π_0. Considérons l'application

$$S \;\longrightarrow\; J = \mathfrak{P}(S)\ , \qquad s \longmapsto \{s\}\ ,$$

et prenons pour $\Phi \subset \operatorname{Fl} J$ l'ensemble des $\mathrm{id}_{\{s\}}$. Donc on cherche une partie J' de J, contenant S, et grande devant π_0 pour l'ordre induit par J. On voit tout de suite que la plus petite partie J' faisant l'affaire est l'ensemble $\mathfrak{P}_{\pi_0}(S)$ des parties de S de cardinal $\leqslant \pi_0$. Mais on trouve

$$\operatorname{card} J' \cdot \pi_0! \;=\; \pi^{\pi_0}\ ,$$

où

$$\begin{aligned} \pi_0! \;&=\; \operatorname{card} \operatorname{Aut}(E_0) \qquad (E_0 \text{ ensemble de cardinal } \pi_0) \\ &=\; \pi_0^{\pi_0} \\ &=\; 2^{\pi_0}\ , \end{aligned}$$

p. 33 [page 115]

donc

$$(*) \qquad \operatorname{card} J' \cdot 2^{\pi_0} \;=\; \pi^{\pi_0}\ .$$

D'autre part, il est immédiat que $\operatorname{card} J' \geqslant \operatorname{card} \mathfrak{P}(E_0) = 2^{\pi_0}$ (où E_0 est une partie de S de cardinal π_0), donc le premier membre de $(*)$ est égal à $\operatorname{card} J'$, donc on trouve

$$\operatorname{card} J' \;=\; \pi^{\pi_0}\ ,$$

sorry !

Finalement, je me suis convaincu que la proposition 4.5.2, et les corollaires et lemmes précédents par lesquels j'ai essayé de l'établir, n'est vrai que pour ces cardinaux $\pi > \pi_0$ tels que

$$\pi^{\pi_0} \;=\; \pi\ ,$$

ce qui, moyennant l'hypothèse du continu généralisée, équivaut à

$$\pi^{\pi_0} \;<\; 2^{\pi}\ (\;=\; \pi^{\pi}\;)$$

(ou encore à $\pi^{\pi_0} \neq 2^{\pi}\ (= \pi^{\pi})$). Je vais donner ici un énoncé rectifié. [page 116]

Commentary · Development (commentators') [ms. 115]

A corrected obstruction to a small directed hull

The purpose of the example on pages 114–115 is to show that the cardinal cost of making an indexing category sufficiently filtered cannot always be avoided. Its chosen ambient poset, however, makes the proposed counterexample fail. In $J = \mathcal{P}(S)$, the family consisting of all singletons together with S has a greatest element. It is therefore directed at every cardinal threshold, has cardinal $|S|$, and contains every prescribed singleton. The family $[S]^{\leq \pi_0}$ is not the smallest directed family with that property. Its cardinality, correctly calculated in the source, is not a lower bound for every possible directed hull.

The required obstruction is a statement about cofinality. We give a direct repair of this passage. We checked the relevant arguments in SGA 4, Exposé I, sections 8–9, and the diagram-completion comparison in Henry (2025a); neither supplies a correction to this particular example. The following elementary application of diagonalization is offered as a repair, without a claim of priority.

Proposition (a singular-cardinal obstruction). [ours] Let $\mu > \aleph_0$ be a singular cardinal of countable cofinality. The poset

$$J = [\mu]^{\leq \aleph_0},$$

ordered by inclusion, is $\aleph_1$-directed. There is no $\aleph_1$-directed subposet $J' \subseteq J$ of cardinal at most μ containing every singleton.

Proof. A countable union of countable sets is countable, so J is $\aleph_1$-directed. If J' were as stated, then for every countable $A \subseteq \mu$, the family of singletons $\{\{a\} : a \in A\}$ would have an upper bound in J'. Thus J' would be cofinal in J.

Choose an increasing sequence of infinite cardinals $\mu_n < \mu$ with supremum μ. If $|J'| \leq \mu$, we can write $J' = \bigcup_{n<\omega} \mathcal{H}_n$ with $|\mathcal{H}_n| \leq \mu_n$. Each union $U_n = \bigcup \mathcal{H}_n$ has cardinal at most $\mu_n \cdot \aleph_0 < \mu$. Choose $a_n \in \mu \setminus U_n$, and put $A = \{a_n : n < \omega\}$. For any $H \in J'$, some n has $H \in \mathcal{H}_n$, and then $a_n \notin H$. Consequently no member of J' contains A, contradicting cofinality. This proves the proposition. □

Taking $\pi_0 = \aleph_0$, $\pi = \mu$, and the prescribed arrows to be the identities of all singletons gives an actual counterexample to Lemma 4.5.5 as originally stated. One may take $\mu = \beth_\omega$, which also lies above the elementary size bounds that occur earlier in the section. The argument establishes failure in ZFC and does not assume the generalized continuum hypothesis.

For comparison, the corrected upper estimate can be proved constructively at the level of categories. Let J be θ^+-filtered, let $\mu > \theta$ satisfy $\mu^\theta = \mu$, and start with at most μ specified arrows. Close them under identities and finite compositions. At each successor stage, choose cocones in J for all diagrams with at most θ arrows in the current subcategory, adjoin their vertices and legs, and again close under composition. There are at most $\mu^\theta = \mu$ such diagrams, since both their shapes and their values can be encoded by at most θ pieces of data from sets of size at most μ. Each stage therefore has at most μ arrows.

Continue this construction for θ^+ stages and take the union. Its cardinal remains at most μ, since $\theta^+ \leq \mu$. Every diagram with at most θ arrows in the union occurs at one stage, by regularity of θ^+, and acquires a cocone at the next stage. The union is therefore θ^+-filtered and gives the desired hull. Without a fixed-point hypothesis, the same construction with the bound $\nu = \mu^\theta$ works because $\nu^\theta = \nu$. This proves the enlarged bound recorded in footnote 38. The two arguments distinguish the valid upper estimate from the invalid minimality assertion and provide both the positive and negative parts needed at this point of the manuscript.

Proposition 4.5.6.

(1°) *Sous les hypothèses générales de 4.5.2 sur C, π_0, π_1, π, les conditions a, a′, a″, b, c′ de cette proposition sont équivalentes (moyennant $\pi \geqslant \pi_1$) ([39]), et impliquent la condition c (F est π-accessible). Quand $\pi^{\pi_0} = \pi$ (notamment quand $\pi = 2^c$, avec $c \geqslant \pi_0$), alors toutes les conditions a à c′ de 4.5.2 sont équivalentes.*

(2°) *Plus généralement et plus précisément, pour $\pi \geqslant \pi_1$ donné, considérons les conditions sur π :*

1) $\pi^{\pi_0} = \pi$.

2) $\mathrm{Filt}^\pi(\mathcal{M})$ (définie dans 4.5.3) est stable par $\varinjlim$ de cardinal $\leqslant \pi$.

3) $\forall$ F dans $\mathcal{M}$, on a $F \simeq \varinjlim_I X_i$, avec I ensemble ordonné grand devant π, les X_i dans $\mathrm{Filt}^\pi(\mathcal{M})$. De plus, si $\pi' > \pi$ et $F \in \mathrm{Filt}^{\pi'}(\mathcal{M})$, on peut prendre I de cardinal $\leqslant \pi'^\pi$.

4) Comme 3), sans la majoration de cardinaux, et en supposant seulement I catégorie grande devant π (pas nécessairement catégorie ordonné).

5) La condition c) de 4.5.2 implique les autres conditions (elles sont équivalentes, par 1°), en d'autres termes

$$\mathcal{M}_\pi \subset \mathrm{Filt}^\pi \qquad \text{(donc } \mathcal{M}_\pi = \mathrm{Filt}^\pi \text{, puisqu'on sait que } \mathrm{Filt}^\pi \subset \mathcal{M}_\pi\text{)} ,$$

p. 34
[page 117]

39. **N.B.** Pour cette équivalence, l'hypothèse que C soit stable par $\varinjlim$ de cardinal $\leqslant \pi$ est inutile, et aussi pour que c′) implique c), et lui soit équivalente si $\pi = \pi^{\pi_0} \geqslant \pi_1$, cf. 4.7.1, p. 161.

Commentary · Exposition [ms. 116]

Two measurements of size

Grothendieck is separating the size of an object from the size of the collection of all maps into it from his chosen test objects. This distinction is the reason for the correction of Proposition 4.5.2. We retain his infinite cardinals $\pi_0 \leq \pi$, and write $\lambda = \pi_0^+$ and $\mu = \pi^+$. Thus "π-accessible object" means μ-presentable object, and a category "large relative to π" is μ-filtered. All assertions here concern ordinary categories.

Let C_0 be a small skeleton of C, with at most π_1 arrows, and put $\mathcal{M} = \mathrm{Ind}'_{\pi_0}(C)$. Its embedding in $C^\wedge$ identifies an object X with the presheaf $c \mapsto \mathrm{Hom}(c, X)$. For $\pi \geq \pi_1$, the following three bounds are equivalent:

$$|\,\mathrm{Fl}(C_0/X)| \leq \pi, \qquad |\mathrm{Ob}\,(C_0/X)| \leq \pi, \qquad |\mathrm{Hom}(c, X)| \leq \pi \quad (c \in C_0).$$

Indeed, an object of C_0/X is a pair (c, u), while an arrow over $a : c \to d$ is determined by its target $v : d \to X$, its source being va. Counting first objects and then arrows proves the equivalence. Such a presheaf is μ-presentable in the presheaf category: its category-of-elements presentation uses at most π representables. Conversely, evaluation at c preserves presentability once $|\mathrm{Hom}_C(c, d)| \leq \pi$; the precise adjunction is explained in the next block. This proves the equivalence with condition c′ without any cardinal exponent assumption.

The distinction becomes concrete in sets. Take C_0 to represent sets of cardinality at most π_0. An object X of Ens is μ-presentable exactly when $|X| \leq \pi$. The forward implication follows by writing X as the μ-filtered union of its subsets of size at most π and factoring id_X through one of them. The converse follows because a function from at most π elements into a μ-filtered colimit can be lifted at one stage, and equality of two such functions can be witnessed at one later stage. On the other hand,

$$X \in \mathrm{Filt}^\pi \quad \Longleftrightarrow \quad |X|^{\pi_0} \leq \pi.$$

For $|X| \geq 2$, the exponent on the right bounds all maps from the objects of C_0, and is itself attained by maps from a set of size π_0; the empty and singleton cases satisfy the same conclusion directly. Consequently equality $\mathrm{Filt}^\pi = (\mathrm{Ens})_\pi$ is equivalent to $\pi^{\pi_0} = \pi$. This proves a genuine necessity result, independently of the unsuccessful power-set argument on manuscript page 114.

The corrected estimate

$$\mathrm{Filt}^\pi \subseteq \mathcal{M}_\pi \subseteq \mathrm{Filt}^{\pi^{\pi_0}}$$

retains useful information at every cardinal. Its second inclusion follows by replacing π by $\rho = \pi^{\pi_0}$: since $(\pi^{\pi_0})^{\pi_0} = \pi^{\pi_0}$, the corrected equivalence applies at ρ, and $\mathcal{M}_\pi \subseteq \mathcal{M}_\rho$. There is no assumption of the generalized continuum hypothesis in this argument.

There is one local repair in the proof on pages 117–118. A fixed Filt^π is not closed under arbitrarily large λ-filtered colimits: arbitrarily large unions of small sets already contradict this. What is needed there is only closure under retracts. It holds immediately, since $\mathrm{Hom}(c, X)$ is a retract of $\mathrm{Hom}(c, Y)$ whenever X is a retract of Y. The implication 4)⇒5) is therefore correct, with this replacement of the printed justification.

où $\mathcal{M}_\pi$ désigne la sous-catégorie strictement pleine de $\mathcal{M}$ formée des objets π-accessibles.

Ceci posé, on a les implications

$$1) \implies 2) \implies 3) \implies 4) \implies 5)\ ,$$

et dans le cas particulier où $\mathcal{M} = (\mathrm{Ens})$, C = sous-catégorie pleine formée des ensembles de cardinal $\leqslant \pi_0$, on a aussi 5) $\implies$ 1), i.e. toutes ces conditions sont équivalentes.

Démonstration.

1) $\implies$ 2). Cf. démonstration de 4.5.4.

2) $\implies$ 3). La catégorie $J = \mathrm{Filt}^\pi / F$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$, Filt^π l'étant, donc J est grande devant π, d'ailleurs $F = \varinjlim_{j \in J} X_j$, où $j \longmapsto X_j$ est le foncteur source

$\mathrm{Filt}^\pi/F \longrightarrow \mathrm{Filt}^\pi$. D'où la représentation voulue de F, quitte à remplacer J par un ensemble ordonné cofinal I, p.ex. en prenant pour I l'ensemble des sous-catégories J de I telles que $\operatorname{card}\mathrm{Fl}\,J \leqslant \pi$ [cette deuxième partie de la phrase "p.ex. ..." demande correction]. La majoration $\operatorname{card} I \leqslant \pi'^{\pi}$, pour $F \in \mathrm{Ob}\,\mathrm{Filt}^{\pi'}$, se fait par AQT [âne qui trotte].

L'implication 3) $\Longrightarrow$ 4) est tautologique.

4) $\Longrightarrow$ 5) ([40]), car si $F \in \mathrm{Ob}\,\mathcal{M}_\pi$, on trouve par 4) que F est facteur direct d'un objet de Filt^π, et Filt^π étant stable par $\varinjlim$ grandes devant π_0, cela implique que Filt^π est stable par facteurs directs, d'où $F \in \mathrm{Ob}\,\mathrm{Filt}^\pi$. [page 118]

Enfin, si $\mathcal{M} = \mathrm{Ens}$, $C = \mathrm{Ens}(\pi_0)$. On note que

$$\mathrm{Filt}^\pi \;=\; \{\; X \in \mathrm{Ob}\,\mathrm{Ens} \mid \operatorname{card}(X)^{\pi_0} \;\leqslant\; \pi \;\}\;.$$

D'autre part, on trouve facilement

$$\begin{aligned}(\mathrm{Ens})_\pi \quad &\overset{\text{déf}}{=} \quad \text{sous-catégorie pleine de (Ens) formée}\\ &\qquad\quad \text{des objets } \pi\text{-accessibles}\\ &= \quad \{X \in \mathrm{Ob}\,\mathrm{Ens} \mid \operatorname{card} X \leqslant \pi\}\;.\end{aligned}$$

Donc on a $(\mathrm{Ens})_\pi \subset \mathrm{Filt}^\pi$ si et seulement si $\pi^{\pi_0} \leqslant \pi$, i.e. $\pi^{\pi_0} = \pi$, q.e.d. ([41]).

Corollaire 4.5.7. *Pour tout cardinal $\pi \geqslant \pi_1$, on a*

$$\mathrm{Filt}^\pi \;\subset\; \mathcal{M}_\pi \;\subset\; \mathrm{Filt}^{\pi^{\pi_0}}\;. \tag{4.5.7.1}$$

L'inclusion $\mathrm{Filt}^\pi \subset \mathcal{M}_\pi$ est l'implication a $\Longrightarrow$ c de la partie 1°) de 4.5.6. Pour prouver $\mathcal{M}_\pi \subset \mathrm{Filt}^{\pi^{\pi_0}}$, on pose $\pi' = \pi^{\pi_0}$ et on note que $\pi'^{\pi_0} = \pi^{\pi_0\cdot\pi_0} = \pi^{\pi_0} = \pi'$. Donc on peut appliquer 1° à π' au lieu de π, et on trouve que $\mathcal{M}_{\pi'} = \mathrm{Filt}^{\pi'}$. Comme $\mathcal{M}_\pi \subset \mathcal{M}_{\pi'}$, on en conclut $\mathcal{M}_\pi \subset \mathrm{Filt}^{\pi'}$, q.e.d.

J'ai oublié de démontrer le 1°) dans 4.5.6. Vu le diagramme d'implications (∗), p. 108, et l'implication a'' $\Longrightarrow$ a déjà prouvé (p. 109), il reste à prouver seulement p. 35

$$\mathrm{c}' \;\Longrightarrow\; \mathrm{a}''\;, \qquad \text{[page 119]}$$

i.e. que F π-accessible *dans* $C^\wedge$ implique $\operatorname{card} F(x) \leqslant \pi \;\forall\; x \in C$. Ceci va résulter du résultat un peu plus général :

Lemme 4.5.8.

1°) Dans la catégorie $\mathcal{E} = (\mathrm{Ens})$, les objets π-accessibles (π un cardinal infini) sont les ensembles X tels que $\operatorname{card} X \leqslant \pi$.

2°) ([42]). Soit C une catégorie équivalente à une petite catégorie, telle que $\forall\; x, y \in \mathrm{Ob}\,C$, on ait $\operatorname{card}\mathrm{Hom}(x,y) \leqslant \pi$. *Soit $\mathcal{E}$ une $\mathfrak{U}$-catégorie stable par $\varinjlim$ grandes devant π, et faiblement π-accessible (i.e. admettant une sous-catégorie génératrice formée d'objets π-accessibles), et stable par produits de cardinal $\leqslant \pi$. Alors pour qu'un objet F de $\underline{\mathrm{Hom}}(C,\mathcal{E})$ soit π-accessible, il* faut *que $\forall\; x \in \mathrm{Ob}\,C$, $F(x)$ soit un objet π-accessible de $\mathcal{E}$, et cette condition est aussi suffisante si* $\operatorname{card}\text{réd}\,\mathrm{Fl}(C) \leqslant \pi$ ([43]).

Démonstration. 1°) $\operatorname{card} X \leqslant \pi \Longrightarrow X$ π-accessible dans $\mathcal{E} = (\mathrm{Ens})$, car $X = \coprod_{x\in X}\{x\}$, et on applique SGA 4 I 9.9. Inversement, supposons X π-accessible, et écrivons $X \simeq \varinjlim_{i\in I} X_i$, où I est l'ensemble des parties de X qui sont de cardinal $\leqslant \pi$. Comme I est grande devant π, l'application identique $X \xrightarrow{\mathrm{id}} X$ se factorise par un ensemble X_i, donc $X_i = X$, donc $\operatorname{card} X = \operatorname{card} X_i \leqslant \pi$, q.e.d.

40. comparer le lemme 4.5.14, page 133.
41. Cf. démonstration de la partie 1°) de 4.5.6, plus bas (bas de page et page suivante).
42. Cf. généralisation 4.14.18, p. 391 b) et c). [page 120]
43. même *sans* condition de stabilité de $\mathcal{E}$ par produits de cardinal $\leqslant \pi$.

2°) Considérons, pour $x \in \mathrm{Ob}\, C$, le foncteur

$$e \xrightarrow{\varepsilon_x} C \ ,$$

d'où un foncteur

$$\varepsilon_x^* \ : \ \underline{\mathrm{Hom}}(C, \mathcal{E}) \longrightarrow \mathcal{E} \ , \qquad F \longmapsto F(x) \ ,$$

admettant un adjoint à droite

$$\varepsilon_{x\,*} \ : \ \mathcal{E} \ \longrightarrow \ \underline{\mathrm{Hom}}(C, \mathcal{E}) \ ,$$

donné par

$$\varepsilon_{x\,*}(E)(y) \ = \ E^{\mathrm{Hom}(x,y)}$$

(sous réserve d'existence des produits de cardinal $\leqslant \pi$). Ce foncteur $\varepsilon_{x\,*}$ est π-accessible en vertu de loc. cit. 9.8.

Ceci posé, soit F un objet π-accessible de $\underline{\mathrm{Hom}}(C, \mathcal{E})$, on voit que $\varepsilon_x^*(F)$ est π-accessible, ε_x^* ayant un adjoint à droite π-accessible :

$$E \ \longmapsto \ \mathrm{Hom}_{\mathcal{E}}(\underbrace{F(x)}_{\varepsilon_x^*(F)}, E) \ \simeq \ \mathrm{Hom}_{\underline{\mathrm{Hom}}(C,\mathcal{E})}(F, \varepsilon_{x\,*}(E))$$

est composé du foncteur π-accessible $\varepsilon_{x\,*}$, et du foncteur covariant π-accessible représenté par F dans $\underline{\mathrm{Hom}}(C, \mathcal{E})$. p. 36

Inversement, si les $F(x)$ sont π-accessibles, prouvons que F l'est, moyennant $\mathrm{card}\, \mathrm{Fl}(C) \leqslant \pi$. Se fait par AQT `[âne qui trotte]`, je ne vais pas l'expliciter ici.

[page 121]

Commentary · Exposition [ms. 120]

The presentability of a diagram

Grothendieck wants to recover the sizes of the values of a presheaf from the size of the presheaf as an object. Evaluation supplies the necessary bridge, but its adjoint must have the correct variance. For a covariant functor $F : C \to \mathcal{E}$, the right adjoint to evaluation at c is

$$R_c(E)(d) = \prod_{a : d \to c} E.$$

The edition writes $E^{\mathrm{Hom}(c,d)}$. That expression has the opposite variance in d and is not the asserted right adjoint. To verify the corrected formula directly, a map $t : F(c) \to E$ determines the component $F(d) \to R_c(E)(d)$ whose projection at $a : d \to c$ is $tF(a)$. Naturality recovers every component from the projection at id_c, establishing the adjunction. This is the pointwise right Kan extension along $\{c\} \to C$; compare Riehl (n.d., Proposition 6.1.5 and Theorem 6.2.1).

Suppose $\mathcal{E}$ has the products and μ-filtered colimits used here, and has a conservative family of representables preserving those colimits. This is the meaning of the generating-family hypothesis inherited from SGA 4, rather than merely faithfulness of those representables. Products indexed by at most π elements commute with μ-filtered colimits in $\mathcal{E}$: applying a conservative representable reduces the assertion to sets. In sets, lift the at most π coordinates at a common stage to obtain surjectivity, and witness their at most π equalities at a common later stage to obtain injectivity. Thus R_c preserves μ-filtered colimits when every $\mathrm{Hom}(d, c)$ has cardinality at most π. If F is μ-presentable, then

$$\mathrm{Hom}_{\mathcal{E}}(F(c), -) \cong \mathrm{Hom}_{[C,\mathcal{E}]}(F, R_c(-))$$

preserves these colimits, so $F(c)$ is μ-presentable.

For the converse, assume a skeleton of C has at most π arrows. The missing AQT argument is an equalizer computation. For any $G : C \to \mathcal{E}$,

$$\mathrm{Nat}(F, G) = \mathrm{Eq}\left(\prod_{c \in \mathrm{Ob}\, C} \mathrm{Hom}(F(c), G(c)) \rightrightarrows \prod_{a : c \to d} \mathrm{Hom}(F(c), G(d)) \right).$$

The two maps send a family (t_c) to $(G(a)t_c)$ and $(t_dF(a))$. If all $F(c)$ are μ-presentable, every factor preserves μ-filtered colimits in G, and so does the displayed equalizer: the total number of coordinates and compatibility conditions is at most π. Since diagram-category colimits are pointwise, this proves presentability of F. No products in $\mathcal{E}$ are required for this direction; only products of hom-sets are used. The source's parenthetical qualification is therefore exact.

This calculation also explains why the bound on the number of arrows cannot be silently replaced by a bound on the number of objects. One must make every naturality equation hold at the same stage. A one-object category may carry arbitrarily many such equations through its endomorphisms.

Proposition 4.5.9. *Soit C une catégorie équivalente à une petite catégorie, et soit $\mathcal{M} = \mathrm{Ind}'_{\pi_0}(C)$, π_0 un cardinal infini donné. On suppose C stable par $\varinjlim$ de cardinal $\leqslant \pi_0$. Pour tout cardinal $\pi \geqslant \pi_0$, soit $\mathcal{M}_\pi \supset C$ la sous-catégorie pleine de $\mathcal{M}$ formée des objets π-accessibles de $\mathcal{M}$. Soit d'autre part $\pi_1 = \sup(\pi_0, \operatorname{card} \mathrm{Fl}\, C)$. Alors $(\mathcal{M}_\pi)_{\pi \geqslant \pi_1}$ est une filtration cardinale de $\mathcal{M}$ ([44]), et de plus, pour $\pi \geqslant \pi_0$, $\mathcal{M}_\pi$ est stable dans $\mathcal{M}$ par $\varinjlim$ de cardinal $\leqslant \pi$.*

Démonstration. La stabilité de $\mathcal{M}_\pi$ est un rappel, cf. SGA 4 I 9.9. Comme on a

$$\mathcal{M}_\pi \ \subset\ \mathrm{Filt}^{\pi^{\pi_0}}$$

pour $\pi \geqslant \pi_1$ (cf. 4.5.7), on voit donc que les $\mathcal{M}_\pi$ sont équivalentes à des petites catégories (condition a) des filtrations cardinales). La condition b) des filtrations cardinales est contenue dans la propriété de stabilité des $\mathcal{M}_\pi$ qu'on vient de rappeler. Prouvons enfin la condition c). Soit donc $\pi \geqslant \pi_0$, et soit x dans $\mathcal{M}$, considérons la catégorie

$$I \ =\ \mathcal{M}_\pi/x\ ,$$

elle est stable par $\varinjlim$ de cardinal $\leqslant \pi$, d'après la stabilité similaire de $\mathcal{M}_\pi$, donc I est grande devant π et équivalente à une petite catégorie, d'autre part, on a [page 122]

$$x \ =\ \varinjlim_{i \in I} x_i\ ,$$

les x_i dans $\mathcal{M}_\pi$ ($\varinjlim$ dans $\mathcal{M}$ des foncteurs $I = \mathcal{M}_\pi/x \longrightarrow \mathcal{M}_\pi$). Quitte à remplacer I par une catégorie ordonnée cofinale, cela prouve la partie qualitative de c. Supposons enfin $x \in \mathrm{Ob}\, \mathcal{M}_{\pi'}$, où $\pi' > \pi$, montrons que l'on a alors

$$\operatorname{card} I_0,\ \operatorname{card} I' \ \leqslant\ \pi'^{\pi} \qquad ([45], [46])\ , \tag{4.5.9.1}$$

ce qui achèvera de prouver que l'on a une filtration cardinale. Il nous faut une majoration des cardinaux.

Lemme 4.5.10 ([47]). *Soit π un cardinal $\geqslant \pi_1$. Alors on a*

$$\operatorname{card} \mathrm{Fl}((\mathrm{Filt}^\pi)_0) \ \leqslant\ 2^\pi\ . \tag{4.5.10.1}$$

On a en effet, en désignant par $C^\wedge(\pi)$ la sous-catégorie strictement pleine de $C^\wedge$ formée des $F : C^\circ \longrightarrow \mathrm{Ens}$ avec $\operatorname{card} F(x) \leqslant \pi$ pour tout x dans C (i.e. F se factorise par $\mathrm{Ens}(\pi)$), et par $C^\wedge(\pi)_0$ une sous-catégorie réduite exhaustive,

$$\operatorname{card} C^\wedge(\pi)_0 \ \leqslant\ 2^\pi\ , \tag{4.5.10.2}$$

p. 37
[page 123]

d'où résulte (4.5.10.1), puisque pour $\pi \geqslant \pi'$, Filt^π est une sous-catégorie pleine de $C^\wedge(\pi')$. Pour établir (4.5.10.2), on note que l'ensemble des classes à isomorphie près de $\mathrm{Ens}(\pi')$ s'identifie à

44. **N.B.** Toutes les conditions des filtrations cardinales sont vérifiées à l'exclusion, quand $\pi \geqslant \pi_0$, de celle de la majoration de cardinaux $\operatorname{card} I \leqslant \pi'^{\pi}$ condition c).

45. où I_0, I'_0 sont des sous-catégories réduites de I, I' telles que $I_0 \hookrightarrow I$, $I'_0 \hookrightarrow I'$ soient des équivalences `[Grothendieck a biffé l'indice 0 de I' dans 4.5.9.1]`.

46. On ne le prouve que si $\pi \geqslant \pi_1$.

47. Donner énonce commun avec 4.5.11, et prouver d'abord 4.5.11.

l'ensemble des cardinaux $\leqslant \pi'$, lequel ensemble est de cardinal $\leqslant \pi'$. Remplaçant $\mathrm{Ens}(\pi)$ par $\mathrm{Ens}(\pi')_0$, C par C_0, on doit majorer $\operatorname{card}\mathrm{Fl}(\underline{\mathrm{Hom}}(C_0, \mathrm{Ens}(\pi')_0))$. Or $\mathrm{Ob}\,\underline{\mathrm{Hom}}(C_0, \mathrm{Ens}(\pi')_0)$ est contenu dans l'ensemble des applications de $\mathrm{Fl}\,C_0$ dans $\mathrm{Fl}(\mathrm{Ens}(\pi')_0)$, le premier est majoré par π_1, le deuxième par $\pi^\pi \times \pi \times \pi = \pi^{2\pi} = \pi^\pi = 2^\pi$ (**N.B.** $\pi < 2^\pi$, d'où $\pi^\pi \leqslant (2^\pi)^\pi = 2^{\pi^2} = 2^\pi$), donc $\mathrm{Ob}\,\underline{\mathrm{Hom}}$ majoré par $(2^\pi)^{\pi_1} = 2^{\pi\pi_1} = 2^\pi$. D'autre part, si F, G sont dans $\underline{\mathrm{Hom}}(C_0, \mathrm{Ens}(\pi_0))$, $\mathrm{Hom}(F, G)$ est majoré par $(\pi^\pi)^{\pi_1} = \pi^\pi = 2^\pi$, donc $\mathrm{Fl}\,\underline{\mathrm{Hom}}$ est majoré par $2^\pi \times 2^\pi \times 2^\pi$, q.e.d.

Corollaire 4.5.11. *Soit $F \in \mathrm{Ob}\ \mathrm{Filt}^\pi$, $F' \in \mathrm{Ob}\ \mathrm{Filt}^{\pi'}$, avec $\pi' \geqslant \pi \geqslant \pi_1$. Alors*

$$\operatorname{card}\mathrm{Hom}(F, F') \leqslant \pi'^\pi \ . \tag{4.5.11.1}$$

C'est essentiellement la même démonstration, légèrement plus simple. (On aurait dû commencer par là.) [page 124]

Corollaire 4.5.12. *Si $\pi' \geqslant \pi \geqslant \pi_1$, on a pour $x \in \mathrm{Ob}\,\mathcal{M}_{\pi'}$*

$$\operatorname{card}(\mathcal{M}_\pi/x)_0 \leqslant \pi'^{(\pi^{\pi_0})} \ . \tag{4.5.12}$$

En effet,

$$\operatorname{card}\mathrm{Ob}\ (\mathcal{M}_\pi/x)_0 \overset{\text{par 4.5.11}}{\leqslant} \underbrace{\underbrace{\operatorname{card}\mathrm{Ob}\ (\mathcal{M}_\pi)_0}_{\leqslant 2^{(\pi^{\pi_0})}\ \text{par 4.5.10}} \times (\pi'^{\pi_0})^{\pi^{\pi_0}}}_{=\pi'^{(\pi^{\pi_0})}} \ ,$$

i.e.

$$\operatorname{card}\mathrm{Ob}\ (\mathcal{M}_\pi/x)_0 \leqslant \pi'^{(\pi^{\pi_0})} \ ,$$

d'où

$$\operatorname{card}\mathrm{Fl}(\mathcal{M}_\pi/x)_0 \leqslant \pi'^{(\pi^{\pi_0})} \times \pi'^{(\pi^{\pi_0})} \times (\pi'^{\pi_0})^{(\pi^{\pi_0})} \leqslant \pi'^{(\pi^{\pi_0})} \ .$$

Cela donne donc (revenant à 4.5.9.1)

$$\operatorname{card} I_0 \leqslant \pi'^{(\pi^{\pi_0})} \ .$$

D'autre part, I' peut se définir en termes de I_0 comme l'ensemble des sous-catégories de I_0 qui sont de cardinal $\leqslant \pi$, donc leur nombre est majoré par $(\operatorname{card} I_0)^\pi \leqslant (\pi'^{\pi^{\pi_0}})^\pi = \pi'^{\pi\pi^{\pi_0}} = \pi'^{(\pi^{\pi_0})}$.

Mais ce n'est pas tout à fait la majoration exigée, puisque

$$\pi'^\pi \leqslant \pi'^{(\pi^{\pi_0})} \qquad ([48]),$$

et qu'il est possible, a priori, que l'inégalité soit stricte ! Apparemment, les "majorations" p. 38 [page 125]

$$\mathcal{M}_\pi \subset \mathrm{Filt}^{\pi^{\pi_0}} \ , \qquad \mathcal{M}_{\pi'} \subset \mathrm{Filt}^{\pi'^{\pi_0}}$$

sont trop grossières. Aussi il s'agit de mieux appréhender les catégories $\mathcal{M}_\pi$, pour $\pi \geqslant \pi_0$ ([49]). Je vais hasarder une

48. **N.B.** On a égalité si on a $\pi' = 2^{c'}$ avec $c' \geqslant \pi^{\pi_0}$, soit $\pi = 2^c$ avec $c \geqslant \pi_0$.

49. Mais on peut utiliser 4.5.10, 4.5.11 pour conclure que pour $x \in \mathrm{Ob}\,\mathcal{M}_{\pi'} \subset \mathrm{Ob}\ \mathrm{Filt}^{\pi'^{\pi_0}}$, on a $\operatorname{card}\mathrm{Fl}(C_0/x) \leqslant (\pi'^{\pi_0})^{\pi_0} = \pi'^{\pi_0}$, on aura donc $x = \varinjlim_J x_j$ ($x_j \in \mathrm{Ob}\,C$, $\varinjlim$ filtrante, $\operatorname{card}\mathrm{Fl}\,J \leqslant \pi'^{\pi_0}$), et en introduisant l'ensemble I des sous-catégories $J' \subset J$ qui sont de cardinal $\leqslant \pi$, et posant $x_{J'} = \varinjlim_{j \in J'} x_j$, on trouve $x = \varinjlim_{J' \in I} x_{J'}$, où cette fois I est un *ensemble ordonné* grand devant π, les $x_{J'} \in \mathcal{M}_\pi$, et $\operatorname{card} I \leqslant (\operatorname{card} J)^\pi \leqslant (\pi'^{\pi_0})^\pi = \pi'^{\pi\pi_0} = \pi'^\pi$, c'est la bonne majoration !

Commentary · Exposition [ms. 124]

The canonical filtration and its cardinal bound

Grothendieck's preferred filtration is now the intrinsic one: $\mathcal{M}_\pi$ consists of the π^+-presentable objects. The strength of Proposition 4.5.9 is that it supplies the required presentations at every sufficiently large π, although the more concrete test $|\mathrm{Hom}(c, X)| \leq \pi$ may fail. The footnote on manuscript page 125 supplies the right construction; counting the whole slice too early obscures it.

First, $\mathcal{M}_\pi$ is closed under colimits with at most π arrows. If $A = \mathrm{colim}_{j\in J} A_j$ and $|\operatorname{Fl} J| \leq \pi$, then $\mathrm{Hom}(A, -) = \lim_{J^{\mathrm{op}}} \mathrm{Hom}(A_j, -)$, and a limit of at most π set-valued functors preserving π^+-filtered colimits again preserves them. This is the elementary closure result used throughout these pages; the historical reference is Artin et al. (1972, Exposé I, 9.8–9.9). Essential smallness follows either from the presheaf bound $\mathcal{M}_\pi \subseteq \mathrm{Filt}^{\pi^{\pi_0}}$ or from the presentation theorem proved below.

For a direct construction, write $X = \mathrm{colim}_{j\in J} c_j$ using $J = C_0/X$. Let P be the poset of subcategories $K \subseteq J$ with at most π arrows, and set

$$X_K = \mathrm{colim}_{k\in K} c_k \quad \text{in } \mathcal{M}.$$

The category P is π^+-directed. A family of at most π such subcategories has a union of at most π arrows; closing the union under identities and finite composition still adds at most π arrows. Every X_K belongs to $\mathcal{M}_\pi$. Moreover $X = \mathrm{colim}_{K\in P} X_K$: a compatible family of maps from the X_K is exactly a cocone on the original diagram, since every object and arrow of J occurs in some K. This proof does not assert that the subcategories K are themselves π_0^+-filtered.

If $X \in \mathcal{M}_{\pi'}$, with $\pi' \geq \pi \geq \pi_1$, then $|\operatorname{Fl}(C_0/X)| \leq (\pi')^{\pi_0}$ by Corollary 4.5.7. The number of choices of K is bounded by

$$|P| \leq \left((\pi')^{\pi_0}\right)^{\pi} = (\pi')^{\pi}.$$

The number of order relations of this infinite poset has the same bound. This proves the quantitative clause of the cardinal filtration without assuming $\pi^{\pi_0} = \pi$.

The numerical lemmas on pages 122–124 are correct after normalizing the stray primes in the proof of 4.5.10. For presheaves with at most π values at each object of a category with at most π arrows, one chooses representative sets among the cardinals at most π, and then structure maps between them. There are at most $(2^\pi)^\pi = 2^\pi$ resulting functors and at most 2^π natural transformations between each pair. Similarly, if the source values are bounded by π and target values by π', then

$$|\operatorname{Nat}(F, G)| \leq \prod_{c\in \mathrm{Ob}\, C_0} |G(c)|^{|F(c)|} \leq (\pi')^{\pi}.$$

The weaker exponent in Corollary 4.5.12 is a valid intermediate estimate. It is not a counterexample to the sharper presentation bound: that bound counts the subdiagrams used above rather than every map from every presentable object at once.

Proposition 4.5.13. *Les hypothèses et notations sont celles de 4.5.9. Soit π un cardinal $\geqslant \pi_0$, et soit $x \in \mathrm{Ob}\,\mathcal{M}$. Considérons les conditions :*

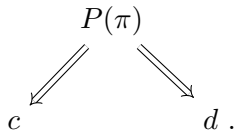
a) Il existe une catégorie I, avec $\operatorname{card}\operatorname{Fl} I \leqslant \pi$, *et un foncteur $i \longmapsto x_i : I \longrightarrow C$, tel que x soit isomorphe à $\varinjlim x_i$.*

a′) Comme a), avec I filtrante.

a″) Comme a), avec I ordonnée filtrante.

b) Il existe un foncteur cofinal $I \longrightarrow C/x$, *avec* $\operatorname{card}\operatorname{Fl} I \leqslant \pi$.

b′) La catégorie filtrante C/x est "essentiellement de cardinal $\leqslant \pi$", i.e. il existe une catégorie ordonnée `[non, cf. b″)]` filtrante I, $\operatorname{card}\operatorname{Fl} I \leqslant \pi$, *et un foncteur cofinal $I \longrightarrow C/x$.*



b″) Comme b′), avec de plus I ordonnée.

c) Il existe une famille de flèches $(u_\alpha)_{\alpha\in A}$, $x_\alpha \longrightarrow x$, épimorphique stricte, indexée par un ensemble A tel que $\operatorname{card} A \leqslant \pi$.

d) On a $x \in \mathrm{Ob}\,\mathcal{M}_\pi$, i.e. x est π-accessible dans $\mathcal{M}$. [page 126]

Ceci posé :

(1°) *Les six premières conditions a, a′, a″, b, b′, b″ sont équivalentes, soit $P(\pi)$, et impliquent les deux dernières,*

Si $\pi \geqslant \pi_1$, alors $P(\pi)$ est équivalente à c.

(2°) *Soit* $\mathrm{Filt}'^{\pi} \subset \mathcal{M}$ *la sous-catégorie strictement pleine de $\mathcal{M}$ formée des objets qui satisfont la condition $P(\pi)$ ci-dessus, et* Filt^{π} *la sous-catégorie strictement pleine définie dans 4.5.3 (p. 109). On a alors*

$$\mathrm{Filt}^{\pi} \ \subset \ \mathrm{Filt}'^{\pi} \ \subset \ \mathcal{M}_{\pi} \ , \tag{4.5.13.1}$$

et pour qu'on ait égalité des trois membres, il suffit qu'on ait $\pi^{\pi_0} = \pi$. (Cf. prop. 4.5.6, page 116). De plus, Filt'^{π} *est stable dans $\mathcal{M}$ par* sommes *de cardinal $\leqslant \pi$.*

(3°) *Les conditions suivantes sur C, π_0, π sont équivalentes.*

p. 39

1) Filt'^{π} *est stable dans $\mathcal{M}$ par $\varinjlim$ de cardinal $\leqslant \pi$.*

1′) Filt'^{π} *est stable par conoyaux de double-flèches.*

2) Tout objet x de $\mathcal{M}$ est de la forme $\varinjlim_{I} x_i$, où x_i dans Filt'^{π}*, I grande devant π.*

3) La condition d) de 1°) implique $P(\pi)$ (donc lui est équivalente), i.e. on a

$$\mathcal{M}_{\pi} \ = \ \mathrm{Filt}'^{\pi} \, .$$

Ces conditions sont satisfaites dans les trois cas suivants : [page 127]

A) $\pi^{\pi_0} = \pi$ (pour mémoire, c'est contenu dans 2°).

B) Les familles épimorphiques strictes dans $\mathcal{M}$ sont épimorphiques strictes universelles.

C) Les limites inductives filtrantes dans $\mathcal{M}$ commutent au changement de base (ce qui est le cas notamment si les $\varinjlim$ filtrantes sont exactes à gauche) ([50]).

Commentary · Development (commentators') [ms. 126]

A small colimit need not be cofinal in the canonical presentation

Grothendieck is looking for a presentation whose size can be read directly from the object. There are two different requirements in Proposition 4.5.13: being the colimit of a small diagram of objects of C, and possessing a small cofinal diagram in C/X. The proof on page 129 establishes the first requirement with a filtered indexing poset; it does not establish cofinality in C/X. The distinction persists even in sets, where all the exactness hypotheses later imposed are satisfied.

A counterexample to a)⇒b). [ours] Take $\pi_0 = \aleph_0$, let C be a skeleton of the countable sets, and let X have cardinality $\pi = \beth_\omega$. Here $\pi \geq \pi_1$, C has countable colimits, and $\mathcal{M} = \mathrm{Ens}$. The set X is the coproduct of its π singleton subsets. It is also the filtered colimit of its finite subsets, indexed by a poset with π arrows. Thus a), a′), and a″) all hold.

Suppose a category I with at most π arrows admitted a cofinal functor $I \to C/X$. Write its objects as maps $u_i : c_i \to X$. For every countable subset $A \subseteq X$, nonemptiness of the comma category $(A \hookrightarrow X) \downarrow I$ would give some i with $A \subseteq u_i(c_i)$. The at most π countable subsets $u_i(c_i)$ would therefore be cofinal among the countable subsets of X.

No such family exists. Indeed, write any family $\mathcal{H}$ of at most π countable subsets as an increasing union $\bigcup_{n<\omega} \mathcal{H}_n$ with $|\mathcal{H}_n| < \pi$. Each union $\bigcup \mathcal{H}_n$ has cardinality less than π. Choose $s_n \in X \setminus \bigcup \mathcal{H}_n$. The countable set $\{s_n : n < \omega\}$ is contained in no member of $\mathcal{H}$: a member belonging to $\mathcal{H}_n$ omits

50. Je suppose que cette condition revient à la même condition sur C, pour les $\varinjlim$ filtrantes de cardinal $\leqslant \pi$.

s_n. This contradiction proves failure of b), hence also of b′) and b″). The choice $\beth_\omega$ avoids any continuum hypothesis; its countable cofinality and its being larger than $2^{\aleph_0}$ are sufficient.

For the corrected positive assertion, let $X = \operatorname{colim}_I c_i$ with $|\operatorname{Fl} I| \leq \pi$. Every finite set of arrows of I gives a finite incidence diagram: introduce one vertex for each object used and one extra vertex for the source of each selected arrow, with its identity arrow to the source vertex and the given arrow to the target vertex. Its colimit belongs to C, because C has finite colimits. Ordering finite sets of arrows by inclusion gives a filtered poset with at most π arrows, and the colimit of these finite presentations is X. A cocone on all of them is exactly a cocone on I. This establishes a)⇒a″), including categories with loops: finite subsets need not generate finite subcategories, which is why the incidence-diagram description is preferable.

Thus a), a′), and a″) are equivalent. Each of b), b′), and b″) implies the corresponding colimit condition, but the two triples cannot be identified. For the rest of our commentary, Filt'^{π} denotes the one-step colimit class defined by a), the class used in the subsequent presentation arguments. This resolves an ambiguity created by the false equivalence in the printed definition; it is not a change to the source text.

Remarque. La filtration de $\mathcal{M}$ pour les Filt'^{π} n'est autre que celle envisagée dans SGA 4 I 9.13, où on fait de plus l'hypothèse B) sur $\mathcal{M}$, qui après-coup n'était plus tellement de mon goût. Toujours est-il que d'après (4.5.13.1), cette filtration se rapproche plus de la "bonne" filtration par les $\mathcal{M}_\pi$, que celle que j'avais eu encore naguère tendance à lui préférer, celle par les Filt^{π}. Elle a d'ailleurs sur cette dernière l'avantage, dans le cas envisagé B), d'être une filtration cardinale (ce qui n'est pas nécessairement le cas pour Filt^{π}, du moins s'il existe des cardinaux infinis $\pi \geqslant \pi_0$ avec $\pi^{\pi_0} \neq \pi$). Je soupçonne maintenant qu'en général (et s'il existe des cardinaux infinis $\pi > \pi_0$ tels que $\pi^{\pi_0} \neq \pi$), en dehors des conditions A) B) C), la filtration par les (Filt'^{π}) n'est *pas* une filtration cardinale. En tous cas, 4.5.6 et la présente proposition, [page 128]
3°, montrent que si soit $(\mathrm{Filt}^{\pi})_{\pi\geqslant\pi_2}$, soit $(\mathrm{Filt}'^{\pi})_{\pi\geqslant\pi_2}$ est une filtration cardinale (π_2 étant un cardinal donné $\geqslant \pi_1$), alors elle coïncide avec la filtration par les $\mathcal{M}_\pi$. Donc apparemment, dans tous les cas où je sais construire une filtration cardinale, sur un paratopos du moins (i.e. sur une catégorie $\mathcal{M}$ stable par petites $\varinjlim$, et dont tous les objets sont accessibles – l'existence d'une filtration cardinale impliquant de plus celle d'une petite sous-catégorie strictement génératrice …), celle-ci n'est autre que celle par les $\mathcal{M}_\pi$ – chose dont je ne m'étais par aperçu en rédigeant SGA 4 I 9.

Commentary · Development (commentators') [ms. 127]

A precise reduction of universality to the generators

Footnote 50 suggests testing condition C) inside the small generating category. As printed, that suggestion needs a qualification: C is only assumed to have colimits with at most π_0 arrows, and it need not have pullbacks. With the latter hypothesis added, the reduction is valid, and the bound π_0 itself suffices. The proof below makes explicit which data must be approximated together.

A bounded test for universal filtered colimits. [ours] Let κ be infinite, let C be essentially small with pullbacks and all colimits indexed by categories with at most κ arrows, and put

$$\lambda = \kappa^+, \qquad \mathcal{M} = \mathrm{Ind}'_\kappa(C).$$

Then ordinary filtered colimits in $\mathcal{M}$ are universal if and only if filtered colimits in C indexed by categories with at most κ arrows are universal in C. Here universality in C means stability under every base change that is a morphism of C. Thus the additional hypothesis is existence of pullbacks in C; no terminal object or colimits of the larger bound π are needed. The marker identifies the present formulation and proof, without a priority claim.

We first recall the presheaf facts that control the proof. The category $\mathcal{M}$ consists of the presheaves on C that carry colimits with at most κ arrows in C to limits of sets. This description follows from the canonical category-of-elements presentation: the preservation condition makes that category λ-filtered, and conversely a λ-filtered colimit of representables has the preservation condition. Limits of such presheaves, and λ-filtered colimits of them, are computed pointwise. Indeed, limits commute with limits, and λ-filtered set colimits commute with limits having at most κ arrows. Consequently λ-filtered colimits in $\mathcal{M}$ commute with finite limits. The embedding $j : C \to \mathcal{M}$ preserves pullbacks,

by Yoneda and the pointwise description of limits. It also preserves the prescribed colimits: for any such colimit $c = \operatorname{colim}_i c_i$ in C and any $F \in \mathcal{M}$,

$$\operatorname{Hom}_{\mathcal{M}}(j(c), F) = F(c) = \lim_i F(c_i) = \lim_i \operatorname{Hom}_{\mathcal{M}}(j(c_i), F).$$

We need a simultaneous diagram approximation. If J has at most κ arrows, every J-diagram in $\mathcal{M}$ is a λ-filtered colimit of C-valued J-diagrams. Here is a direct verification of this instance of the diagram construction used earlier. Let E be the full subcategory of $\mathcal{M}^J$ consisting of the C-valued diagrams, up to isomorphism. It is essentially small and closed under colimits with at most κ arrows, since those colimits are computed pointwise and preserved by j. For a diagram D, the category E/D is therefore λ-filtered: take the colimit of any diagram of at most κ arrows in that slice. The empty diagram is handled by its initial object.

To see that the canonical diagram $E/D \to \mathcal{M}^J$ has colimit D, use the free diagrams

$$L_a(c)(b) = \coprod_{J(a,b)} c \qquad (a, b \in J,\ c \in C).$$

They belong to E, since every indexing set $J(a,b)$ has at most κ elements, and L_a is left adjoint to evaluation at a. A cocone from E/D to a diagram G therefore assigns compatible maps $c \to G(a)$ to all maps $c \to D(a)$ from C. The canonical presentation of $D(a)$ gives a unique map $t_a : D(a) \to G(a)$. For an arrow $a \to b$ in J, the induced maps $L_b(c) \to L_a(c)$ show that the t_a satisfy naturality. Finally, for any $A \to D$ in E/D, testing with all maps $L_a(c) \to A$ shows that its given cocone map is $A \to D \xrightarrow{t} G$. Those tests suffice because the maps from C to every $A(a)$ are jointly epimorphic. This proves the universal property and hence the simultaneous approximation. A small skeleton of E/D supplies a small filtered index.

Assume now the bounded universality hypothesis in C. First consider a filtered category I with at most κ arrows, a diagram $D : I \to \mathcal{M}$ with a cocone to Z, and a map $T \to Z$. We will prove the more flexible comparison

$$(*) \qquad \operatorname{colim}_{i \in I}(T \times_Z D_i) \longrightarrow T \times_Z \operatorname{colim}_{i \in I} D_i$$

is an isomorphism. Adjoin to I the cocone vertex z, all arrows $i \to z$, and one further vertex t with an arrow $t \to z$, imposing the cocone relations. The resulting shape still has at most κ arrows. Apply the simultaneous approximation to this entire shape. We obtain a λ-filtered diagram, indexed by p, of data

$$D_p : I \to C, \qquad D_p \longrightarrow Z_p, \qquad T_p \longrightarrow Z_p,$$

whose colimit is exactly the original data. In particular, one does not assume that Z_p is the colimit of D_p.

Put $Q_p = \operatorname{colim}_I D_p$ in C. Applying the assumed universality to the base change

$$T_p \times_{Z_p} Q_p \longrightarrow Q_p$$

gives, in C and hence in $\mathcal{M}$,

$$\operatorname{colim}_{i \in I}(T_p \times_{Z_p} D_{p,i}) \simeq T_p \times_{Z_p} Q_p.$$

All objects and pullbacks in this equation lie in C, and the preceding facts ensure that its colimit and pullbacks are preserved by j. Take the λ-filtered colimit over p. On the left, interchange the two colimits and commute the p-colimit with each pullback. On the right, commute it with the displayed pullback and use

$$\operatorname{colim}_p Q_p = \operatorname{colim}_p \operatorname{colim}_i D_{p,i} \simeq \operatorname{colim}_i D_i.$$

The resulting isomorphism is exactly (*). Setting $Z = \operatorname{colim}_I D_i$ proves universality for every bounded filtered diagram in $\mathcal{M}$.

It remains to remove the bound on I. Let I be any small filtered category, and let P be the poset of its filtered subcategories with at most κ arrows. Every set of at most κ arrows of I lies in such a subcategory. Start by closing the selected arrows under identities and finite composition. Choose in I a cocone for every finite diagram in the resulting subcategory, add its objects and arrows, and close under composition again. Repeat this operation countably many times. At each step there

are at most κ finite diagrams and at most κ new arrows; the final union still has at most κ arrows. Every finite diagram in the union occurs at some stage and receives a cone at the next, so the union is filtered. If the initial selection is empty, first choose one object of I.

The same construction applied to the union of at most κ members of P proves that P is λ-directed. Every object and arrow of I occurs in some member of P, so for any $D : I \to \mathcal{M}$ the cocone universal property gives

$$\operatorname{colim}_{K\in P} \operatorname{colim}_{i\in K} D_i \simeq \operatorname{colim}_{i\in I} D_i.$$

Apply the already proved comparison (*) to each restricted diagram $D|_K$, with the fixed cocone to Z and the fixed arrow $T \to Z$. Taking the λ-filtered colimit over P, and again commuting it with pullback, proves (*) for arbitrary filtered I. This is condition C).

Conversely, if condition C) holds in $\mathcal{M}$, apply it to a bounded filtered diagram in C and a base-change arrow in C. The embedding j preserves its colimit and pullbacks and reflects isomorphisms, so the corresponding comparison in C is an isomorphism. This proves the converse and the theorem.

With $\kappa = \pi_0$, this gives a precise affirmative form of footnote 50. Without the pullback hypothesis the phrase "the same condition on C" needs a relative formulation using pullbacks calculated in $\mathcal{M}$; it is not the intrinsic statement just proved. The argument addresses the proposed reduction of C), and makes no assertion about the separate implication B)⇒C).

Démonstration de 4.5.13.

Prouvons 1°. On a les implications tautologiques

$$\begin{array}{ccccc} \mathrm{b}'' & \Longrightarrow & \mathrm{b}' & \Longrightarrow & \mathrm{b} \\ \Downarrow & & \Downarrow & & \Downarrow \\ \mathrm{a}'' & \Longrightarrow & \mathrm{a}' & \Longrightarrow & \mathrm{a}\ , \end{array} \qquad (^{51})\ ,$$

et pour prouver l'équivalence de ces six conditions, il suffit de prouver

$$\mathrm{a} \implies \mathrm{b}''\ .$$

Si on a

$$x \simeq \varinjlim_{I} x_i\ , \qquad \operatorname{card} \mathrm{Fl}\, I \leqslant \pi\ ,$$

p. 40 [page 129]

soit I' l'ensemble des *sous-diagrammes* $J \subset I$ finis de I, ordonné par inclusion, donc I' est un ensemble ordonné filtrant, et du fait que C est stable par $\varinjlim$ finies, on trouve un foncteur

$$J \longmapsto x_J = \varinjlim_{i\in J} x_i \ :\ I' \longrightarrow C\ ,$$

et on aura

$$x \simeq \varinjlim_{J\in I'} x_J\ .$$

D'autre part, on a

$$\begin{aligned} \operatorname{card} I' &= \operatorname{card} \mathfrak{P}_f(\ \underbrace{\mathrm{Fl}(I)}_{\text{de card} \leqslant \pi}\ ) \\ &\leqslant \pi + \pi^2 + \ \cdots\ + \pi^n + \ \ldots \\ &\leqslant \pi\aleph_0 = \pi\ , \end{aligned}$$

q.e.d. Pour établir 1°, il reste à établir

$$\begin{array}{ccc} & P(\pi) & \\ \swarrow & & \searrow \\ \mathrm{c} & & \mathrm{d}\ , \end{array}$$

51. compte tenu que C est strictement génératrice dans $\mathcal{M}$, donc $x \simeq \varinjlim_{i\in C/x} x_i$.

et l'implication inverse c $\Longrightarrow P(\pi)$ quand $\pi \geqslant \pi_1$. Mais $P(\pi) \Longrightarrow$ c est une tautologie, et $P(\pi) \Longrightarrow$ d puisque $\mathcal{M}_\pi$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$. Reste à prouver que c $\Longrightarrow P(\pi)$ si $\pi \geqslant \pi_1$.

Commentary · Development (commentators') [ms. 128]

One step of colimits already gives all presentable objects

The useful question remaining after the preceding counterexample is whether the one-step colimit class Filt'^{π} is smaller than $\mathcal{M}_\pi$. In fact the two classes coincide for every $\pi \geq \pi_0$. The general presentation theorem is known; it is discussed as Remark 1.30 of Adámek–Rosický in the primary proof of Barton (2019). We give a direct proof in Grothendieck's setting. The marker below identifies our formulation and proof, rather than a claim that the theorem is new.

A bounded presentation theorem, with an explicit flattening proof. [ours] Suppose C is essentially small and closed under colimits with at most π_0 arrows, and $\mathcal{M} = \mathrm{Ind}'_{\pi_0}(C)$. Let D_π be the full subcategory of objects expressible as a colimit in $\mathcal{M}$ of a C-valued diagram with at most π arrows. Then

$$D_\pi = \mathcal{M}_\pi \qquad (\pi \geq \pi_0).$$

In particular D_π is closed under all colimits with at most π arrows, without the extra hypotheses A), B), or C) of Proposition 4.5.13.

The point requiring proof is that a map into a presentation can itself be recorded using only boundedly many of its data. Let $Y = \mathrm{colim}_{j\in J}\, d_j$, with $d_j \in C$, and let $P_0(J)$ be the poset of subcategories of J with at most π_0 arrows. This poset is π_0^+-directed: take unions of at most π_0 arrow sets and close under finite composition. For $K \in P_0(J)$, choose $d_K = \mathrm{colim}_K\, d_j$ in C. The embedding $C \to \mathcal{M}$ preserves these colimits. Their universal properties give compatible transition maps, and

$$Y = \mathrm{colim}_{K\in P_0(J)}\, d_K.$$

This equality follows by identifying cocones, since every object and arrow of J appears in some K. Every $c \in C$ is π_0^+-presentable in $\mathcal{M}$. Hence a map $c \to Y$ factors through some d_K. Two maps can be factored through the same d_K by passing to a common upper bound. Notice that K itself need not be filtered.

We now prove closure under coequalizers. Let $f, g : X \rightrightarrows Y$ be maps between objects of D_π, and choose presentations

$$X = \mathrm{colim}_{i\in I}\, c_i, \qquad Y = \mathrm{colim}_{j\in J}\, d_j, \qquad |\operatorname{Fl} I|, |\operatorname{Fl} J| \leq \pi.$$

Writing $s_i : c_i \to X$ for the first cocone, choose, for every i, one $K_i \in P_0(J)$ and two arrows

$$u_i, v_i : c_i \rightrightarrows d_{K_i}$$

whose composites into Y are fs_i and gs_i. Construct a graph of objects of C as follows. Retain the objects and arrows of the J-diagram. For each i, add a fresh vertex with value d_{K_i} and the complete colimit cone $d_j \to d_{K_i}$ for $j \in K_i$. Add a further fresh vertex with value c_i, and the two arrows u_i, v_i into that d_{K_i}. The free category on this graph, equipped with the assigned composites in C, has at most π arrows. Indeed, there are at most π choices of i, each adds at most π_0 edges, and taking finite paths preserves the infinite bound π. One may also impose the original diagram relations; the bound is unchanged.

A cocone on the original J-diagram with target Z is a map $h : Y \to Z$. Its extension to every new vertex d_{K_i} is forced uniquely, because the displayed cone on K_i is a genuine colimit cone in C and in $\mathcal{M}$. Its extension to the new copy of c_i exists precisely when $hfs_i = hgs_i$, and is then unique. These equalities for all i are equivalent to $hf = hg$, since the presentation maps s_i are jointly epimorphic. Thus cocones on the augmented diagram are exactly maps out of $\mathrm{coeq}(f, g)$. This proves that this coequalizer belongs to D_π. No compatibility between the choices of the K_i is needed: only equations on the jointly epimorphic presentation maps are being imposed.

The class D_π is also closed under coproducts of at most π objects, by taking disjoint unions of their indexing categories. The standard expression of a colimit as a coequalizer of two coproducts now proves closure under every diagram with at most π arrows. The inclusion $D_\pi \subseteq \mathcal{M}_\pi$ follows from closure of presentable objects under these colimits.

For the converse, express an arbitrary X as a colimit of a small C-valued diagram. Its subcategories of at most π arrows give a π^+-filtered presentation of X by objects of D_π, exactly as in the

preceding block. If $X \in \mathcal{M}_\pi$, its identity factors through one term, so X is a retract of an object $Y \in D_\pi$. A retract $X \xrightarrow{i} Y \xrightarrow{r} X$, $ri = 1$, is the coequalizer of 1_Y and ir. Closure under coequalizers gives $X \in D_\pi$, completing the proof.

This supplies the positive answer sought on pages 127–128 and 138. Iterated closure and one-step closure agree here; the bounded cofinal class and the pointwise presheaf bound can still be smaller. The three notions differ because only the first permits the additional relations introduced by the flattening construction.

Supposons donc qu'on ait une famille épimorphique stricte [page 130]

$$x_\alpha \longrightarrow x \qquad (\alpha \in A,\ \operatorname{card} A \leqslant \pi)\ ,$$

cela signifie donc que x est limite inductive d'un système inductif indexé par la catégorie B ayant comme ensemble d'objets $A \amalg (A \times A)$, les flèches non identiques étant représentées par les flèches canoniques

$$\begin{array}{ccc} & x_\alpha \times_x x_\beta & \\ {\scriptstyle p_{\alpha,\beta}}\swarrow & & \searrow{\scriptstyle q_{\alpha,\beta}} \\ x_\alpha & & x_\beta\ . \end{array}$$

(**N.B.** B n'est par une catégorie ordonnée, car pour l'objet (α, α), représenté par $x_\alpha \times_x x_\alpha$, il y a *deux* flèches dans l'objet α, représenté par x_α. Mais on a évidemment $\operatorname{card} \mathrm{Fl}(B) \leqslant \pi$.) Si on savait que C est stable par produits binaires et par passage à des sous-objets (ici les $x_\alpha \times_x x_\beta \ \subset\ x_\alpha \times x_\beta$), on aurait prouvé la condition a). À défaut, utilisons encore le fait que C est génératrice par épimorphismes (même stricts) et choisissons pour tout couple (α, β) un ensemble épimorphique de flèches :

$$\underbrace{x_{\alpha,\beta,\gamma}}_{\in \mathrm{Ob}\, C_0} \xrightarrow{u_{\alpha,\beta,\gamma}} x_\alpha \times_x x_\beta\ ,$$

où C_0 est une sous-catégorie réduite exhaustive de C. La flèche $u_{\alpha,\beta,\gamma}$ est connue quand on connaît les composés p. 41 [page 131]

$$\begin{array}{ccc} & & x_\alpha \\ & {\scriptstyle v_{\alpha,\beta,\gamma}}\nearrow & \\ x_{\alpha,\beta,\gamma} & & \\ & {\scriptstyle w_{\alpha,\beta,\gamma}}\searrow & \\ & & x_\beta\ , \end{array}$$

donc pour $x_{\alpha,\beta,\gamma} \in \mathrm{Ob}\, C_0$ fixé, les choix possibles pour $u_{\alpha,\beta,\gamma}$ sont de cardinal majoré par $\pi_1\pi_1 = \pi_1$, de plus on a $\operatorname{card} \mathrm{Ob}\, C_0 \leqslant \pi_1$, donc le nombre total des flèches $v_{\alpha,\beta,\gamma}$, $w_{\alpha,\beta,\gamma}$ (pour α, β fixés) est majoré par $\pi_1 \cdot \pi_1 = \pi_1$. Donc le nombre total des flèches $u_{\alpha,\beta,\gamma}$, pour α, β, γ variables, est majoré par $\pi \cdot \pi_1 = \pi$ (si $\pi \geqslant \pi_1$). Donc x est représenté par une catégorie I ayant comme objets l'ensemble somme de A et de l'ensemble des indices triples α, β, γ, et pour chaque tel indice, exactement deux flèches $v_{\alpha,\beta,\gamma}$, $w_{\alpha,\beta,\gamma}$ non identiques de source cet objet, et allant respectivement dans x_α, x_β. On a donc $\operatorname{card} \mathrm{Fl}\, I \leqslant \pi$, et on a un foncteur $I \longrightarrow C$, $\alpha \longmapsto x_\alpha$, $(\alpha, \beta, \gamma) \longmapsto x_{\alpha,\beta,\gamma}$, tel que $x = \varinjlim_{i \in I} x_i$. Cela achève la démonstration de 1°).

Prouvons 2°. La première inclusion (4.5.13.1) est tautologique, la deuxième ne fait qu'exprimer $P(\pi) \Longrightarrow$ d. Le fait que $\pi^{\pi_0} = \pi$ implique l'égalité des membres extrêmes est un rappel de 4.5.6. Reste à prouver que Filt'^{π} est stable dans $\mathcal{M}$ par sommes de cardinal $\leqslant \pi$. Mais si $(x_\alpha)_{\alpha \in A}$ est une famille d'objets de Filt'^{π}, avec $\operatorname{card} A \leqslant \pi$, et si $x = \coprod_{\alpha \in A} x_\alpha$, prenant pour tout x_α un foncteur $\varphi_\alpha : I_\alpha \longrightarrow C$, avec $\operatorname{card} \mathrm{Fl}\, I_\alpha \leqslant \pi$, tel que x_α soit la $\varinjlim$ dans $\mathcal{M}$ de ce foncteur, on trouve que x est $\varinjlim$ du foncteur $\varphi : I \longrightarrow C$ défini par les φ_α, où $I = \coprod_\alpha I_\alpha$ (somme dans Cat). Il est évident que $\operatorname{card} \mathrm{Fl}(I) \leqslant \pi \cdot \pi = \pi$, ce qui achève de prouver 2°. [page 132]

Commentary · Exposition [ms. 131]

Strict epimorphic presentations and the number of relations

Grothendieck's counting argument on pages 130–131 gives a useful concrete form of the one-step presentation theorem. It should be read with the hypothesis $x_\alpha \in C$ in condition c); this is used in every hom-set estimate, although it is absent from the printed statement. Without it the identity of an arbitrary X would satisfy c), making the proposed characterization vacuous.

Suppose $(c_\alpha \to X)_{\alpha\in A}$ is a strict epimorphic family, $|A| \le \pi$, with all $c_\alpha \in C$. Because $\mathcal{M}$ has pullbacks, strictness means that X is the colimit of the family together with all intersections $c_\alpha \times_X c_\beta$ and their two projections. An intersection need not lie in C. To replace it, use all maps $c \to c_\alpha \times_X c_\beta$ with $c \in C_0$. Such a map is determined by its two composites $c \to c_\alpha, c \to c_\beta$. For $\pi \ge \pi_1$, there are at most π_1 choices for each fixed pair (α, β), and at most $\pi^2\pi_1 = \pi$ choices altogether.

Form a category with one vertex for each c_α and one vertex for each selected c, with two arrows from the latter vertex to its two targets. Its colimit is X. To verify this, a cocone gives maps $c_\alpha \to Z$ agreeing after every selected map into an intersection. The family of selected maps is jointly epimorphic on that intersection, so the two maps from the intersection to Z agree. Strictness of the original family then gives one and only one map $X \to Z$. This proves condition a) directly and justifies the arrow count. The two projections for $\alpha = \beta$ must both be retained; the indexing category is not generally a poset.

Conversely, the legs of any colimit diagram form a strict epimorphic family: a family compatible with all equalities in the common target is in particular compatible with every arrow of the diagram, and therefore descends uniquely by the colimit property. Thus, for $\pi \ge \pi_1$, condition c), with its missing domain requirement restored, characterizes $D_\pi = \mathcal{M}_\pi$.

The presentation theorem also sharpens the counts left unfinished around (4.5.9.1). Throughout this count assume $\pi' \ge \pi \ge \pi_1$. When $\pi \ge \pi_1$, there are at most 2^π isomorphism classes of diagrams of at most π arrows with values in C_0, and hence at most 2^π objects in a skeleton of $\mathcal{M}_\pi$. If $A \in \mathcal{M}_\pi$ and $X \in \mathcal{M}_{\pi'}$, then a one-step presentation of A gives

$$|\mathrm{Hom}(A, X)| \le \prod_{i\in \mathrm{Ob}\, I} |\mathrm{Hom}(c_i, X)| \le \big((\pi')^{\pi_0}\big)^{\pi} = (\pi')^{\pi}.$$

Taking $\pi' = \pi$ in the hom estimate also bounds the arrows in a skeleton of $\mathcal{M}_\pi$ by 2^π. An arrow of the slice is determined by such an arrow $A \to B$ and a map $B \to X$. Consequently a skeleton of $\mathcal{M}_\pi/X$ has at most $(\pi')^\pi$ arrows. The sharper bound is therefore available even for the canonical slice, once the bounded presentation theorem has been established.

Prouvons 3°. On a les implications tautologiques $1 \Longrightarrow 1'$, et $1' \Longrightarrow 1$, puisque Filt'^{π} est stable par sommes de cardinal $\leqslant \pi$. Donc $1 \Longleftrightarrow 1'$, et implique que pour tout x dans $\mathcal{M}$, $I = \mathrm{Filt}'^{\pi}/x$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$, donc est grand devant π. Comme $x \simeq \varinjlim_{i\in I} x_i$, [page 133]
cela prouve que $1 \Longrightarrow 2$. L'implication $2 \Longrightarrow 3$ est standard, et résulte de $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_\pi$, je vais expliciter dans un

Lemme 4.5.14. *Soient $\mathcal{M}$ une catégorie stable par petites $\varinjlim$, π un cardinal infini, $\mathcal{M}_0$ une sous-catégorie strictement pleine de $\mathcal{M}$. Considérons les conditions*

a) $\mathcal{M}_0$ est une sous-catégorie strictement génératrice, et stable dans $\mathcal{M}$ par $\varinjlim$ de cardinal $\leqslant \pi$.

b) Pour tout objet de $\mathcal{M}$, on a un isomorphisme

$$x \simeq \varinjlim_{i\in I} x_i\ ,$$

les x_i dans $\mathcal{M}_0$, I grande devant π.

b′) Comme b), avec I catégorie ordonnée. p. 42

c) $\mathcal{M}_\pi \subset \mathcal{M}_0$ (où $\mathcal{M}_\pi$ est la sous-catégorie strictement pleine de $\mathcal{M}$ formée des objets π-accessibles).

On a donc les implications

$$a \implies b \iff b' \implies c\,,$$

et si on suppose $\mathcal{M}_0 \subset \mathcal{M}_\pi$, et $\mathcal{M}_\pi$ sous-catégorie strictement génératrice de $\mathcal{M}$, alors les quatre conditions a, b, b′, c sont équivalentes, et équivalent à $\mathcal{M}_0 = \mathcal{M}_\pi$ ([52]).

Enfin (revenant à la démonstration de 4.5.13, 3°), l'implication 3) $\Longrightarrow$ 1) provient du fait [page 134] que $\mathcal{M}_\pi$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$.

Reste à prouver que ces conditions, i.e. la stabilité de Filt'^{π} par conoyaux de double-flèches, est satisfaite dans les cas A) B) C), le cas A) étant d'ailleurs déjà connu. Le cas B) résulte immédiatement de la transitivité des familles épimorphiques strictes universelles, et c'est d'ailleurs aussi contenu explicitement (stabilité de Filt'^{π} par $\varinjlim$ de cardinal $\leqslant \pi$) dans SGA 4 I 9.13 (sinon dans l'énoncé, du moins c'est signalé dans la démonstration). En rédigeant SGA 4 I 9, je savais donc qu'on a $\mathcal{M}_\pi \subset \mathrm{Filt}'^{\pi}$ pour tout π, mais l'inclusion, plus évidente pourtant dans le cas d'espèce, $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_\pi$ (quand on suppose les objets de C π_1-accessibles) m'avait apparemment échappé ?

Commentary · Development (commentators') [ms. 134]

The retract missing from the abstract lemma

Grothendieck isolates Lemma 4.5.14 to make the passage from presentations to presentability reusable. Its essential mechanism is correct: presentability factors the identity through one stage. What this produces is a retract, and a strictly full subcategory need not contain all retracts of its objects.

A counterexample to b)⇒c) in Lemma 4.5.14. [ours] Fix an infinite cardinal π, take $\mathcal{M} = \mathrm{Ens}$, and let $\mathcal{M}_0$ be the full subcategory of sets of cardinality at most π except the singleton sets. Every object of $\mathcal{M}_0$ is π-accessible, and $\mathcal{M}_0$ is essentially small and strictly generating: its two-element sets already map jointly surjectively to every nonempty set. Also $\mathcal{M}_\pi$ is strictly generating, so the additional hypotheses in the last sentence of the printed lemma are satisfied.

For a set X with at least two elements, use the poset of its subsets A with $2 \leq |A| \leq \pi$. This is π^+-directed, because a union of at most π such subsets still has at most π elements, and its colimit is X. The empty set has its constant presentation. For a singleton, index a diagram by the ordinal π^+, put the two-element set $\{0,1\}$ at every stage, and use the constant map with value 0 for every strict transition. Identities remain identities, and composition is respected because the constant map is idempotent. The ordinal is π^+-directed, and the colimit of this diagram is a singleton. Thus b′), and hence b), hold for every X. Condition c) fails, since a singleton is π-accessible but is not in $\mathcal{M}_0$.

The corrected implication is

$$\text{b} \quad \Longrightarrow \quad \mathcal{M}_\pi \subseteq \{\text{retracts of objects of } \mathcal{M}_0\}.$$

Its proof is exactly the identity-factorization argument. Adding closure of $\mathcal{M}_0$ under retracts restores b)⇒c), and restores the final equivalence when the other hypotheses of the lemma hold. In the applications, essential smallness of the relevant slices has already been established; an abstract formulation should retain an appropriate small-presentation hypothesis when using $\mathcal{M}_0/X$ as an indexing category.

Under the small-presentation hypothesis just specified, the implication a)⇒c), which is the one used in Proposition 4.5.17, survives. Closure under colimits of size at most π includes coequalizers, hence splitting of idempotents. Starting from the canonical dense presentation, the same closure makes $\mathcal{M}_0/X$ π^+-filtered; the resulting retract therefore belongs to $\mathcal{M}_0$. Likewise our proof that $D_\pi = \mathcal{M}_\pi$ established coequalizer closure before invoking identity factorization. The repair does not weaken the final canonical filtration theorem.

Reste à traiter le cas C). (J'ai l'impression qu'il est un peu plus général que le cas B), i.e. que la condition B) sur $\mathcal{M}$ implique C), mais non inversement. Ainsi, la condition C) est vérifiée dès que $\mathcal{M}$ correspond à une espèce de structure algébrique définie en termes de $\varprojlim$ [page 135] *finies*, i.e. quand $\mathcal{M}$ est de la forme $\mathrm{Ind}(C)$, C stable par $\varinjlim$ *finies*, alors que je doute que

52. cf. démonstration de proposition 4.5.6, 4 $\Longrightarrow$ 5, page 117.

la condition B) soit toujours satisfaite pour ces catégories. Par exemple dans la catégorie Cat (qui est un paratopos de cette espèce), les $\varinjlim$ filtrantes sont exactes à gauche, mais je ne crois pas que les familles épimorphiques strictes soient universelles. Prenons p.ex. deux homomorphismes de groupes $G_0 \xrightarrow{u_0} G$, $G_1 \xrightarrow{u_1} G$ tels que $G_0 * G_1 \longrightarrow G$ soit surjectif, alors cette famille à deux éléments est épimorphique stricte dans Gr et dans Cat ([53]), mais n'est pas forcément épimorphique stricte universelle, même si p.ex. $G_0 = G_1 = H$, $G = H \times H$, et u_0, u_1 sont des injections $H \rightrightarrows H \times H$, données par $u_0(h) = (h, 1)$, et $u_1(h) = (1, h)$. Si je prends l'application diagonale $H \longrightarrow H \times H$, les images inverses de u_0, u_1 sont le même objet de $\mathcal{M}/H$, savoir $e \longrightarrow H$, et cette famille n'est épimorphique stricte que si H est le groupe unité.)

Le cas C) va résulter du résultat plus précis :

Corollaire 4.5.15. *Sous les conditions générales de 4.5.13, supposons que dans $\mathcal{M}$ les* $\varinjlim$ filtrantes *commutent au changement de base (p.ex. les* $\varinjlim$ *filtrantes sont exactes). Alors pour tout $\pi \geqslant \pi_1$,* Filt'^{π} *est formée des $x \in \mathrm{Ob}\,\mathcal{M}$ satisfaisant la condition suivante.* [page 136]

Commentary · Examples [ms. 135]

A free product repairs the group example

Grothendieck wants to show that universality of filtered colimits is compatible with failure of universality for strict epimorphic families. The intended distinction is sound, but the two axes of $H \times H$ do not give the promised example. For nontrivial H, their common intersection is the trivial group. Maps from the two copies of H to $H * H$ agree on that intersection, but do not extend to $H \times H$: the images of the two factors would have to commute. The normal form in a free product shows that nonidentity elements in the two factors do not commute. Thus the axes are not a strict epimorphic family, contrary to the assertion retained in footnote 53.

A nearby example proves exactly what is needed. Put

$$G = \langle a, b \mid a^2 = b^2 = 1 \rangle = C_2 * C_2, \qquad A = \langle a \rangle, \quad B = \langle b \rangle.$$

The inclusions $A \to G$ and $B \to G$ form a strict epimorphic family in groups. Any compatible pair of maps out of A and B extends uniquely to the free product; their intersection is trivial, so compatibility imposes only agreement on the unit. The element ab has infinite order, since every nonzero power has a nonempty reduced word. Hence $K = \langle ab \rangle$ is infinite cyclic, and reduced-word normal form gives

$$K \cap A = 1 = K \cap B.$$

Pulling the family back along $K \hookrightarrow G$ therefore gives two copies of $1 \to K$. This family is not even jointly epimorphic: the trivial homomorphism $K \to C_2$ and the homomorphism sending ab to the nonidentity element agree on both copies of 1.

The same construction works in Cat by viewing groups as one-object categories. A compatible pair of functors $BA, BB \to \mathcal{D}$ must select the same object of $\mathcal{D}$, because their restrictions to the common terminal category agree. Their homomorphisms into that object's automorphism group extend uniquely to $A * B$. This proves strict epimorphy in Cat itself, with arbitrary target categories, rather than merely in its subcategory of groups. Pullback along $BK \to BG$ gives the same failure.

Finally, ordinary filtered colimits in Cat commute with finite limits. One direct verification uses the nerve. For every finite ordinal $[n]$, a functor $[n] \to \mathrm{colim}_i \mathcal{A}_i$ is specified by finitely many objects, arrows, and composition equalities, so it occurs at one stage of a filtered diagram; equality between two such functors is likewise witnessed at a later stage. Thus the nerve preserves filtered colimits. It also preserves limits and reflects isomorphisms. In simplicial sets the required commutation is pointwise the familiar set-theoretic fact, so it holds in categories. This settles the direction relevant to Grothendieck's example: condition C) does not imply condition B). The converse suggestion B)⇒C) is a separate assertion, not established by this example.

c′) Il existe une famille de flèches $(u_\alpha)_{\alpha \in A}$, $u_\alpha : x_\alpha \longrightarrow x$, dans $\mathcal{M}$, qui est épimorphique stricte universelle *(i.e. couvrante pour la topologie canonique de $\mathcal{M}$), avec $x_\alpha \in \mathrm{Ob}\,C$ $\forall\ \alpha \in A$, et* $\mathrm{card}\,A \leqslant \pi$. p. 43

53. !, c'est *faux* en général, mais vrai dans le cas particulier plus bas.

Démonstration : il faut prouver que cette condition équivaut à la condition c) de 4.5.13 1°). Comme on a c′ ⟹ c trivialement, il reste à montrer que c ⟹ c′. Mais on a vu dans 4.5.13 1°) que c implique a″, i.e. qu'on a un isomorphisme

$$x = \varinjlim_{i\in I} x_i ,$$

les x_i dans C, et I ensemble *ordonné filtrant*, avec $\operatorname{card} I \leqslant \pi$. Il reste à voir que si x dans $\mathcal{M}$ est une limite inductive *filtrante* d'objets x_i, alors l'ensemble des flèches $x_i \longrightarrow x$ est épimorphique stricte *universelle.* Or cela est immédiat, car pour $x' \longrightarrow x$, on a $x' = \varinjlim_i x'_i$ (par hypothèse C), où $x'_i = x' \times_x x_i$, donc la famille $x'_i \longrightarrow x'$ est épimorphique stricte, q.e.d.

Prouvons maintenant que dans le cas C, la condition de 3°, 1 est satisfaite, i.e. que Filt'^{π} est stable par $\varinjlim$ de cardinal $\leqslant \pi$. Cela résulte aussitôt du [page 137]

Corollaire 4.5.16. (de 4.5.15). *Sous les conditions de 4.5.15 (i.e. la condition C) de 4.5.13, 3°), soit x un objet de $\mathcal{M}$, et supposons qu'il existe une famille* épimorphique universelle *$(x_\alpha \longrightarrow x)_{\alpha\in A}$ de flèches de $\mathcal{M}$, avec $x_\alpha \in \mathrm{Ob}\ \mathrm{Filt}'^{\pi}$ pour tout $\alpha \in A$, et $\operatorname{card} A \leqslant \pi$. Alors $x \in \mathrm{Ob}\ \mathrm{Filt}'^{\pi}$.*

En effet, l'hypothèse sur x_α équivaut, en vertu de 4.5.15, à l'existence d'une famille épimorphique stricte universelle de flèches $(x_{\alpha\beta} \longrightarrow x_\alpha)_{\beta\in B_\alpha}$, avec $\operatorname{card} B_\alpha \leqslant \pi$ et les $x_{\alpha\beta}$ dans C. Soit $B = \coprod_{\alpha\in A} B_\alpha$, on a alors $\operatorname{card} B \leqslant \pi^2 = \pi$, et d'autre part, la famille des flèches composées $x_{\alpha\beta} \longrightarrow x_\alpha \longrightarrow x$ indexée par B est épimorphique stricte universelle (par transitivité de ce type de familles), donc $x \in \mathrm{Ob}\ \mathrm{Filt}'^{\pi}$, q.e.d.

Avec tout ça, on n'a toujours pas donné de caractérisation de $\mathcal{M}_\pi$ lui-même, qui est meilleure que Filt^{π} et Filt'^{π} du point de vue catégorique, car seuls les $\mathcal{M}_\pi$ définissent une filtration cardinale, et de plus ils ont les propriétés de stabilité désirables dans ce contexte, [page 138] pour les $\varinjlim$ de cardinal $\leqslant \pi$. Le seul critère non tautologique que j'arrive à dégager dans le cas général (pour tout $\pi \geqslant \pi_0$, et sans hypothèse d'exactitude supplémentaire sur $\mathcal{M}$) est le suivant, beaucoup moins "explicite" ou "calculatoire" que les critères très concrets pour Filt^{π} et pour Filt'^{π} :

Commentary · Development (commentators') [ms. 137]

Universal epimorphisms can conceal too many relations

Grothendieck's condition C) gives a useful covering interpretation of a small presentation. If $X = \operatorname{colim}_{i\in I} X_i$ is filtered and such colimits commute with pullback, then every pullback of its cocone is again a colimit cocone, hence is strictly epimorphic. Combined with the finite-diagram replacement above, this proves Corollary 4.5.15: for $\pi \geq \pi_1$, the one-step colimit class consists exactly of objects with a universal strict epimorphic family of at most π maps from C.

Corollary 4.5.16 replaces "strict epimorphic" by "epimorphic" for the outer family, although its proof still uses strict descent. The weaker hypothesis does not suffice. The following example isolates the missing information: a surjection can cover every element while supplying none of the relations.

A counterexample to Corollary 4.5.16 as printed. [ours] Let $\mathcal{R}$ be the category whose objects are pairs (S, R) with $R \subseteq S^{\mathbb{N}}$, and whose arrows are functions preserving this one countably-ary relation. We first verify the ambient hypotheses, so that the example does not rely on a category outside the scope of the proposition.

Limits have the usual underlying set-theoretic limits, with a tuple declared related precisely when every projection is related. A colimit has the underlying set-theoretic colimit, and its relation is the union of the images of the relations in the diagram. These descriptions follow directly by testing cones and cocones. All these colimits are universal. Indeed, for a colimit $(S, R) = \operatorname{colim}_i(S_i, R_i)$ and an arrow $(T, Q) \to (S, R)$, the underlying set of the pulled-back colimit is T, by universality of set colimits. If $q \in Q$, its image in R comes from some $r_i \in R_i$, by the definition of the colimit relation. Pairing the coordinates of q and r_i gives a related tuple in $(T, Q) \times_{(S,R)} (S_i, R_i)$ mapping to q. Thus its colimit relation is all of Q, proving the assertion, including condition C).

Let C be a skeleton of objects with countable underlying set and countable relation. It is closed under countable colimits by the preceding formula. Its objects are $\aleph_1$-presentable. To lift a map

from such an object into an $\aleph_1$-filtered colimit, lift its countably many elements, choose witnesses for its countably many related tuples, and then witness the resulting countably many coordinate equalities at one common stage. This produces a relation-preserving lift; the same common-stage argument proves eventual equality of two lifts. Every object is an $\aleph_1$-filtered union of its countable partial substructures: take countable sets of elements and countable sets of related tuples, including the countably many coordinates of the chosen tuples. These choices form a countably directed poset. Therefore $\mathcal{R} \simeq \mathrm{Ind}'_{\aleph_0}(C)$, with $\pi_0 = \aleph_0$. There are at most $2^{\aleph_0}$ arrows in a skeleton of C: code countable carriers by subsets of $\mathbb{N}$, countable relations by countable lists of sequences, and maps by functions between countable sets.

Epimorphisms in $\mathcal{R}$ are exactly the maps surjective on underlying sets. Surjectivity suffices because the forgetful functor is faithful. If a map misses an element, two functions to the two-element set equipped with its full relation can distinguish that element while agreeing on the image; both are morphisms. Such epimorphisms are universal, since pullbacks are set-theoretic on carriers.

Choose $\pi = \beth_\omega$ and a set S of cardinality π. The arrow

$$q : (S, \varnothing) \longrightarrow (S, S^{\mathbb{N}}), \qquad q = \mathrm{id}_S,$$

is universally epimorphic. Its source is π^+-presentable: its hom-functor is simply $\mathrm{Hom}_{\mathrm{Ens}}(S, U(-))$, where U preserves colimits. Its target is not π^+-presentable. Indeed, $|S^{\mathbb{N}}| > \pi$. To see this directly, partition any purported list of at most π sequences into an increasing union of sublists L_n of cardinality less than π, and choose the nth coordinate outside the coordinates appearing there. The resulting sequence differs from every listed sequence.

Now write $(S, S^{\mathbb{N}})$ as the colimit of (S, R_0) over all subsets $R_0 \subseteq S^{\mathbb{N}}$ with $|R_0| \leq \pi$. This index is π^+-directed, and the transition maps are identities on carriers. If the target were presentable, its identity would factor through some (S, R_0). The factor map would necessarily be the identity on S, which preserves the full relation only if $S^{\mathbb{N}} \subseteq R_0$, an impossibility. The source belongs to D_π already as a coproduct of π singleton structures with empty relation, whereas the target does not, since $D_\pi \subseteq \mathcal{M}_\pi$. The single arrow q therefore violates precisely the conclusion of Corollary 4.5.16, with $\pi \geq \pi_1$ and all its other hypotheses satisfied.

The same category even satisfies B). A family is strictly epimorphic precisely when it is jointly surjective on carriers and every relation tuple of its target is the image of a relation tuple in one member. For necessity, strictness implies joint epimorphy, and the preceding two-point test proves joint surjectivity. Factor the family through the structure on the same carrier with only the image relation. The factor maps are compatible with the original family, so strictness supplies a map back to that structure. Joint surjectivity forces its underlying function to be the identity, hence forces every target tuple to lie in the image relation. Conversely, compatible maps out of the family agree on each underlying pairwise intersection, since the intersection structure has the set-theoretic pullback as carrier. They therefore descend to a unique function on the target carrier; the tuple condition makes this function a morphism. Both conditions are preserved by pullback, by the coordinate-pairing argument above. Thus the counterexample is entirely about the omission of strictness, not a failure of either exactness condition.

The positive statement is restored by requiring the outer family to be universally strict epimorphic. Choose the universal strict covers of its members furnished by Corollary 4.5.15. Their composites form a universal strict cover of the target by transitivity, with at most $\pi \cdot \pi = \pi$ terms, so 4.5.15 applies again. This is the covering-composition principle for the canonical topology (Artin et al., 1972, Exposé II, 2.5–2.6). We found no published treatment of this particular counterexample to the manuscript assertion; the proof is supplied here without a claim of priority.

Proposition 4.5.17. *Soit π un cardinal $\geqslant \pi_0$. Alors $\mathcal{M}_\pi$ est égal à la plus petite sous-catégorie strictement pleine de $\mathcal{M}$, contenant C, et stable par $\varinjlim$ de cardinal $\leqslant \pi$.* (Il est important de noter qu'il *ne suffit pas* de dire : stable par $\varinjlim_I$, avec I *grande devant* π_0, et $\operatorname{card} I \leqslant \pi$. On trouve alors Filt^π, qui risque d'être une catégorie strictement plus petite que $\mathcal{M}_\pi$. Ce n'est pas non plus la catégorie des $\varinjlim_I x_i$, avec $x_i \in C\ \forall\ i \in \mathrm{Ob}\, I$, et $\operatorname{card} \mathrm{Fl}\, I \leqslant \pi$ – puisque cette catégorie-là est Filt'^π.)

Démonstration. Soit $\mathcal{M}'$ la catégorie de l'énoncé, on a donc $\mathcal{M}' \subset \mathcal{M}_\pi$, puisque $\mathcal{M}_\pi$

contient C et est stable par les $\varinjlim$ de cardinal $\leqslant \pi$. Inversement, le lemme 4.5.14, a $\Longrightarrow$ c.

Commentary · Present state [ms. 138]

The closure description and the later presentation theorem

Grothendieck ends this portion with a characterization that is intrinsic to the category: start with its chosen small collection of π_0^+-presentable objects and close under colimits having at most π arrows. Proposition 4.5.17 is correct. The generating collection lies in $\mathcal{M}_\pi$, and that class is closed under the prescribed colimits. Conversely, the canonical filtered presentation and the splitting of its resulting retract give the reverse inclusion. Only a)⇒c) of the corrected Lemma 4.5.14 is needed.

The additional warning that a single colimit of this size cannot suffice should not be retained as a present-day conclusion. Our explicit flattening proof shows that such one-step colimits already form $\mathcal{M}_\pi$. The general theorem is the assertion attributed to Adámek–Rosický, Remark 1.30, in Barton (2019); Barton's authored proof removes the retract using good diagrams and the fat small object argument. That proof also records why replacing arbitrary small colimits by colimits that are π_0^+-filtered is a stronger demand. The arithmetic obstruction exposed by sets remains real for the latter demand.

There are therefore two distinct outcomes to the exploratory discussion. The intrinsic filtration exists at every rank $\pi \geq \pi_1$, with the stated quantitative bound, and its one-step colimit description needs no extra exactness condition. The full canonical presheaf presentation can still have too many maps, and a small presentation need not be cofinal in it. The unrepaired implication in Lemma 4.5.14 and the group example do not invalidate these positive results; their corrections explain which arguments actually prove them.

Overview · XVIII-a

The opening of Chapter XVIII asks what a category of coefficients must retain if the formal operations of sheaf theory are to survive outside a topos. Grothendieck begins with colimits and a small dense collection of test objects. The proposed tensor then forces him to ask whether continuity conditions define a reflective category, and that question leads to accessibility. The long investigation of cardinal filtrations is therefore part of the construction of coefficients. His letter to Thomason of 2 April 1991 explicitly describes this chapter as a return to the accessibility ideas of SGA 4, Exposé I, Section 9 (Grothendieck, 1991a; Artin et al., 1972).

These pages run from manuscript page 50 to page 138, corresponding to printed pages 1–43 of the edition. They contain Sections 4.1–4.5: pseudo-topoi and the tensor problem, its small-presheaf formulation, the proposed accessibility criterion, the restricted ind-completion, and the intrinsic cardinal filtration. The text often records an unsuccessful proof and then retains the objection which caused its abandonment. A faithful reading has to preserve this exploratory structure. An assertion subsequently withdrawn is not evidence that the intended theorem is false; conversely, the truth of the final theorem does not validate an intermediate equivalence.

We work in a fixed Grothendieck universe and use smallness relative to that universe. One translation governs the entire discussion. If π is infinite, a category called *grande devant* π is filtered with respect to diagrams having at most π arrows. In the modern regular-cardinal convention it is π^+-filtered. Grothendieck's π-accessible objects are consequently π^+-presentable objects. His cocomplete categories with accessible small generators are locally presentable categories; the broader modern notion of an accessible category does not include cocompleteness. The cardinal attached to an object and one uniform cardinal for a chosen small generating family must also be distinguished.

A pseudo-topos has enough density for the dual special adjoint functor theorem. Colimit-preserving functors out of it have right adjoints, and a contravariant set-valued functor taking colimits to limits is representable. These facts make the opening construction plausible. They also expose a distinction in the motivating terminology. If morphisms of pseudo-topoi are described by their inverse-image functors, then the actual bicategorical product has underlying category $\mathcal{M} \times \mathcal{N}$: a cocontinuous functor out of that category is determined by its restrictions to $(m, 0)$ and $(0, n)$. The proposed $\mathcal{M} \boxtimes \mathcal{N}$ represents functors cocontinuous in each variable separately. It is a tensor, with **Set** as unit, rather than this Cartesian product. For Grothendieck topoi the tensor nevertheless agrees with the product in the more restrictive category of topoi and geometric morphisms; Pitts's Theorem 2.3 proves the ordinary comparison (Pitts, 1985).

The tensor is first described as the category of bifunctors

$$\mathcal{M}^{\mathrm{op}} \times \mathcal{N}^{\mathrm{op}} \longrightarrow \mathbf{Set}$$

which take colimits to limits separately. Density embeds it in a presheaf category on a small product of test categories. This proves local smallness and gives a useful formula for its continuous extensions, but it does not by itself provide the reflector. Nor does the naive external product of two representable presheaves usually satisfy the continuity condition: the empty colimit already forces both representing objects to be terminal. The example $\mathbf{Ab} \boxtimes \mathbf{Ab} \simeq \mathbf{Ab}$ makes the failure concrete. Its external tensor is the ordinary tensor product over $\mathbb{Z}$, and it cannot be recovered from the Cartesian product formula suggested in the manuscript.

Accessibility supplies the missing reflector. Choose a common regular cardinal and small full subcategories of presentable objects closed under colimits below that cardinal. Separate continuity can now be imposed by orthogonality to a *set* of maps between small presheaves.

The commentary constructs the reflection by alternately adjoining extensions and identifying extensions which agree on their domains. Presentability controls the length of the construction. The resulting category is again locally presentable, and reflection of representables supplies its elementary tensors. This gives a complete existence proof in the setting that the chapter is trying to isolate. Kelly's treatment of categories with prescribed colimits supplies the ordinary categorical background (Kelly, 1982, Section 6.5). Lurie's tensor on presentable ∞-categories is a later comparison with the same universal pattern, not a substitute for the ordinary cardinal estimates here (Lurie, 2017, Section 4.8.1).

The structural assertion behind Theorem 4.3.6 survives the failure of its first numerical proof. Starting from a small dense family of presentable objects, close that family under suitably small colimits. Every slice of the resulting category over an object is filtered at the required rank, and its canonical colimit is that object. The ind-object Hom formula proves full faithfulness. Thus the category is a restricted ind-completion. This argument does not require the provisional filtration by sizes of categories of elements to have the properties claimed for it on pages 72–76. The latter proof uses an unestablished directed-hull bound and imports a covering estimate from SGA 4 without its universality hypothesis. The manuscript's own corrective footnotes are justified.

Section 4.4 gives the complementary construction. When C has colimits of diagrams with at most π arrows, its π^{+}-ind-completion is cocomplete and is the free cocomplete category which preserves those existing colimits. The proof passes through cofinality, simultaneous presentations of diagrams, bounded coproducts, and the expression of an arbitrary indexing category as a directed union of small subcategories. We supply the omitted comma-adjunction argument and separate the existence of individual ind-presentations from closure under filtered colimits. The unrestricted claim that restriction on all functor categories is fully faithful is false; the needed restriction to functors preserving the density presentations is fully faithful and repairs the universal-property proof. Henry's recent theorem gives an exact modern comparison for these diagram presentations, with the hypotheses on the diagram shape and on C stated explicitly (Henry, 2025a).

The difference between ordinary and more highly filtered ind-objects is essential. Let C consist of countable sets. Its $\aleph_1$-ind-completion is sets, but the ordinary ind-object obtained from finite subsets of $\mathbb{Z}$ has, at c, only the finite-image maps $c \to \mathbb{Z}$. Translation gives it a $\mathbb{Z}$-action which cannot occur at any nonempty equivariant representable stage. This answers negatively the specific cofinality question on manuscript page 94. It also explains why the restricted completion need not be closed under ordinary filtered colimits calculated in the presheaf category.

Section 4.5 measures an object in two ways. Write $\mathcal{M}_\pi$ for its intrinsic presentability layer, and Filt^π for the layer whose restricted nerve has at most π maps from each test object, once the chosen small category itself is bounded by π. In sets, with tests of size at most π_0, these conditions read respectively

$$|X| \le \pi, \qquad |X|^{\pi_0} \le \pi.$$

They need not coincide. The corrected comparison is

$$\mathrm{Filt}^\pi \subseteq \mathcal{M}_\pi \subseteq \mathrm{Filt}^{\pi^{\pi_0}}.$$

The fixed-point condition $\pi^{\pi_0} = \pi$ restores equality. No continuum hypothesis is needed for the comparison itself. The counterexample sketched in the manuscript by a supposedly smallest directed family of subsets is not valid; the commentary replaces it with a diagonal argument at a singular cardinal of countable cofinality.

There is a second distinction within the proposed primed filtration. An object may be the colimit of a diagram of at most π objects and arrows from C without admitting a cofinal diagram of that size in C/X. For C the countable sets and $|X| = \beth_\omega$, the coproduct of the singleton subsets gives the first presentation. A cofinal presentation would give at most $\beth_\omega$

countable subsets cofinal among all countable subsets of X, which the same diagonal argument excludes. Thus the two triples of conditions in Proposition 4.5.13 cannot be identified.

The positive outcome is stronger than the closing warning on page 138 suggests. The class of *one-step* colimits of C-diagrams with at most π arrows is already $\mathcal{M}_\pi$, for every $\pi \geq \pi_0$. The commentary proves closure under coequalizers by recording, for each generator in a presentation of the source, only the bounded portion of a target presentation through which its two images factor. This keeps the enlarged diagram within the original cardinal bound. Coproducts and splitting of idempotents finish the proof. The general presentation theorem is known; Barton's authored proof discusses its earlier attribution and the difficulty with the originally cited justification (Barton, 2019). Our argument is included as a direct repair in Grothendieck's setting, without a claim of priority. It also yields the sharper bounds on the number of objects and arrows which the chapter seeks.

Two later corrections prevent the descent arguments from obscuring that conclusion. Presentability factors an identity through a stage as a *retract*; Lemma 4.5.14 must retain closure under retracts before replacing this by membership in the chosen subcategory. And a universal epimorphism need not transmit a bound on the number of relations. A category of sets with one countably-ary relation gives a counterexample to Corollary 4.5.16 even when all colimits are universal. Requiring the outer family to be universally *strict* epimorphic restores the corollary. Both corrections leave the intrinsic filtration theorem intact.

Footnote 50 suggests testing universality of filtered colimits in the generating category. We prove a precise version: if C also has pullbacks, then ordinary filtered colimits in $\mathrm{Ind}'_{\pi_0}(C)$ are universal exactly when the filtered colimits in C with at most π_0 arrows are universal. The proof approximates the entire cocone and its base-change arrow together, and then expresses any filtered indexing category as a π_0^{+}-directed union of filtered subcategories with at most π_0 arrows. The additional pullback hypothesis makes the test intrinsic to C.

The remaining verification limits concern the disputed implication in Proposition 4.3.1 for arbitrary pseudo-topoi and the suggestion that universality of strict epimorphic families implies universality of ordinary filtered colimits. We do not describe these as literature-established open problems. The relevant older discussions of density, ind-objects, and the distinction between formal and realized colimits are cross-referenced where they are used.

XVIII-b · Chapter XVIII, part 2 of 5 · manuscript pages 127–228

p. 39

1) Filt'^{π} *est stable dans* $\mathcal{M}$ *par* $\varinjlim$ *de cardinal* $\leqslant \pi$.

1′) Filt'^{π} *est stable par conoyaux de double-flèches.*

2) Tout objet x *de* $\mathcal{M}$ *est de la forme* $\varinjlim_{I} x_i$, *où* x_i *dans* Filt'^{π}, I *grande devant* π.

3) La condition d) de 1°) implique $P(\pi)$ *(donc lui est équivalente), i.e. on a*

$$\mathcal{M}_\pi \;=\; \mathrm{Filt}'^{\pi}\,.$$

[page 127]

Ces conditions sont satisfaites dans les trois cas suivants :

A) $\pi^{\pi_0} = \pi$ *(pour mémoire, c'est contenu dans 2°).*

B) Les familles épimorphiques strictes dans $\mathcal{M}$ *sont épimorphiques strictes universelles.*

C) Les limites inductives filtrantes dans $\mathcal{M}$ *commutent au changement de base (ce qui est le cas notamment si les* $\varinjlim$ *filtrantes sont exactes à gauche)* ([50]).

Remarque. La filtration de $\mathcal{M}$ pour les Filt'^{π} n'est autre que celle envisagée dans SGA 4 I 9.13, où on fait de plus l'hypothèse B) sur $\mathcal{M}$, qui après-coup n'était plus tellement de mon goût. Toujours est-il que d'après (4.5.13.1), cette filtration se rapproche plus de la "bonne" filtration par les $\mathcal{M}_\pi$, que celle que j'avais eu encore naguère tendance à lui préférer, celle par les Filt^{π}. Elle a d'ailleurs sur cette dernière l'avantage, dans le cas envisagé B), d'être une filtration cardinale (ce qui n'est pas nécessairement le cas pour Filt^{π}, du moins s'il existe des cardinaux infinis $\pi \geqslant \pi_0$ avec $\pi^{\pi_0} \neq \pi$). Je soupçonne maintenant qu'en général (et s'il existe des cardinaux infinis $\pi > \pi_0$ tels que $\pi^{\pi_0} \neq \pi$), en dehors des conditions A) B) C), la filtration par les (Filt'^{π}) n'est *pas* une filtration cardinale. En tous cas, 4.5.6 et la présente proposition, 3°, montrent que si soit $(\mathrm{Filt}^{\pi})_{\pi\geqslant\pi_2}$, soit $(\mathrm{Filt}'^{\pi})_{\pi\geqslant\pi_2}$ est une filtration cardinale (π_2 étant un cardinal donné $\geqslant \pi_1$), alors elle coïncide avec la filtration par les $\mathcal{M}_\pi$. Donc apparemment, dans tous les cas où je sais construire une filtration cardinale, sur un paratopos du moins (i.e. sur une catégorie $\mathcal{M}$ stable par petites $\varinjlim$, et dont tous les objets sont accessibles – l'existence d'une filtration cardinale impliquant de plus celle d'une petite sous-catégorie strictement génératrice …), celle-ci n'est autre que celle par les $\mathcal{M}_\pi$ – chose dont je ne m'étais par aperçu en rédigeant SGA 4 I 9.

[page 128]

Démonstration de 4.5.13.

Prouvons 1°. On a les implications tautologiques

$$\begin{array}{ccccc} \mathrm{b}'' & \Longrightarrow & \mathrm{b}' & \Longrightarrow & \mathrm{b} \\ \Downarrow & & \Downarrow & & \Downarrow \\ \mathrm{a}'' & \Longrightarrow & \mathrm{a}' & \Longrightarrow & \mathrm{a}\,, \end{array} \qquad ([51])\,,$$

et pour prouver l'équivalence de ces six conditions, il suffit de prouver

$$\mathrm{a} \;\Longrightarrow\; \mathrm{b}''\,.$$

p. 40

Si on a

$$x \;\simeq\; \varinjlim_{I} x_i\,, \qquad \mathrm{card}\,\mathrm{Fl}\,I \;\leqslant\; \pi\,,$$

[page 129]

soit I' l'ensemble des *sous-diagrammes* $J \subset I$ finis de I, ordonné par inclusion, donc I' est un ensemble ordonné filtrant, et du fait que C est stable par $\varinjlim$ finies, on trouve un foncteur

$$J \longmapsto x_J \;=\; \varinjlim_{i\in J} x_i \;:\; I' \longrightarrow C\,,$$

50. Je suppose que cette condition revient à la même condition sur C, pour les $\varinjlim$ filtrantes de cardinal $\leqslant \pi$.

51. compte tenu que C est strictement génératrice dans $\mathcal{M}$, donc $x \simeq \varinjlim_{i\in C/x} x_i$.

et on aura

$$x \simeq \varinjlim_{J \in I'} x_J \ .$$

D'autre part, on a

$$\begin{aligned} \operatorname{card} I' &= \operatorname{card} \mathfrak{P}_f(\ \underbrace{\operatorname{Fl}(I)}_{\text{de card} \leqslant \pi}\ ) \\ &\leqslant \pi + \pi^2 + \ \cdots\ + \pi^n + \ \ldots \\ &\leqslant \pi \aleph_0 \ = \ \pi \ , \end{aligned}$$

q.e.d. Pour établir 1°, il reste à établir

$$\begin{array}{ccc} & P(\pi) & \\ \swarrow\!\!\swarrow & & \searrow\!\!\searrow \\ \mathrm{c} & & \mathrm{d} \ , \end{array}$$

et l'implication inverse $\mathrm{c} \Longrightarrow P(\pi)$ quand $\pi \geqslant \pi_1$. Mais $P(\pi) \Longrightarrow \mathrm{c}$ est une tautologie, et $P(\pi) \Longrightarrow \mathrm{d}$ puisque $\mathcal{M}_\pi$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$. Reste à prouver que $\mathrm{c} \Longrightarrow P(\pi)$ si $\pi \geqslant \pi_1$.

Commentary · Exposition [ms. 128]

The intrinsic size of an object

Grothendieck is trying to replace a convenient measure of the size of a presentation by a measure belonging to the object itself. This is the reason for the repeated comparison of Filt^π, Filt'^π and $\mathcal{M}_\pi$. The first two remember how an object has been assembled from a chosen small category C; the third asks which diagrams a represented functor can see. A change of presentation should not alter the last answer.

There is a shift of convention to make before using modern references. In these pages "grand devant π" means that every diagram having at most π arrows admits a cocone. Thus, with $\lambda = \pi^+$, this is λ-filteredness, and an object called π-accessible here is λ-presentable in the usual terminology. No regularity of π is being assumed. The successor π^+ is regular, and it is this regular cardinal which enters the standard interchange theorem for sets. We shall retain the manuscript's indices while making this translation whenever a modern formulation is needed.

The essential calculation is

$$\operatorname{Hom}\left(\varinjlim_{j\in J} X_j, \varinjlim_{i\in I} Y_i\right) = \varprojlim_{j\in J} \operatorname{Hom}\left(X_j, \varinjlim_{i\in I} Y_i\right).$$

If $|\operatorname{Fl} J| \leq \pi$, I is π^+-filtered and every X_j is π-accessible, the right side becomes $\varprojlim_j \varinjlim_i \operatorname{Hom}(X_j, Y_i)$ and then $\varinjlim_i \varprojlim_j \operatorname{Hom}(X_j, Y_i)$. The last interchange holds in sets: at most π representatives can be put at one stage, and at most π required equalities can be made true at a later stage. This proves closure of $\mathcal{M}_\pi$ under the indicated colimits. It also explains why relations, and not merely generators, enter a size bound.

The historical comparison with Artin et al. (1972, Exposé I, §9) concerns this same passage from bounded presentations to bounded represented functors. The manuscript's provisional claim that one of the presentation filtrations is automatically the intrinsic filtration must therefore be read with its hypotheses. The following pages repeatedly repair precisely that identification. The relevant modern recognition theorem is the characterization by a small strong generator of presentable objects, recorded as Theorem 1.20 in Adámek and Rosický (1994); the word "strong" carries mathematical content.

[page 130]

Supposons donc qu'on ait une famille épimorphique stricte

$$x_\alpha \longrightarrow x \qquad (\alpha \in A,\ \operatorname{card} A \leqslant \pi) \ ,$$

cela signifie donc que x est limite inductive d'un système inductif indexé par la catégorie B ayant comme ensemble d'objets $A \amalg (A \times A)$, les flèches non identiques étant représentées par les flèches canoniques

$$\begin{array}{ccc} & x_\alpha \times_x x_\beta & \\ {\scriptstyle p_{\alpha,\beta}} \swarrow & & \searrow {\scriptstyle q_{\alpha,\beta}} \\ x_\alpha & & x_\beta \ . \end{array}$$

Commentary · Exposition [ms. 129]

Finite pieces of a diagram

Grothendieck wants to make an arbitrary bounded colimit into an ordinary filtered colimit without enlarging its cardinal. His argument works if a finite subdiagram is a finite set of constraints. It would not work if it meant a finite subcategory closed under composition: one endomorphism can generate infinitely many arrows.

Here is a precise construction which also makes the counting transparent. For a finite set V of objects of I and a finite set E of arrows whose endpoints lie in V, put

$$X_{V,E} = \operatorname{coeq}\left(\coprod_{f \in E} X_{s(f)} \rightrightarrows \coprod_{v \in V} X_v \right).$$

The two maps use respectively the inclusion of the source summand and the given arrow followed by the inclusion of its target. These are finite colimits and therefore belong to C. Enlarging (V, E) induces a canonical map of coequalizers. The ordered set of these pairs is filtered, has cardinal at most π when $|\operatorname{Fl} I| \leq \pi$, and its colimit is $\varinjlim_I X_i$. Indeed, a compatible family of maps from all $X_{V,E}$ to an object Y is exactly a family of maps $X_i \to Y$ satisfying every arrow relation of I. This proves the asserted universal property, including diagrams with loops.

The calculation illustrates an advantage of the primed filtration. It allows arbitrary bounded presentations to be flattened into a single bounded filtered presentation when finite colimits in C are available. It does not replace ordinary filteredness by π_0^+-filteredness. The latter requires simultaneous solutions of much larger families of constraints and is the source of the cardinal exponent appearing later.

(**N.B.** B n'est par une catégorie ordonnée, car pour l'objet (α, α), représenté par $x_\alpha \times_x x_\alpha$, il y a *deux* flèches dans l'objet α, représenté par x_α. Mais on a évidemment $\operatorname{card} \operatorname{Fl}(B) \leqslant \pi$.) Si on savait que C est stable par produits binaires et par passage à des sous-objets (ici les $x_\alpha \times_x x_\beta \ \subset \ x_\alpha \times x_\beta$), on aurait prouvé la condition a). À défaut, utilisons encore le fait que C est génératrice par épimorphismes (même stricts) et choisissons pour tout couple (α, β) un ensemble épimorphique de flèches :

$$\underbrace{x_{\alpha,\beta,\gamma}}_{\in \operatorname{Ob} C_0} \xrightarrow{u_{\alpha,\beta,\gamma}} x_\alpha \times_x x_\beta \ ,$$

où C_0 est une sous-catégorie réduite exhaustive de C. La flèche $u_{\alpha,\beta,\gamma}$ est connue quand on connaît les composés p. 41 [page 131]

$$\begin{array}{ccc} & & x_\alpha \\ & {\scriptstyle v_{\alpha,\beta,\gamma}} \nearrow & \\ x_{\alpha,\beta,\gamma} & & \\ & {\scriptstyle w_{\alpha,\beta,\gamma}} \searrow & \\ & & x_\beta \ , \end{array}$$

donc pour $x_{\alpha,\beta,\gamma} \in \operatorname{Ob} C_0$ fixé, les choix possibles pour $u_{\alpha,\beta,\gamma}$ sont de cardinal majoré par $\pi_1 \pi_1 = \pi_1$, de plus on a $\operatorname{card} \operatorname{Ob} C_0 \leqslant \pi_1$, donc le nombre total des flèches $v_{\alpha,\beta,\gamma}$, $w_{\alpha,\beta,\gamma}$ (pour α, β fixés) est majoré par $\pi_1 \cdot \pi_1 = \pi_1$. Donc le nombre total des flèches $u_{\alpha,\beta,\gamma}$, pour α, β, γ

variables, est majoré par $\pi \cdot \pi_1 = \pi$ (si $\pi \geqslant \pi_1$). Donc x est représenté par une catégorie I ayant comme objets l'ensemble somme de A et de l'ensemble des indices triples α, β, γ, et pour chaque tel indice, exactement deux flèches $v_{\alpha,\beta,\gamma}$, $w_{\alpha,\beta,\gamma}$ non identiques de source cet objet, et allant respectivement dans x_α, x_β. On a donc $\operatorname{card} \mathrm{Fl}\, I \leqslant \pi$, et on a un foncteur $I \longrightarrow C$, $\alpha \longmapsto x_\alpha$, $(\alpha, \beta, \gamma) \longmapsto x_{\alpha,\beta,\gamma}$, tel que $x = \varinjlim_{i \in I} x_i$. Cela achève la démonstration de 1°).

Prouvons 2°. La première inclusion (4.5.13.1) est tautologique, la deuxième ne fait qu'ex- [page 132]
primer $P(\pi) \Longrightarrow \mathrm{d}$. Le fait que $\pi^{\pi_0} = \pi$ implique l'égalité des membres extrêmes est un rappel de 4.5.6. Reste à prouver que Filt'^{π} est stable dans $\mathcal{M}$ par sommes de cardinal $\leqslant \pi$. Mais si $(x_\alpha)_{\alpha \in A}$ est une famille d'objets de Filt'^{π}, avec $\operatorname{card} A \leqslant \pi$, et si $x = \coprod_{\alpha \in A} x_\alpha$, prenant pour tout x_α un foncteur $\varphi_\alpha : I_\alpha \longrightarrow C$, avec $\operatorname{card} \mathrm{Fl}\, I_\alpha \leqslant \pi$, tel que x_α soit la $\varinjlim$ dans $\mathcal{M}$ de ce foncteur, on trouve que x est $\varinjlim$ du foncteur $\varphi : I \longrightarrow C$ défini par les φ_α, où $I = \coprod_\alpha I_\alpha$ (somme dans Cat). Il est évident que $\operatorname{card} \mathrm{Fl}(I) \leqslant \pi \cdot \pi = \pi$, ce qui achève de prouver 2°.

Prouvons 3°. On a les implications tautologiques $1 \Longrightarrow 1'$, et $1' \Longrightarrow 1$, puisque Filt'^{π} est stable par sommes de cardinal $\leqslant \pi$. Donc $1 \Longleftrightarrow 1'$, et implique que pour tout x dans $\mathcal{M}$, $I = \mathrm{Filt}'^{\pi}/x$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$, donc est grand devant π. Comme $x \simeq \varinjlim_{i \in I} x_i$, [page 133]
cela prouve que $1 \Longrightarrow 2$. L'implication $2 \Longrightarrow 3$ est standard, et résulte de $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_\pi$, je vais expliciter dans un

Lemme 4.5.14. *Soient $\mathcal{M}$ une catégorie stable par petites $\varinjlim$, π un cardinal infini, $\mathcal{M}_0$ une sous-catégorie strictement pleine de $\mathcal{M}$. Considérons les conditions*

a) $\mathcal{M}_0$ est une sous-catégorie strictement génératrice, et stable dans $\mathcal{M}$ par $\varinjlim$ de cardinal $\leqslant \pi$.

b) Pour tout objet de $\mathcal{M}$, on a un isomorphisme

$$x \simeq \varinjlim_{i \in I} x_i \ ,$$

les x_i dans $\mathcal{M}_0$, I grande devant π.

b′) Comme b), avec I catégorie ordonnée. p. 42

c) $\mathcal{M}_\pi \subset \mathcal{M}_0$ (où $\mathcal{M}_\pi$ est la sous-catégorie strictement pleine de $\mathcal{M}$ formée des objets π-accessibles).

On a donc les implications

$$a \implies b \iff b' \implies c \ ,$$

et si on suppose $\mathcal{M}_0 \subset \mathcal{M}_\pi$, et $\mathcal{M}_\pi$ sous-catégorie strictement génératrice de $\mathcal{M}$, alors les quatre conditions a, b, b′, c sont équivalentes, et équivalent à $\mathcal{M}_0 = \mathcal{M}_\pi$ ([52]).

Enfin (revenant à la démonstration de 4.5.13, 3°), l'implication 3) $\Longrightarrow$ 1) provient du fait [page 134]
que $\mathcal{M}_\pi$ est stable par $\varinjlim$ de cardinal $\leqslant \pi$.

Commentary · Development (commentators') [ms. 133]

The retract which a filtered presentation supplies

Grothendieck is isolating the argument which should identify the small stages with the intrinsically accessible objects. The argument does identify them when the stages are closed under the stated colimits. The standalone lemma goes further than its proof permits: presentability gives a retract, and strict fullness does not put that retract back into the subcategory.

Corrected implication. Suppose every object of $\mathcal{M}$ is a π^+-filtered colimit of objects of $\mathcal{M}_0$. Then every object of $\mathcal{M}_\pi$ is a retract of an object of $\mathcal{M}_0$. Consequently the printed implication $b \Rightarrow c$ holds if $\mathcal{M}_0$ is closed under retracts.

To prove this, write $X = \varinjlim_i X_i$ with $X_i \in \mathcal{M}_0$. If X is π-accessible, its identity is represented by some $s : X \to X_i$. Writing $r : X_i \to X$ for the colimit map gives $rs = 1_X$. Nothing in this argument says that X itself belongs to an arbitrary strictly full subcategory. If $\mathcal{M}_0$ is closed under

52. cf. démonstration de proposition 4.5.6, 4 $\Longrightarrow$ 5, page 117.

the colimits in condition a, the missing conclusion does follow: r is a coequalizer of sr and 1_{X_i}, so $X \in \mathcal{M}_0$. This is why the later use of $a \Rightarrow c$ in Proposition 4.5.17 remains sound.

Counterexample to the unrestricted lemma. [ours] In Ens, let $\mathcal{M}_0$ contain exactly the sets of cardinal at most π other than singletons. This is a strictly full subcategory of $\mathcal{M}_\pi$. Every set with at least two elements is the π^+-filtered union of its subsets of cardinal at most π whose cardinal is not one: the union of at most π such subsets is another such subset, and each element belongs to a two-element subset. The empty set has its constant presentation.

For the singleton, index by the ordinal $\lambda = \pi^+$, put $X_\alpha = \{0, 1\}$, and give every strictly increasing transition the idempotent map e with $e(0) = e(1) = 0$. The identity transitions are identities, and $e^2 = e$ makes this a functor. Its colimit is a singleton, since every element becomes 0 at a later stage. The ordinal is π^+-filtered, but the singleton is absent from $\mathcal{M}_0$. Thus even the additional assumptions $\mathcal{M}_0 \subset \mathcal{M}_\pi$ and density of $\mathcal{M}_\pi$ do not repair the printed equivalence.

The retract principle is standard in the theory of presentable objects; the same argument appears in the higher categorical formulation of Lurie (2009, Lemma 5.4.2.4). We include the explicit counterexample to audit this particular formulation; it is not a claim of priority. Our literature comparison concerns the valid retract statement, not an alleged later proof of the erroneous implication.

Reste à prouver que ces conditions, i.e. la stabilité de Filt'^{π} par conoyaux de double-flèches, est satisfaite dans les cas A) B) C), le cas A) étant d'ailleurs déjà connu. Le cas B) résulte immédiatement de la transitivité des familles épimorphiques strictes universelles, et c'est d'ailleurs aussi contenu explicitement (stabilité de Filt'^{π} par $\varinjlim$ de cardinal $\leqslant \pi$) dans SGA 4 I 9.13 (sinon dans l'énoncé, du moins c'est signalé dans la démonstration). En rédigeant SGA 4 I 9, je savais donc qu'on a $\mathcal{M}_\pi \subset \mathrm{Filt}'^{\pi}$ pour tout π, mais l'inclusion, plus évidente pourtant dans le cas d'espèce, $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_\pi$ (quand on suppose les objets de C π_1-accessibles) m'avait apparemment échappé ?

Reste à traiter le cas C). (J'ai l'impression qu'il est un peu plus général que le cas B), i.e. que la condition B) sur $\mathcal{M}$ implique C), mais non inversement. Ainsi, la condition C) est vérifiée dès que $\mathcal{M}$ correspond à une espèce de structure algébrique définie en termes de $\varprojlim$ *finies*, i.e. quand $\mathcal{M}$ est de la forme $\mathrm{Ind}(C)$, C stable par $\varinjlim$ *finies*, alors que je doute que la condition B) soit toujours satisfaite pour ces catégories. Par exemple dans la catégorie Cat (qui est un paratopos de cette espèce), les $\varinjlim$ filtrantes sont exactes à gauche, mais je ne crois pas que les familles épimorphiques strictes soient universelles. Prenons p.ex. deux homomorphismes de groupes $G_0 \xrightarrow{u_0} G$, $G_1 \xrightarrow{u_1} G$ tels que $G_0 * G_1 \longrightarrow G$ soit surjectif, alors cette famille à deux éléments est épimorphique stricte dans Gr et dans Cat ([53]), mais n'est pas forcément épimorphique stricte universelle, même si p.ex. $G_0 = G_1 = H$, $G = H \times H$, et u_0, u_1 sont des injections $H \rightrightarrows H \times H$, données par $u_0(h) = (h, 1)$, et $u_1(h) = (1, h)$. Si je prends l'application diagonale $H \longrightarrow H \times H$, les images inverses de u_0, u_1 sont le même objet de $\mathcal{M}/H$, savoir $e \longrightarrow H$, et cette famille n'est épimorphique stricte que si H est le groupe unité.) [page 135]

Le cas C) va résulter du résultat plus précis :

Corollaire 4.5.15. *Sous les conditions générales de 4.5.13, supposons que dans $\mathcal{M}$ les $\varinjlim$ filtrantes commutent au changement de base (p.ex. les $\varinjlim$ filtrantes sont exactes). Alors pour tout $\pi \geqslant \pi_1$, Filt'^{π} est formée des $x \in \mathrm{Ob}\,\mathcal{M}$ satisfaisant la condition suivante.* [page 136]

Commentary · Examples [ms. 135]

A strict covering family which loses strictness under pullback

Grothendieck wants an elementary reason that exactness of filtered colimits is weaker than universality of every strict epimorphic family. Groups do provide that reason, but the direct-product example printed here does not: its initial family is already non-strict. The corrective footnote withdraws the general assertion and mistakenly exempts this special case.

53. !, c'est *faux* en général, mais vrai dans le cas particulier plus bas.

Take $H = C_2$, and regard its two copies as the coordinate subgroups of $C_2 \times C_2$. Their intersection is trivial. Map the first generator to $(12) \in S_3$ and the second to $(23) \in S_3$. These homomorphisms are compatible on every overlap test: if two maps into the two coordinate subgroups have the same composite into the direct product, both composites are trivial. A common extension would send the two commuting coordinate generators to two noncommuting transpositions. Hence no extension exists. The family is not strictly epimorphic in groups. The same argument applies to one-object group categories, so it is not strictly epimorphic in Cat either.

Replace the direct product by

$$G = C_2 * C_2 = \langle a, b \mid a^2 = b^2 = 1 \rangle.$$

The two free-factor inclusions are strictly epimorphic in groups. Compatibility on the intersection imposes no relation, and the universal property of the free product gives the unique extension. They are strictly epimorphic as functors of one-object categories as well. Compatibility forces the chosen target objects to coincide; the two homomorphisms into the automorphism group of that object then extend uniquely to G.

Now let $K = \langle ab \rangle$. The reduced-word description shows that ab has infinite order, so $K \simeq \mathbb{Z}$, and that K meets either free factor trivially. Pullback along $K \hookrightarrow G$ gives the family consisting of two copies of $1 \to \mathbb{Z}$. This family is not even epimorphic: the zero endomorphism and the identity of $\mathbb{Z}$ agree after both maps. Thus strict epimorphic families in groups, and in categories, need not be universal. Filtered colimits in both examples are nevertheless left exact; their objects, arrows or algebraic operations are governed by finite equations in sets.

The repair preserves the intended distinction while changing the ambient group. It also warns against replacing a strict epimorphic family by the assertion that its images generate a target. Generation detects uniqueness of an extension; strictness requires existence for every compatible family.

p. 43

c′) Il existe une famille de flèches $(u_\alpha)_{\alpha \in A}$, $u_\alpha : x_\alpha \longrightarrow x$, *dans* $\mathcal{M}$, *qui est* épimorphique stricte universelle *(i.e. couvrante pour la topologie canonique de* $\mathcal{M}$*), avec* $x_\alpha \in \mathrm{Ob}\, C$ $\forall\ \alpha \in A$, *et* $\mathrm{card}\, A \leqslant \pi$.

Démonstration : il faut prouver que cette condition équivaut à la condition c) de 4.5.13 1°). Comme on a c′ $\Longrightarrow$ c trivialement, il reste à montrer que c $\Longrightarrow$ c′. Mais on a vu dans 4.5.13 1°) que c implique a″, i.e. qu'on a un isomorphisme

$$x \;=\; \varinjlim_{i \in I} x_i \ ,$$

les x_i dans C, et I ensemble *ordonné filtrant*, avec $\mathrm{card}\, I \leqslant \pi$. Il reste à voir que si x dans $\mathcal{M}$ est une limite inductive *filtrante* d'objets x_i, alors l'ensemble des flèches $x_i \longrightarrow x$ est épimorphique stricte *universelle.* Or cela est immédiat, car pour $x' \longrightarrow x$, on a $x' = \varinjlim_i x'_i$ (par hypothèse C), où $x'_i = x' \times_x x_i$, donc la famille $x'_i \longrightarrow x'$ est épimorphique stricte, q.e.d.

Prouvons maintenant que dans le cas C, la condition de 3°, 1 est satisfaite, i.e. que Filt'^{π} est stable par $\varinjlim$ de cardinal $\leqslant \pi$. Cela résulte aussitôt du [page 137]

Corollaire 4.5.16. (de 4.5.15). *Sous les conditions de 4.5.15 (i.e. la condition C) de 4.5.13, 3°), soit x un objet de* $\mathcal{M}$*, et supposons qu'il existe une famille* épimorphique universelle $(x_\alpha \longrightarrow x)_{\alpha \in A}$ *de flèches de* $\mathcal{M}$*, avec* $x_\alpha \in \mathrm{Ob}\, \mathrm{Filt}'^{\pi}$ *pour tout* $\alpha \in A$, *et* $\mathrm{card}\, A \leqslant \pi$. *Alors* $x \in \mathrm{Ob}\, \mathrm{Filt}'^{\pi}$.

En effet, l'hypothèse sur x_α équivaut, en vertu de 4.5.15, à l'existence d'une famille épimorphique stricte universelle de flèches $(x_{\alpha\beta} \longrightarrow x_\alpha)_{\beta \in B_\alpha}$, avec $\mathrm{card}\, B_\alpha \leqslant \pi$ et les $x_{\alpha\beta}$ dans C. Soit $B = \coprod_{\alpha \in A} B_\alpha$, on a alors $\mathrm{card}\, B \leqslant \pi^2 = \pi$, et d'autre part, la famille des flèches composées $x_{\alpha\beta} \longrightarrow x_\alpha \longrightarrow x$ indexée par B est épimorphique stricte universelle (par transitivité de ce type de familles), donc $x \in \mathrm{Ob}\, \mathrm{Filt}'^{\pi}$, q.e.d.

Avec tout ça, on n'a toujours pas donné de caractérisation de $\mathcal{M}_\pi$ lui-même, qui est meilleure que Filt^{π} et Filt'^{π} du point de vue catégorique, car seuls les $\mathcal{M}_\pi$ définissent une [page 138]

filtration cardinale, et de plus ils ont les propriétés de stabilité désirables dans ce contexte, pour les $\varinjlim$ de cardinal $\leqslant \pi$. Le seul critère non tautologique que j'arrive à dégager dans le cas général (pour tout $\pi \geqslant \pi_0$, et sans hypothèse d'exactitude supplémentaire sur $\mathcal{M}$) est le suivant, beaucoup moins "explicite" ou "calculatoire" que les critères très concrets pour Filt^{π} et pour Filt'^{π} :

Commentary · Present state [ms. 137]

What the covering argument actually proves

Grothendieck is using descent along a bounded covering family to keep a presentation bounded. Corollary 4.5.15 makes the necessary descent condition explicit: the families are universally *strictly* epimorphic. In Corollary 4.5.16 the word "strictement" disappears from the hypothesis, although the proof still invokes transitivity of precisely that stronger notion.

With the stronger hypothesis restored, the proof is complete. Replace each X_α by a universal strict cover with at most π sources in C. The composite is again a universal strict cover, and its index set has cardinal at most $\pi \cdot \pi = \pi$. Corollary 4.5.15 applies. The weaker printed hypothesis does not justify that invocation of transitivity. We have not established a counterexample satisfying all the standing hypotheses, in particular $\pi \geq \pi_1$, and therefore record a gap in this proof rather than declaring its conclusion false.

There is a second point in the preceding "cela résulte aussitôt". Stability under universal strict covers is not, by itself, stability under arbitrary colimits. An arbitrary colimit cocone is strictly epimorphic but need not remain epimorphic after pullback, as the free-product example shows even when filtered colimits are exact. Thus the proposed deduction of the full case C of Proposition 4.5.13 requires an additional argument. The audit keeps that issue separate from the valid universal-cover calculation and from the general intrinsic closure statement which follows.

Proposition 4.5.17. *Soit π un cardinal $\geqslant \pi_0$. Alors $\mathcal{M}_\pi$ est égal à la plus petite sous-catégorie strictement pleine de $\mathcal{M}$, contenant C, et stable par $\varinjlim$ de cardinal $\leqslant \pi$.* (Il est important de noter qu'il *ne suffit pas* de dire : stable par $\varinjlim_I$, avec I *grande devant* π_0, et $\operatorname{card} I \leqslant \pi$. On trouve alors Filt^{π}, qui risque d'être une catégorie strictement plus petite que $\mathcal{M}_\pi$. Ce n'est pas non plus la catégorie des $\varinjlim_I x_i$, avec $x_i \in C \ \forall\ i \in \operatorname{Ob} I$, et $\operatorname{card} \operatorname{Fl} I \leqslant \pi$ – puisque cette catégorie-là est Filt'^{π}.)

Démonstration. Soit $\mathcal{M}'$ la catégorie de l'énoncé, on a donc $\mathcal{M}' \subset \mathcal{M}_\pi$, puisque $\mathcal{M}_\pi$ contient C et est stable par les $\varinjlim$ de cardinal $\leqslant \pi$. Inversement, le lemme 4.5.14, a $\Longrightarrow$ c.

Commentary · Exposition [ms. 138] p. 44 [page 139]

Why closing under relations gives the right category

Grothendieck now replaces a single bounded presentation by a closure operation. This is a less explicit description, but it has the advantage of being intrinsic once the initial generating category has been fixed. The distinction is between allowing one layer of relations and allowing every further relation needed by the construction.

Let D be the smallest strictly full subcategory containing C and closed under colimits indexed by categories of cardinal at most π. The represented-functor calculation already gives $D \subset \mathcal{M}_\pi$. To obtain the reverse inclusion, use the canonical presentation of an object X by D/X. Density supplies its colimit, and bounded-colimit closure makes the indexing category π^+-filtered. If X is π-accessible, its identity factors through one stage. The resulting retract is a coequalizer of an idempotent and an identity, and therefore still lies in D. This is the complete version of the short appeal to Lemma 4.5.14.

For sets, the construction is particularly concrete. Starting with a singleton and closing under at most π-sized coproducts and coequalizers gives every set of cardinal at most π, and these are exactly the π^+-presentable sets. A map from such a set into a π^+-filtered union is represented at one stage because its at most π elements can be treated simultaneously; equality of two maps is treated in the same way. Conversely, a larger set is the π^+-filtered union of its subsets of cardinal at most π, and its identity cannot factor through a proper subset. This simple model explains the intended statement without identifying an arbitrary one-step presentation with the completed closure.

4.6 Caractérisation des catégories paratopos (démonstration de 4.3.6)

Il est temps de revenir à la démonstration du théorème 4.3.6 (p. 70-71), celle que j'avais donnée étant incomplète (et erronée – j'affirmais que $(\mathrm{Filt}^{\pi})_{\pi\geqslant\pi_0}$ est une filtration cardinale, ce qui est faux si on n'admet que $\pi^{\pi_0}=\pi$ pour tout $\pi\geqslant\pi_1$).

On avait vu l'équivalence des conditions a, a′, b, soit PTA. Je vais achever la démonstration par le schéma logique

$$(*)\qquad \text{PTA} \implies \text{d)} \implies \text{c)} \implies \text{PTA}\ .$$

Prouvons PTA $\Longrightarrow$ d), i.e. que si $\mathcal{M}$ est un pseudo-topos accessible, alors existe un cardinal infini π_0, et une petite catégorie C_0 stable par $\varinjlim$ de cardinal $\leqslant\pi_0$, et une équivalence de catégories

$$(4.6.1)\qquad \mathcal{M}\xrightarrow{\sim}\mathrm{Ind}'_{\pi_0}(C_0)\ .$$

Plus précisément, on a ceci :

Proposition 4.6.1. *Soit $\mathcal{M}$ un paratopos, i.e. une $\mathfrak{U}$-catégorie $\mathcal{M}$ stable par petites $\varinjlim$, admettant une sous-catégorie pleine génératrice S équivalent à une petite catégorie, formée d'objets accessibles de $\mathcal{M}$. Soit π_0 un cardinal tel que les objets de S soient π_0-accessibles (i.e. $S\subset\mathcal{M}_{\pi_0}$), et soit C la plus petite sous-catégorie strictement pleine de $\mathcal{M}$, contenant S et stable par $\varinjlim$ de cardinal $\leqslant\pi_0$. Alors*

1°) C est équivalente à une petite catégorie.

2°) $C=\mathcal{M}_{\pi_0}$, sous-catégorie strictement pleine de $\mathcal{M}$ formée des objets π_0-accessibles. [page 140]

3°) Le foncteur canonique

$$\mathrm{Ind}'_{\pi_0}(C)\xrightarrow[\sim]{[\varphi]}\mathcal{M}$$

(défini à isomorphisme unique près par la condition que son composé avec l'inclusion $C\hookrightarrow\mathrm{Ind}'_{\pi_0}(C)$ soit isomorphe à l'inclusion $C\longrightarrow\mathcal{M}$, et que φ commute aux petites $\varinjlim$, ou encore aux $\varinjlim$ filtrantes grandes devant π_0 – cf. 4.4.16, page 101) est une équivalence de catégories ([54]).

Démonstration. 1°) On va construire C par induction transfinie, en posant

$$\begin{aligned} C_0 &= \text{sous-catégorie strictement pleine de } \mathcal{M} \text{ engendrée par } S.\\ C_{\alpha+1} &= \text{sous-catégorie strictement pleine de } \mathcal{M} \text{ engendrée par les } \varinjlim_{I} \text{ dans}\\ &\quad\ \mathcal{M} \text{ d'objets de } C_\alpha, \text{ avec } I \text{ catégorie telle que } \operatorname{card}\mathrm{Fl}\, I\leqslant\pi_0.\\ C_\alpha &= \textstyle\bigcup_{\alpha'<\alpha} C_{\alpha'} \quad \text{si } \alpha \text{ est un ordinal limite.}\end{aligned}$$

Cela définit de façon unique les C_α (pour tout petit cardinal α). Par la définition de C, on voit par induction transfinie que les C_α sont contenues dans C. Soit α_0 le premier ordinal tel que $\operatorname{card}\alpha_0>\pi_0$, donc l'ensemble I_{α_0} des cardinaux $\alpha<\alpha_0$ est grand devant π_0. Je dis qu'on a $C_{\alpha_0}=C$. Pour ceci, il suffit de voir que C_{α_0} est stable par $\varinjlim$ de cardinal $\leqslant\pi$. Mais si I est une catégorie telle que $\operatorname{card}\mathrm{Fl}\, I\leqslant\pi_0$, et $\varphi: I\longrightarrow C_{\alpha_0}=\bigcup_{\alpha<\alpha_0}C_\alpha$ un foncteur, alors la définition de α_0 implique que φ se factorise en $\varphi_\alpha: I\longrightarrow C_\alpha$, avec $\alpha<\alpha_0$ ([55]). Donc $\varinjlim\varphi\in\mathrm{Ob}\, C_{\alpha+1}\subset\mathrm{Ob}\, C_{\alpha_0}$, ce qui montre la stabilité requise. p. 45 [page 141]

54. donc on a aussi $\mathrm{Ind}'_{\pi_0}(C_0)\xrightarrow{\sim}\mathcal{M}$, où C_0 est une *petite* catégorie équivalente à C.

55. Un peu court. Il faut invoquer le fait que I_{α_0} est grande devant π_0.

Commentary · Exposition [ms. 140]

The small category behind a cocomplete category

Grothendieck's purpose is to recover a small category which contains all the operations needed to reconstruct $\mathcal{M}$. The transfinite argument does not require a precise estimate for every Hom set. It requires only that each stage have a set of isomorphism classes, that its Hom sets be small, and that the closure operation stabilize at a specified regular ordinal.

Put $\lambda = \pi_0^+$. Choose a small skeleton at each stage. There is a set of categories with at most π_0 arrows, a set of functors from each of them to that skeleton, and hence a set of chosen colimits. Local smallness then makes the full category on those chosen objects small. At limit stages take the union of the chosen sets of objects and then the full category they span. All these operations remain in the fixed universe.

If a diagram with at most π_0 arrows takes values in C_λ, its objects occur at at most π_0 earlier stages. Regularity of λ bounds those stages by a single $\alpha < \lambda$. Its colimit therefore occurs in $C_{\alpha+1}$. This proves C_λ is closed under the required colimits, and proves stabilization. The source's references to "cardinaux" in the indexing sequence must here mean ordinals; it is their cofinality which the proof uses.

The remaining reconstruction has a different, categorical, content. For $X_i, Y_j \in C$ and the relevant filtered indices,

$$\mathrm{Hom}_{\mathcal{M}}(\varinjlim_i X_i, \varinjlim_j Y_j) \simeq \varprojlim_i \varinjlim_j \mathrm{Hom}_C(X_i, Y_j).$$

This is the Hom formula for the filtered completion. It proves full faithfulness. The category C/X has the bounded colimits inherited from C and is therefore λ-filtered; density makes its colimit X. This proves essential surjectivity. These two arguments establish Proposition 4.6.1 independently of the sharper numerical estimate criticized in the next block.

Pour voir que C est équivalente à une petite catégorie, il suffit de le voir pour les C_α, en procédant par induction transfinie. Cela résulte du lemme suivant, immédiat :

Lemme 4.6.1.1.

1°) La limite inductive C d'un système inductive filtrant $(C_i)_{i\in I}$ de catégories C_i équivalentes à des petites catégories est équivalente à une petite catégorie. Si $\operatorname{card}\operatorname{réd}(C_i) \leqslant \pi$ *pour tout i, et* $\operatorname{card} I \leqslant \pi$, *alors* $\operatorname{card}\operatorname{réd}(C) \leqslant \pi$ *(π étant un cardinal infini). Ici, pour toute catégorie $\mathcal{A}$, je pose* $\operatorname{card}\mathcal{A} = \operatorname{card}\operatorname{Fl}\mathcal{A}$, $\operatorname{card}\operatorname{réd}(\mathcal{A}) = \operatorname{card}(\mathcal{A}_0)$, *où $\mathcal{A}_0$ est une catégorie réduite équivalente à $\mathcal{A}$.* [page 142]

2°) Soit $C_0 \subset \mathcal{M}$ une sous-catégorie pleine d'une catégorie $\mathcal{M}$, π_0 un cardinal infini, et soit C_0' la sous-catégorie strictement pleine de $\mathcal{M}$ engendrée par les limites inductives dans $\mathcal{M}$ (représentables dans $\mathcal{M}$) de foncteurs $I \longrightarrow C_0$, avec I catégorie telle que $\operatorname{card} I \leqslant \pi_0$. *Si C_0 est équivalente à une petite catégorie, il en est de même de C_0'. Plus précisément, si* $\operatorname{card}\operatorname{réd}(C_0) \leqslant \pi_1$, *$\pi_1$ un cardinal infini, alors* $\operatorname{card}\operatorname{réd}(C_0') \leqslant \pi_1^{\pi_0}$ ([56]).

Corollaire 4.6.1.2. *$\mathcal{M}$ et C_0 étant comme dans 2°) ci-dessus, soit C la plus petite sous-catégorie strictement pleine de $\mathcal{M}$ contenant C_0, et stable par $\varinjlim$ de cardinal $\leqslant \pi_0$ (celles qui sont représentables dans $\mathcal{M}$). Si C_0 est équivalente à une petite catégorie, il en est de même de C. Plus précisément, si* $\operatorname{card}\operatorname{réd}(C_0) \leqslant \pi_1$, *où π_1 est un cardinal infini, alors on a* $\operatorname{card}\operatorname{réd}(C) \leqslant \pi_1^{\pi_0}$ ([57]). [page 143]

Le 3°) se prouve par la démonstration transfinie précédente, on prouve par récurrence transfinie que

$$\operatorname{card}\operatorname{réd} C_\alpha \;\leqslant\; \pi_1^{\pi_0}$$

pour tout α. C'est OK pour $\alpha = 0$ par hypothèse (puisque $\pi_1 \leqslant \pi_1^{\pi_0}$). Si c'est vrai pour C_α, alors 2°) assure que

$$\operatorname{card}\operatorname{réd} C_\alpha \;\leqslant\; (\pi_1^{\pi_0})^{\pi_0} \;=\; \pi_1^{\pi_0\cdot\pi_0} \;=\; \pi_1^{\pi_0}\ ,$$

56. Cette majoration n'est par prouvée et probablement fausse si on ne fait pas des hypothèses un peu plus strictes.

57. majoration non prouvée, probablement fausse, cf. annotation ci-dessus.

enfin, si α est un ordinal limite $< \alpha_0$, on aura $C_\alpha = \bigcup_{\alpha'<\alpha} C_{\alpha'}$, donc

$$\operatorname{card}\operatorname{réd} C_\alpha \;\longrightarrow\; \pi_0 \cdot \pi_1^{\pi_0} \;=\; \pi_1^{\pi_0}$$

(vu que $\pi_1^{\pi_0} \geqslant \pi_0$), en vertu du 1° ci-dessus, et compte tenu du fait que $\operatorname{card} I_\alpha \leqslant \pi_0$. Soit π_0' le cardinal successeur de π_0, alors la même majoration nous donne

$$\operatorname{card}\operatorname{réd} C_{\alpha_0} \;\leqslant\; \pi_0'\pi_1^{\pi_0}\ .$$

Mais on a $\pi_1^{\pi_0} \geqslant 2^{\pi_0} > \pi_0$, donc $\pi_1^{\pi_0} \geqslant \pi_0'$, donc $\pi_1^{\pi_0} \geqslant \pi_0'$, donc $\pi_0'\pi_1^{\pi_0} = \pi_1^{\pi_0}$, d'où p. 46

$$\operatorname{card}\operatorname{réd} C_{\alpha_0} \;\leqslant\; \pi_1^{\pi_0}\ ,$$

ce qui est la majoration annoncée.

[page 144]

Commentary · Development (commentators') [ms. 143]

Counting presentations does not count all new arrows

Grothendieck has correctly counted the possible small diagrams, but then uses that count as a bound on the morphisms between their colimits. The warning in footnotes 56 and 57 identifies the problem accurately. A colimit can acquire many maps *from* an old object, and its universal property controls maps out of the colimit, not these maps into it.

Counterexample to the stated cardinal estimate. [ours] Let $\kappa > 2^{\aleph_0}$, and consider algebras with a binary operation m_ξ for every $\xi < \kappa$, subject only to the equations

$$m_\xi(x, x) = x \qquad (\xi < \kappa).$$

This is a finitary equational category. Its free algebra $F(1)$ on one generator has one element: induction on terms reduces every term in that generator to the generator itself. Thus the full subcategory C_0 with sole object $F(1)$ has one arrow.

The binary coproduct $F(1) \amalg F(1)$ is $F(2)$. Its elements include the terms $m_\xi(x, y)$, and these are pairwise distinct. To verify the last assertion without assuming a normal-form theorem, fix $\xi \neq \eta$ and interpret the operations on $\{0, 1\}$, taking m_ξ to be the first projection and m_η the second projection. Assign either projection to every remaining operation. All the idempotence equations hold, but the two specified terms have different values at $(0, 1)$. They cannot therefore be equal in the free algebra. It follows that

$$|\operatorname{Hom}(F(1), F(2))| = |F(2)| \geq \kappa > 2^{\aleph_0}.$$

Take $\pi_0 = \pi_1 = \aleph_0$. The hypothesis $\operatorname{card}\operatorname{réd} C_0 \leq \pi_1$ holds, but the full closure under even one binary coproduct has more than $\pi_1^{\pi_0}$ arrows in a skeleton. This disproves the quantitative assertions of Lemma 4.6.1.1(2) and Corollary 4.6.1.2 as stated. Their qualitative essential-smallness assertions remain true by the preceding argument.

The construction is an application of the standard free-algebra method, used here to test this particular estimate. We checked the primary representation discussions in Adámek and Rosický (1994) and the manuscript's two warnings; we did not locate this exact counterexample there. The marking records our supplied argument, without a priority claim.

A separate edge case affects Corollary 4.6.2(1). In Ens the one-object full subcategory $S = \{1\}$ is dense, so the printed definition gives $\pi_1 = \operatorname{card}\operatorname{réd} S = 1$. The proposed upper bound is then $1^\pi = 1$, although $\mathcal{M}_\pi$ contains many nonisomorphic objects. One must first replace π_1 by an infinite bound, such as $\max(\aleph_0, \operatorname{card}\operatorname{réd} S)$. Moreover the equality $\pi_1^\pi = 2^\pi$ used there requires $2 \leq \pi_1 \leq \pi$, exactly as the following proof shows. These corrections remove the immediate numerical contradictions; they do not retroactively validate an estimate obtained from the false unrestricted lemma. We retain the small-category reconstruction and distinguish it from the unproved quantitative refinement.

Prouvons 4.6.1 2°, i.e. $C = \mathcal{M}_{\pi_0}$. On a $C \subset \mathcal{M}_{\pi_0}$, puisque par hypothèse $S \subset \mathcal{M}_{\pi_0}$, et on sait que $\mathcal{M}_{\pi_0}$ est stable par $\varinjlim$ de cardinal $\leqslant \pi_0$. D'autre part, on a $\mathcal{M}_{\pi_0} \subset C$, en vertu de 4.5.19 a $\Longrightarrow$ c appliqué à C, qui est strictement génératrice dans $\mathcal{M}$, S l'étant, et $C \supset S$, et stable par $\varinjlim$ de cardinal $\leqslant \pi_0$ par construction.

Prouvons enfin 3°. Cela équivaut à ceci :

Lemme 4.6.1.3. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie stable par* petites $\varinjlim$ *, π_0 un cardinal, $\mathcal{M}_0$ une sous-catégorie de $\mathcal{M}$* strictement génératrice, *stable par $\varinjlim$ de cardinal $\leqslant \pi_0$, et formée d'objets π_0-accessibles. (En vertu de 4.6.1 2° déjà prouvée, appliqué à $S = \mathcal{M}_0$, si $\mathcal{M}_0$ est strictement pleine, on a donc $\mathcal{M}_0 = \mathcal{M}_{\pi_0}$.) Alors le foncteur canonique*

$$\mathrm{Ind}'_{\pi_0}(\mathcal{M}_0) \longrightarrow \mathcal{M}$$

est une équivalence de catégories.

Le fait que ce facteur est pleinement fidèle résulte aussitôt de l'hypothèse que les objets de $\mathcal{M}_0$ soient π_0-accessibles :

$$\begin{aligned}\mathrm{Hom}_{\mathcal{M}}(\varinjlim_{i\in I} \underbrace{X_i}_{\in\mathcal{M}_0},\ \varinjlim_{j\in J} \underbrace{Y_j}_{\in\mathcal{M}_0}\ ) &\simeq \varprojlim_{i\in I} \underbrace{\mathrm{Hom}_{\mathcal{M}}(X_i,\ \varinjlim_{j\in J} Y_j)}_{\varinjlim_{j\in J}\mathrm{Hom}(X_i,Y_j)} \\ &\simeq \underline{\mathrm{Hom}}_{\mathrm{Ind}_{\pi_0}(\mathcal{M})}((X_i),(Y_j))\ .\end{aligned}$$

Reste à voir que ce foncteur est essentiellement surjectif. Comme $\mathcal{M}_0$ est strictement [page 145]
génératrice, il s'ensuit que tout $x \in \mathcal{M}$ s'écrit

$$x = \varinjlim_{i\in I} x_i\ ,$$

où $I = \mathcal{M}_0/x$, et les $x_i \in \mathcal{M}_0$. L'hypothèse que $\mathcal{M}_0$ est stable par $\varinjlim$ de cardinal $\leqslant \pi_0$ implique la même propriété pour $I = \mathcal{M}_0/x$, donc I est grande devant π_0. Donc $(x_i)_{i\in I}$ définit un objet de $\mathrm{Ind}_{\pi_0}\mathcal{M}_0$, dont l'image dans $\mathcal{M}$ est isomorphe à x, q.e.d. (Comparer SGA 4 I 9.18.)

Corollaire 4.6.2. *Sous les conditions de 4.6.1, prenons pour π_0* le plus petit *cardinal tel que les objets de S soient π_0-accessibles. Pour tout $\pi \geqslant \pi_0$, soit $\mathcal{M}_\pi$ la sous-catégorie strictement pleine de $\mathcal{M}$ formée des objets π-accessibles, qui est aussi (par 4.6.1 2°) l'enveloppe de C dans $\mathcal{M}$ stable par $\varinjlim$ de cardinal $\leqslant \pi$.*

1°) Soit $\pi_1 = \mathrm{card}\,\mathrm{réd}\,S$. On a alors

$$\mathrm{card}\,\mathrm{réd}\,\mathcal{M}_\pi \leqslant \pi_1^\pi \qquad (= 2^\pi \text{ si } \pi \geqslant \pi_0). \tag{4.6.2.1}$$

p. 47

2°) $(\mathcal{M}_\pi)_{\pi\geqslant\pi_1}$ est une filtration cardinale de $\mathcal{M}$, où $\pi_1 = \sup(\pi_0, \mathrm{card}\,S)$. [page 146]

Démonstration. La majoration (4.6.2.1) est contenue dans 4.6.1.2, où π_0 est devenu π. Si $\pi \geqslant \pi_1$, on a

$$(*) \qquad \pi_1^\pi = 2^\pi$$

car on a $\pi_1 \geqslant 2$, d'où $\pi_1^\pi \geqslant 2^\pi$, d'autre part, on a $\pi_1 \leqslant 2^{\pi_1}$, d'où $\pi_1^\pi \leqslant (2^{\pi_1})^\pi = 2^{\pi_1\pi} = 2^\pi$, puisque $\pi_1\pi = \pi$ pour $\pi \geqslant \pi_1$; d'où $(*)$.

L'assertion 2° est mise pour mémoire ; en vertu de $\mathcal{M} \simeq \mathrm{Ind}'_{\pi_0}\mathcal{M}_{\pi_0}$, on peut supposer que l'on a $\mathcal{M} = \mathrm{Ind}'_{\pi_0}(\mathcal{M}_{\pi_0})$, et on peut alors appliquer 4.5.9. On aurait d'ailleurs envie de dire que $(\mathcal{M}_\pi)_{\pi\geqslant\pi_0}$ est une filtration cardinale, sans se borner aux $\pi \geqslant \pi_1$. C'est vrai sauf pour la majoration de cardinaux dans la condition c) de la définition des filtrations cardinales (SGA 4 I 9.12) :

$$\underbrace{x}_{\in \mathrm{Ob}\,\mathcal{M}_{\pi'}} = \varinjlim_{i\in I} \underbrace{x_i}_{\in \mathrm{Ob}\,\mathcal{M}_\pi}\ , \qquad I \text{ grande devant } \pi \text{ et } \mathrm{card}\,I \leqslant \pi'^\pi$$

[page 147]

pour $\pi' \geqslant \pi$. Il faut supposer, pour cette majoration, que $\pi \geqslant \pi_1$.

On peut à présent achever la démonstration de 4.3.6, en prouvant les deux dernières implications $(*)$ (p. 139). On a d $\Longrightarrow$ c, i.e. si $\mathcal{M} \simeq \mathrm{Ind}'_{\pi_0}(C)$, C stable par limites inductives de cardinal $\leqslant \pi_0$, et C équivalente à une petite catégorie, alors $\mathcal{M}$ est stable par petites $\varinjlim$ (4.4.13, p. 95-96), ses éléments sont accessibles, et elle admet une filtration cardinale (cf. 4.5.9). Mais il faut vérifier quand même que les éléments de C sont π_0-accessibles. C'est contenu dans SGA 4 I 9.18, qui affirme que la pleine fidélité du foncteur $\mathrm{Ind}_{\pi_0}(C) \longrightarrow \mathcal{M}$ *équivaut* au fait que les éléments de C sont π_0-accessibles dans $\mathcal{M}$. La démonstration dans loc. cit. n'était pas claire, le "il suffit" a été vu bas de la page 144. Le "il faut" ne me paraît pas clair, avec la généralité donnée dans loc. cit. – et à présent je vois que c'est même faux, comme on voit en posant pour C la catégorie unité e, donc $\mathrm{Ind}'_{\pi_0} C \simeq e$, et l'assertion affirmant que si e est immergée pleinement dans $\mathcal{M}$ (donc par un objet *rigide* de $\mathcal{M}$, i.e. un objet a tel que $\mathrm{End}\, a = \{\mathrm{id}_a\}$), alors a est $\aleph_0$-accessible. C'est faux dans la catégorie des anneaux, où $\mathbf{R}$ est un objet rigide non $\aleph_0$-accessible !

[page 148]

Commentary · Examples [ms. 147]

A rigid object need not be small

Grothendieck's objection to the converse in SGA 4 is decisive. Full faithfulness of a completion functor can be vacuous when the chosen subcategory generates very little of the ambient category. A rigid object makes the point in the smallest possible example.

In the category of unital rings, every endomorphism $f : \mathbb{R} \to \mathbb{R}$ is the identity. It is injective because its kernel is an ideal in a field and $f(1) = 1$. A positive real number is the square of a nonzero real number, so its image is positive. Thus f preserves the order, and it fixes $\mathbb{Q}$. If $f(x) \neq x$, a rational number strictly between them contradicts order preservation. Hence $\mathrm{End}(\mathbb{R}) = \{1\}$.

Nevertheless $\mathbb{R}$ is not $\aleph_0$-accessible in the manuscript's convention. Let I be the ordered set of its countable unital subrings. The subring generated by a countable union of countable subrings is countable, so I is $\aleph_1$-filtered. Its union is $\mathbb{R}$, since every individual real belongs to a countable subring. If $\mathrm{Hom}(\mathbb{R}, -)$ preserved this colimit, the identity would factor through one countable subring $A \subset \mathbb{R}$. The composite of that factorization with the inclusion would be the identity, forcing $A = \mathbb{R}$, a contradiction.

The full subcategory on $\mathbb{R}$ is nevertheless equivalent to the terminal category, and its filtered completion is again terminal. Its inclusion into rings is fully faithful. This proves that the necessity assertion of Artin et al. (1972, Exposé I, Corollary 9.18(a)), taken at the stated generality, is false. For the intended application $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$ there is no difficulty: evaluation at $c \in C$ computes $\mathrm{Hom}(c, -)$, and the relevant filtered colimits of presheaves are pointwise. It is this calculation, rather than full faithfulness alone, which gives presentability.

Dans le cas qui nous occupe, $\mathcal{M} = \mathrm{Ind}'_{\pi_0} C$, il faut visiblement utiliser le calcul explicite des $\varinjlim$ grandes devant π_0 dans $\mathrm{Ind}'_{\pi_0} C \subset C^\wedge$, elles se calculent en effet "argument par argument", cf. 4.4.15.

Cela achève la démonstration de c $\Longrightarrow$ d dans $(*)$, page 139. Enfin l'implication c $\Longrightarrow$ PTA est tautologique, l'existence d'une filtration cardinale impliquant celle d'une petite sous-catégorie strictement génératrice. Cela achève la démonstration de 4.3.6.

Je vais redonner une formulation légèrement plus précise de 4.3.6., en précisant les cardinaux, et en y rajoutant une condition supplémentaire, inspirée par SGA 4 I 9.11 (revue et corrigée, cf. une annotation à l'exemplaire `[de Grothendieck]` de SGA 4 I ([58])).

p. 48

Théorème 4.6.3. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie.*

(1°) *Les conditions suivantes sont équivalentes pour un cardinal infini π_0 :*

58. N. Éd. Cette annotation dit "cf. résultat plus simple ci-dessus, si C est *strictement* génératrice" et le résultat en question, également en annotation marginale sur l'exemplaire de Grothendieck, est :

Corollaire. *Soit F admettant* `[une]` *sous-catégorie génératrice par épimorphismes stricts, formée d'objets accessibles, alors* tout *objet de F est accessible (utiliser 7.2. (i) b)).*

a_{π_0}) *$\mathcal{M}$ est une catégorie $\mathfrak{U}$-π_0-paratopos, i.e. $\mathcal{M}$ est stable par petites $\varinjlim$, et contient une petite sous-catégorie pleine* [strictement] *génératrice S, formée d'objets π_0-accessibles de $\mathcal{M}$.*

b_{π_0}) *Il existe une petite catégorie S, et un foncteur pleinement fidèle et π_0-accessible $\mathcal{M} \xrightarrow{i} S^\wedge$, admettant un adjoint à gauche.*

[page 149]

c_{π_0}) *Il existe une petite catégorie C, stable par $\varinjlim$ de cardinal $\leqslant \pi_0$, telle que $\mathcal{M} \simeq \mathrm{Ind}'_{\pi_0}(C)$.*

c'_{π_0}) *Comme c), avec C seulement équivalente à une petite catégorie.*

2°) *Ces conditions impliquent que $\mathcal{M}$ est stable par petites $\varinjlim$ et petites $\varprojlim$, et la condition :*

e_{π_0}) *Pour toute catégorie I grande devant π_0, le foncteur*

$$L = \varinjlim_I : \underline{\mathrm{Hom}}(I, \mathcal{M}) \longrightarrow \mathcal{M}$$

est exact à gauche (donc exact).

Cette condition implique notamment ceci :

$\alpha(\pi_0)$ *Sur la catégorie des double-flèches de $\mathcal{M}$, le foncteur* Ker *(à valeurs dans $\mathcal{M}$) est π_0-accessible.*

$\beta(\pi_0)$ *Pour toute flèche $y \leqslant x$ dans $\mathcal{M}$, le foncteur changement de base $\mathcal{M}/x \longrightarrow \mathcal{M}/y$ est π_0-accessible.*

([59]).

[page 150]

Commentary · Later developments [ms. 149]

Paratopoi and locally presentable categories

Grothendieck is now giving two descriptions of the same cocomplete category: a presentation by small objects and a reflection from a presheaf category. In modern language his π_0-paratopos is a locally π_0^+-presentable category. The connection with the work of Gabriel and Ulmer (1971) is structural; the publisher's contents place presentable objects, generators, and locally presentable categories together in the central part of that monograph. The equivalences used here are recorded more explicitly as Theorems 1.20 and 1.46 in the publisher's chapter introduction to Adámek and Rosický (1994).

The adjunction explains the equivalence with the presheaf formulation. If $L : \widehat{S} \rightleftarrows \mathcal{M} : N$ is a reflection and N preserves π_0^+-filtered colimits, then

$$\mathrm{Hom}_{\mathcal{M}}(Lh_s, X) \simeq N(X)(s).$$

Thus each reflected representable Lh_s is π_0-accessible. Since a presheaf is the colimit of its representables and L preserves colimits, these objects generate $\mathcal{M}$. Conversely, restricted Yoneda on a suitable small category of presentables is fully faithful, and its left adjoint sends a presheaf to the corresponding weighted colimit in $\mathcal{M}$.

There is a missing hypothesis in the later variable-cardinal statement, part 3(c). It says only that $\mathcal{M} \simeq \mathrm{Ind}'_{\pi_0}(S)$ for small S, omitting that S admits colimits of cardinal at most π_0. The proof on manuscript page 152 restores the hypothesis. Without it, take S to be a discrete category on two objects. Every filtered diagram in S is constant, so its filtered completion is still S, which has no coproduct of its two distinct objects. The corrected statement is the cocomplete recognition theorem; allowing arbitrary S leads instead to the accessible categories of the next section.

3°) *Les conditions suivantes sont équivalentes.*

a) $\mathcal{M}$ est une catégorie $\mathfrak{U}$-paratopos, i.e. est stable par petites $\varinjlim$, et contient une petite sous-catégorie pleine S génératrice par épimorphismes strictes, et formée d'objets accessibles.

a′) Comme a), mais en exigeant que $\mathcal{M}$ soit faiblement accessible, i.e. que tout *objet de $\mathcal{M}$ soit accessible.*

b) Il existe une petite catégorie S et un foncteur pleinement fidèle et accessible $\mathcal{M} \hookrightarrow S^\wedge$ admettant un adjoint à gauche.

ⓒ *Il existe un cardinal infini π_0, une petite catégorie S, et une équivalence $\mathcal{M} \simeq \mathrm{Ind}'_{\pi_0}(S)$.*

c′) Comme c, en supposant seulement S équivalente à une petite catégorie.

d) $\mathcal{M}$ est stable par petites $\varinjlim$, est faiblement accessible, i.e. tous ses objets sont accessibles, et admet une filtration cardinale.

p. 49

ⓔ ([60]). *$\mathcal{M}$ est stable par petites $\varinjlim$, contient une petite sous-catégorie pleine strictement génératrice, et il existe un cardinal infini π_0 tel que la condition e_{π_0} de 2°) soit satisfaite.*

ⓔ′ *Comme e, mais en exigeant, au lieu de e_{π_0}, la condition plus faible conjonction de $\alpha(\pi_0)$ et $\beta(\pi_0)$ dans 2°.*

Démonstration. La partie 1° a déjà été démontrée. La première assertions dans 2°), [page 151]
savoir la stabilité de $\mathcal{M}$ par petites $\varprojlim$, est bien connue (résulte de stabilité par petites $\varprojlim$, et de l'existence d'une petite famille génératrice, cf. SGA 4 I 8.12.7, version duale de l'annotation marginale). La validité de la condition e_{π_0} résulte du fait qu'elle est valable dans $C^\wedge$ (où C est la catégorie mentionnée dans 1°, c_{π_0}), et du fait que les $\varprojlim$ dans $\mathcal{M}$, et les $\varinjlim$ grandes devant π_0 dans $\mathcal{M}$, se calculent dans $C^\wedge$. On trouve d'ailleurs de même :

Corollaire 4.6.4. *Si $\mathcal{M}$ est une catégorie $\mathfrak{U}$-π_0-paratopos, alors pour tout cardinal $\pi \geqslant \pi_0$, et tout catégorie J telle que* $\mathrm{card}\, J \leqslant \pi$, *le foncteur*

$$\underline{\mathrm{Hom}}(J, \mathcal{M}) \xrightarrow{\varprojlim_J} \mathcal{M}$$

est π-accessible, ou ce qui revient au même, pour toute petite catégorie I grande devant π, le foncteur

$$\underline{\mathrm{Hom}}(I, M) \xrightarrow{\varinjlim_I} \mathcal{M}$$

commute aux $\varprojlim$ de cardinal $\leqslant \pi$.

[page 152]

Commentary · Exposition [ms. 151]

Exactness comes from the set-valued model

Grothendieck wants the cardinal used for generation also to control the passage between limits and colimits. This is available because the small-category presentation gives a faithful calculation of the particular colimits in question, not because an arbitrary colimit-preserving reflection is left exact.

Let C admit colimits indexed by categories of cardinal at most π_0. The objects of $\mathrm{Ind}_{\pi_0}(C)$ may be identified with the presheaves which take these colimits to limits. One implication follows because representables have this property and π_0^+-filtered colimits of sets commute with such limits. Conversely, if F has the property, then its category of elements C/F is π_0^+-filtered: the colimit in C of any bounded diagram of elements receives the unique compatible element supplied by preservation. The empty diagram gives nonemptiness. The canonical Yoneda presentation of F is therefore a presentation of the required filtered kind.

Limits of these presheaves are pointwise, since limits commute with limits. Their π_0^+-filtered colimits are pointwise by the set-theoretic interchange theorem. Evaluating any proposed comparison

59. **Question.** Condition e_{π_0} (voire, le couple $\alpha(\pi_0) + \beta(\pi_0)$ plus l'existence d'une petite sous-catégorie strictement génératrice (et la stabilité de $\mathcal{M}$ par petites $\varinjlim$), implique-t-il que $\mathcal{M}$ est un π_0-paratopos ? Je présume que non.)

60. C'est là la caractérisation intrinsèque la plus jolie des paratopos par la modalité "économie", l'autre, l'énoncé structurel, est ⓒ .

map at $c \in C$ consequently reduces it to the corresponding comparison in sets. In particular, for $\pi \geq \pi_0$ and $|\operatorname{Fl} J| \leq \pi$, the map

$$\varinjlim_{i \in I} \varprojlim_{j \in J} F_{ij} \longrightarrow \varprojlim_{j \in J} \varinjlim_{i \in I} F_{ij}$$

is an isomorphism whenever I is π^+-filtered. This proves Corollary 4.6.4 and includes the equalizer and base-change assertions in Theorem 4.6.3(2).

The converse recognition argument in part 3 is stated by reference to a corrected use of Artin et al. (1972, Exposé I, Proposition 9.11). Its conclusion allows an increase of cardinal. The set of subobjects and the set of generating maps into each object enter that argument, so exactness at one prescribed rank does not itself put the generators at that rank. The question in footnote 59 asks precisely whether this increase can be avoided.

D'autre part, le fait que e_{π_0} implique $\alpha(\pi_0)$ et $\beta(\pi_0)$ est immédiat.

La partie 3°), en ce qui concerne l'équivalence des conditions a) à d), est contenue dans 1°, et l'équivalence avec d) a été vue également (la seule chose non tautologique étant que la condition c), savoir $\mathcal{M} \simeq \mathrm{Ind}_{\pi_0}(C)$ avec C petite et stable par $\varinjlim$ de cardinal $\leqslant \pi_0$, implique l'existence d'une filtration cardinale, ce qui a été vu dans 4.5.9, et réaffirmé dans 4.6.2 2° ci-dessus). D'autre part, que ces conditions a) à d) impliquent ⓔ , et que ⓔ implique e′, a été vu dans 2°. Donc il reste à voir que les conditions de e′ impliquent a), et pour ceci, il reste à établir que les éléments de $\mathcal{M}$ sont accessibles. Mais c'est ce qui est établi dans SGA 4 I 9.11, à cela près que l'énoncé de la condition c), deuxième cas, est canulé, et devrait être remplacé par la condition $\beta(\pi_0)$ (la condition $\alpha(\pi_0)$ figurant dans la condition a) de loc. cit.).

[page 153]

Commentary · Development (commentators') [ms. 152]

Exactness does not determine the generating cardinal

Grothendieck suspects that the fixed-cardinal converse in footnote 59 is false. A topological example gives a negative answer for every infinite cardinal in his convention. It makes the obstruction visible in open covers: colimits may be exact while no nonzero object can be detected at the proposed size.

Proposition. [ours] For every infinite π_0 there is a Grothendieck topos with a small dense subcategory and exact filtered colimits which is not a π_0-paratopos. In fact its only π_0^+-presentable object is the initial object.

Put $\lambda = \pi_0^+$, $\kappa = \lambda^+$, and choose a set X of cardinal κ. Give it the topology whose nonempty opens are the complements of subsets of cardinal less than κ. This is a topology: finite unions of the excluded small subsets remain small, and an arbitrary union of nonempty opens contains one such open. Every nonempty open has cardinal κ. Let $\mathcal{E} = \mathrm{Sh}(X)$.

We first describe an obstruction valid for any noninitial sheaf F. Its support U, the image of $F \to 1$ regarded as an open subset of X, is nonempty. Equivalently, U is the set of points where F has a nonempty stalk; it is open because a germ comes from a local section. Choose distinct points $x_\alpha \in U$ for $\alpha < \lambda$, and set

$$U_\beta = U \setminus \{x_\alpha : \beta \leq \alpha < \lambda\} \qquad (\beta < \lambda).$$

Each U_β is open, since the removed set has cardinal at most $\lambda < \kappa$. The opens increase, their union is U, and each is a proper subset of U. The ordinal λ is a λ-filtered indexing poset: every set of fewer than λ ordinals below it is bounded below it.

Write $F_\beta = F \times U_\beta$, where an open is identified with its subterminal sheaf. Then

$$F = \varinjlim_{\beta < \lambda} F_\beta.$$

This equality can be checked on stalks. At a point in U the point eventually belongs to U_β, and the stalk then equals F_x; outside U every stalk is empty. Each map $F_\beta \to F$ is a monomorphism. If F were λ-presentable, its identity would factor through one of these monomorphisms. A monomorphism with a right inverse is an isomorphism, forcing the supports U_β and U to be equal. This contradicts their construction. Thus no noninitial F is λ-presentable.

For completeness, $\mathcal{E}$ has the other properties in the question; the general sheaf-theoretic facts used here are in Artin et al. (1972, Exposé II, Theorem 4.1 and Corollary 4.1.1). The category of opens is small, and its representable sheaves give the usual dense generating family. All colimits exist by sheafifying presheaf colimits. Filtered colimits are left exact: they are computed by first taking a pointwise filtered colimit of presheaves and then applying the left exact associated-sheaf functor; finite limits of sheaves agree with finite limits of presheaves. Hence e_{π_0} holds, as do $\alpha(\pi_0)$ and $\beta(\pi_0)$. Since X is nonempty, the topos is nondegenerate and cannot be generated by its initial object alone. It is therefore not a π_0-paratopos.

The construction uses the standard sheaf-theoretic relation between support and open covers; it does not contradict the variable-cardinal theorem, since a sheaf topos is locally presentable at a sufficiently large rank. We checked the primary SGA 4 material on sheaves and accessibility and the representation descriptions in Adámek and Rosický (1994); searches concerning compact topologies and presentable sheaves did not locate this exact co-small formulation. The proof is supplied as a development of the manuscript's question, without a claim of priority.

Remarque 4.6.5. Les développements des sections 4.4, 4.5, 4.6 précisent et affirment considérablement, à bien des égards, la théorie des filtrations cardinales de SGA 4 I 9. Il en est ainsi, tout au moins, dans le cas des $\mathfrak{U}$-catégories $\mathcal{M}$ stables par petites $\varinjlim$. Dans loc. cit. on travaille avec des $\mathfrak{U}$-catégories légèrement plus générales, celles satisfaisant la *condition* p. 50
L : il existe un cardinal infini π_0 tel que $\mathcal{M}$ soit stable par petites $\varinjlim$ *grandes devant* π_0. Je présume cependant qu'on doit pouvoir améliorer de façon similaire la théorie des filtrations cardinales *accessibles*, en s'inspirant du corollaire 9.18 de loc. cit., établissant une équivalence de catégories

$$\mathcal{M} \simeq \mathrm{Ind}_{\pi_0}(C) ,$$

pour un cardinal π_0 et une petite catégorie C convenable. Ici, on ne peut plus supposer C stable par tel ou tel type de $\varinjlim$. Néanmoins, 4.4.15 nous dit que sans autre hypothèse sur C, $\mathcal{M} \overset{\text{déf}}{=} \mathrm{Ind}_{\pi_0}(C)$ satisfait bien à L_{π_0}, i.e. est stable (et même stable dans $C^\wedge$)
par petites $\varinjlim$ grandes devant π_0. [page 154]

Ceci vu, j'ai envie d'appeler *accessible* une catégorie $\mathcal{M}$ qui admet une filtration cardinal, et qui est de plus faiblement accessible `[i.e.]` dont tout objet est accessible. Et de hasarder une

Conjecture 4.6.6 ([61]). *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie. Conditions équivalentes :*

a) $\mathcal{M}$ satisfait la condition L, et admet une petite catégorie strictement génératrice formée d'objets accessibles.

⇑ *b) Il existe une petite catégorie C, et un cardinal infini π_0, tel que $\mathcal{M}$ soit équivalente à la catégorie $\mathrm{Ind}'_{\pi_0}(C)$.*

⇑ *c) $\mathcal{M}$ est "accessible", i.e. est faiblement accessible (tout objet accessible) et admet une filtration cardinale.*

On a b $\Longrightarrow$ a $\Longleftarrow$ c de façon tautologique, et c $\Longrightarrow$ b a été vu dans loc. cit. 9.18, donc on a la suite

$$\mathrm{c} \Longrightarrow \mathrm{b} \Longrightarrow \mathrm{a} ,$$

donc il resterait à établir a $\Longrightarrow$ c.

Le travail accompli (et la sueur versée) dans 4.5 nous préservera d'ailleurs, le moment [page 155]
venu, d'erreurs fort naturelles dans la description d'une filtration cardinale, à partir d'une sous-catégorie S strictement génératrice : ce n'est ni Filt^π, ni Filt'^π, mais quelque chose de plus subtil – peut-être faut-il prendre encore la catégorie $\mathcal{M}_\pi$, ou alors saturer S par les limites inductives de cardinal $\leqslant \pi$ qui veulent bien être représentables dans $\mathcal{M}$: on trouve alors une $\mathrm{Filt}''^\pi \subset \mathcal{M}_\pi$, et si ces Filt''^π donnent bien une filtration cardinale, on doit avoir forcément $\mathcal{M}_\pi \subset \mathrm{Filt}''^\pi$, donc finalement $\mathrm{Filt}''^\pi = \mathcal{M}_\pi$. Donc je m'attends à ce qu'en tout

61. Tout ceci sera considérablement précisé dans la théorie qui sera développé dans les sections 4.7, 4.16.

état de cause, la filtration cardinale (si elle existe) se fasse par les $\mathcal{M}_\pi$. La condition a) de loc. cit. 9.12 ($\mathcal{M}_\pi$ équivalente à une petite catégorie), et la majoration de cardinaux dans loc. cit. c), ne doit pas faire de difficultés, et la condition b) est OK. La difficulté

[page 156]

Commentary · Context [ms. 155]

Removing cocompleteness changes the problem

Grothendieck is now testing which part of the reconstruction survives when many colimits do not exist. The small objects can still be intrinsically accessible, but the category $\mathcal{M}_\pi/X$ need not be filtered. A collection of small objects is therefore not yet a collection of small stages of every object.

The modern definition of an accessible category makes the missing presentation part explicit. For a regular λ, one asks for λ-filtered colimits and a small full category of λ-presentable objects from which every object is obtained by such a colimit. Equivalently, the category is a suitable filtered completion of a small category, after allowing retracts among its presentables. This is the structural alternative in Conjecture 4.6.6(b). Its relation to the source's proposed "cardinal filtration" requires the generalized filtration developed next; one should not substitute a modern definition into condition (a) and thereby turn the unproved implication into a tautology.

There is a useful chronological distinction. Gabriel and Ulmer (1971) had treated the cocomplete theory, while Makkai and Paré (1989) had already developed accessible categories and their categorical constructions before these manuscript pages. Adámek and Rosický (1994) subsequently provided a systematic account of both theories. These references place the present calculations in an established mathematical development; they do not establish that Grothendieck was using those treatments here. The source's immediate interlocutor is its own SGA 4 terminology, whose meaning of "accessible category" is reconsidered explicitly in §4.8.

What has been proved on these pages is enough for the cocomplete case. What remains to be proved for a general completion is control of the indices and their retracts. That is why the next section studies three related filtrations instead of assuming that a single bound on a presentation is already the correct invariant.

provient du fait que $\mathcal{M}_\pi$ n'étant pas même stable par sommes et conoyaux de double-flèches (quand ceux-ci ne sont pas représentés dans $\mathcal{M}$), la catégorie $\mathcal{M}_\pi/x$ (pour x dans $\mathcal{M}$) n'a aucune raison d'être filtrante, pour autant que je vois, ni a fortiori d'être grande devant π. p. 51
Donc il n'est pas trop clair comment dès lors représenter x comme $\varinjlim_I x_i$, les x_i dans $\mathcal{M}_\pi$ et I grande devant π.

Il faut bien dire que dans SGA 4 I 9, je ne donne aucun *exemple* d'une filtration cardinale sur une catégorie où les petites $\varinjlim$ quelconques ne seraient représentables (cf. loc. cit. 9.13). Peut-être après tout est-ce contre-nature de vouloir elles au delà ? ? Il faut peut-être attendre d'y être forcé, pour essayer de développer une théorie en dehors du cadre des paratopos.

4.6.7. Nous sommes à présent en mesure de reformuler les kyrielles de conditions un peu techniques a) à f) du théorème 2.6 (p. 25 dans XVIII) concernant le caractère "spécial à gauche" de l'ensemble $\mathrm{Mon}(\mathcal{M}) \subset \mathrm{Fl}(\mathcal{M})$: [page 157]

Proposition 4.6.7 ([62]). *Les conditions préliminaires sur la $\mathfrak{U}$-catégorie $\mathcal{M}$, assurant la validité du théorème XVIII 2.6, sous une forme très légèrement modifié (savoir en modifiant dans 2.6 d) la condition de stabilité de* Filt^π *par quotients, en une propriété d'exactitude d) ci-dessous), équivaut à l'ensemble de six conditions suivantes a) à f).*

$$\begin{cases} \text{a)} & \mathcal{M} \text{ est stable par petites } \varinjlim . \\ \text{b)} & \mathcal{M} \text{ admet une petite sous-catégorie strictement génératrice.} \\ \text{c)} & \text{Les limites inductives filtrantes dans } \mathcal{M} \text{ sont exactes.} \end{cases}$$

Ces conditions impliquent que $\mathcal{M}$ est une catégorie $\mathfrak{U}$-paratopos *(cf. 4.6.3, 3°), et en particulier que les objets de $\mathcal{M}$ sont* accessibles, *et que $\mathcal{M}$ admet une filtration cardinale $(\mathcal{M}_\pi)_{\pi \geqslant \pi_0}$*

62. Peut-être on pourrait appeler ces catégories des catégories "*paratopos parabéliens*" ? ?

telle que pour tout $\pi \geqslant \pi_0$, $\mathcal{M}_\pi$ soit stable par $\varinjlim$ de cardinal $\leqslant \pi$ (en fait, on aura $\mathcal{M}_\pi =$ sous-catégorie pleine des objets π-accessibles de $\overrightarrow{\mathcal{M}}$). Aussi, elles impliquent la stabilité de $\mathcal{M}$ par petites $\varprojlim$. D'autre part, les trois conditions suivantes sont des conditions de stabilité pour les monomorphismes.

d) Soit $f : X \longrightarrow Y$ une flèche dans $\mathcal{M}$ et $R = X \times_Y X \rightrightarrows X$, alors $X/R \longrightarrow Y$ est un monomorphisme – en d'autres termes, f se factorise en un composé ip, avec i monomorphe et p un épimorphisme effectif.

[page 158]

e) Si A_1, A_2 sont deux sous-objets d'un objet B de $\mathcal{M}$, et $A_0 = A_1 \cap A_2 \overset{déf}{=} A_1 \times_B A_2$, alors $A_1 \amalg_{A_0} A_2 \longrightarrow B$ est un monomorphisme. (Noter la proche parenté des conditions d) et e).)

f) L'ensemble $\mathrm{Mon}(\mathcal{M})$ *des monomorphismes dans $\mathcal{M}$ est stable par cochangement de base.*

En fait, il n'est pas clair que ces conditions, et notamment d), suffisent à entraîner la stabilité des $\mathcal{M}_\pi$ par quotients (seulement par quotients effectifs), comme postulé dans 2.6 d). Mais dans l'énoncé et la démonstration donnée dans XV cor. 7.4 (p. 98-99), on se contentait d'une forme un peu plus faible de cette propriété de stabilité, en se bornant aux quotients Z' de $Z \in \mathrm{Ob}\,\mathcal{M}_\pi$ *tels* qu'il n'existe pas de sous-objet Z'_0 de Z', distinct de Z', et tel que $Z \longrightarrow Z'$ se factorise par Z'_0 ; on exigeait donc que $Z' \in \mathrm{Ob}\,\mathcal{M}_\pi$. Mais si la condition d) est satisfaite, il s'ensuit aussitôt qu'un quotient Z' de Z ayant cette propriété supplémentaire est nécessairement effectif, d'où résulte bien que $Z' \in \mathrm{Ob}\,\mathcal{M}_\pi$.

p. 52

Commentary · Examples [ms. 158] [page 159]

The three conditions on monomorphisms

Grothendieck returns to the purpose of the size theory: constructing and controlling monomorphisms without losing the boundedness needed by a transfinite argument. The three categorical conditions separate an image factorization, the formation of a union, and a pushout. They agree in familiar exact settings but express different demands.

In an abelian category, condition (d) is the equality of image and coimage. For subobjects $A_1, A_2 \subset B$, the kernel of $A_1 \oplus A_2 \to B$, $(a_1, a_2) \mapsto a_1 + a_2$, is the image of

$$A_1 \cap A_2 \longrightarrow A_1 \oplus A_2, \qquad t \longmapsto (t, -t).$$

The pushout over the intersection is the quotient by this kernel, so it embeds in B. This proves (e). If $A \hookrightarrow B$ is monic and $f : A \to C$, its pushout is $(B \oplus C)/\{(a, -f(a)) : a \in A\}$, with the evident categorical cokernel interpretation. The map from C is monic: an element $(0, c)$ in the displayed image forces $a = 0$ because $A \to B$ is monic, and then $c = 0$. The same statement follows from the corresponding kernel diagram in any abelian category. This proves (f).

The distinction is visible in groups. For the two coordinate subgroups of $C_2 \times C_2$, the pushout over their trivial intersection is $C_2 * C_2$; its map to the direct product kills the nontrivial commutator, so (e) fails. For (f), take the normal Klein four subgroup $V \subset A_4$ and a surjection $q : V \to C_2$ with kernel generated by one of its nonidentity elements. In the pushout of $V \hookrightarrow A_4$ along q, that element is killed. Its conjugates in A_4 are the other two nonidentity elements of V, so all of V is killed. An element of V mapping to the generator of C_2 is therefore killed too. The induced map from C_2 is not monic. For commutative unital rings, the pushout of $\mathbb{Z} \hookrightarrow \mathbb{Q}$ along $\mathbb{Z} \to \mathbb{F}_p$ is the zero ring, so $\mathbb{F}_p \to 0$ gives another failure of (f).

The last paragraph of the source uses an extremal quotient: a map which cannot factor through a proper subobject. Under (d), its effective-epi–mono factorization has an invertible mono, hence the quotient is effective. This reduction is correct. One must still keep track of the size of the kernel-pair presentation when asserting preservation of π-accessibility; finite-colimit closure alone does not bound a kernel pair of an arbitrary quotient.

Corollaire 4.6.8. *Les conditions d), e), f) de 4.6.7 sont satisfaites si $\mathcal{M}$ est une catégorie abélienne. Donc l'ensemble des conditions a) à f) est satisfait dans chacun des deux cas suivants :*

1) $\mathcal{M}$ est une catégorie abélienne où les limites inductives filtrantes sont représentables et exactes, et admettant une petite catégorie strictement génératrice ([63]).

2) $\mathcal{M}$ est un topos.

Remarque 4.6.9. Je ne suis par sûr de connaître d'autres exemples où les conditions de 4.6.7 sont vérifiées, que ceux signalés dans 4.6.8 ci-dessus ([64]). On notera que le cas 1°) qui y est mentionné est celui de Tohoku, où j'établis l'existence de "suffisamment d'objets injectifs" dans une telle catégorie abélienne. Dans Tohoku, je me borne à supposer l'existence d'une petite sous-catégorie, *génératrice pour les monomorphismes*, condition en apparence plus faible que celle énoncée dans 4.6.8 1°). Mais dans une catégorie abélienne, les deux notions (et leurs diverses variantes dans SGA 4 I 7.1) sont équivalentes en vertu de SGA 4 I 7.3 (i).

Par contre, il semble que les conditions e) f) ne sont pratiquement jamais vérifiées pour les [page 160]
catégories définies par les espèces de structure algébrique "définissables par produits finis" sans plus, tel les groupes, les anneaux (de toutes sortes), etc. Mais la catégorie des groupes *commutatifs*, étant abélienne, est une exception. (On peut d'ailleurs l'interpréter comme $\mathcal{M} \boxtimes \mathcal{M}$, où $\mathcal{M} = (\mathrm{Gr})$, et on peut se demander dès lors s'il y a quelque généralisations aux catégories paratopos de cette forme, $\mathcal{M}$ étant une catégorie paratopos …)

[page 161]

Commentary · Examples [ms. 160]

Pointed sets and the return to homological algebra

Grothendieck asks for examples beyond abelian categories and topoi. Pointed sets give a small but useful additional example of all six conditions. It shows that the monomorphism properties do not by themselves force additivity or the topos axioms.

The category Ens_* has all colimits, obtained from disjoint unions and quotient identifications while identifying the specified basepoints. Finite pointed sets form an essentially small dense category, and every pointed set is the filtered union of its finite pointed subsets. Filtered colimits and finite limits are computed on underlying sets with their induced basepoints, so filtered colimits are exact. These verify (a), (b), and (c).

For (d), a pointed map factors through its image, with a surjection onto that image; the surjection is the coequalizer of its kernel pair. For (e), two pointed subsets of a pointed set have intersection containing the basepoint, and their pushout over that intersection is precisely their union. For (f), the pushout of an inclusion $A \subset B$ along a pointed map $A \to C$ is the quotient of $B \amalg C$ identifying each a with its image. Such identifications do not identify two distinct elements of C: any passage through B can return to C only through the same element of the embedded subset A. Thus C still embeds in the pushout.

This category is not abelian: the coproduct of two pointed two-element sets has three elements, whereas their product has four. It is not a nondegenerate topos either: its initial and terminal objects coincide, while a topos with $0 \simeq 1$ is degenerate. Thus the example answers the concrete request for further settings without suggesting a classification.

The reference to Tôhoku has a different force. Grothendieck (1957, Theorem 1.10.1) proves the existence of enough injectives under AB5 and a generator. The present conditions seek a categorical environment in which analogous constructions with monomorphisms can be made beyond the additive case. Finally, the familiar identification of group objects in groups with abelian groups follows from interchange: the internal multiplication and the ambient multiplication have the same unit and satisfy $(ab) * (cd) = (a * c)(b * d)$; substituting units shows that the two multiplications coincide and are commutative. This explains the concrete phenomenon behind the closing suggestion, but supplies no general theorem for the speculative construction $\mathcal{M} \boxtimes \mathcal{M}$.

4.7 $\mathrm{Ind}_\pi C$ (C quelconque) et filtrations cardinales généralisées.

Je sens le besoin de me lancer dans des développements à ce sujet, pour parvenir à une meilleure compréhension de la notion de *partie accessible* d'un paratopos, et du théorème de

63. C'est le cas étudié dans "Tohoku".

64. ou qui s'en déduisent trivialement (produits etc.)

stabilité pour les paratopos par certaines opérations-clef sur ceux-ci.

Dans la suite, C désigne une catégorie équivalente à une petite catégorie, C_0 une sous-catégorie réduite exhaustive, π_0 un cardinal infini. Nous posons

(4.7.1) $$\mathcal{M} \;=\; \mathrm{Ind}_{\pi_0} C \;\subset\; C^{\wedge} \qquad ([65])\,.$$

On se propose d'introduire sur $\mathcal{M}$ diverses filtrations ± "cardinales", par des propriétés correspondantes sur un objet F de $\mathcal{M} \subset C^{\wedge}$, que je vais à présent introduire, en m'inspirant de 4.5.2 (p. 107) et 4.5.6 (p. 116).

Proposition 4.7.1. *Posons $\pi_1 = \sup(\pi_0, \operatorname{card} C_0)$. Soit $\pi \geqslant \pi_0$ un cardinal, et considérons les conditions suivantes (dépendant de π) sur un objet F de $\mathcal{M}$:*

a) $\operatorname{card} C_0/F \leqslant \pi$ *(i.e.* $\operatorname{card} \mathrm{Fl}\, C_0/F \leqslant \pi$*).*

a′) $\operatorname{card} \mathrm{Ob}\, C_0/F \leqslant \pi$.

a″) $\operatorname{card} F(x) \leqslant \pi$ *pour tout $x \in \mathrm{Ob}\, C$ (**N.B.** il suffit de l'exiger pour x dans C_0).*

Commentary · Exposition [ms. 161]

Presentation size and intrinsic smallness

Grothendieck now removes the existence of small colimits from the hypotheses on C. This changes the task. A presheaf may still be assembled from objects of C by sufficiently filtered colimits, but a construction performed on such presentations need not be available inside C itself. He therefore keeps several measures of size in play until he can prove that they agree.

For this section put $\lambda = \pi_0^+$. A category "grande devant π_0" is a λ-filtered category: every diagram having at most π_0 arrows admits a cocone. The category $\mathcal{M} = \mathrm{Ind}_{\pi_0} C$ is thus the ordinary λ-Ind completion, regarded as a full subcategory of $\widehat{C} = \mathrm{Ens}^{C^{\mathrm{op}}}$. Its λ-filtered colimits are computed pointwise. Grothendieck's $\mathcal{M}_\pi$ consists of the π^+-presentable objects, those F for which $\mathrm{Hom}(F, -)$ preserves π^+-filtered colimits. The successor is essential: his diagrams have cardinality $\leq \pi$, whereas modern regular-cardinal notation uses cardinality strictly below the filtering cardinal.

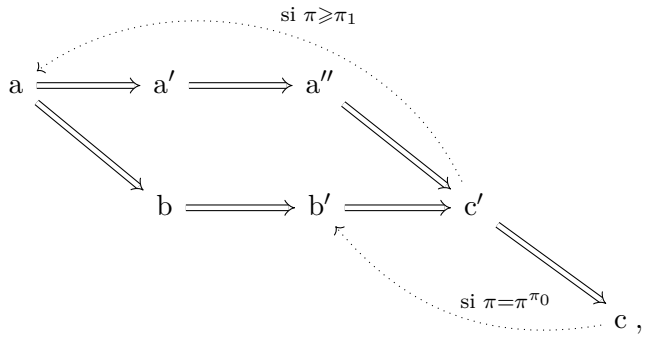
The three tests in Proposition 4.7.1 now have distinct meanings. Conditions (a)–(a″) measure a particular presheaf through its elements. Condition (b) bounds a presentation by representables while retaining λ-filteredness. Condition (c) measures the object intrinsically in $\mathcal{M}$. The intermediate (c′) is intrinsic in the larger category $\widehat{C}$ and can initially be stronger. Finally Filt'^{π} is a closure under repeated bounded filtered colimits, whereas Filt^{π} asks for one presentation. The prime has changed meaning from the preceding cocomplete discussion; here its definition is the one in (b′), not a presentation by arbitrary colimits in an ambient cocomplete category.

Two easy implications deserve to be made explicit. Representables are π^+-presentable in $\widehat{C}$, and a colimit of at most π such presentable objects is again π^+-presentable, because π^+-filtered colimits of sets commute with limits over categories of at most π arrows. This gives $\mathrm{Filt}'^{\pi} \subseteq (\widehat{C})_\pi$. Since $\mathcal{M} \hookrightarrow \widehat{C}$ preserves the filtered colimits in question, ambient presentability implies presentability in $\mathcal{M}$. Neither argument bounds the number of objects of C.

The cardinal π_1 enters when one replaces the total number of elements by a pointwise bound. If $|\mathrm{Fl}\, C_0| \leq \pi$ and every $|F(c)| \leq \pi$, then C_0/F has at most π arrows. Without the bound on C_0, this summation is unavailable. The printed unconditional arrow (a″)⇒(c′) must therefore be treated separately; the example below shows an actual failure, rather than merely an incomplete proof.

b) *On a $F = \varinjlim_{i \in I} x_i$, avec les $x_i \in \mathrm{Ob}\, C$, I une catégorie (pas nécessairement ordonnée) grande devant π_0, et telle que* $\operatorname{card} I \leqslant \pi$. *(**N.B.** en vertu de 4.4.2 (p.79), pour I donnée, ceci équivaut à l'existence d'un foncteur cofinal $I \longrightarrow C/F$, ou encore $I \longrightarrow C_0/F$.)* ([66]).

b′) *On a $F \in \mathrm{Ob}\, \mathrm{Filt}'^{\pi}$, où Filt'^{π} est la plus petite sous-catégorie strictement pleine de $\mathcal{M}$ contenant C, et stable par $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$.*



65. **N.B.** Je désigne maintenant par $\mathrm{Ind}C$, $\mathrm{Ind}_\pi C$ ce qui précédemment était noté $\mathrm{Ind}'C$, $\mathrm{Ind}'_\pi C$.

66. **N.B.** On désignera par $\mathrm{Filt}^{\pi} \subset \mathcal{M}$ la sous-catégorie strictement pleine de $\mathcal{M}$ formée des F satisfaisant cette condition.

c) *On a $F \in \mathrm{Ob}\,\mathcal{M}_\pi$, i.e. F est un objet π-accessible de $\mathcal{M}$.*

c′) *On a $F \in \mathrm{Ob}\,C^\wedge_\pi$, i.e. F est un objet π-accessible de $C^\wedge$.*

Ceci posé, on a le diagramme d'implications suivant.

où les deux implications en pointillés, $c' \Longrightarrow a$ et $c \Longrightarrow b$, sont conditionnelles soumises à la condition $\pi \geqslant \pi_1$, resp. $\pi = \pi^{\pi_0}$.

Corollaire 4.7.2. [page 163]

1°) Si $\pi \geqslant \pi_1$, les six conditions a, a′, a″, b, b′, c′ sont équivalentes, et la condition en question (qu'on peut écrire $F \in \mathrm{Ob}\,\mathrm{Filt}^\pi$ où $F \in \mathrm{Ob}\,\mathrm{Filt}'^\pi$ indifféremment) implique c :

$$\mathrm{Filt}^\pi \;=\; \mathrm{Filt}'^\pi \;\subset\; \mathcal{M}_\pi \qquad \textit{si } \pi \geqslant \pi_1 \tag{4.7.2.1}$$

(alors qu'en général, pour $\pi \geqslant \pi_0$, on a

$$\mathrm{Filt}^\pi \;\subset\; \mathrm{Filt}'^\pi \;(\subset C^\wedge_\pi \cap \mathcal{M}) \;\subset\; \mathcal{M}_\pi \qquad \textit{si } \pi \geqslant \pi_0). \tag{4.7.2.2}$$

2°) Quand $\pi = \pi^{\pi_0}$, p.ex. quand π est de la forme 2^c, avec $c \geqslant \pi_0$, alors les conditions b, b′, c, c′ sont équivalentes, i.e. on a

$$\mathrm{Filt}^\pi \;=\; \mathrm{Filt}'^\pi \;=\; (C^\wedge)_\pi \cap \mathcal{M} \;=\; \mathcal{M}_\pi\,. \tag{4.7.3.2}$$

3°) Quand $\pi \geqslant \pi_1$ et $\pi = \pi^{\pi_0}$, alors les sept conditions a), a′), a″), b) , b′), c) , c′) sont équivalentes, donc en particulier

$$\mathrm{Filt}^\pi \;=\; \mathrm{Filt}'^\pi \;=\; C^\wedge_\pi \cap \mathcal{M} \;=\; \mathcal{M}_\pi \qquad (\pi \geqslant \pi_1 \textit{ et } \pi = \pi^{\pi_0}). \tag{4.7.2.4}$$

Démonstration de 4.7.1. Les implications $\mathrm{a} \Longrightarrow \mathrm{a}' \Longrightarrow \mathrm{a}''$ sont tautologiques, ainsi que $\mathrm{b} \Longrightarrow \mathrm{b}'$. L'implication $\mathrm{b}' \Longrightarrow \mathrm{c}'$ provient de la stabilité de $C^\wedge_\pi$ par $\varinjlim$ de cardinal $\leqslant \pi$, et du fait que les $\varinjlim$ du type envisagé (en particulier, grandes devant π_0) *dans* $\mathcal{M}$ sont les mêmes que dans $C^\wedge$, i.e. se calculent "argument par argument" (cf. 4.4.15, p. 99). Ceci, plus le fait que l'inclusion $\mathcal{M} \hookrightarrow C^\wedge$ est pleinement fidèle, implique aussi $\mathrm{c}' \Longrightarrow \mathrm{c}$. p. 54

L'implication $\mathrm{a}'' \Longrightarrow \mathrm{c}'$ se voit comme dans 4.5.6 (p. 119) en appliquant le lemme 4.5.8 1° et 2°, au cas de $C^\wedge = \underline{\mathrm{Hom}}(C^\circ, \mathcal{E})$, où $\mathcal{E} = (\mathrm{Ens})$. L'implication conditionnelle inverse $\mathrm{c}' \Longrightarrow \mathrm{a}''$, pour $\pi \geqslant \pi_1$, se voit comme dans loc. cit., en appliquant ce lemme 4.5.8. Il reste donc à établir encore les trois implications [page 164]

$$(*) \qquad \begin{cases} \mathrm{a} & \Longrightarrow & \mathrm{b} & \\ \mathrm{a}'' & \Longrightarrow & \mathrm{a} & \text{si } \pi \geqslant \pi_1 \\ \mathrm{c} & \Longrightarrow & \mathrm{b} & \text{si } \pi = \pi^{\pi_0}. \end{cases}$$

Mais a $\Longrightarrow$ b est tautologique, en prenant $I = C_0/F$, puisqu'on sait que C_0/F est grande devant π_0 et que $F = \varinjlim_{i\in I} x_i$, pratiquement par définition de $\mathcal{M} = \underbrace{\mathrm{Ind}_\pi(C)}_{\simeq \mathrm{Ind}_\pi C_0} \subset C^\wedge$. Donc il reste à établir les deux implications conditionnelles de $(*)$. L'implication a$''$ $\Longrightarrow$ a pour $\pi \geqslant \pi_1$ s'établit comme dans 4.5.2 (cf. page 109), c'est essentiellement sorital. Reste à établir

$$(*) \qquad \text{c} \implies \text{b} \qquad \text{si } \pi = \pi^{\pi_0} .$$

Nous aurons besoin du résultat auxiliaire : [page 165]

Lemme 4.7.3. *Soit $\pi \geqslant \pi_0$ tel que $\pi^{\pi_0} = \pi$ (donc en fait $\pi > \pi_0$). Pour tout objet F de $\mathcal{M}$, on a*

$$F = \varinjlim_{i\in I} x_i \qquad (^{67}) . \tag{4.7.3.1}$$

Si de plus $\pi' > \pi$ et $F \in \mathrm{Ob}\,\mathrm{Filt}^{\pi'}$, alors on peut prendre I telle que

$$\mathrm{card}\, I \leqslant \pi'^{\pi} . \tag{4.7.3.2}$$

Commentary · Examples [ms. 164]

A pointwise singleton with a large presentation

Grothendieck wants the presheaf description to give a manageable test for accessibility. A thin category separates the pointwise size from the amount of data needed to present the presheaf, and makes the missing hypothesis in (a$''$)⇒(c$'$) visible without any algebraic complications.

Fix an infinite $\pi \geq \pi_0$, and let $\kappa > \pi$ be a regular cardinal. Take C to be the ordinal κ, with one arrow $\alpha \to \beta$ when $\alpha \leq \beta$. This is a small category in the working universe, and it is π^+-filtered: a family of at most π ordinals below κ has a supremum below κ. Write $h_\beta = C(-, \beta)$. Its value at α is a singleton if $\alpha \leq \beta$ and empty otherwise. Consequently

$$F = \varinjlim_{\beta<\kappa} h_\beta$$

is the terminal presheaf, with $F(\alpha) = \{*\}$ at every object. In particular $F \in \mathrm{Ind}_{\pi_0} C$, and condition (a$''$) holds even with the bound 1.

Yet there is no natural transformation $F \to h_\beta$: evaluation at $\beta + 1$ would require a map from a singleton to the empty set. Thus

$$\varinjlim_{\beta<\kappa} \mathrm{Hom}(F, h_\beta) = \varnothing, \qquad \mathrm{Hom}\left(F, \varinjlim_{\beta<\kappa} h_\beta\right) = \{1_F\}.$$

The same presentation witnesses failure of π^+-presentability both in $\widehat{C}$ and in $\mathrm{Ind}_{\pi_0} C$. Conditions (c$'$) and (c) fail. All arrows and colimits used here are ordinary categorical ones; there is no issue of a choice of model for the Ind completion.

The repair to Proposition 4.7.1 is to impose $\pi \geq \pi_1$ on the arrow (a$''$)⇒(c$'$), or to use condition (a), which bounds the whole category of elements. Under that size hypothesis, the six-way equivalence of Corollary 4.7.2(1) is unaffected. One should not extend that equivalence to small π merely because all the values of a presheaf happen to be small.

En effet, on a

$$F = \varinjlim_{j\in J} x_j \qquad \text{avec } J = C_0/F \qquad (^{68}) ,$$

avec J grande devant π_0. Soit alors

$$I = \begin{array}{l}\text{ensemble des sous-catégories } J' \text{ de } J \textit{ grandes devant } \pi_0,\\ \text{et telles que } \mathrm{card}\, J' \leqslant \pi.\end{array} \tag{4.7.3.3}$$

Je dis que I (ordonné par inclusion) *est grand devant* π ([69]). Cela résulte aussitôt du lemme 4.5.5, p. 113, (énoncé d'abord, de façon erronée, en supposant seulement $\pi > \pi_0$ et non $\pi^{\pi_0} = \pi$). Posons alors, pour tout $J' \in I$,

$$x_{J'} \;=\; \varinjlim_{j \in J'} x_j \;,$$

on a donc

$$x_{J'} \;\in\; \mathrm{Ob}\,\mathrm{Filt}^{\pi}$$

par définition de I et de Filt^{π}. D'autre part,

$$J' \;\longmapsto\; x_{J'} \;:\; I \;\longrightarrow\; \mathrm{Filt}^{\pi}$$

est un foncteur, donc [page 166]

$$\varinjlim_{J' \in I} x_{J'} \;\simeq\; \varinjlim_{j \in J} x_j \;\simeq\; x \;,$$

d'où la première assertion de 4.7.3. Reste la majoration de cardinaux pour $F \in \mathrm{Ob}\,\mathrm{Filt}^{\pi}$. Dans ce cas, quitte à remplacer C_0/F par une catégorie cofinale grande devant π_0, $\mathrm{card}\, J \leqslant \pi'$. On voit alors tout de suite que $\mathrm{card}\, I \leqslant \pi'^{\pi_0}$, ce qui est la majoration annoncée.

Nous pouvons maintenant prouver l'implication $(*)$, page 164, i.e.

$$\mathcal{M}_{\pi} \;\subset\; \mathrm{Filt}^{\pi} \qquad (\text{pour } \pi = \pi^{\pi_0}).$$

Soit donc F dans $\mathcal{M}_{\pi}$, i.e. π-accessible, écrivons F sous la forme (4.7.3.2), avec I grande devant π. Par définition de la π-accessibilité, appliqué à $F \xrightarrow{\mathrm{id}} F \simeq \varinjlim F_i$, on voit que F est un facteur direct d'un F_i, donc d'un objet de Filt^{π}. Faute de savoir que Filt^{π} est stable par facteurs directs, on ne peut en conclure que F est dans Filt^{π} (aussi je ne peux prouver c $\Longrightarrow$ b), mais seulement que F est dans Filt'^{π}, qui, lui, est stable par $\varinjlim$ grandes devant π_0, de cardinal π donné $> \pi_0$, donc aussi stable par facteurs directs. Cela achève la démonstration [page 167] de 4.7.1, et en même temps on obtient :

Commentary · Exposition [ms. 166]

Removing the retract without increasing the bound

Grothendieck's factorization of 1_F is the decisive accessibility argument, but it initially produces a retract of one stage. He explicitly stops short of the claimed implication (c)⇒(b). The missing step has a positive answer. It belongs to the retract-removal result of Makkai–Paré, Proposition 2.3.11; an accessible verification and a stronger closure statement are given by Chen (2021, Corollaries 4.13 and 4.15, including footnote 2). We give the elementary construction needed here, keeping track of the number of arrows.

Retract lemma. Let $\pi \geq \pi_0$ be infinite. If a presheaf H is a retract of

$$F = \varinjlim_{i \in I} h_{c_i}, \qquad I \text{ is } \pi_0^{+}\text{-filtered}, \qquad |\,\mathrm{Fl}\, I| \leq \pi,$$

then H has a presentation of the same form with an indexing category having at most π arrows. No closure property of C is needed.

Proof. Choose $s : H \to F$ and $r : F \to H$ with $rs = 1_H$, and put $e = sr$. Let $q_i : h_{c_i} \to F$ be the presentation maps. By Yoneda and pointwise computation of the colimit, for each i there are an object $t(i)$ of I and a morphism $v_i : c_i \to c_{t(i)}$ satisfying

$$q_{t(i)} h_{v_i} = e q_i.$$

67. les x_i dans Filt^{π}, I ensemble ordonné grand devant π.
68. où J peut aussi se remplacer par une catégorie cofinale dans [?] C_0/F grande devant π_0.
69. cf. démonstration 4.7.5, page 168-171.

Put $\alpha_i = rq_i$. Define J to have the same *labelled* objects as I. A morphism from label i to label j is an actual morphism $u : c_i \to c_j$ satisfying $\alpha_j h_u = \alpha_i$. Inside this category retain only the subcategory generated by the images of all arrows of I and by the arrows $v_i : i \to t(i)$. The latter are morphisms over H, since $re = r$. Finite compositions of an infinite set of at most π generators give at most π arrows, so $|\operatorname{Fl} J| \leq \pi$.

We check filteredness with all compatibility conditions included. Let $D : K \to J$ have at most π_0 arrows. For each vertex a of K, use the chosen map $v_{D(a)}$; choose an I-cocone on their targets and call its vertex k. This produces maps

$$w_a : c_{D(a)} \longrightarrow c_k, \qquad q_k h_{w_a} = s\alpha_{D(a)},$$

each a composite of a chosen v_i with an I-arrow. For an arrow $f : a \to b$ of K, the two maps $w_b D(f)$ and w_a have equal composites into F, because the α_i are a cocone over H. Equality in the filtered colimit

$$F(c_{D(a)}) = \varinjlim_{i \in I} C(c_{D(a)}, c_i)$$

is witnessed after an I-arrow out of k. There are at most π_0 such equalities. The π_0^+-filteredness of I gives a single further arrow $k \to l$ which makes all of them hold simultaneously: take a cocone on the diagram consisting of k, the chosen witnesses, and the arrows from k to them. The resulting maps $c_{D(a)} \to c_l$ are arrows of J and form the required cocone. This also handles the empty diagram, since I is nonempty. Thus J is π_0^+-filtered.

Finally the maps α_i induce $\varinjlim_J h_{c_i} \to H$. At an object c of C, every element of $H(c)$ lifts along s to $F(c)$ and therefore comes from some $C(c, c_i)$; the map is surjective. Suppose two such representatives $u : c \to c_i$ and $u' : c \to c_j$ have the same image in $H(c)$. After composition with v_i and v_j, their images in $F(c)$ are equal, since both are the image under s of that common element. Filteredness supplies a common I-stage where the two representatives agree. The arrows to that stage, and v_i, v_j, all belong to J, so the original representatives agree in the colimit over J. The map is injective at every c, hence an isomorphism. □

Apply the lemma to the retract produced on manuscript p. 166. At $\pi^{\pi_0} = \pi$ it proves the originally intended equality

$$\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi} = (\widehat{C})_{\pi} \cap \mathcal{M} = \mathcal{M}_{\pi}.$$

Thus the statement of Corollary 4.7.2(2) survives, while the proof actually written on these pages requires this additional argument. The construction uses the author's explicit permission that an indexing category need not be ordered; replacing it by a cofinal poset without a cardinal estimate would lose the point of the lemma.

Corollaire 4.7.4. *Si $\pi \geqslant \pi_0$ est tel que $\pi^{\pi_0} = \pi$, alors on a*

$$\mathrm{Filt}'^{\pi} \;=\; (\mathrm{Filt}^{\pi})^{\natural}\,, \tag{4.7.4.1}$$

i.e. Filt'^{π} *est formée des objets F de $\mathcal{M}$ qui sont facteurs directs d'un objet de* Filt^{π}.

En effet, comme $\mathrm{Filt}^{\pi} \subset \mathrm{Filt}'^{\pi}$, et que $(\mathrm{Filt}^{\pi})^{\natural} \subset \mathrm{Filt}'^{\pi}$, et que Filt'^{π} est stable par facteurs directs, on a $(\mathrm{Filt}^{\pi})^{\natural} \subset \mathrm{Filt}'^{\pi}$ pour tout $\pi \geqslant \pi_0$. Mais inversement, comme $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_{\pi}$, l'argument précédent montre que pour $\pi = \pi^{\pi_0}$, on a $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_{\pi} \subset (\mathrm{Filt}^{\pi})^{\natural}$, ce qui prouve 4.7.3.

Remarque 4.7.4.1 `[deux fois 4.7.4.1]`. Bien sûr, par 4.7.2, 1°, dès que $\pi \geqslant \pi_1$, on a même $\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi}$ (sans avoir à supposer $\pi = \pi^{\pi_0}$), donc *si* $\pi > \pi_0$ (ce qui sera la cas si $\pi_1 > \pi_0$, i.e. $\pi_1 \neq \pi_0$). Filt'^{π} étant stable par facteurs directs, Filt^{π} l'est aussi, (4.7.4.1) est satisfait trivialement. Mais si $\pi = \pi_1 = \pi_0$, on a $\mathrm{Filt}^{\pi} = \mathrm{Filt}^{\pi_0} = \mathrm{Filt}'^{\pi_0} =$ sous-catégorie des foncteurs *représentables* dans C (équivalent à C), et celle-ci n'est égale à $C^{\natural}$ dans $\mathcal{M}$ que si C est karoubienne, cf. … ci-dessous.

4.7.5. Pour que la démonstration de 4.7.1 soit complète, il me faudrait encore donner une démonstration de 4.5.5, p. 113, qui est le lemme technique clef pour établir le

p. 56

Commentary · Examples [ms. 167]

The initial level already contains idempotent splittings

Grothendieck's concern about retracts also reaches the endpoint $\pi = \pi_0$. Here the literal assertion that Filt^{π_0} consists only of representables is false under the definition just given. The obstruction is present in the smallest possible nontrivial idempotent category.

Let E have one object $*$ and endomorphism monoid $\{1, e\}$ with $e^2 = e$ and $e \neq 1$. Every diagram $K \to E$, of any size, admits a cocone whose components are e: for either possible arrow a of E, one has $ea = e$. Hence E is λ-filtered for every regular λ. It has no terminal object, since its unique object has two endomorphisms.

Take $C = E$. The representable h_* has value $\{1, e\}$. The natural endomorphism induced by e sends both elements to e, and its image is the singleton presheaf P. The colimit of the diagram $E \to \widehat{E}$ that sends the object to h_* and e to this endomorphism is P. It is a π_0^+-filtered presentation with just two indexing arrows, so $P \in \mathrm{Filt}^{\pi_0}$. It is not representable, since its value has one element rather than two.

This also clarifies the phrase "cofinale à e" in footnote 76. The unique functor $E \to e$ is final, as it is for any nonempty filtered category. This neither makes E equivalent to e nor supplies a final functor $e \to E$. In particular it does not say that the colimit of every diagram on E is one of its values. The relevant conclusion of the smallness assumption is a retract, as the next argument shows.

The corrected general statement is

$$\mathrm{Filt}^{\pi_0} = \mathrm{Filt}'^{\pi_0} = \mathcal{M}_{\pi_0} \simeq \mathrm{Kar}(C).$$

Indeed, if I is π_0^+-filtered and $|\mathrm{Fl}\, I| \leq \pi_0$, the identity diagram of I has a cocone $u_i : i \to i_*$. For any diagram $D : I \to \widehat{C}$, these arrows induce a map from its colimit L to $D(i_*)$. Its composite with $D(i_*) \to L$ is 1_L, by the colimit universal property. Thus a bounded presentation at the initial level gives a retract of a representable. Conversely every retract of a representable is the colimit of the two-arrow idempotent category just used. The same argument shows that this class is closed under further colimits of the prescribed size, proving the equality with Filt'^{π_0}.

For the equality with $\mathcal{M}_{\pi_0}$, write a π_0^+-presentable object as its defining π_0^+-filtered colimit of representables and factor its identity through one stage. Conversely representables are presentable and retracts preserve presentability. This is the ordinary categorical form of the idempotent-completion statement in Lurie (2009, Lemma 5.4.2.4). In particular the conclusion does not require C itself to be Karoubian. What Karoubian completeness provides is the further identification $\mathrm{Kar}(C) \simeq C$.

Lemme 4.7.5.1 (utilisé dans la démonstration de 4.7.3). *Soient π_0, π deux cardinaux infinis, avec $\pi \geqslant \pi_0$ et $\pi^{\pi_0} = \pi$ (donc $\pi > \pi_0$). Soit J une catégorie grande devant π_0. Alors l'ensemble I, ordonné par inclusion, des sous-catégories J' de J qui sont grandes devant π_0, et telles que* $\mathrm{card}\, J' \leqslant \pi$, *est grand devant π. (De plus, si* $\mathrm{card}\, J \leqslant \pi'$, *on a* $\mathrm{card}\, I \leqslant \pi'^{\pi}$.*)*

Il faut donc montrer le

Corollaire 4.7.5.2 ([70]) (c'est le lemme 4.5.5 non encore démontré). *Sous les conditions de 4.7.5, soit $K \subset \mathrm{Fl}J$ tel que* $\mathrm{card}\, K \leqslant \pi$. *Alors il existe $J' \in I$ tel que $K \subset J'$.*

On sait, π étant infini, que la catégorie K' engendrée par K est aussi de cardinal $\leqslant \pi$, donc on peut supposer que K "est" une sous-catégorie de J. On va construire une $J' \in I$ contenant K, en construisant par récurrence transfinie une suite croissante K_α de sous-catégories de J, avec $\mathrm{card}\, K_\alpha \leqslant \pi$, indexée par les ordinaux α tels que $\boxed{\mathrm{card}\, \alpha \leqslant \pi}$:

[page 169]

1°) $K_0 = K$.

2°) $K_\alpha = \bigcup_{\beta<\alpha} K_\beta$ ($= \varinjlim K_\beta$) si α est un ordinal limite (donc $\mathrm{card}\, K_\alpha \leqslant \pi$, puisque les $\mathrm{card}\, K_\beta \leqslant \pi$).

3°) $K_{\alpha+1}$ déduit de K_α de la façon suivante. Si K_α est grande devant π_0, on prend $K_{\alpha+1} = K_\alpha$ (donc, compte tenu de 2°, on aura $K_{\alpha'} = K_\alpha$ pour $\alpha' \geqslant \alpha$ – la construction transfinie s'arrête …). Sinon, $K_{\alpha+1}$ s'obtient ainsi :

70. Comparer avec la démonstration de 4.6.1.2.

a) pour toute partie A de cardinal $\leqslant \pi_0$ de $\mathrm{Ob}\, K_\alpha$, on choisit un majorant x_A dans J (on a envie de le prendre dans K_α, s'il y a un majorant dans K_α) ;

b) pour tout couple x, y d'objets de K_α, et toute partie de cardinal $\leqslant \pi_0$ de $\mathrm{Hom}_{K_\alpha}(x,y)$, on choisit une flèche $u_B : y \longrightarrow z_B$ dans J, qui égalise les $v_\beta \in B$ (et on prend cette flèche dans K_α, quand c'est possible) ;

c) on prend pour $K_{\alpha+1}$ la plus petite sous-catégorie contenant les id_{x_A} et les u_B.

Il faut vérifier que

$$\mathrm{card}\, K_{\alpha+1} \ \leqslant\ \pi\ .$$

Le nombre des choix possibles pour $A \in \mathfrak{P}_{\leqslant\pi_0}(\mathrm{Ob}\, J)$ est $\leqslant \pi^{\pi_0} = \pi$, le nombre des choix possibles pour $B \in \mathfrak{P}_{\pi_0}(\mathrm{Fl}\, J)$ est aussi $\leqslant \pi^{\pi_0} = \pi$, donc le nombre des flèches de la forme id_{x_A} ou u_B est $\leqslant \pi + \pi = \pi$. Mais alors la sous-catégorie $K_{\alpha+1}$ de J engendrée par cet ensemble de flèches est de cardinal $\leqslant 1$. Soit alors α_0 le plus petit ordinal tel que [page 170] p. 57

$$\mathrm{card}\, \alpha_0 \ >\ \pi_0\ ,$$

on a donc

$$\mathrm{card}\, \alpha_0 \ =\ \text{cardinal successeur de } \pi_0 \leqslant \pi\ ,$$

puisque $\pi^{\pi_0} = \pi$, d'où $\pi > \pi_0$ (car $\pi^{\pi_0} = \pi_0^{\pi_0} \geqslant 2^{\pi_0} > \pi_0$). Ainsi, α_0 fait partie des ordinaux α admissibles (i.e. tels que $\mathrm{card}\, \alpha \leqslant \pi$). Je dis que K_{α_0} *est grande devant* π_0 (ce qui prouvera 4.7.5.2, en prenant $J' = K_{\alpha_0}$). Cela résulte immédiatement du fait que

$$K_{\alpha_0} \ =\ \bigcup_{\alpha<\alpha_0} K_\alpha \qquad \text{(réunion } \textit{croissante}\text{)},$$

et que l'ensemble des $\alpha < \alpha_0$ est *grande devant* π_0 ([71]). Donc tout ensemble d'objets ou de flèches de K_{α_0}, de cardinal $\leqslant \pi_0$, est contenu dans un K_α avec $\alpha < \alpha_0$.

Cela implique, s'il s'agit d'un ensemble d'objets, qu'il y a un majorant commun dans $K_{\alpha+1}$, a fortiori dans K_{α_0}. S'il s'agit d'une partie d'un $\mathrm{Hom}_{K_\alpha}(x,y)$, qu'il y a un égalisateur $y \longrightarrow z$ dans $K_{\alpha+1}$, a fortiori dans K_{α_0}. Donc le critère PF_π 1,2 de 4.4.4 (page 89) est satisfait par K_{α_0}, ce qui achève la démonstration de 4.7.5.2. [page 171]

Commentary · Exposition [ms. 170]

Closing a small diagram under filteredness witnesses

Grothendieck is building a categorical version of a downward size argument: a prescribed small part of a filtered indexing category should lie inside a small filtered subcategory. The fixed-point assumption $\pi^{\pi_0} = \pi$ is exactly what pays for adjoining all witnesses of size at most π_0 at each step. The proof is sound after two pieces of construction data, implicit in the prose but absent from clause 3(c), are restored.

Let J be π_0^+-filtered and let K be a set of at most π arrows. First include their endpoints and identities and close under composition. This gives a subcategory K_0 with at most π arrows. At a successor stage retain *all* arrows of K_α. For each set $A \subseteq \mathrm{Ob}\, K_\alpha$ of cardinality at most π_0, choose an object z_A and arrows $a \to z_A$ for all $a \in A$, and adjoin the arrows as well as their target. Include the empty set here, so that nonemptiness is ensured even when K_0 is empty. For each pair of objects x, y and each family $B \subseteq K_\alpha(x,y)$ of cardinality at most π_0, adjoin an arrow $y \to z_B$ which coequalizes B. Then close under identities and finite composition. At a limit stage take the union.

There are at most $\pi^{\pi_0} = \pi$ choices of a small family of existing arrows or objects. Each contributes at most π_0 new arrows. Closing under composition still leaves at most π arrows. Thus all K_α with $|\alpha| \leq \pi$ have size at most π. The printed reference to subsets of $\mathrm{Ob}\, J$ and $\mathrm{Fl}\, J$ in the counting argument must refer to the current K_α; there is no bound on J itself. Likewise the printed final bound 1 is π.

71. expliciter ceci en un

Lemme. *Soit π_0 un cardinal, $\alpha_0 = \alpha_{\pi_0'}$ (π_0' le successeur de π_0) le plus petit ordinal tel que* $\mathrm{card}\, \alpha_0 > \pi_0$, *alors $I_{\alpha_0} = \{\alpha \mid \alpha < \alpha_0\}$ est grand devant π_0.*

Set $\delta = \pi_0^+$, regarded as its initial ordinal. It is regular, and $\delta \leq \pi$ because $\pi^{\pi_0} = \pi$ forces $\pi > \pi_0$. A family of at most π_0 arrows of K_δ is contained in some earlier K_α: take the supremum of their appearance stages, which is below δ. The next stage supplies the required common target or common coequalizer. These two properties imply the full cocone criterion. For a diagram of at most π_0 arrows, first send all vertices to one target; for each diagram arrow compare the two induced maps to that target. Coequalize each pair, send the resulting targets to one common target, and then coequalize the resulting family of parallel arrows out of the first common target. This produces one map which coequalizes every pair. Thus K_δ is π_0^+-filtered.

This proves the extension lemma. It also proves that the poset $\mathscr{I}$ of all such subcategories is π^+-directed: a family of at most π of them has union of arrow sets of cardinality at most π, and the extension construction supplies an upper bound. Every arrow of J lies in an object of $\mathscr{I}$. A compatible family of cocones on the restrictions to those subcategories is therefore exactly a cocone on all of J. Applying the universal property twice gives

$$\varinjlim_{J' \in \mathscr{I}} \varinjlim_{j \in J'} D(j) \;\simeq\; \varinjlim_{j \in J} D(j).$$

If $|\operatorname{Fl} J| \leq \pi'$, then $|\mathscr{I}| \leq (\pi')^\pi$, since every subcategory is determined by at most π arrows. This is the announced bound in Lemma 4.7.3; the exponent π_0 printed in its proof on p. 166 is not the bound established by this counting.

The same construction is the familiar mechanism for raising the index of accessibility; compare Vasey (2020, Theorem 3.4). In the higher categorical setting its poset form is used in Lurie (2009, Lemma 5.4.2.8 and Proposition 5.4.2.9). In each form the essential work is to retain enough witnesses while keeping their total size under control.

Corollaire 4.7.6 (de 4.7.1). *Pour tout cardinal $\pi \geqslant \pi_0$, on a*

$$(4.7.6.1) \qquad \underbrace{\mathrm{Filt}'^{\pi}}_{\substack{si\ \pi \geqslant \pi_1 \\ =\ \mathrm{Filt}^{\pi}}} \;\subset\; \mathcal{M}_\pi \;\subset\; \underbrace{\mathrm{Filt}^{\pi^{\pi_0}}}_{\substack{si\ \pi^{\pi_0} \geqslant \pi_1 \\ =\ \mathrm{Filt}^{\pi^{\pi_0}}}} \qquad (= (\mathrm{Filt}^{\pi^{\pi_0}})^\natural \text{ par cor. 4.7.4}),$$

donc si $\pi \geqslant \pi_1$, on a aussi

$$(4.7.6.2) \qquad \mathrm{Filt}^{\pi} \;\subset\; \mathcal{M}_\pi \;\subset\; \mathrm{Filt}^{\pi^{\pi_0}} \qquad (si\ \pi^{\pi_0} \geqslant \pi_1).$$

En effet, $\mathrm{Filt}'^{\pi} \subset \mathcal{M}_\pi$ n'est autre que l'implication b′ $\Longrightarrow$ c de 4.7.1, d'autre part, on a $\pi \leqslant \pi^{\pi_0}$, d'où

$$\mathcal{M}_\pi \;\subset\; \mathcal{M}_{\pi^{\pi_0}} \;=\; \mathrm{Filt}'^{\pi^{\pi_0}},$$

où la dernière égalité provient de $\mathcal{M}_{\pi'} = \mathrm{Filt}'^{\pi'}$ si $\pi'^{\pi_0} = \pi'$, i.e. de (4.7.2.3) (page 163), en faisant $\pi' = \pi^{\pi_0}$, compte tenu que $\pi'^{\pi_0} = (\pi^{\pi_0})^{\pi_0} = \pi^{\pi_0 \cdot \pi_0} = \pi^{\pi_0} = \pi$.

Proposition 4.7.7. *Considérons C, C_0, $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, $\pi_1 = \sup(\pi_0, \operatorname{card} \operatorname{Fl} C_0)$ comme précédemment. Pour tout cardinal $\pi \geqslant \pi_0$, soit $\mathcal{F}^\pi$ la sous-catégorie strictement pleine* Filt'^{π} *(resp. $(C^\wedge)_\pi \cap \mathcal{M}$, resp. $\mathcal{M}_\pi$) dans $\mathcal{M}$. Alors la filtration croissante $(\mathcal{F}^\pi)_{\pi \geqslant \pi_0}$ de $\mathcal{M}$ par les sous-catégories $\mathcal{F}^\pi$ satisfait les conditions suivantes.* [page 172]

a) Pour tout $\pi \geqslant \pi_0$, $\mathcal{F}^\pi$ est équivalente à une petite catégorie.

b) $\mathcal{M}$ satisfait à L_{π_0} *(i.e. est stable par $\varinjlim$ filtrantes grandes devant π_0), et pour tout $\pi \geqslant \pi_0$, $\mathcal{F}^\pi$ est stable par les limites filtrantes grandes devant π_0 et de cardinal $\leqslant \pi_0$ [?].* p. 58

c) Si $\pi \geqslant \pi_0$ est tel que $\boxed{\pi^{\pi_0} = \pi,}$ *alors pour tout F dans $\mathcal{M}$, on a un isomorphisme*

$$F \;=\; \varinjlim_{i \in I} x_i\,,$$

les x_i dans $\mathcal{F}^\pi$, et I catégorie ordonnée grande devant π_0. Si de plus $\pi' > \pi$ et $F \in \operatorname{Ob} F^{\pi'}$, on peut prendre I telle que

$$(4.7.7.1) \qquad \operatorname{card} I \;\leqslant\; \pi'^{\pi} \qquad \underline{si}\ \pi'^{\pi} \geqslant \pi_1. \qquad \text{[page 173]}$$

d) Si $\pi \geqslant \pi_0$, on a $\mathcal{F}^\pi \subset \mathcal{M}_\pi$, i.e. les objets de $\mathcal{F}^\pi$ sont π-accessibles.

N.B. Ce sont là exactement, à part d), les conditions a), b), c) des filtrations cardinales de SGA 4 I 9.7.12, à cela près seulement que dans c), on se restreint ici aux ordinaux π tels que $\pi^{\pi_0} = \pi$ ([72]). La condition supplémentaire d) est une "condition d'accessibilité", cf. plus bas.

Démonstration de 4.7.7. a) Comme on a

$$\mathrm{Filt}'^{\pi} \ \subset \ (C^\wedge)_\pi \cap \mathcal{M} \ \subset \ \mathcal{M}_\pi \ ,$$

on est réduit à prouver que $\mathcal{M}_\pi$ est équivalente à une petite catégorie. On est ramené au cas $\pi \geqslant \pi_1$, $\pi = \pi^{\pi_0}$, auquel cas on a $\mathcal{M}_\pi = \mathrm{Filt}^\pi$. En fait, on trouve :

Corollaire 4.7.7.1 `[deux fois 4.7.7.1]` ([73]). *Si $\pi \geqslant \pi_1$, on a*

$$\begin{cases} \operatorname{card} \text{réd}\, \mathrm{Filt}^\pi & \leqslant \ 2^\pi \\ \operatorname{card} \text{réd}\, \mathrm{Filt}'^{\pi} & \leqslant \ \operatorname{card} \text{réd}\, \mathcal{M}_\pi \ \leqslant \ 2^{(\pi^{\pi_0})} \qquad (= 2^\pi \text{ si } \pi^{\pi_0} = \pi). \end{cases}$$

La deuxième majoration résulte de la première et de

$$\mathcal{F}^\pi \ \subset \ \mathcal{M}_\pi \ \subset \ \mathrm{Filt}^{\pi^{\pi_0}} \qquad (\text{pour } \pi^{\pi_0} \geqslant \pi_1) \qquad ([74]).$$

Pour la première, on utilise la condition a$''$) de 4.7.1 (qui caractérise Filt^π pour $\pi \geqslant \pi_1$). Je passe sur les détails de la vérification.

Prouvons 4.7.2 b). La condition L_{π_0} est connue, reste la stabilité de $\mathcal{F}^\pi$. Dans le cas de Filt'^{π}, elle est acquise par définition. Dans les cas $C^\wedge_\pi \cap \mathcal{M}$ et $\mathcal{M}_\pi$, elle résulte de la stabilité de la notion de π-accessibilité par $\varinjlim$ de cardinal $\leqslant \pi$, soit dans $C^\wedge$, soit dans $\mathcal{M}$ (compte tenu que $C^\wedge$ et $\mathcal{M}$ ont une famille génératrice C formée d'objets π_0-accessibles, donc π-accessibles). [page 174]

Prouvons c) : c'est essentiellement le lemme 4.7.3, compte tenu que l'on a

$$\mathrm{Filt}^\pi \ \subset \ \mathcal{F}^\pi \ ,$$

sauf qu'il faut faire attention à la majoration de cardinaux, $\operatorname{card} I \leqslant \pi'^{\pi}$. Mais si $F \in \operatorname{Ob} \mathcal{F}^{\pi'}$, comme par (4.7.6.1) p. 59

$$\mathcal{F}^{\pi'} \ \subset \ \underbrace{\mathcal{M}_{\pi'}}_{\subset \mathcal{M}_{\pi'^\pi} \subset \mathrm{Filt}'^{\pi'^\pi}} \ \subset \ \mathrm{Filt}'^{\pi'^{\pi_0}},$$

donc a fortiori

$$\mathcal{F}^{\pi'} \ \subset \ \mathrm{Filt}^{\pi'^\pi} \ \underbrace{=}_{\text{si } \pi'^\pi \geqslant \pi_1} \ \mathrm{Filt}^{\pi'^\pi},$$

d'où, par 4.7.3, avec π' remplacé par $\pi'^\pi = \pi''$, la possibilité de prendre I avec

$$\operatorname{card} I \ \leqslant \ \pi''^\pi \ = \ (\pi'^\pi)^\pi \ = \ \pi'^{\pi \cdot \pi} \ = \ \pi'^\pi,$$

ce qui achève la démonstration.

Remarque 4.7.7.2. J'ai été obligé, dans l'énoncé de la condition c), de faire intervenir un deuxième cardinal π_1, et ceci faut de savoir si, pour π'' tel que $\pi'' = \pi''^{\pi_0}$, $\mathrm{Filt}^{\pi''}$ est stable par facteurs directs. (Il faudrait, pour bien faire, soit prouver qu'il est stable, donc qu'on a dans 4.7.1 c $\Longrightarrow$ b, i.e. $\mathcal{M}_\pi \subset \mathrm{Filt}^\pi$ (et non seulement c $\Longrightarrow$ b$'$, i.e. $\mathcal{M}_\pi \subset \mathrm{Filt}'^{\pi}$) si $\pi = \pi^{\pi_0}$, ou bien faire un contre-exemple!) Cet ingrédient un peu étrange, on sera hélas obligé de le traîner dans la définition des filtrations cardinales généralisées, si on ne veut s'interdire de regarder dans le cas présent $(\mathcal{F}^\pi)_{\pi \geqslant \pi_0}$ comme une telle filtration, et ne s'autoriser que de regarder $(\mathcal{F}^\pi)_{\pi \geqslant \pi_1}$ comme telle, ce qui me paraîtrait ridicule. Pratiquement (même si théoriquement [page 175]

72. et *de plus*, dans la majoration (4.7.7.1), aux cardinaux $\pi' > \pi$ tels que l'on ait de plus $\pi'^\pi \geqslant \pi_1$ (ce qui est automatique si on a $\pi \geqslant \pi_1$, ce qui est le cas, vu que $\pi = \pi^{\pi_0} \geqslant 2^{\pi_0}$, si on a $2^{\pi_0} \geqslant \pi_1$.)

73. Comparer avec 4.7.19.

74. Cf. (4.7.6.2).

l'introduction de π_1 dans la description d'une filtration cardinale généralisée était bel et bien nécessaire) on n'aura guère des cas où il faille faire mention de π_1 dans la condition c. En effet, $\pi \geqslant \pi_0$ et $\pi^{\pi_0} = \pi$ impliquent $\pi \geqslant 2^{\pi_0}$, et dès lors $\pi'^{\pi} \geqslant 2^{(2^{\pi_0})}$. Si donc $\pi_1 \leqslant 2^{(2^{\pi_0})}$, i.e. $\operatorname{card} C_0 \leqslant 2^{(2^{\pi_0})}$, alors la condition $\pi^{\pi'} \geqslant \pi_1$ dans c) est automatiquement satisfaite, et il n'y a donc pas à la mentionner. Or il est bien rare qu'on ait à faire à des petites catégories C_0, dont le cardinal soit $>$ puissance du continu c, et a fortiori, telle que $\operatorname{card} C_0 > 2^c$. Si par [page 176]
contre $\operatorname{card} C_0 \leqslant 2^c$, comme $2^c \leqslant 2^{(2^{\pi_0})}$ (puisque $\pi_0 \geqslant \aleph_0$), on aura bien $\pi_1 \leqslant 2^{(2^{\pi_0})}$, et on est tranquille.

Commentary · Later developments [ms. 175]

The bounded closure question has a positive answer

Grothendieck introduces the second threshold π_1 because he has not yet removed retracts or shown that a bounded iteration can be replaced by one bounded presentation. The general closure result now available answers precisely this difficulty. For infinite $\pi > \pi_0$, set $\lambda = \pi_0^+$ and $\mu = \pi^+$. Then Chen (2021, Corollary 4.13) identifies the closure of representables under μ-small λ-filtered colimits with the presheaves admitting a single such presentation. In the notation of these pages this says

$$\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi} \qquad (\pi > \pi_0).$$

The endpoint follows from the idempotent calculation above. The fixed-point presentability statement is the Makkai–Paré result recovered in Chen's Corollary 4.15. This answers the question on pp. 175–176 affirmatively; it is not an open problem of the current theory.

The distinction between the two arguments remains useful. Retract closure alone repairs the inference in the proof of 4.7.1 and suffices at $\pi^{\pi_0} = \pi$. The statement about arbitrary repeated colimits also resolves $\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi}$ when no fixed-point condition holds. One cannot obtain the latter merely by writing a formal double colimit: a diagram of already presented objects has transition maps which need not have been specified at chosen presentation stages. The bounded closure theorem supplies the necessary control of these maps.

These improvements do not make every cardinal useful for $\mathcal{M}$. Equality of the two *presentation* filtrations is distinct from equality with the *intrinsic* filtration $\mathcal{M}_\pi$. The latter compares the ability to lift morphisms out of an object with the size of a presentation inside the chosen Ind completion. The arithmetic condition in the small-subcategory construction still has work to do there.

Définition 4.7.8. Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie. On appelle $\mathfrak{U}$-*filtration cardinale généralisée* (ou simplement filtration cardinale généralisée, quand $\mathfrak{U}$ est sous-entendu) la donnée d'un cardinal infini π_0, et d'une filtration $(\mathcal{F}^\pi)_{\pi \geqslant \pi_0}$ de $\mathcal{M}$ par des sous-catégories strictement pleines $\mathcal{F}^\pi$, indexées par les $\mathfrak{U}$-cardinaux $\geqslant \pi_0$, et satisfaisant les conditions a) b) c) énoncées dans 4.7.7, où dans c) on pose

$$\pi_1 \;=\; \sup(\pi_0, \operatorname{card} \text{réd}\, \mathcal{F}^{\pi_0})\,. \tag{4.7.8.1}$$

(Donc si $\operatorname{card} \text{réd}\, \mathcal{F}^{\pi_0} \leqslant 2^{(2^{\pi_0})}$, il n'y a pas à tenir compte de la condition $\pi'^{\pi} \geqslant \pi_1$, cf. 4.7.7.1.) On dit que la filtration cardinale généralisée (fcg) est *accessible*, si elle satisfait de plus la condition d). On dit qu'elle est *canonique* si on a même

$$\mathcal{F}^\pi \;=\; \mathcal{M}_\pi \tag{4.7.8.2}$$

pour tout $\pi \geqslant \pi_0$.

Proposition 4.7.9. *Soient $(\mathcal{F}^\pi)_{\pi \geqslant \pi_0}$ une fcg sur la $\mathfrak{U}$-catégorie $\mathcal{M}$, et $\pi > \pi_0$ un cardinal tel que $\pi^{\pi_0} = \pi$. Alors on a* p. 60 [page 177]

$$\begin{cases} \mathcal{M}_\pi \subset \mathcal{F}^\pi \quad \textit{(si } \pi = \pi^{\pi_0}\textit{)}, \\ \textit{donc } \mathcal{M}_\pi = \mathcal{F}^\pi \textit{ si de plus la fcg est } \text{accessible}. \end{cases} \tag{4.7.9.1}$$

Commentary · Exposition [ms. 176]

Reading the generalized filtration axioms

Grothendieck's purpose is to retain only the properties of the preceding constructions that are needed to recover the category from its small objects. Two subscripts in the printed statement of 4.7.7 obscure that purpose. In (b), the closure bound is printed π_0 followed by the editors' question mark; the proof on p. 174 uses π. In (c), the presenting poset is printed large relative to π_0; Lemma 4.7.3 gives a poset large relative to π, and the factorization of a π-accessible object's identity on p. 177 requires this stronger assertion. We retain the edition's text, but the following discussion of its consequences uses those two repaired conditions explicitly.

In modern notation an accessible generalized filtration thus consists of increasing, essentially small, replete full subcategories $\mathcal{F}^\pi$, each consisting of π^+-presentable objects, with the specified bounded closure and generation properties. At a fixed point $\pi^{\pi_0} = \pi$, every object has a π^+-filtered presentation by objects of $\mathcal{F}^\pi$. An identity map out of a π^+-presentable object then factors through one stage, producing a retract. Closure under the permitted colimits supplies its splitting, and hence

$$\mathcal{F}^\pi = \mathcal{M}_\pi.$$

This is the content of 4.7.9. The hypothesis on the presenting index cannot be weakened to mere π_0^+-filteredness in this step: presentability at the larger cardinal says nothing about preservation of an arbitrary less-filtered colimit.

The cardinal estimates in 4.7.7.1 express essential smallness quantitatively. Write $\rho \geq \pi_1$. A presheaf with at most ρ elements at each object of a skeleton C_0 can be described by sets chosen inside ρ and functions assigned to the arrows of C_0. There are at most 2^ρ choices: $|\operatorname{Fl} C_0| \leq \rho$, there are at most 2^ρ functions between subsets of ρ, and $(2^\rho)^\rho = 2^\rho$. Between two such presheaves there are at most

$$(\rho^\rho)^{|\operatorname{Ob} C_0|} \leq 2^\rho$$

natural transformations. Consequently a skeleton of this full category has at most 2^ρ arrows. Taking $\rho = \pi$ gives the first estimate for Filt^π; taking $\rho = \pi^{\pi_0}$ gives the estimate for $\mathcal{M}_\pi$ after the inclusion of 4.7.6. This proves the details omitted on p. 173.

Finally, for any $\pi \geq \pi_0$, let $\rho = \pi^{\pi_0}$. Since $\rho^{\pi_0} = \rho$, monotonicity of presentability yields

$$\mathcal{F}^\pi \subseteq \mathcal{M}_\pi \subseteq \mathcal{M}_\rho = \mathcal{F}^\rho.$$

The equality $\mathcal{M}_\pi = \mathcal{M}_\rho$ printed in the proof of 4.7.10 must be an inclusion. Even in sets, increasing the cardinal bound admits genuinely larger objects. The conclusion (4.7.10.1) has the correct direction.

Démonstration ([75]). Appliquant la condition c) des fcg à un $F \in \operatorname{Ob}\mathcal{M}_\pi$, on trouve que F est facteur direct d'un $x_i \in \operatorname{Ob}\mathcal{F}^\pi$. Comme $\mathcal{F}^\pi$ est stable par $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$, et que *de plus* $\pi > \pi_0$, on conclut que :

Lemme 4.7.9.1 `[deux fois 4.7.9.1]`. *Si $\pi > \pi_0$ ([76]), $\mathcal{F}^\pi$ est stable par facteurs directs.*

D'où résulte que $F \in \mathcal{F}^\pi$, d'où (4.7.9.1).

Corollaire 4.7.10. *Supposons la fcg accessible. Pour tout cardinal $\pi \geqslant \pi_0$, on a*

$$\mathcal{F}^\pi \ \subset\ \mathcal{M}_\pi \ \subset\ \mathcal{F}^{\pi^{\pi_0}}\ (=\ \mathcal{M}_{\pi^{\pi_0}})\,. \tag{4.7.10.1}$$

En effet, $\mathcal{F}^\pi \subset \mathcal{M}_\pi$ par définition de fcg accessibles, et $\mathcal{M}_\pi = \mathcal{M}_{\pi^{\pi_0}}$ (puisque $\pi \leqslant \pi^{\pi_0}$), or $\mathcal{M}_{\pi^{\pi_0}} = \mathcal{F}^{(\pi^{\pi_0})}$ en vertu de (4.7.9.1) appliqué à $\pi' = \pi^{\pi_0}$ au lieu de π (vu que $\pi'^{\pi_0} = \pi'$), d'où (4.7.10.1). On notera que cette inclusion généralise (4.7.9.1), elle donne $\mathcal{F}^\pi = \mathcal{M}_\pi$ si $\pi = \pi^{\pi_0}$.

4.7.11. Il me semble que les seules filtrations cardinales généralisées utiles sont celles qui sont *accessibles.* Par la suite, je vais me borner à ce cas. Comme alors $\mathcal{F}^\pi \subset \mathcal{M}_\pi$, on en conclut que le foncteur canonique [page 178]

75. `[Dans ce qui suit, $\mathcal{F}^\pi$ a parfois été écrit $\mathcal{F}_\pi$, souvent corrigé en $\mathcal{F}^\pi$ par l'auteur. Nous écrivons $\mathcal{F}^\pi$ partout.]`

76. Mais $\mathcal{F}^{\pi_0}$ n'est pas forcément stable par facteurs directs, comme on voit en prenant $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, C une petite catégorie non karoubienne, et la filtration cardinale pour les Filt'^π – on note que $\mathrm{Filt}'^{\pi_0} = \mathrm{Filt}^{\pi_0} \simeq e$, vu qu'une catégorie grande devant π_0 et de cardinal $\leqslant \pi_0$ est cofinale à e.

(4.7.11.1) $$\mathrm{Ind}_\pi(\mathcal{F}^\pi) \hookrightarrow \mathcal{M}$$

prolongeant l'inclusion $\mathcal{F}^\pi \subset \mathcal{M}$, de façon à commuter aux $\varinjlim$ grandes devant π, est *pleinement fidèle.* De plus, lorsque $\pi^{\pi_0} = \pi$, la condition c) de fcg nous dit entre autres que ce foncteur est essentiellement surjectif, donc que c'est une *équivalence de catégories* :

(4.7.11.2) $$\mathrm{Ind}_\pi(\mathcal{F}^\pi) \xrightarrow{\sim} \mathcal{M} \qquad (\text{si } \pi = \pi^{\pi_0}).$$

Proposition 4.7.12. *Soit $(\mathcal{F}^\pi)_{\pi\geqslant\pi_0}$ une fcg accessible (fcga) sur la $\mathfrak{U}$-catégorie $\mathcal{M}$, et soit π un cardinal $\geqslant \pi_0$. Les conditions suivantes sont équivalentes.*

a) Le foncteur pleinement fidèle (4.7.11.1) est essentiellement surjectif, i.e. est une équivalence de catégories.

b) Pour tout $F \in \mathrm{Ob}\,\mathcal{M}$, $\mathcal{F}^\pi/F$ est une catégorie filtrante et grande devant π.

Quand ces conditions sont satisfaites, et si $\pi > \pi_0$, on a p. 61

(4.7.12.1) $$\mathcal{F}^\pi = \mathcal{M}_\pi .$$

Démonstration. L'équivalence de a) et b) résulte aussitôt de 4.4.2 et de la définition des catégories grandes devant π (p. 81). Que ces conditions impliquent $\mathcal{F}^\pi = \mathcal{M}_\pi$, i.e. $\mathcal{M}_\pi \subset \mathcal{F}^\pi$ [page 179] dans le cas où $\pi > \pi_0$, se voit comme (4.7.9.1) en utilisant le lemme 4.7.9.1.

Définition 4.7.13.

1°) Un cardinal $\pi \geqslant \pi_0$ est dit *cardinal utile* pour la fcga $(\mathcal{F}^\pi)_{\pi\geqslant\pi_0}$, s'il satisfait les conditions équivalentes a) et b) de 4.7.12, et si de plus dans le cas où $\pi = \pi_0$, on a $\mathcal{F}^\pi = \mathcal{M}_\pi$. (Donc si π est un cardinal utile, on a toujours $\mathcal{F}^\pi = \mathcal{M}_\pi$.) Dans le cas contraire, on dit que π est un *cardinal superflu* (pour le fcga donnée).

2°) Un cardinal π est dit *régulier* pour la fcg donnée, s'il est utile, et si de plus la majoration de cardinaux énoncée dans (4.7.7.1) est valable.

4.7.14 Ainsi, tous les cardinaux $\pi \geqslant \pi_0$ tels que $\pi^{\pi_0} = \pi$ sont utiles, et même réguliers pour la filtration cardinale [générale**isée**] donnée. Notons que si tous les cardinaux $\pi \geqslant \pi_0$ sont utiles, alors on a $\mathcal{F}^\pi = \mathcal{M}_\pi$ pour tout $\pi \geqslant \pi_0$, donc la fcga est canonique. Notons aussi que dans tous les cas, si $(\mathcal{F}^\pi)_{\pi\geqslant\pi_0}$ est une fcga, alors $(\mathcal{M}_\pi)_{\pi\geqslant\pi_0}$ en est une aussi.
En effet, la condition a) des fcg (cf. 4.7.7) résulte de la même condition pour $(\mathcal{F}^\pi)$, et de [page 180] (4.7.10.1), $\mathcal{M}_\pi \subset \mathcal{F}^{\pi^{\pi_0}}$. La condition b) est une propriété générale de la π-accessibilité, compte tenu que $(\mathcal{F}^{\pi_0})_0$ est une petite sous-catégorie génératrice formée d'objets π_0-accessibles de $\mathcal{M}$. La condition d) est satisfaite tautologiquement, et il reste à vérifier la condition c). Mais on a vu que pour $\pi = \pi^{\pi_0}$, on a $\mathcal{M}_\pi = \mathcal{F}^\pi$ (4.7.9.1), donc la condition c) pour $(\mathcal{M}_\pi)$ résulte de la même condition pour $(\mathcal{F}^\pi)$. Ainsi, on trouve :

Commentary · Exposition [ms. 179]

Recovering the category at a useful cardinal

Grothendieck's useful cardinal is a cardinal at which the chosen level of the filtration actually presents the whole category. This is stronger than the assertion that its objects are small. The distinction explains both the comparison functor in 4.7.11 and the later preference for the canonical filtration.

Let $A \subseteq \mathcal{M}_\pi$ be an essentially small full subcategory, and assume $\mathcal{M}$ admits π^+-filtered colimits. Its extension

$$T : \mathrm{Ind}_\pi A \longrightarrow \mathcal{M}$$

is fully faithful. Indeed, for presentations $X = \varinjlim_i a_i$ and $Y = \varinjlim_j b_j$ over π^+-filtered categories,

$$\mathrm{Hom}_{\mathcal{M}}(TX, TY) \simeq \varprojlim_i \varinjlim_j \mathrm{Hom}_A(a_i, b_j),$$

using the universal property in the first variable and presentability in the second. This is also the Hom formula in the Ind category. The extension has all of $\mathcal{M}$ as its essential image precisely when every object has such a presentation.

The equivalent condition in 4.7.12 uses the canonical presentation. If A/F is π^+-filtered and the restricted Yoneda functor determined by A is fully faithful, then the canonical map

$$\varinjlim_{(a\to F)\in A/F} a \longrightarrow F$$

is an isomorphism. To see this, apply $\mathrm{Hom}(a_0, -)$ for $a_0 \in A$: presentability moves it inside the colimit, and the category-of-elements calculation identifies the resulting set with $\mathrm{Hom}(a_0, F)$. Full faithfulness of restricted Yoneda reflects the isomorphism. If T is already an equivalence, the same category-of-elements description proves the converse immediately. However, density of a fixed-point level does not by itself imply density of every smaller level. The stated generalized-filtration axioms do not supply that missing hypothesis. The next block exhibits a counterexample to (b)⇒(a) in the proposition as printed; the repair is to require the level A to be dense, or to require its canonical cocones to be colimit cocones.

At a useful level every π^+-presentable object is a retract of a member of A. Taking $A = \mathcal{F}^\pi$ and using its retract closure gives $\mathcal{F}^\pi = \mathcal{M}_\pi$. This explains the equality in the endpoint clause of Definition 4.7.13, with usefulness understood through the realization equivalence rather than the faulty bare slice criterion; it is not an additional form of cardinal arithmetic. Nor is "regular for the filtration" the usual set-theoretic regularity of the cardinal π. It means useful together with a specified quantitative presentation bound. The ordinary regular filtering cardinal in all these statements is π^+, regardless of the cofinality of π itself.

Replacing $\mathcal{F}^\pi$ by $\mathcal{M}_\pi$ preserves the generalized filtration. Essential smallness follows from $\mathcal{M}_\pi \subseteq \mathcal{F}^{\pi^{\pi_0}}$. Bounded closure is the general fact that π^+-presentables are closed under colimits of diagrams having at most π arrows whenever those colimits exist. For the quantitative part, if $F \in \mathcal{M}_{\pi'}$, first use

$$F \in \mathcal{F}^{(\pi')^{\pi_0}}.$$

Then apply the old generation bound at the fixed-point level π. The new index has cardinal at most

$$\big((\pi')^{\pi_0}\big)^{\pi} = (\pi')^{\pi}.$$

This supplies the small substitution omitted from the proof of 4.7.15: equality of the two filtrations at the generating level π alone does not identify their arbitrary target levels π'.

Commentary · Development (commentators') [ms. 179]

A filtered slice need not be a presentation

Grothendieck wants to recognize a useful level by its slices, so that the Ind realization can be checked without choosing presentations. This recognition needs a density hypothesis. The ordinary category-of-elements theorem applies to a presheaf on the chosen level; identifying its realization with the original object is a separate assertion. The following example shows that the axioms stated in 4.7.7–4.7.8 do not imply it. We checked the general recognition criteria for Ind completions cited above; none dispenses with the generation requirement. The example is supplied as a local audit result, without a priority claim.

Counterexample to the slice criterion in 4.7.12 [ours]. For every infinite π_0, there is an accessible generalized filtration satisfying even the repaired strong forms of (b) and (c), such that $\mathcal{F}^{\pi_0}/X$ is π_0^+-filtered for every X, but $\mathrm{Ind}_{\pi_0}(\mathcal{F}^{\pi_0}) \to \mathcal{M}$ is not essentially surjective.

Proof. Let $\mathcal{M} = \mathrm{Ens}$, let $\theta = 2^{\pi_0}$, and define

$$\mathcal{F}^\pi = \begin{cases} \{\varnothing\}, & \pi_0 \le \pi < \theta, \\ \mathrm{Ens}_{\le\pi}, & \pi \ge \theta. \end{cases}$$

Take replete full subcategories; the first is equivalent to the one-object category. This is an increasing exhaustive filtration. Each level is essentially small. It consists of π^+-presentable sets. Sets have all the required filtered colimits. A filtered colimit of empty sets is empty, while a colimit indexed by a

category with at most π arrows of sets of size at most π again has size at most π. Thus condition (b), even with the intended bound π, holds.

If $\pi^{\pi_0} = \pi$, then necessarily $\pi \geq 2^{\pi_0} = \theta$. Every set X is the union of its subsets of cardinality at most π, indexed by the π^+-directed poset $[X]^{\leq\pi}$. If $X \in \mathcal{F}^{\pi'}$ with $\pi' > \pi$, the indexing poset has cardinal at most $(\pi')^\pi$. The threshold determined by $\mathcal{F}^{\pi_0}$ is $\pi_1 = \pi_0$, so its proviso is automatic. This verifies condition (c), with the stronger, intended π^+-filtered index. All accessible generalized-filtration axioms are satisfied.

For every set X there is exactly one map $\varnothing \to X$. Thus $\mathcal{F}^{\pi_0}/X$ is a one-object one-arrow category and is π_0^+-filtered. But a filtered colimit of copies of $\varnothing$ remains $\varnothing$. The realization $\mathrm{Ind}_{\pi_0}(\mathcal{F}^{\pi_0}) \to \mathrm{Ens}$ has only the empty set in its essential image, and is not an equivalence. □

The correction is substantive. A slice may be filtered because the chosen level sees almost nothing. Requiring the level to be dense restores the proof in the preceding block. Alternatively replace condition (b) by the conjunction that the slice is π^+-filtered and that its canonical diagram has colimit F. The later conclusions about useful cardinals should use the equivalence in condition (a); the counterexample does not affect the fixed-point levels, where the generation axiom supplies actual presentations.

Proposition 4.7.15. *Si $(\mathcal{F}^\pi)_{\pi\geqslant\pi_0}$ est une fcga sur la $\mathfrak{U}$-catégorie $\mathcal{M}$, il en est de même de $(\mathcal{M}_\pi)_{\pi\geqslant\pi_0}$. De plus, tout cardinal utile (resp. régulier) pour la première filtration, l'est pour la seconde (appelée la fcg* canonique associée *à la filtration cardinale* `[généralisée]` *donnée).*

La dernière assertion résulte du fait que si π est utile pour $(\mathcal{F}^\pi)$, alors on a $\mathcal{F}^\pi = \mathcal{M}_\pi$.

4.7.16. Il me semble qu'on peut dire que la fcg canonique associée à une fcga donnée est [page 181] toujours "meilleure" que celle-ci (si celle-ci n'est canonique, i.e. si les deux ne sont égales), à cause des deux faits suivants :

a) justement parce qu'elle est *canonique*, i.e. ne dépend d'aucun autre choix que celui du seul cardinal π_0, et

b) parce qu'il y a a priori plus des cardinaux utiles et de cardinaux réguliers pour la fcg canonique.

Donc au total, il me semble que les filtrations cardinales `[généralisées]` les seules utiles sont celles qui sont canoniques.

Notons qu'une filtration cardinale (au sens de SGA 4 I 9, que je conserve ici) qui est de plus p. 62 *accessible* (i.e. $\mathcal{F}^\pi \subset \mathcal{M}_\pi$ pour tout $\pi \geqslant \pi_0$), n'est autre qu'une fcga canonique, telle que *tous* les cardinaux sont réguliers (a fortiori utiles) pour ladite filtration. Je présume (sans avoir cependant construit d'exemple) que les filtrations cardinales `[généralisées]` canoniques des catégories de la forme $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, C une petite catégorie *karoubienne* (pour que π_0 soit un cardinal utile) ne sont pas forcément des fc (non généralisées, i.e. au sens SGA), i.e. je présume qu'il arrive qu'il y ait des cardinaux $\pi \geqslant \pi_0$ non réguliers, et même superflus.

Il me faut enfin étudier ce qui se passe quand on change le cardinal initial π_0 d'une fcga. [page 182]

Commentary · Present state [ms. 181]

Useful cardinals and the accessibility spectrum

Grothendieck suspects that an accessible category may have larger nonuseful cardinals. The relevant modern invariant is its *accessibility spectrum*. The sharp relation $\kappa \lhd \lambda$ between regular cardinals requires every set of size below λ to have a cofinal family of its subsets of size below κ, of cardinality below λ. It controls the general raising theorem. The equation $\pi^{\pi_0} = \pi$ implies $\pi_0^+ \lhd \pi^+$, since a set of size at most π has at most π subsets of size at most π_0. A mere inequality between cardinals does not give this control.

The example in Vasey (2020, Remark 3.7 and Example 3.8), attributed there to Adámek–Rosický, settles the existence question in 4.7.16. We give the details, including the explicit successor ranks and the unbounded choice needed for 4.8.6(4). The latter is an elementary verification of the cited criterion, not a priority claim.

Fix $\kappa = \aleph_1$, and let $\mathcal{D}$ be the category of nonempty κ-directed posets and monotone maps. For every regular $\lambda \geq \kappa$, its λ-filtered colimits are computed as filtered colimits of posets: representatives

and order relations can be compared at a common stage, and fewer than κ elements acquire an upper bound at one stage. We first verify that

$$P \text{ is } \lambda\text{-presentable in } \mathcal{D} \quad \Longleftrightarrow \quad |P| < \lambda.$$

For the forward implication, adjoin a new greatest element $\top$ to P. The resulting poset $P^{\top}$ is the λ-directed union of the subposets $S \cup \{\top\}$ for $S \subseteq P$, $|S| < \lambda$. Every stage belongs to $\mathcal{D}$, because it has a greatest element. If P is presentable, the inclusion $P \hookrightarrow P^{\top}$ factors through one stage. Its image then forces $P \subseteq S$, proving $|P| < \lambda$. Conversely, when $|P| < \lambda$, lift a map from P into a λ-filtered colimit by choosing representatives for its elements and witnesses for all its order relations. There are fewer than λ choices. A common stage makes them into a monotone map. Fewer than λ equality witnesses likewise prove essential uniqueness. This is exactly preservation of the colimit by $\mathrm{Hom}(P, -)$.

Every object P of $\mathcal{D}$ is a κ-directed union of its subposets having fewer than κ elements and a greatest element. Indeed, the union of fewer than κ such subposets has fewer than κ elements; adjoin an upper bound in P to obtain a larger subposet of the same kind. These subposets cover P. Their isomorphism classes form a set and they are κ-presentable by the criterion just proved. Thus $\mathcal{D}$ is $\aleph_1$-accessible. An idempotent on one of these presentables splits through its image, which is again κ-directed and has fewer than κ elements. Taking a skeleton C of the presentables therefore gives a small idempotent-complete category with

$$\mathcal{D} \simeq \mathrm{Ind}_{\aleph_0} C.$$

This meets the Karoubian-base requirement in 4.7.16.

Now let $\theta > \kappa$ be any singular cardinal of countable cofinality, and put $\lambda = \theta^{+}$. We claim that the inclusion poset $[\theta]^{<\kappa}$ has no cofinal subset of cardinality at most θ. Suppose a candidate family is $\mathscr{A} = \bigcup_{n<\omega} \mathscr{A}_n$, where $|\mathscr{A}_n| \le \theta_n < \theta$, $\theta_n \ge \kappa$, and $\sup_n \theta_n = \theta$. Since every member has cardinality below κ, the union of $\mathscr{A}_n$ has cardinality at most θ_n. Choose $a_n \in \theta$ outside that union. The countable set $\{a_n : n < \omega\}$ lies in $[\theta]^{<\kappa}$ but is contained in no member of $\mathscr{A}$, a contradiction.

The poset $Q = [\theta]^{<\kappa}$ itself belongs to $\mathcal{D}$. If it were a λ-filtered colimit of λ-presentables, each stage would have at most θ elements. For each $a < \theta$, choose a stage representing $\{a\} \in Q$. There are fewer than λ such choices, so one later stage has image $Y \subseteq Q$ containing all these singletons. A monotone image of a κ-directed poset is κ-directed. Therefore Y is cofinal in Q: any subset of θ of size below κ is contained in an upper bound of its singletons in Y. But $|Y| \le \theta$, contradicting the preceding paragraph. Thus $\mathcal{D}$ is not θ^{+}-accessible.

For a first explicit pair one may take $\theta = \aleph_\omega$. Singular cardinals of countable cofinality are unbounded, so this *one* category has arbitrarily large nonuseful manuscript cardinals $\pi = \theta$, although its initial cardinal $\pi_0 = \aleph_0$ is useful. Moreover its small dense subcategory C remains formed of θ^{+}-presentables and it has θ^{+}-filtered colimits. Hence it also gives the dense-presentable-generator separation requested in 4.8.6(1). Questions about the presentability ranks or internal sizes of individual objects are different; compare Lieberman et al. (2019, Definitions 2.5 and 2.10).

Commentary · Exposition [ms. 181]

Usefulness already gives the quantitative bound

Grothendieck's distinction between useful and regular cardinals reflects the unresolved presentation problem at this point of the manuscript. Once the retract-free presentation theorem is available, a useful cardinal is regular, and the proviso involving π_1 can be omitted. We include the argument because the requirement that the index be ordered deserves its own cardinal check.

Suppose $\mathrm{Ind}_{\pi}(A) \simeq \mathcal{M}$, where $A = \mathcal{F}^{\pi} = \mathcal{M}_{\pi}$, and let $F \in \mathcal{F}^{\pi'}$ with $\pi' > \pi$. Set $\mu = (\pi')^{\pi}$. Then $\mu^{\pi} = \mu$, and F is μ^{+}-presentable. Apply the fixed-point presentation theorem, now with initial cardinal π and generating category A: it gives a π^{+}-filtered category J of at most μ arrows and a presentation of F by objects of A. This estimate is independent of $|\operatorname{Fl} A|$.

To make the index ordered, put $\kappa = \pi^{+}$. We show that a κ-filtered category J with $|\operatorname{Fl} J| \le \mu = \mu^{\pi}$ has a cofinal functor from a κ-directed poset P with $|P| \le \mu$. Begin with a discrete poset labelled by the objects of J and its evident functor u to J. Build larger posets through κ stages. Every existing element will have fewer than κ predecessors. At a successor stage, for each subset S of the current poset of size below κ, take its downward closure and adjoin a new upper element.

This downward closure has size below κ; choose a cocone on its image in J to define the value of the new element and all new transition maps.

We also impose cofinality. For each pair p, q of existing elements and each fork $j \to u(p)$, $j \to u(q)$ in J, adjoin another upper element over the downward closure of $\{p, q\}$, choosing its image cocone to include this fork. The category of this augmented diagram still has fewer than κ arrows, so such a cone exists. In both constructions the predecessors of a new element are exactly the selected downward-closed set. Distinct new elements are initially incomparable; composition is defined by the chosen cocone, so the functor remains well defined. At limit stages take unions.

There are at most $\mu^{<\kappa} = \mu$ choices at each stage and $\kappa \leq \mu$ stages. Thus $|P| \leq \mu$. Regularity of κ ensures that any subset of P of size below κ is present at one earlier stage, and then receives an upper bound, so P is κ-directed. For each $j \in J$, the comma category $j\backslash P$ is nonempty because the initial stage includes j. Any two of its objects are joined to a common object by one of the added fork cones. The functor $P \to J$ is therefore cofinal. Reindexing the presentation of F along it retains the bound

$$|P| \leq \mu = (\pi')^{\pi}.$$

This is the full ordered-index bound in Definition 4.7.13, with no threshold proviso. Thus useful-but-nonregular cardinals do not occur under the repaired realization definition. Superfluous cardinals still occur, as the accessibility-spectrum discussion explains. The source's distinction is a faithful record of the stage reached in its argument, but should not be carried into a statement of the current theory.

Proposition 4.7.17. *Soit $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0}$ une fcga sur la $\mathfrak{U}$-catégorie $\mathcal{M}$, et soit π_0' un cardinal $\geqslant \pi_0$. Alors $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0'}$ est une fcga sur $\mathcal{M}$, qui est canonique si celle de départ est canonique. Pour un cardinal $\pi \geqslant \pi_0'$, celui-ci est utile pour $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0'}$ si et seulement s'il l'est pour $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0}$. Pour qu'il soit régulier pour $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0'}$, il* suffit *qu'il le soit pour $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0}$, et c'est aussi nécessaire quand on suppose de plus que $2^{\pi} \geqslant \pi_1' \overset{déf}{=} \sup(\pi_0', \operatorname{card} \operatorname{réd} \mathcal{F}^{\pi_0'})$, a fortiori quand $\pi \geqslant \pi_1'$.*

Démonstration. Les conditions a) b) sont trivialement satisfaites par la deuxième filtration, étant satisfaites par la première, ainsi que d) si elle l'est par la première. Il en est de même de la condition c) si $\pi = \pi^{\pi_0'}$, qui implique en effet $\pi^{\pi_0} = \pi$, puisqu'en général

$$\pi \leqslant \pi^{\pi_0} \leqslant \pi^{\pi_0'}.$$

Reste à examiner la majoration de cardinaux

$$\operatorname{card} I \longrightarrow \pi'^{\pi} \qquad \text{si } F \in \operatorname{Ob} \mathcal{F}^{\pi'} \text{ et } \pi'^{\pi} \geqslant \pi_1',$$

où cette fois $\pi_1' = \sup(\pi_0', \operatorname{card} \operatorname{réd} \mathcal{F}^{\pi_0'})$. En tout état de cause, on a $\pi_1' \geqslant \pi_1$, donc $\pi'^{\pi} \geqslant \pi_1'$ [page 183] implique $\pi'^{\pi} \geqslant \pi_1$, donc on peut appliquer la condition c) des fcg pour $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0}$, pour conclure qu'elle reste encore vérifiée. Donc en somme, *toutes* les conditions des fcg (resp. fcga) sont trivialement vérifiées pour la fcg *restreinte* de la première. De même, le fait qu'un cardinal $\pi' \geqslant \pi_0'$ est utile est trivialement indépendant de quelle des deux filtrations on considère, elle ne dépend que de la donnée du cardinal π' et de la sous-catégorie $\mathcal{F}^{\pi'}$ de $\mathcal{M}$. Reste la majoration de cardinaux, dans le cas où on s'intéresse à la *régularité* de π' pour les fcga envisagées. La majoration exigée est la même, mais la condition préalable de validité de cette majoration, savoir

$$\pi'^{\pi} \geqslant \pi_1' \qquad \text{resp.} \qquad \pi'^{\pi} \geqslant \pi_1,$$

n'est pas la même. Comme $\pi_1' \geqslant \pi_1$, on voit que la condition préalable est moins restrictive dans le cas de la première filtration, que de la seconde, d'où le "il suffit" dans la dernière assertion. Mais lorsque $2^{\pi} \geqslant \pi_1'$, même la plus restrictive est automatiquement vérifiée, puisque [page 184] $\pi'^{\pi} \geqslant 2^{\pi} \geqslant \pi_1'$, et alors la régularité de π pour la deuxième filtration implique la régularité pour le première, q.e.d.

Corollaire 4.7.18. *Supposons π_0 régulier pour la fcga ([77]). Si on restreint la fcga $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0}$* p. 63

aux cardinaux $\pi \geqslant \pi_0'$, où $\pi_0' \geqslant \pi_1$, alors on trouve une fcga où la majoration de cardinaux (pour $\pi = \pi^{\pi_0}$) est valable sans condition préalable $\pi'^{\pi} \geqslant \pi_1'$; plus précisément, on a alors

$$\pi_1' \leqslant 2^{(\pi_0'^{\pi_0})} \qquad \textit{(a fortiori } \pi_1' \leqslant 2^{(2^{\pi_0'})}\textit{)}, \tag{4.7.18.1}$$

donc la condition préalable $\pi'^{\pi} \geqslant \pi_1'$ est automatiquement vérifiée si $\pi \geqslant \pi_0$, $\pi = \pi^{\pi_0'}$, $\pi' > \pi$ (cf. remarque 4.7.7.2).

Ceci équivaut donc à la majoration de cardinaux suivante (appliquée au cas de $\pi = \pi_0'$).

Lemme 4.7.19. *Supposons π_0 régulier pour la fcga $(\mathcal{F}^{\pi})_{\pi \geqslant \pi_0}$. Alors pour tout cardinal $\pi \geqslant \pi_1$ ($\overset{déf}{=} \sup(\pi_0, \operatorname{card} \operatorname{réd} \mathcal{F}^{\pi_0})$), on a*

$$\operatorname{card} \operatorname{réd} \mathcal{F}^{\pi} \leqslant 2^{(\pi^{\pi_0})}, \tag{4.7.19.1}$$

et si $\pi' \geqslant \pi_1$ et $F \in \operatorname{Ob} \mathcal{F}^{\pi'}$, on a

$$\operatorname{card} \operatorname{réd} \mathcal{F}^{\pi}/F \leqslant \pi'^{(\pi^{\pi_0})} \qquad ([78]). \tag{4.7.19.2}$$

Démonstration du lemme. Comme π_0 est régulier, posant $C = \mathcal{F}^{\pi_0} = \mathcal{M}_{\pi_0}$, on trouve [page 185]
$\mathcal{M} \simeq \operatorname{Ind}_{\pi_0}(C)$, donc on peut supposer $\mathcal{M} = \operatorname{Ind}_{\pi_0}(C)$, et appliquer les résultats prouvés pour les catégories de cette forme. Comme $\mathcal{F}^{\pi} \subset \mathcal{M}_{\pi}$, $\mathcal{F}^{\pi'} \subset \mathcal{M}_{\pi'}$, les majorations (4.7.9.1) et (4.7.9.2) sont contenues dans

$$(*) \qquad \left\{ \begin{array}{rcll} \operatorname{card} \operatorname{réd} \mathcal{M}_{\pi} & \leqslant & 2^{(\pi^{\pi_0})} & \\ \operatorname{card} \operatorname{réd} \mathcal{M}_{\pi}/F & \leqslant & \pi'^{(\pi^{\pi_0})} & \text{si } F \in \operatorname{Ob} \mathcal{M}_{\pi'}, \text{ avec} \\ & & & \pi' \geqslant \pi \geqslant \pi_1. \end{array} \right\} \text{ pour } \pi \geqslant \pi_1 \qquad ([79]).$$

La première de ces majorations n'est autre que la deuxième majoration dans 4.7.7.1. Notons qu'on a bien

$$2^{(\pi^{\pi_0})} \leqslant 2^{(2^{\pi})},$$

ce qui résulte en effet de

$$\pi^{\pi_0} \leqslant 2^{\pi},$$

qu'on prouve en notant que $\pi < 2^{\pi}$, d'où $\pi^{\pi_0} \leqslant (2^{\pi})^{\pi_0} = 2^{\pi \cdot \pi_0} = 2^{\pi}$ puisque $\pi \geqslant \pi_0$. Il reste à établir la deuxième majoration

$$(*) \qquad \operatorname{card} \operatorname{réd} \mathcal{M}_{\pi}/F \leqslant \pi'^{(\pi^{\pi_0})} \qquad \text{si } F \in \operatorname{Ob} \mathcal{M}_{\pi'}, \text{ avec } \pi' \geqslant \pi \geqslant \pi_1.$$

(On n'en a pas besoin pour 4.7.18, mais ce sera sans doute utile par ailleurs.) On utilise $\mathcal{M}_{\pi'} \subset \operatorname{Filt}^{\pi'^{\pi_0}}$ si $\pi' \geqslant \pi_1$ (4.7.6.2), donc si $F \in \operatorname{Ob} \mathcal{M}_{\pi'}$, on a

Commentary · Exposition [ms. 184]

Changing the starting point and bounding a slice

Grothendieck wants the filtration to be intrinsic enough that deleting its first levels does not change the useful cardinals which remain. The only part of the definition that remembers the starting point quantitatively is the threshold π_1. Proposition 4.7.17 records this bookkeeping correctly once the repaired filtration axioms are used.

If $\pi_0' \geq \pi_0$ and $\pi^{\pi_0'} = \pi$, then

$$\pi \leq \pi^{\pi_0} \leq \pi^{\pi_0'} = \pi.$$

77. Il suffit pour cela que π_0 soit utile, i.e. $\mathcal{M} \xleftarrow{\sim} \operatorname{Ind}_{\pi_0}(\mathcal{F}^{\pi_0} = \mathcal{M}_{\pi_0})$, cela implique régulier, cf. 4.8.5.

78. **N.B.** J'ignore si on peut remplacer dans ces majorations π^{π_0} par π_0.

79. Comparer avec majorations $\operatorname{card} \operatorname{réd} \operatorname{Filt}^{\pi} \leqslant 2^{\pi}$, $\operatorname{card} \operatorname{réd} \operatorname{Filt}^{\pi}/F \leqslant \pi'^{\pi}$, si $F \in \operatorname{Ob} \operatorname{Filt}^{\pi'}$, avec $\pi' \geqslant \pi \geqslant \pi_1$, majorations plus agréables que celles de (4.7.19). Il faudrait quand même s'assurer sur un exemple si les majorations plus sympathiques ne seraient pas valables dans le cas général.

The old generation property therefore applies. The new threshold π_1' is at least π_1, so its size proviso is more restrictive and the old bound implies the new one. Usefulness concerns the same full subcategory $\mathcal{F}^\pi$ and the same realization functor, hence is unchanged. For regularity the converse needs the proviso to be automatic: $2^\pi \geq \pi_1'$ ensures $(\pi')^\pi \geq \pi_1'$ whenever $\pi' > \pi$. No additional category-theoretic argument is hidden here.

The slice estimate in 4.7.19 can be proved without the extra ordering $\pi' \geq \pi$ imposed midway through its proof. Assume only the stated $\pi, \pi' \geq \pi_1$ and set

$$a = \pi^{\pi_0}, \qquad b = (\pi')^{\pi_0}, \qquad \Gamma = (\pi')^a.$$

Choose a skeleton of C and of $\mathcal{M}_\pi$. Its object set and arrow set have cardinal at most 2^a. For $G \in \mathcal{M}_\pi$ and $F \in \mathcal{M}_{\pi'}$, the preceding bounds give $|G(c)| \leq a$ and $|F(c)| \leq b$. Hence

$$\begin{aligned} |\operatorname{Hom}(G,F)| &\leq \prod_{c \in \operatorname{Ob} C_0} |F(c)|^{|G(c)|} \\ &\leq (b^a)^{|\operatorname{Ob} C_0|} \leq \big((\pi')^{\pi_0}\big)^{a\pi_1} = (\pi')^a = \Gamma. \end{aligned}$$

The product, rather than a bare sum, is the direct count of all component maps of a natural transformation; naturality can only reduce the number. The infinite-cardinal identities use $\pi_0, \pi_1 \leq a$. Since $\pi' \geq 2$, also $2^a \leq \Gamma$. There are therefore at most Γ objects in the chosen representative slice, and at most

$$\Gamma^2\, 2^a = \Gamma$$

arrows. This proves $\operatorname{card} \operatorname{réd}(\mathcal{M}_\pi / F) \leq (\pi')^{\pi^{\pi_0}}$ in exactly the range of the statement. All counts are counts on skeletons; the literal set of objects of a replete full subcategory need not itself be small.

For 4.7.18 one needs only the first count, with $\pi = \pi_0'$. It gives $\pi_1' \leq 2^{(\pi_0')^{\pi_0}} \leq 2^{2^{\pi_0'}}$. If $\pi^{\pi_0'} = \pi$, then $\pi \geq 2^{\pi_0'}$, and $(\pi')^\pi \geq 2^\pi \geq \pi_1'$. This is the precise reason the threshold disappears after increasing the initial level.

p. 64

Commentary · Development (commentators') [ms. 185] [page 186]

Two different proposed improvements of the counting bounds

Grothendieck asks two different questions in the footnotes to 4.7.19. Footnote 78 literally asks whether the exponent π^{π_0} can be replaced by π_0. Footnote 79 asks about the more plausible bounds 2^π and $(\pi')^\pi$. These must be separated: the first has an elementary negative answer already for sets. We record the calculation because it prevents a small printed exponent from being mistaken for a still-open refinement. This is a local verification given here, not a claim of priority.

Failure of a uniform initial exponent [ours]. Fix an infinite π_0. In Ens, let $\mathcal{F}^\rho$ be the sets of cardinality at most ρ, and let $\pi = \pi' = 2^{\pi_0}$. Then

$$\operatorname{card} \operatorname{réd} \mathcal{F}^\pi > 2^{\pi_0}, \qquad \operatorname{card} \operatorname{réd}(\mathcal{F}^\pi / 1) > (\pi')^{\pi_0}.$$

Thus neither occurrence of π^{π_0} in 4.7.19 can uniformly be replaced by π_0.

Proof. We first verify the categorical setting. A set X with $|X| \leq \rho$ is ρ^+-presentable: a map from X to a ρ^+-filtered colimit has at most ρ elementwise witnesses, and all witnesses and equalities can be moved to a common stage. If $|X| > \rho$, its presentation as the union of subsets of cardinality at most ρ, indexed by the ρ^+-directed poset of those subsets, prevents the identity of X from factoring through a stage. Thus $\mathcal{F}^\rho = \mathcal{M}_\rho$. Every set is a filtered union of its subsets of cardinality at most π_0, so π_0 is useful for this canonical filtration. A skeleton C of $\mathcal{F}^{\pi_0}$ has at most 2^{π_0} arrows and at least that many endomorphisms of a π_0-element set; hence its reduced cardinal is exactly 2^{π_0} and $\pi_1 = \pi$.

Now choose X with $|X| = \pi$. It has exactly $\pi^\pi = 2^\pi$ endomorphisms. Any skeleton containing a representative of its isomorphism class has the same number of endomorphisms of that representative. Therefore $\operatorname{card} \operatorname{réd} \mathcal{F}^\pi \geq 2^\pi > \pi = 2^{\pi_0}$. In the slice over the singleton, the unique map $X \to 1$ has precisely the same endomorphism set. Hence

$$\operatorname{card} \operatorname{réd}(\mathcal{F}^\pi / 1) \geq 2^\pi > \pi = (2^{\pi_0})^{\pi_0} = (\pi')^{\pi_0}.$$

The strict inequalities are Cantor's theorem, and all hypotheses of 4.7.19 are met. □

In fact the elementary upper count also gives $\operatorname{card}\operatorname{réd}\mathcal{F}^\pi = 2^\pi$ in this example, so the first bound proposed in footnote 79 is sharp for sets. That observation does not prove its validity for arbitrary accessible categories. Our checks of the sources cited here, including the bounded-colimit theorem of Chen and the discussion of sizes by Lieberman–Rosický–Vasey, did not locate a proof or counterexample for the full pair of numerical inequalities in footnote 79 with these exact hypotheses. We leave that specific comparison unsettled; we do not label it a recognized open problem of the literature.

$$\operatorname{card} F(x) \longrightarrow \pi'^{\pi_0} \qquad \forall\, x \in \operatorname{Ob} C,$$

donc si $G \in \operatorname{Ob}\mathcal{M}_\pi \subset \operatorname{Ob}\operatorname{Filt}^{\pi^{\pi_0}}$, d'où

$$\operatorname{card} G(x) \leqslant \pi^{\pi_0} \qquad \forall\, x \in \operatorname{Ob} C,$$

on trouve

$$\operatorname{card}\operatorname{Hom}(G,F) \leqslant \underbrace{\underbrace{\operatorname{card}(\operatorname{Ob} C)}_{\leqslant \pi_1} \cdot (\pi'^{\pi_0})^{(\pi^{\pi_0})}}_{\pi'^{\pi_0}\cdot\pi^{\pi_0} = \pi'^{(\pi^{\pi_0})}},$$

d'où

$$\operatorname{card}\operatorname{Ob}\mathcal{M}_\pi/F \leqslant \underbrace{\underbrace{\operatorname{card}(\operatorname{Ob}\mathcal{M}_\pi)}_{\leqslant 2^{(\pi^{\pi_0})}} \cdot \pi'^{(\pi^{\pi_0})}}_{\gamma = \pi'^{\pi^{\pi_0}}},$$

et enfin

$$\operatorname{card}\operatorname{Fl}\mathcal{M}_\pi/F \leqslant \underbrace{\underbrace{\gamma\cdot\gamma}_{\gamma=\pi'^{(\pi^{\pi_0})}} \cdot \underbrace{\operatorname{card}(\operatorname{Fl}\mathcal{M}_\pi)}_{\leqslant 2^{(\pi^{\pi_0})}}}_{\pi'^{(\pi^{\pi_0})}},$$

ce qui est la majoration annoncée (la même que celle prouvée dans 4.5.12, la démonstration étant essentiellement la même).

4.7.20. Une fcg canonique est dite *maximale* (où *strictement canonique*) si elle n'est par déduite d'une fcg canonique strictement plus étendue $(\mathcal{F}^\pi)_{\pi\geqslant\pi_{00}}$ (donc avec $\pi_{00} < \pi_0$). Donc si $\mathcal{M}$ admet une fcga, alors elle admet même une fcg strictement canonique, et cette dernière est de plus unique. On va revenir là-dessus dans la section suivante. [page 187]

4.8 Catégories $\mathfrak{U}$-accessibles

Proposition 4.8.1. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie, π_0 un cardinal infini. Considérons les conditions suivantes :*

a) $\mathcal{M}$ satisfait à L_{π_0} (i.e. est stable par petites $\varinjlim$ grandes devant π_0), et contient une petite sous-catégorie pleine S strictement génératrice, *formée d'objets π_0-accessibles.*

b) Il existe une petite catégorie C, et une équivalence de catégories

$$\mathcal{M} \simeq \operatorname{Ind}_{\pi_0}(C).$$

c) $\mathcal{M}$ admet une filtration cardinale généralisée accessible $(\mathcal{F}^\pi)_{\pi\geqslant\pi_0}$, ayant π_0 comme cardinal initial, et telle que π_0 soit un cardinal utile pour ladite filtration.

c′) Comme c), avec π_0 cardinal régulier (et non seulement utile) pour la filtration cardinale généralisée accessible en question, et cette filtration étant supposée de plus canonique. p. 65 [page 188]

On a alors le diagramme d'implications

$$c' \iff c \iff b \implies a.$$

4.8.1.1. Il me faut ici préciser la terminologie, sur ce que j'entends par sous-catégorie (pleine) C *strictement génératrice* dans $\mathcal{M}$. Pour ceci, je me réfère à SGA 4 I 7.2, (i), aux conditions équivalentes b) et c) de loc. cit. :

ⓑ $\forall\, F \in \operatorname{Ob}\mathcal{M}$, la flèche canonique

$$\varinjlim_{i \in C/F} x_i \longrightarrow F$$

est un isomorphisme.

ⓒ Le foncteur canonique

$$\begin{array}{ccc} \mathcal{M} & \longrightarrow & C^\wedge \\ F & \longmapsto & (\underbrace{x}_{\in \operatorname{Ob} C} \longmapsto \underbrace{\operatorname{Hom}_{\mathcal{M}}(x,F)}_{\in \operatorname{Ob}(\mathrm{Ens})}) \end{array}$$

est pleinement fidèle.

Ces conditions impliquent :

a) C est génératrice dans $\mathcal{M}$ par épimorphismes stricts, i.e. pour tout F dans $\mathcal{M}$, la famille des flèches $x \longrightarrow F$ de source dans C, de but F, est épimorphique stricte.

Et lorsque $\mathcal{M}$ est stable par produits fibrés, cette condition a) est équivalente aux précédentes. Dans loc. cit. j'affirme

Commentary · Exposition [ms. 188]

Density records all relations [page 189]

Grothendieck now separates the existence of sufficiently filtered colimits from the assertion that a small family actually generates every object by such colimits. The distinction is indispensable once arbitrary colimits are unavailable. We continue to write $\lambda = \pi_0^+$: his π_0-accessible objects are the objects whose covariant Hom functors preserve λ-filtered colimits. His strictly generating functors are usually called *dense* functors. Thus the principal assertion of 4.8.1 is that a category of the form $\mathrm{Ind}_{\pi_0}(C)$ has a dense small subcategory of λ-presentable objects. The converse with that very same cardinal requires a separate argument; it is not included in the proposition's displayed implication chain. For an arbitrary generalized filtration, the term useful must retain the comparison-equivalence condition of 4.7.12: filteredness of its initial overcategories alone does not imply density, as the earlier audit explains. The canonical ind-completion examples satisfy the density hypothesis.

The density criterion can be proved without assuming that the ambient category has arbitrary colimits. Let $i : C \to \mathcal{M}$, and set $N_i X(c) = \mathrm{Hom}(i(c), X)$. A natural transformation $N_i X \to N_i Y$ is exactly a compatible family of maps $i(c) \to Y$ indexed by objects $(c, p : i(c) \to X)$ of C/X. Consequently

$$\mathrm{Nat}(N_i X, N_i Y) \cong \lim_{(c,p) \in (C/X)^{\mathrm{op}}} \mathrm{Hom}(i(c), Y).$$

Full faithfulness of N_i says precisely that the evident cocone with vertex X has the colimit universal property. The assertion supplies this particular colimit; it does not presuppose all colimits in $\mathcal{M}$. This is the content of the equivalence between b) and c) in 4.8.2, and explains the usefulness of the formulation inherited from SGA 4, I, 7.2 (Artin et al., 1972).

The passage through strict epimorphic families checks a different-looking compatibility condition. A family $(p_a : X_a \to X)$ is strict epimorphic when maps $u_a : X_a \to Y$ descend uniquely whenever $u_a v = u_b w$ for every pair $v : Z \to X_a$, $w : Z \to X_b$ with $p_a v = p_b w$. Density implies this property for the family of all maps from $i(C)$: its compatibility condition includes the arrows of C/X. Conversely, when i is fully faithful, the compatibility along C/X implies the required compatibility for arbitrary Z. Indeed, apply the joint epimorphicity of the family of all $i(c) \to Z$, which follows from the strict epimorphic hypothesis at Z, and use fullness to regard their composites with v, w as arrows of C. This explains exactly where the full faithfulness hypothesis enters. It also prevents us from replacing a dense subcategory by a mere collection of generators without recording its morphisms.

cette équivalence sans hypothèse restrictive sur $\mathcal{M}$ – mais en annotation marginale j'affirme que cette assertion est *fausse*, en dehors de l'hypothèse d'existence des produits fibrés dans $\mathcal{M}$. Pourtant, je viens de vérifier la démonstration donnée dans loc. cit. de l'implication a $\Longrightarrow$ b, et elle est correcte. Mais peut-être l'annotation résulte-t-elle d'une confusion entre la condition a), et la condition suivante, plus faible a priori, et qui lui ressemble comme un frère :

a′) Il existe une famille de flèches $u_i : x_i \longrightarrow F$, de source dans C, et de but F, qui est épimorphique stricte (cf. SGA 4 I 10.3).

On a envie de dire que quand on *agrandisse* une famille de flèches épimorphique stricte, en rajoutant d'autres flèches de même but, elle doit rester épimorphique stricte ("a fortiori") – ce qui donne l'impression que a′) doit impliquer a), donc lui être équivalent. Mais si on essaye de prouver cette propriété hypothétique de stabilité pour les familles épimorphiques strictes, p. 66
on voit qu'on n'y arrive que si on suppose que la famille initiale est de plus *épimorphique* [page 190]
universelle (si les produits fibrés existent dans $\mathcal{M}$), ou (sous la réserve précédente) si pour tout $x' \longrightarrow F$, le crible de $\mathcal{M}/F'$ image inverse du crible de $\mathcal{M}/F$ engendré par les $x_i \longrightarrow F$ est un "crible épimorphique". Cela fait entrevoir en effet qu'il doit y avoir des cas où la condition a′) est satisfaite, mais non la condition a) (équivalente à b et à c).

Mais nous sommes alors confrontés à la situation très déplaisante : si C est une sous-catégorie strictement génératrice de $\mathcal{M}$, il ne s'ensuit pas pour autant qu'une sous-catégorie pleine C' de $\mathcal{M}$ telle que $C' \supset C$ soit également strictement génératrice ! Or j'ai toujours utilisé précédemment, sans y réfléchir à deux fois, qui si C est strictement génératrice, il en est de même de $C' \supset C$. Donc il faudra que je sois à présent très attentif, et que je vérifie [page 191]
si cette erreur $\pm$ tacite rend inopérantes certaines démonstrations, voire même, rend faux certains énoncés. Aussi, il me faudrait donner un exemple où C est strictement génératrice, mais $C' \supset C$ ne l'est pas.

Finalement, réflexion faite, ces ennuis craints disparaissent. Je vais énoncer un résultat en forme :

Proposition 4.8.2. *Soient C, $\mathcal{M}$ deux $\mathfrak{U}$-catégories, $i : C \longrightarrow \mathcal{M}$ un foncteur, d'où un foncteur*

$$\begin{cases} \varphi : \mathcal{M} \longrightarrow C^\wedge \\ \varphi(X) = (x \longmapsto \mathrm{Hom}_{\mathcal{M}}(i(x), X)) \end{cases} \tag{4.8.2.1}$$

(foncteur composé $\mathcal{M} \xrightarrow{can.} \mathcal{M}^\wedge \underbrace{\xrightarrow{i^*}}_{\substack{\text{i.e. composition} \\ \text{avec } i}} C^\wedge$). Pour tout X dans $\mathcal{M}$, on considère la catégorie $C/X \simeq C/\varphi(X)$, et l'injection [?] canonique (dans $\mathcal{M}^\vee$)

$$\varinjlim_{x \in C/X} i(x) \longrightarrow X. \tag{4.8.2.2}$$

1°) Considérons les conditions suivantes.

- ⓐ *Pour tout $X \in \mathrm{Ob}\,\mathcal{M}$, la famille des flèches $i(x) \longrightarrow X$, indexée par $\mathrm{Ob}\,C/X$, est épimorphique stricte.*
- ⓑ *Pour tout $X \in \mathrm{Ob}\,\mathcal{M}$, la flèche canonique 4.8.2.2. est un isomorphisme, i.e. fait de X une $\varinjlim$ des foncteurs canoniques $C/X \longrightarrow \mathcal{M}$.* [page 192]
- ⓒ *Le foncteur φ (4.8.2.1) est pleinement fidèle.*

On a alors les implications

$$\mathrm{b} \Longleftrightarrow \mathrm{c} \Longrightarrow \mathrm{a},$$

et si on suppose i pleinement fidèle, alors les trois conditions a, b, c *sont équivalentes.* (**N.B.** On dit que le foncteur $i : C \longrightarrow \mathcal{M}$ est *strictement générateur*, si les conditions équivalentes b, c sont satisfaites. Si C est une sous-catégorie de $\mathcal{M}$ (pas nécessairement p. 67

pleine), on dit que C est *strictement génératrice* si le foncteur d'inclusion est strictement générateur, i.e. satisfait aux conditions équivalentes b), c). Pour ceci, il faut donc que la condition a) soit satisfaite, i.e. que pour tout X dans $\mathcal{M}$, la famille des flèches $x \longrightarrow X$ de source dans C, de but X, soit épimorphique stricte, et cette condition est aussi suffisante quand C est sous-catégorie pleine de $\mathcal{M}$.)

2°) ([80]). *Supposons que i soit strictement générateur* ([81]). *Alors pour tout objet X de $\mathcal{M}$, la famille des flèches $i(x) \longrightarrow X$, indexée par $\mathrm{Ob}\, C/X$, est non seulement épimorphique stricte (condition a) dans 1°), mais de plus, toute famille de flèches de but X, incluant la famille précédente, est également épimorphique stricte.*

3°) Considérons un diagramme commutatif de foncteurs de $\mathfrak{U}$-catégories :

[page 193]

$$\begin{array}{ccc} C & \xrightarrow{\alpha} & C' \\ & {\scriptstyle i}\searrow \quad \swarrow{\scriptstyle i'} & \\ & E & \end{array}$$

Si le foncteur i est strictement générateur ([82]), *et si de plus i' est pleinement fidèle, alors i' est strictement générateur.*

Corollaire 4.8.3. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie, C une sous-catégorie strictement génératrice, C' une sous-catégorie* pleine *de $\mathcal{M}$ qui contient C, alors C' est strictement génératrice.*

C'est en effet un cas particulier de 4.8.2 3°.

Démonstration de 4.8.2. La démonstration de 1°) est celle de SGA 4 I 7.2 (i). (Où on suppose que C est une sous-catégorie pleine de $\mathcal{M}$, mais la démonstration donnée prouve en fait l'énoncé donné ici.) Prouvons 2°). Rajoutons donc à la famille des [page 194]

$$i(x) \longrightarrow X \qquad (x \in \mathrm{Ob}\, C/X)$$

une famille

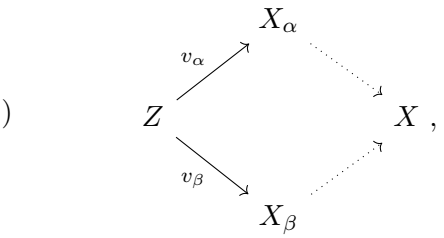
$$X_\alpha \xrightarrow{p_\alpha} X \qquad (\alpha \in A)$$

de nouvelles flèches, et prouvons que la famille totale ainsi obtenue est encore épimorphique stricte. On doit donc prouver que si Y est un objet de $\mathcal{M}$, et si on a une famille de flèches $u_x : i(x) \longrightarrow Y$, $u_\alpha : X_\alpha \longrightarrow Y$, satisfaisant la condition de compatibilité habituelle pour des couples de flèches :

(v_x, v_y)

$$\begin{array}{ccccc} & & i(x) & & \\ & {\scriptstyle v_x}\nearrow & & \searrow{\scriptstyle p_x} & \\ Z & & & & X\ , \\ & {\scriptstyle v_y}\searrow & & \nearrow{\scriptstyle p_y} & \\ & & i(y) & & \end{array}$$

ou p. 68



(v_x, v_α)

$$\begin{array}{ccccc} & & i(x) & & \\ & {\scriptstyle v_x}\nearrow & & \searrow{\scriptstyle p_x} & \\ Z & & & & X\ , \\ & {\scriptstyle v_\alpha}\searrow & & \nearrow{\scriptstyle p_\alpha} & \\ & & X_\alpha & & \end{array}$$

ou [page 195]

80. [2° se trouve sur la page 193.]
81. Il suffit même qu'il satisfasse la condition plus faible a) de 1°).
82. En fait, il suffit qu'il satisfasse la condition plus faible c) de 1°).

(v_α, v_β)

savoir les relations

$$(*) \qquad \begin{cases} u_x v_x = u_y v_y \\ u_x v_x = u_\alpha v_\alpha \\ u_\alpha v_\alpha = u_\beta v_\beta, \end{cases}$$

alors il existe une flèche

$$u : X \longrightarrow Y$$

(nécessairement unique, d'après la propriété c) d'épimorphicité stricte de la famille initiale indexée par C/X) telle qu'on ait

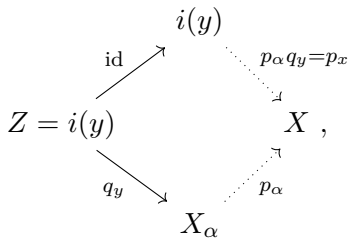
$$(*) \qquad \begin{cases} up_x = v_x & \text{pour tout } x \in \operatorname{Ob} C/X \\ up_\alpha = v_\alpha & \text{pour tout } \alpha \in A. \end{cases}$$

Or d'après la propriété a), il existe un unique $u : X \longrightarrow Y$, de telle façon que la première des relations $(*)$ soit satisfaite, pour tout $x \in \operatorname{Ob} C/X$. Donc il s'agit seulement de prouver que pour cet u, on a pour tout α la relation

[page 196]

$$up_\alpha = u_\alpha.$$

Or, en appliquant la propriété a) à X_α au lieu de X, on veut que la famille des flèches



$$i(y) \xrightarrow{q_y} X_\alpha$$

(indexée par C/X_α) est épimorphique stricte, a fortiori épimorphique. Donc pour prouver $up_\alpha = u_\alpha$, il suffit de prouver qu'on a

$$(**) \qquad (up_\alpha)q_y = u_\alpha q_y$$

pour toute y dans C/X_α. Mais c'est là une conséquence de la compatibilité $(*)$ (deuxième formule), appliquée au cas suivant,

p. 69

on a donc, en posant $x = (y, p_\alpha q_y) \in \operatorname{Ob} C/X$,

$$\underbrace{u_x \circ \mathrm{id}_{i(y)}}_{u_x} = u_\alpha q_y ,$$

donc pour prouver $(**)$, il reste à vérifier

$$u_x = \underbrace{(up_\alpha)q_y}_{u(p_\alpha q_y) = up_x} ,$$

[page 197]

qui est en effet vérifiée par définition de u_x. Cela achève de prouver 2°.

Prouvons 3°. Comme i' est pleinement fidèle, en vertu de 1°, pour prouver que i' est strictement génératrice, il suffit d'établir que pour tout objet X de $\mathcal{M}$, la famille des flèches $i'(x') \longrightarrow X$, indexée par $\mathrm{Ob}\, C'/X$, est épimorphique stricte. Or cette famille contient la famille des $\underbrace{i'(\alpha(x))}_{=i(x)} \longrightarrow X$, indexée par $\mathrm{Ob}\, C/X$. Donc il résulte de l'hypothèse sur i, et de 2°, que cette famille est épimorphique stricte. On a gagné ! Ouf …

Démonstration de 4.8.1. On a

$$\mathrm{c}' \implies \mathrm{c} \implies \mathrm{b} \implies \mathrm{a}\,,$$

la première implication tautologique, la seconde résultant du fait que π_0 cardinal régulier pour la fcga envisagée, implique que

$$\mathcal{M} \xleftarrow{\sim} \mathrm{Ind}_{\pi_0}(\mathcal{F}^{\pi_0})\ ,$$

$\mathcal{F}^{\pi_0}$ équivalente à une petite catégorie, d'où b).

Enfin b) $\implies$ a) résulte du fait que $\mathrm{Ind}_{\pi_0}(C)$ est stable par $\varinjlim$ grandes devant π_0 (4.4.15), et que C est une sous-catégorie strictement génératrice de $\overrightarrow{\mathrm{Ind}}_{\pi_0}(C)$, formée d'objets π_0-accessibles. Il nous faut expliciter le [page 198]

Commentary · Exposition [ms. 197]

The apparent difficulty with enlargement disappears

Grothendieck is checking that his earlier constructions survive enlargement of the generating category. The worry on manuscript pages 190–191 is withdrawn by Proposition 4.8.2; it is not an unresolved defect in the preceding theory. The useful fact is stronger than the permanence of density. Suppose that for every object Z, the family of all maps $i(c) \to Z$ is strict epimorphic. Adjoin arbitrary maps $q_a : Z_a \to X$ to the canonical family over X. Given compatible descent data on the enlarged family, its restriction supplies a unique $u : X \to Y$. To prove $uq_a = u_a$, precompose with every $i(c) \to Z_a$. Each resulting equality is already among the compatibility equations of the enlarged family. These maps are jointly epimorphic, so $uq_a = u_a$. Thus this particular strict epimorphic family remains strict after enlargement, with no pullback hypothesis.

There is also a short proof directly with natural transformations. If $C \subset C' \subset \mathcal{M}$, C' is full, and C is dense, a transformation $N_{C'}X \to N_{C'}Y$ restricts to a unique arrow $u : X \to Y$ on C. For $p : c' \to X$ and every $a : c \to c'$, naturality gives

$$\eta_{c'}(p)a = \eta_c(pa) = upa.$$

The maps from C to c' are jointly epimorphic, hence $\eta_{c'}(p) = up$. Faithfulness follows by restriction. Therefore C' is dense. This proof isolates the global hypothesis missing from the tempting assertion that *every* strict epimorphic family is preserved by arbitrary enlargement: the testing families are available at every newly adjoined domain.

Two local notational slips should not obscure this argument. In the display on manuscript page 195 the required equations are $up_x = u_x$ and $up_\alpha = u_\alpha$, not equations with the auxiliary comparison maps v_x, v_α. Footnote 82 should refer to condition a), as does footnote 81: condition c) is the density condition itself, so it is not a weaker assumption. Both readings are present in the edition and are retained in the transcription.

Lemme 4.8.4. *Soit C une $\mathfrak{U}$-catégorie, π_0 un cardinal infini. Alors C est strictement génératrice dans $\mathcal{M} = \mathrm{Ind}\, C$ et dans $\mathcal{M} = \mathrm{Ind}_{\pi_0} C$.*

En effet, le foncteur canonique $\mathcal{M} \longrightarrow C^\wedge$ est pleinement fidèle, et on applique le critère c) de 4.8.2. [page 199]

Pour achever de prouver 4.8.1, il reste donc à établir l'implication

$$\mathrm{a} \implies \mathrm{c}'\,.$$

Supposons donc que $\mathcal{M}$ satisfasse à L_{π_0}, et admette une petite sous-catégorie strictement génératrice S, formée d'objets π_0-accessibles, donc un foncteur canonique

$$\mathrm{Ind}_{\pi_0} S \longrightarrow \mathcal{M} ,$$

prolongeant l'inclusion $S \hookrightarrow \mathcal{M}$, de façon à commuter aux $\varinjlim$ grandes devant π_0, et du fait que $S \subset \mathcal{M}_{\pi_0}$, ce foncteur est *pleinement fidèle.* Mais comment prouver qu'il est essentiellement surjectif ? Ce ne sera d'ailleurs pas vrai sans autre hypothèse sur S. L'idée naturelle est de saturer S pour les $\varinjlim$ de cardinal $\leqslant \pi_0$ représentables dans $\mathcal{M}$, et notamment par facteurs directs, mais même alors (et même en admettant que $\mathcal{M}_{\pi_0}$ lui-même est équivalent à une petite catégorie, et prenant $C = \mathcal{M}_{\pi_0}$), il n'est pourtant pas clair que le foncteur pleinement fidèle $\mathrm{Ind}_{\pi_0} C \longrightarrow \mathcal{M}$ soit essentiellement surjectif, ce qui équivaudrait aussi à dire que pour tout F dans $\mathcal{M}$, C/F est grande devant π_0. Il n'est en effet pas même clair que C/F soit filtrante. [page 200]

Donc finalement, je doute qu'on ait a) $\Longrightarrow$ c′) ou seulement a) $\Longrightarrow$ b), la situation n'est pas bien comprise visiblement.

Mais prouvons quand même

$$\mathrm{b} \implies \mathrm{c}' .$$

Pour ceci, on peut supposer $\mathcal{M} = \mathrm{Ind}_{\pi_0} C$, C petite. On sait alors que la filtration de $\mathcal{M}$ par les $(\mathcal{M}_\pi)_{\pi \geqslant \pi_0}$ est une fcga (prop. 4.7.7 et définition 4.7.8), et même une fcg *canonique.* De plus, je dis que le cardinal π_0 est *utile* et même régulier pour cette filtration (ce qui achèvera de prouver c′). On a un résultat un peu plus précis :

Corollaire 4.8.5. *Soient C une catégorie équivalente à une petite catégorie, π_0 un cardinal infini, $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C) \subset C^\wedge$. Alors :* [page 201]

1°) π_0 est un cardinal utile *et même régulier pour la fcg canonique $(\mathcal{M}_\pi)_{\pi \geqslant \pi_0}$ de $\mathcal{M}$.*

2°) $\mathcal{M}_{\pi_0} = C^\natural$ (sous-catégorie pleine de $\mathcal{M} = \mathrm{Ind}_{\pi_0} C$ formée des facteurs directs dans $\mathcal{M}$ d'objets de C), et $\mathcal{M}_{\pi_0}$ est une enveloppe de Karoubi de C.

([54], [55]).

Démonstration. p. 71

1°) On sait déjà que

$$(*) \qquad \mathrm{Ind}_{\pi_0} \mathcal{M}_{\pi_0} \longrightarrow \mathcal{M}$$

est pleinement fidèle, et pour voir que c'est essentiellement surjectif, on note que l'on a

$$\mathcal{M} \simeq \mathrm{Ind}_{\pi_0} C \hookrightarrow \mathrm{Ind}_{\pi_0} \mathcal{M}_{\pi_0} \longrightarrow \mathcal{M} ,$$

le composé étant isomorphe au foncteur identique, est essentiellement surjectif, donc aussi $(*)$. Cela prouve donc que π_0 est un cardinal utile pour la filtration envisagée, prouvons que ce cardinal est même régulier, donc que pour

$$F \in \mathrm{Ob}\, \mathcal{M}_\pi , \qquad \text{avec } \pi > \pi_0,\ \pi^{\pi_0} \geqslant \pi_1$$

54. **Corollaire 4.8.5.1.** *Si C est karoubienne, alors $\mathcal{M}_{\pi_0} \subset C^\wedge$ est la catégorie formée des foncteurs* représentables *dans $C \xrightarrow{\sim} \mathcal{M}_{\pi_0}$.*

55. **4.8.5.2.** Expliciter aussi ceci : Soit $u : C \longrightarrow C'$ un foncteur, avec C, C' équivalentes à des petites catégories. Conditions équivalentes :

a) u induit $\mathrm{Kar}\, C \xrightarrow{\sim} \mathrm{Kar}\, C'$.

a′) u pleinement fidèle, et tout objet de C' est isomorphe à un facteur direct d'un objet de l'image essentielle.

b) $\mathrm{Ind}(u) : \mathrm{Ind}(C) \longrightarrow \mathrm{Ind}(C')$ est une équivalence.

c) $\mathrm{Ind}_{\pi_0}(u) : \mathrm{Ind}_{\pi_0}(C) \longrightarrow \mathrm{Ind}_{\pi_0}(C')$ est une équivalence (π_0 un cardinal infini donné).

d) $u_! : C^\wedge \longrightarrow C'^\wedge$ est une équivalence.

d′) $u_* : C'^\wedge \longrightarrow C^\wedge$ est une équivalence [plutôt $u_* : C^\wedge \longrightarrow C'^\wedge$].

d″) $u^* : C'^\wedge \longrightarrow C^\wedge$ est une équivalence.

on a

$$F \;=\; \varinjlim_{I} x_i \;, \qquad x_i \in \mathrm{Ob}\,\mathcal{M}_{\pi_0},\; I \text{ grande devant } \pi_0,\; \mathrm{card}\, I \leqslant \pi^{\pi_0}.$$

Pour ceci, on utilise (4.7.6.2), page 171, [page 202]

$$\mathcal{M}_\pi \;\subset\; \mathrm{Filt}^{\pi^{\pi_0}} \qquad (\text{si } \pi \geqslant \pi_0,\; \pi^{\pi_0} \geqslant \pi_1),$$

et la définition de $\mathrm{Filt}^{\pi'}$ (pour $\pi' \geqslant \pi_0$) nous montre que c'est là la conclusion cherchée.

Prouvons donc 2°). Comme $\mathcal{M}_{\pi_0}$ est stable par les $\varinjlim$ inductives finies qui sont représentables dans $\mathcal{M}$ (SGA 4 I 9.9), il est stable par facteurs directs, et comme il contient C, on a donc $C^\natural \subset \mathcal{M}_{\pi_0}$. L'inclusion inverse $\mathcal{M}_{\pi_0} \subset C^\natural$ se voit de la façon standard, en écrivant un objet F de $\mathcal{M}_{\pi_0}$ comme $\varinjlim_I x_i$, les x_i dans C, I grande devant π_0, alors F est facteur direct d'un des x_i.

Le fait que $C^\natural$ est une *enveloppe de Karoubi* de C dans $\mathcal{M} \subset C^\wedge$ provient du fait que $\mathcal{M}$ est stable par facteurs directs, et que C est une sous-catégorie pleine de $\mathcal{M}$, cf. SGA 4 I (? …).

4.8.6. Questions ouvertes. On a ainsi prouvé 4.8.1 revu et corrigé. Il reste la question :

1) Donner un exemple où 4.8.1 a) est vérifié, mais non b) etc. ([56]).
2) Dégager des conditions supplémentaires serviables qui, jointes à a), impliquent b), donc c, c′.

Signalons aussi pour mémoire les questions suivantes. [page 203]

3) Soit $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, et $\pi > \pi_0$. Alors Filt^π est-il stable par facteurs directs ? Cela est-il vrai du moins si $\pi = \pi^{\pi_0}$, ou ce qui revient au même (cf. 4.7.3), a-t-on dans ce cas $\mathrm{Filt}^\pi = \mathrm{Filt}'^\pi$? Si oui, il serait inutile dans la description 4.7.7 des filtrations cardinales, dans la majoration de cardinaux (4.7.7.1), $\mathrm{card}\, I \leqslant \pi'^\pi$, de mettre l'hypothèse restrictive $\pi'^\pi \geqslant \pi_1$.

Commentary · Exposition [ms. 202]

The compact part is an idempotent completion

Grothendieck identifies the part of an ind-completion that is already present at its initial cardinal. This is the first place where the completion by retracts must be treated as a structural operation. For $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, every representable is λ-presentable, and so is every retract of a representable. Conversely, write a λ-presentable F as a λ-filtered colimit $\varinjlim_i y(c_i)$. Preservation of that colimit by $\mathrm{Hom}(F, -)$ makes 1_F factor through one of its terms:

$$F \xrightarrow{s} y(c_i) \xrightarrow{r} F, \qquad rs = 1_F.$$

Hence $\mathcal{M}_{\pi_0}$ is exactly the retract closure of $y(C)$. Idempotents split in $\mathcal{M}$: a filtered presentation of the splitting is obtained by iterating the idempotent along an ordinal of cofinality greater than π_0, or by the finite idempotent indexing category used earlier in this commentary. Since idempotents split in the presheaf category, their splitting objects lie in the ind-completion. We have therefore proved

$$\mathcal{M}_{\pi_0} \simeq \mathrm{Kar}(C), \qquad \mathrm{Ind}_{\pi_0}(\mathcal{M}_{\pi_0}) \simeq \mathcal{M}.$$

The second equivalence follows either from the same presentations or by factoring the identity through the fully faithful comparison functor. It is the useful-cardinal assertion of 4.8.5; the separate quantitative notion called regularity in the manuscript additionally uses the presentation-size estimate from 4.7.6.

The list in footnote 84 is the corresponding Morita invariance statement. A fully faithful $u : C \to C'$ whose image contains every object of C' up to retract induces an equivalence on idempotent completions. Restriction then induces an equivalence of presheaf categories: any set-valued presheaf extends uniquely, up to unique isomorphism, across a split idempotent, because its value at that retract must be the image of the induced idempotent of a set. The left and right

56. Il suffit de trouver un cardinal non régulier, pour la fcg canonique d'une $\mathcal{M} = \mathrm{Ind}_{\pi_0} C$.

Kan extensions are the inverse equivalences. They also preserve the indicated ind-subcategories. Conversely, an equivalence induced on Ind_{π_0} identifies its λ-presentable objects, and therefore identifies $\mathrm{Kar}(C)$ with $\mathrm{Kar}(C')$. The same argument at $\lambda = \aleph_0$ gives ordinary Ind. This proves the equivalences in the footnote; the variance of u_* must be $C^\wedge \to C'^\wedge$, as the editors already indicate.

The modern higher-categorical formulation identifies the compact objects of an ind-completion with the idempotent completion of its input (Lurie, 2009, Lemma 5.4.2.4). The ordinary proof above shows which part of that statement is already fully present here: the identity of a compact object factors through a single stage, and the resulting projector is the only extra object that completion has introduced at this cardinal.

Pour avoir une réponse affirmative à cette question, pour π donné, il suffirait (et probablement faudrait) d'avoir une réponse affirmative à celle-ci : Soient $\mathcal{D}$, $\mathcal{D}_0$ deux catégories grandes devant π_0, $\mathcal{D}_0$ facteur direct de $\mathcal{D}$, $\mathcal{D}$ admettant une catégorie cofinale I grande devant π_0, de cardinal $\leqslant \pi$. Alors en est-il de même de $\mathcal{D}_0$? Si p est une rétraction de $\mathcal{D}$ sur $\mathcal{D}_0$, la difficulté est que je ne sais pas si p est foncteur cofinal. En fait, je vois que ce n'est pas toujours le cas, même si $\mathcal{D}$ est finie. Prenons p.ex. pour $\mathcal{D}_0$ une catégorie ayant objet final e, et une flèche $x \longrightarrow e$ qui n'est pas un isomorphisme, et admettant une section (p.ex. $\mathcal{D}_0$ la sous-catégorie pleine de $\mathbf{\Delta}$ formée par $\mathbf{\Delta}_0$, $\mathbf{\Delta}_1$: $\mathbf{\Delta}_0 \underset{\partial_1}{\overset{\partial_0}{\rightrightarrows}} \mathbf{\Delta}_1$). Soit $\mathcal{D}$ déduit de $\mathcal{D}_0$ en ajoutant un objet final $\tilde{e}$. Alors $\mathcal{D}_0$, $\mathcal{D}$ sont filtrantes, et on obtient une rétraction de $\mathcal{D}$ sur $\mathcal{D}_0$, envoyant $\tilde{e}$ sur x. Ce foncteur n'est pas cofinal, car un foncteur cofinal doit envoyer $\tilde{e}$ en e. p. 72 [page 204]

Plus généralement, si $\mathcal{D}_0$ est une catégorie telle qu'il existe une flèche

$$(*) \qquad \alpha : e_{\mathcal{D}_0^\wedge} \longrightarrow x_0$$

dans $\mathcal{D}_0^\wedge$, avec $x_0 \in \mathrm{Ob}\,\mathcal{D}_0$, alors on voit que $\mathcal{D}_0$ est grande devant π_0 quel que soit le cardinal infini π_0, et que d'autre part, désignant encore par $\mathcal{D}$ la catégorie déduite de $\mathcal{D}_0$ en lui ajoutant un objet final, il y a une rétraction de $\mathcal{D}$ sur $\mathcal{D}_0$ qui envoie $e_{\mathcal{D}}$ dans x_0. Cette rétraction n'est cofinale que si x_0 est un objet final de $\mathcal{D}_0$, i.e. si et seulement si $(*)$ est un isomorphisme. Supposons qu'il n'en soit pas ainsi. Mais il y a un foncteur cofinal de la sous-catégorie I_0 de $\mathcal{D}_0$, telle que $\mathrm{Ob}\, I_0 = \{x_0\}$, $\mathrm{Fl}\, I_0 = \mathrm{End}_{I_0}(x_0) = \{p, \mathrm{id}_{x_0}\}$, où p est le composé $x_0 \xrightarrow{\text{can.}} e_{\mathcal{D}_0^\wedge} \xrightarrow{\alpha} x_0$. Donc pas de contre-exemple de cette façon !

4) Considérons $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, C petite, et considérons la filtration canonique $(\mathcal{M}_\pi)_{\pi \geqslant \pi_0}$. Donner des exemples où il y a des cardinaux non utiles, ou mieux, ou pour tout cardinal π, existe un cardinal $\pi' > \pi$ qui soit non utile. (Cela donnera l'exemple demandé dans 1°.) D'autre part, donner des exemples de cardinaux utiles qui ne soient réguliers – si possible, comme tantôt, de tels cardinaux aussi grands qu'on veut. [page 205]

Commentary · Examples [ms. 204]

A retraction can fail cofinality without losing a small presentation

Grothendieck's example separates two operations that are easy to confuse: retracting a category and choosing a final functor into it. Take the full subcategory $D_0 \subset \mathbf{\Delta}$ on [0] and [1]. Its terminal object is [0], while [1] → [0] has two sections. Choose one, $s : [0] \to [1]$. Adjoin a new terminal object t to D_0, obtaining D. The maps

$$a \longrightarrow [0] \xrightarrow{s} [1] \qquad (a \in D_0)$$

form a natural cocone, so they define a retraction $p : D \to D_0$ with $p(t) = [1]$ and $p|_{D_0} = 1$. This p is not final. If it were, then for every $a \in D_0$ the colimit of $\mathrm{Hom}(a, p(-))$ would be a singleton. Since D has terminal object t, that colimit is $\mathrm{Hom}(a, [1])$. Taking $a = [0]$ gives two elements.

Nevertheless a finite final indexing category remains. More generally a section $1 \to y(x)$ of the terminal presheaf map $y(x) \to 1$ determines an idempotent $e : x \to x$. For every arrow $v : a \to x$, naturality gives $ev = \alpha_a$, independent of v. Let E have one object and endomorphisms $1, e$, with

$e^2 = e$. The functor $E \to D_0$ picking x is final: in $(a \downarrow E)$ every object $v : a \to x$ maps, using e, to α_a. This comma category is nonempty and connected. The category E is itself large in front of every cardinal: the constant components e give a cocone on every diagram in E. Thus a failed retraction argument supplies no counterexample to bounded ind-presentations.

Question 4.8.6(3) is answered affirmatively by the retract-presentation argument in our commentary on §4.7. The conclusion holds for the manuscript's indexing convention, which allows non-ordered filtered categories. If one insists on a poset presentation, a finite indexing category with a nontrivial idempotent can no longer be used without changing its size; this is precisely why the indexing convention belongs in the statement. At fixed points $\pi^{\pi_0} = \pi$, the equality $\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi}$ then follows from 4.7.3. The example here explains why the proof should work on presentations themselves, rather than assuming that an arbitrary categorical retraction is final.

Définition 4.8.7. Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie, π_0 un cardinal infini. On dit que $\mathcal{M}$ est π_0-*accessible* si $\mathcal{M}$ est équivalente à une catégorie $\mathrm{Ind}_{\pi_0}(C)$, C une petite catégorie, i.e. si elle satisfait aux conditions équivalentes b, c, c′ de 4.8.1 (impliquant la condition a), sans doute strictement plus faible). On dit que $\mathcal{M}$ est accessible s'il existe un cardinal tel que $\mathcal{M}$ soit π_0-accessible (**N.B.** si π_0 est un tel cardinal, alors tout cardinal $\pi > \pi_0$ tel que $\pi^{\pi_0} = \pi$, notamment les cardinaux π'^{π_0}, avec $\pi' \geqslant 2$, ont la même propriété), ou ce qui revient au même [page 206]
d'après 4.8.1, si $\mathcal{M}$ admet une fcga, ou encore une fcg canonique.

Commentaire 4.8.8. Cette définition est en contradiction avec la terminologie introduite dans SGA 4 I 9.4 (p. 114) ; on désignera dorénavant sous les noms de "catégorie faiblement π_0-accessible", "catégorie faiblement accessible" les notions introduites dans 9.4 – i.e. les catégories admettant une sous-catégorie pleine génératrice (pas même strictement génératrice) dont les objets sont π_0-accessibles (resp. accessibles).

Notons que si $\mathcal{M}$ est π_0-accessible (resp. accessible), la condition de 4.8.1 nous dit que $\mathcal{M}$ est faiblement π_0-accessible (resp. faiblement accessible), et même qu'il existe une petite sous-catégorie pleine *strictement* génératrice, qui soit formée d'objets π_0-accessibles (resp. accessibles). Je doute fort que cette dernière condition nécessaire soit aussi suffisante pour que $\mathcal{M}$ soit π_0-accessible (resp. accessible). Mais en vertu de 4.6.3.3 (p. 150), il en est ainsi si p. 73
on suppose C stable par petites $\varinjlim$, ou ce qui revient au même, moyennant L_{π_0}, stable par limites inductives de cardinal $\leqslant \pi_0$.

Proposition 4.8.9. *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie accessible (4.8.7), π_0 un cardinal tel que $\mathcal{M}$ satisfait à L_{π_0}. Conditions équivalentes :* [page 207]

a) $\mathcal{M}$ est une catégorie paratopos (cf. 4.6.3, 3°, p. 150).

b) $\mathcal{M}$ est stable par petites limites inductives.

b′) $\mathcal{M}$ est stable par limites inductives de cardinal $\leqslant \pi_0$.

b″) (Si $\mathcal{M}$ est équivalente à une catégories $\mathrm{Ind}_{\pi_0} C$, avec C une petite catégorie karoubienne.*) La catégorie C est stable (en elle-même) par limites inductives de cardinal $\leqslant \pi_0$.*

c) $\mathcal{M}$ est stable par petites limites projectives.

c′) (Sous l'hypothèse $\mathcal{M} \simeq \mathrm{Ind}_{\pi_0}(C)$, et quand on se donne un cardinal π tel que $\pi = \pi^{\pi_0} \geqslant \pi_1 = \sup(\pi_0, \mathrm{card\,réd}\, C)$.) $\mathcal{M}_\pi$ est stable par $\varprojlim$ finies, et $\mathcal{M}$ est stable par petits produits infinis (ou encore, par $\varprojlim$ filtrantes).

c″) Il existe un cardinal infini π, et une petite catégorie $\mathcal{D}$ stable par $\varprojlim$ finies, telle que $\mathcal{M} \simeq \mathrm{Ind}_{\pi}(\mathcal{D})$, de plus $\mathcal{M}$ stable par produits infinis (ou encore par $\varprojlim$ filtrantes).

([57], [58]).

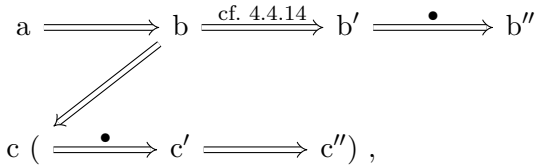
57. **N.B.** L'équivalence de c′, c″ avec les autres conditions n'est pas établie (ici, mais seulement dans 4.11 plus bas.)

58. **N.B.** Les critères c′, c″ me paraissent plus techniques et moins utiles `[c′, c″ ci-dessus sont mis en parenthèses]`.

Commentary · Present state [ms. 206]

Accessibility and the chosen cardinal

Grothendieck's change of terminology brings the chapter to the modern structural notion: an accessible category is generated by a small subcategory under sufficiently filtered colimits, with the generators presentable at the same cardinal. His earlier weak notion only asked for a small generating family of accessible objects. The cardinal is part of the assertion. In particular, the existence of a dense family of μ-presentable objects and of μ-filtered colimits does not by itself provide the filtered presentation required in the definition.



Questions 4.8.6(1) and the nonuseful-cardinal part of (4) have a common concrete answer. Let $\mathcal{K}$ be the category of nonempty $\aleph_1$-directed posets and monotone maps. It is $\aleph_1$-accessible: each object is the $\aleph_1$-directed union of its countable subposets with a greatest element. Its λ-presentable objects, for regular $\lambda \geq \aleph_1$, are precisely the posets of cardinal less than λ. Our commentary on §4.7 proves these facts and the resulting obstruction, following Vasey (2020, Example 3.8). For every singular $\theta > \aleph_1$ of countable cofinality, the poset $[\theta]^{<\aleph_1}$ has no cofinal subset of cardinal at most θ. If it were a θ^+-filtered colimit of θ^+-presentables, a single stage image would contain all θ singleton subsets. That image would be $\aleph_1$-directed and of cardinal at most θ, hence would be a forbidden cofinal subset. Thus $\mathcal{K}$ is not θ^+-accessible, although its original small dense family of countable presentables remains θ^+-presentable. It satisfies 4.8.1(a), but not (b), at manuscript cardinal θ. Taking arbitrarily large such θ answers the unbounded version of (4) for this one category.

The modern change-of-cardinal theorem explains the allowed upward steps through a sharp-inequality hypothesis; see Lurie (2009, Proposition 5.4.2.9 and Remark 5.4.2.10). Grothendieck's sufficient equation $\pi^{\pi_0} = \pi$ is a concrete way to ensure the requisite closure of small subsets under the previous stage's operations. The example shows why the cardinal condition has mathematical content.

For question (2), cocompleteness is a sufficient condition already established in 4.6.3. More economically, adjoining the existence of all colimits with at most π_0 arrows to L_{π_0} supplies cocompleteness by the earlier decomposition of a small diagram into bounded pieces. The closure of the chosen generators under those colimits then makes the overcategories filtered at the required cardinal. This is a repair by adding operations that create cones, rather than merely adding more generators.

The useful-but-nonregular alternative in question (4) is excluded by the repaired presentation argument of §4.7. If π is useful in the sense of the comparison equivalence, write $\mathcal{M} = \mathrm{Ind}_\pi(\mathcal{M}_\pi)$. For $\pi' > \pi$ put $\mu = (\pi')^\pi$, so that $\mu^\pi = \mu$. Given $F \in \mathcal{M}_{\pi'} \subseteq \mathcal{M}_\mu$, the fixed-point presentation theorem, with base category $\mathcal{M}_\pi$, supplies a π^+-filtered presentation of F of size at most μ. The bounded cofinal-poset construction in our commentary on §4.7 makes this index ordered without increasing its size. This is precisely the quantitative regularity required in 4.7.13, without an additional threshold π_1. The nonuseful cardinals supplied above therefore exhaust the possible kind of failure asked for in question (4).

Démonstration. Les implications suivantes sont tautologiques, ou déjà ± connues :

où seules les implications pointées $b' \Longrightarrow b''$ et $c \Longrightarrow c'$ demandent une démonstration. Pour [page 208]
$b' \Longrightarrow b''$, on note que l'hypothèse C karoubienne implique que $C \simeq \mathcal{M}_{\pi_0}$ (4.8.5, 2°), or on sait que $\mathcal{M}_{\pi_0}$ est stable dans $\mathcal{M}$ par limites inductives de cardinal $\leqslant \pi_0$ (et celles-ci sont représentables dans $\mathcal{M}$ en vertu de b′), donc $\mathcal{M}_{\pi_0}$ admet des $\varinjlim$ du type envisagé, donc C aussi.

$c \Longrightarrow c'$. Notons que si $\mathcal{M} = \mathrm{Ind}_{\pi_0}(C)$, alors les $\varprojlim$ représentables dans $\mathcal{M}$ se calculent dans $C^\wedge$. Il s'ensuit que si $\pi \geqslant \pi_1$, alors Filt^π est stable par $\varprojlim$ finies (Filt^π étant donné alors par la condition a″ de 4.7.1), d'autre part, si de plus $\pi^{\pi_0} = \pi$, π est un cardinal utile, donc $\mathcal{M} \simeq \mathrm{Ind}_\pi(\mathcal{D})$, où $\mathcal{D} = \mathrm{Filt}^\pi = \mathcal{M}_\pi$. Il suffit maintenant de voir que $\mathrm{Ind}_\pi(\mathcal{D})$ est alors stable par $\varprojlim$ finies, pour conclure qu'il en est de même de $\mathcal{M}$, donc que $\mathcal{M}$ est stable par limites

projectives quelconques, s'il l'est par petites produites ou par petites $\varprojlim$ filtrantes, d'où c′. Il reste donc à prouver le lemme suivant.

Lemme 4.8.10. *Soient C une petite catégorie, π_0 un cardinal infini, $\pi_1 = \sup(\pi_0, \operatorname{card} \text{réd}\, C)$.* p. 74
Supposons Ind_{π_0} stable par $\varprojlim$ finies (resp. et d'un certain type). Alors pour tout $\pi \geqslant \pi_1$, [page 209]
Filt^{π} est stable par lesdites $\varprojlim$. (Donc aussi $\mathcal{M}_\pi = \mathrm{Filt}^{\pi}$, si $\pi = \pi^{\pi_0}$.) Plus généralement, soit J une petite catégorie telle que $\mathrm{Ind}_{\pi_0} C$ soit stable par $\varprojlim$ de type J, et soit $c = \operatorname{card} \text{réd}\, J$, supposons que $\pi^c = \pi$ (p.ex. c fini). Alors Filt^{π} est stable dans $\mathcal{M}$ par $\varprojlim$ de type J. (Donc il en est de même de $\mathcal{M}_\pi = \mathrm{Filt}^{\pi}$, si de plus $\pi^{\pi_0} = \pi$.)

On utilise le critère a″ de 4.7.1, savoir $\operatorname{card} F(x) \leqslant \pi$ pour tout $x \in C$, pour l'appartenance à Filt^{π}. On peut supposer J réduite, donc $\operatorname{card} \mathrm{Ob}\, J \leqslant c$. Comme le foncteur d'inclusion $\mathrm{Ind}_{\pi_0}(C) \longrightarrow C^{\wedge}$ commute aux $\varprojlim$ quelconques, le calcul de $\varprojlim_{j \in J} x_j$ dans $C^{\wedge}$ fibre par fibre montre que dans $C^{\wedge}$, on a

$$X \overset{\text{déf}}{=} \varinjlim_{j \in J} x_j \;=\; \underbrace{\prod_{j \in \mathrm{Ob}\, J} x_j}_{\text{produit dans } C^{\wedge}} \quad ,$$

d'où

$$\operatorname{card} X(x) \;\leqslant\; \prod_{j \in \mathrm{Ob}\, J} \underbrace{\operatorname{card} x_j(x)}_{\leqslant \pi} \;\leqslant\; \pi^c \ ,$$

d'où (sans autre hypothèse sur π que $\pi \geqslant \pi_1$)

$$\varprojlim_{j \in J} x_j \;\in\; \mathrm{Ob}\, \mathrm{Filt}^{\pi^c} \ , \tag{4.8.10.1}$$

d'où la conclusion voulue si $\pi^c = \pi$, q.e.d.

[page 210]

Commentary · Exposition [ms. 209]

Limits are bounded by products

Grothendieck's cardinal estimate makes finite limits manageable at sufficiently large stages of the filtration. It uses the restricted Yoneda embedding, not a special property of the object being limited. An existing limit in $\mathcal{M}$ is carried to the pointwise limit of its restricted representable functors, because each $\mathrm{Hom}(c, -)$ preserves limits. If $X = \lim_{j \in J} X_j$, then

$$X(c) \hookrightarrow \prod_{j \in \mathrm{Ob}\, J} X_j(c), \qquad |X(c)| \leq \pi^{|\mathrm{Ob}\, J|}$$

whenever $|X_j(c)| \leq \pi$. The source display has two slips: an inductive limit in place of a projective one, and an equality with the product in place of an inclusion. A limit imposes the compatibility equations associated with the arrows of J; deleting those equations generally enlarges it. The next displayed inequality is correct and is all the proof needs.

For example, let J be the parallel-pair category and take two functions $f, g : A \rightrightarrows B$. Its limit is the equalizer $\{a \in A : f(a) = g(a)\}$, with the redundant B-coordinate determined by a. For $A = B = \{0, 1\}$, $f = 1$, and g the transposition, that limit is empty, while the product over the two objects of J has four elements. Thus the equality cannot be read literally even in sets. For a finite nonempty shape and infinite π, the estimate becomes $\pi^{|\mathrm{Ob}\, J|} = \pi$; the empty shape is the terminal presheaf and has singleton values. The latter should be treated separately when the notation $\mathrm{Filt}^{\pi^0} = \mathrm{Filt}^1$ would fall outside the filtration's declared range. This proves the intended finite-limit bound without changing any substantive conclusion of 4.8.10.

Nous allons prouver les implications supplémentaires

$$\mathrm{b}'' \implies \mathrm{b}\ , \qquad \mathrm{c} \implies \mathrm{b}\ , \qquad \mathrm{c}'' \overset{?}{\implies} \mathrm{c}\ ,$$

ce qui achève la démonstration.

L'implication b″ $\Longrightarrow$ a est contenue dans 4.6.3.

Pour l'implication c $\Longrightarrow$ b, on note que la stabilité de $\mathcal{M}$ par petites $\varinjlim$ équivaut à l'assertion que toute petite limite projective de foncteurs $\mathcal{M} \xrightarrow{\xi_i}$ Ens représentables, est représentable. Or les objets de $\mathcal{M}$ étant accessibles ($\mathcal{M}$ étant accessible), les foncteurs représentables ξ_i sont accessibles, donc aussi leur $\varprojlim$ (SGA 4 I 9.7). D'autre part, le foncteur ξ est exact à gauche, comme $\varprojlim$ de foncteurs représentables donc exactes à gauche. Donc le fait que ξ est représentable résulte du

Lemme 4.8.11. *Soit $\mathcal{M}$ une catégorie accessible, stable par $\varprojlim$ finies, $\mathcal{M} \longrightarrow$ Ens un foncteur. Pour que ξ soit représentable, il faut et il suffit qu'il soit exact à gauche et accessible. Donc (SGA 4 I 8.12.8.1) si $\mathcal{M}$ est stable par petites $\varprojlim$, ξ est représentable si et seulement s'il commute auxdites $\varprojlim$, et qu'il soit accessible.*

p. 75

Commentary · Examples [ms. 210]

Prorepresentability is the missing word

Grothendieck is trying to recover colimits from completeness by representing a limit of covariant representable functors. That strategy is sound, but the first sentence of Lemma 4.8.11, as printed, is false: accessibility and preservation of finite limits imply *prorepresentability*, not representability. This is exactly the conclusion of the cited SGA 4, I, 8.13.2(b). The following sentence, which adds all small limits, is the representability statement; SGA 4, I, 8.12.8.1 supplies the additional step (Artin et al., 1972).

An explicit example keeps the two conclusions apart. Put $A_n = \{0,1\}^n$, with the truncation surjections $A_{n+1} \to A_n$, and define a covariant functor on sets by

$$T(X) = \varinjlim_{n<\omega} X^{A_n}.$$

The transition maps repeat a function on the two extensions of each binary word. Thus $T(X)$ is the set of functions from $\{0,1\}^{\mathbb{N}}$ to X which depend on finitely many coordinates. It is equally the functor of continuous maps from the Cantor space to the discrete space X; compactness ensures that such a map factors through some A_n.

Each functor X^{A_n} preserves all limits and filtered colimits, since A_n is finite. Filtered colimits commute with finite limits in sets. It follows, by interchanging two colimits for the accessibility assertion, that T is finitary and preserves finite limits. However, the comparison

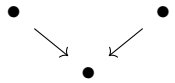
$$T(\{0,1\}^{\mathbb{N}}) \longrightarrow \prod_{k<\omega} T(\{0,1\})$$

does not contain the family of coordinate functions in its image. A preimage would have to be the identity function on $\{0,1\}^{\mathbb{N}}$, which depends on every coordinate. Therefore T fails to preserve this countable product and cannot be representable. Its defining inverse system (A_n) is its prorepresentation. This is a fully explicit counterexample to the printed first sentence, with $\mathcal{M} = \mathrm{Set}$ satisfying even stronger hypotheses than those stated.

The application $c \Rightarrow b$ in 4.8.9 survives. If $D : K \to \mathcal{M}$ is small and $\mathcal{M}$ is accessible and complete, the functor

$$H(X) = \varprojlim_{k \in K^{\mathrm{op}}} \mathrm{Hom}(Dk, X)$$

preserves all small limits. Choose a sufficiently large useful cardinal so that all Dk are presentable and K has smaller cardinality. Interchange of its defining small limit with sufficiently filtered colimits makes H accessible. The solution-set form of the adjoint functor theorem now represents H, and its representing object is $\varinjlim_K D$.



For completeness, the required solution set consists of all pairs (A, a) with A in a small presentable generating subcategory at a suitable cardinal and $a \in H(A)$. Every (X, x) receives a map from such a pair because H preserves the generating filtered colimits. The category of elements of H is complete, since H preserves all limits. A complete locally small category with a small weakly initial family has an initial object: take the product of the family to obtain a weakly initial object P, then equalize all endomorphisms of P. If $e : E \to P$ is that equalizer, choose $r : P \to E$ by weak initiality.

Since $ere = e$, monicity gives $re = 1_E$. For any $h : E \to E$, the endomorphism ehr of P satisfies $ehre = e$, hence $h = 1_E$. Equalizers of two maps out of E, together with weak initiality of E, then show uniqueness of every such map. Thus E is initial. This proves the representability step with the hypothesis actually needed.

Le "il faut" est remis pour mémoire, on vient de le voir comme conséquence du fait que tout objet de $\mathcal{M}$ est accessible. Le "il suffit" est essentiellement SGA 4 I 8.13.2.b), sauf que dans loc. cit. on suppose $\mathcal{M}$ munie d'une fc *stricte.* Mais la démonstration donnée dans loc. cit. montre aussi pour une fcga, en choisissant dans loc. cit. (p. 137) π tel que ξ soit π-accessible, et de plus π soit utile pour la filtration cardinale généralisée envisagée.

Reste à prouver $c'' \overset{?}{\Longrightarrow} c$, sous réserve que ce soit bien vrai. Ce serait une conséquence du lemme suivant (où $\mathcal{D}$, π sont remplacés par C, π_0).

Lemme 4.8.12 (?) ([88]). *Soient C_0 une petite catégorie, π_0 un cardinal infini. Si C est stable par $\varprojlim$ finies, alors $\mathrm{Ind}_{\pi_0} C$ également.*

L'assertion similaire pour $\mathrm{Ind}(C)$, au lieu de $\mathrm{Ind}_\pi C$, est établie dans SGA 4 I 8.9.1 c). Mais il n'est pas clair sans plus que $\mathrm{Ind}_\pi C$ soit stable dans $\mathrm{Ind}(C)$ par $\varprojlim$ finies, dans le cas envisagé. De façon précise, si $F = \varprojlim_{j\in J} F_j$, les F_j dans $\mathrm{Ind}_\pi C$, F dans $\varprojlim \mathrm{Ind}(C) \subset C^\wedge$, on sait [page 212]
que C/F est filtrant et il faut voir qu'il est filtrante grande devant π_0. On est ramené aux trois cas où $J = \emptyset$, $J = e \amalg e$, et $J =$  . Les deux premiers cas sont essentiellement triviaux (car e, et un produit de deux catégories grandes devant π_0, sont grandes devant π_0), le troisième cas par contre n'a pas l'air trivial a priori. C'est lié visiblement à la question des représentations indicielles de foncteurs $J \longrightarrow \mathrm{Ind}_{\pi_0}(C)$, pour $\mathrm{card\,réd}\, J \leqslant \pi_0$ – i.e. la validité de 4.4.13 b) en dehors de l'hypothèse que C soit stable par $\varinjlim$ de cardinal $\leqslant \pi_0$. Il nous faudra y revenir très prochainement, car cette question m'apparaît à présent une question-clef, pour les propriétés de stabilité de la notion de catégorie accessible (en dehors d'aucune hypothèse d'existence de $\varinjlim$ ou $\varprojlim$).

Proposition 4.8.13 ([89]). *Soit C une catégorie équivalente à une petite catégorie, et soit $\pi_0 \geqslant \mathrm{card}\, réd\, C$ un cardinal infini. Alors $\mathcal{M} = \mathrm{Ind}_{\pi_0} C = \mathcal{M}_{\pi_0}$ (i.e. tous les objets de $\mathrm{Ind}_{\pi_0} C$ sont π_0-accessibles), et $\mathcal{M}$ est une enveloppe de Karoubi de C.*

[page 213]

Commentary · Exposition [ms. 212]

Finite limits of a bounded ind-completion

Grothendieck isolates the real issue in Lemma 4.8.12: the pointwise limit must still admit a presentation with the stronger filteredness condition. The statement is true. Its ordinary ind-version is SGA 4, I, 8.9.1(c), and the later manuscript returns to it in 4.11.7 (Artin et al., 1972; Grothendieck, 1990–1991n). We give the bounded argument, since it needs only a span and does not assume an indexed representation theorem for arbitrary finite categories with endomorphisms.

Suppose C has finite limits, and put $\lambda = \pi_0^+$. The terminal presheaf is represented by the terminal object of C. For two λ-filtered presentations, the product indexing category is λ-filtered and filtered colimits commute with finite products in sets; hence their product is a λ-filtered colimit of the representing products. It remains to treat a pullback $F \times_H G$.

Choose small λ-filtered presentations $F = \varinjlim_i y(a_i)$, $G = \varinjlim_j y(b_j)$, and $H = \varinjlim_k y(c_k)$. Let L have objects (i, j, k, u, v), where $u : a_i \to c_k$ and $v : b_j \to c_k$ induce the given maps to H. Its arrows are triples of index arrows making the two squares commute. The category L is λ-filtered. To see this, begin with a diagram in L having fewer than λ arrows. Choose cones on its i-, j-, and k-components. The maps from the resulting a_i, b_j to H factor at some stages of the c-diagram, since representables are λ-presentable. Move them and the previously chosen k-cone to a common stage. Each desired compatibility equation holds in H, so it holds after a further transition. There are

88. Lemme non prouvé ici – cf. démonstration 4.11.7 (non achevée).

89. *Pas prouvé.* Mais OK si $\pi_0 > \mathrm{card\,réd}\, C$, cf. 4.15.10, p. 462.

fewer than λ such equations; λ-filteredness supplies one further stage satisfying all of them. The resulting object of L is the required cone. The same argument with an empty starting diagram gives nonemptiness.

There is a canonical comparison

$$\varinjlim_{(i,j,k,u,v)\in L} y(a_i \times_{c_k} b_j) \longrightarrow F \times_H G.$$

Evaluate at $d \in C$. A pair of elements on the right is represented by maps $d \to a_i$, $d \to b_j$ whose images agree in $H(d)$. Factor the two maps to H through a common c_k and enlarge k until their composites from d agree; the pair then factors through $a_i \times_{c_k} b_j$. This proves surjectivity. If two representatives have the same image, first move their i- and j-indices forward until the two coordinate maps agree; then choose a common k and impose the finitely many compatibility equations just used in the filteredness proof. The two representatives become equal in the left-hand colimit. This proves injectivity, naturally in d.

The displayed comparison is therefore an isomorphism. Its source is a λ-filtered colimit of representables, which proves the lemma. Together with arbitrary products it supplies all small limits. If instead all small cofiltered limits are assumed, an arbitrary product is the inverse limit of its finite subproducts, indexed by the opposite of the directed poset of finite subsets. Thus the alternative formulation using filtered projective limits in 4.8.9 is justified as well.

Signalons tout de suite les corollaires suivants.

Corollaire 4.8.14 ([90]). *Soit $\mathcal{M}$ une $\mathfrak{U}$-catégorie. Conditions équivalentes :*

a) $\mathcal{M}$ est accessible, et est équivalent à une petite catégorie.

a′) $\mathcal{M}$ est accessible, et il existe un cardinal infini π_0 tel que tous les objets de $\mathcal{M}$ soient π_0-accessibles (i.e. $\mathcal{M} = \mathcal{M}_{\pi_0}$).

b) $\mathcal{M}$ est équivalente à une petite catégorie, et est karoubienne, i.e. stable par facteurs directs ([91]).

L'équivalence de a) et a′) est claire, puisque $\mathcal{M}$ admet une filtration cardinale généralisée canonique $(\mathcal{M}_\pi)_{\pi\geqslant\pi_0}$, formée des catégories équivalentes à des petites catégories (condition a) des fcg), et telle que toute telle sous-catégorie soit contenue dans un des $\mathcal{M}_\pi$ (résulte de la condition b) des fcg). Comme $\mathcal{M}_{\pi_0}$ est équivalente à une petite catégorie, et est karoubienne (étant stable par $\varinjlim$ filtrantes grandes devant π_0), il est clair aussi que a′) $\Longrightarrow$ b). Reste à prouver b) $\Longrightarrow$ a′), or cela résulte aussitôt de 4.8.13 appliqué à $\mathcal{M}$, qui montre de plus qu'on peut prendre pour π_0 n'importe quel cardinal infini tel que $\pi_0 \geqslant \operatorname{card}\text{réd}\,\mathcal{M}$. p. 76

[page 214]

Commentary · Examples [ms. 213]

An accessible category can have an accessible opposite

Grothendieck's proposed converse in footnote 91 would turn accessibility on both sides into a smallness criterion. Partial injections show why the existence of many filtered colimits is insufficient for this purpose. Let $\mathcal{P}$ have small sets as objects and partial injective functions as arrows. Thus an arrow $X \dashrightarrow Y$ consists of a subset $D \subseteq X$ and an injection $D \hookrightarrow Y$. Taking the inverse partial function defines an isomorphism $\mathcal{P}^{\mathrm{op}} \cong \mathcal{P}$. This category is finitely accessible; precise published treatments of the example include Heunen (2013, §3.2, Proposition 3.6, Lemma 3.8, Theorem 3.9). We give a direct argument, also keeping track of the larger cardinals used in this chapter.

Adjoining a basepoint identifies $\mathcal{P}$ with the category of pointed sets and pointed functions whose fibre over each nonbasepoint has at most one element. A partial function sends points outside its domain to the basepoint. Let $(X_i)_{i\in I}$ be a filtered diagram in $\mathcal{P}$, and form its colimit L_* in pointed sets. The canonical map $(X_i)_* \to L_*$ has at most one element over every nonbasepoint. Indeed, if two points of X_i have the same nonzero image, filteredness gives a stage at which they have the same nonzero image; the transition map is a partial injection, so the points were equal. Consequently the canonical maps define partial injections $X_i \dashrightarrow L$, where $L = L_* \setminus \{*\}$.

90. *Pas prouvé.* Si finalement, cf. 4.15.10, et 4.15.11, pages 462-463.

91. **N.B.** Ceci implique que $\mathcal{M}$ et $\mathcal{M}^\circ$ sont accessible, et je conjecture que la réciproque est vraie également.

The same argument proves the universal property within $\mathcal{P}$. A cocone $X_i \dashrightarrow Y$ gives a unique pointed function $L_* \to Y_*$. If two nonzero elements of L_* have the same nonzero image, represent them at a common stage. The cocone map at that stage is injective wherever it is defined; hence the representatives, and therefore the two colimit elements, coincide. The induced map is a partial injection. Thus filtered colimits exist in $\mathcal{P}$ and are created by this embedding into pointed sets.

Now let λ be an infinite regular cardinal. A set A of cardinal $< \lambda$ is λ-presentable in $\mathcal{P}$. To factor a partial injection $A \dashrightarrow L$ through a λ-filtered diagram, choose a representative for each of its fewer than λ defined values and move them to one stage. Distinct colimit values cannot have coincident representatives, so this gives a partial injection with exactly the prescribed domain. If two such factorizations have the same composite to L, the equality of their values, including any values that become the basepoint, is witnessed at later stages. There are fewer than λ witnesses; λ-filteredness puts them at one stage. This proves both surjectivity and injectivity of the presentability comparison map.

Conversely, X is the colimit of its subsets of cardinal $< \lambda$, ordered by inclusion. This poset is λ-filtered by regularity. If X were λ-presentable, its identity would factor through one of these inclusions $B \hookrightarrow X$. The composite being the total identity forces $X = B$, so $|X| < \lambda$. We have therefore proved the exact description

$$\mathcal{P}_\lambda^{\mathrm{pres}} = \{X : |X| < \lambda\}, \qquad \mathcal{P} \simeq \mathrm{Ind}_\lambda\big(\mathcal{P}_\lambda^{\mathrm{pres}}\big),$$

where Ind_λ in this display has its modern, regular-cardinal meaning. In the notation of the manuscript take $\lambda = \pi^+$: the π-accessible sets in $\mathcal{P}$ are exactly those of cardinal at most π. A skeleton of this subcategory is small, including its partial injections.

An isomorphism in $\mathcal{P}$ is an ordinary bijection: an inverse under partial composition forces both domains to be the whole sets. Thus $\mathcal{P}$ has objects of every small cardinality and is not essentially small relative to the chosen universe. Both it and its opposite are accessible. The conjectured converse is false; the equivalence in Corollary 4.8.14 between small accessible categories and small idempotent-complete categories is unaffected. The obstruction is visible without any higher category theory: a coproduct of two singleton sets does not exist in $\mathcal{P}$. The cocones in which exactly one singleton map is defined force both structural arrows to be everywhere defined and their images to be distinct. The cocone sending both singleton points to the same singleton then cannot factor through a partial injection. Completeness hypotheses cannot be dropped from the familiar duality restrictions for locally presentable categories.

4.8.15. Démonstration de 4.8.13. Nous allons prouver :

Lemme 4.8.15.1. *Sous les conditions de 4.8.13, soit $F \in \mathrm{Ob}\,\mathcal{M}$, $x \in \mathrm{Ob}\,C$, alors*

$$(*) \qquad \mathrm{card}\,F(x) \leqslant \pi_0 .$$

Ceci signifie donc, en vertu de 4.7.7, a$''$ $\Longrightarrow$ b pour $\pi \geqslant \pi_1$, compte tenu qu'ici $\pi_J = \pi_0$, $\pi = \pi_0$, qu'on a $F \in \mathrm{Filt}^{\pi_0}$, d'où a fortiori $F \in \mathcal{M}_{\pi_0}$, ce qui implique $\mathcal{M} = \mathcal{M}_{\pi_0}$, i.e. la proposition 4.8.13, compte tenu de 4.8.5. Donc tout revient à prouver $(*)$.

Écrivons

$$F = \varinjlim_{i \in I} x_i , \qquad \text{les } x_i \in \mathrm{Ob}\,C,\ I \text{ ensemble ordonné grand devant } \pi_0,$$

d'où

$$F(x) = \varinjlim_{i \in I} \mathrm{Hom}_C(x, x_i) .$$

On peut supposer

$$\mathrm{card}\,C = \pi_0 ,$$

quitte à remplacer C par une catégorie réduite équivalente.

Pour tout $\xi \in \mathrm{Ob}\,C$, soit

$$I_\xi = \{i \in I \mid x_i = \xi\} ,$$

alors

$$I \;=\; \bigcup_{\xi\in \mathrm{Ob}\, C} I_\xi \;,$$

réunion d'une famille de parties de I de cardinal $\mathrm{card}\,\mathrm{Ob}\,C \leqslant \pi_0$. Comme I est grand devant π_0, on voit que cela implique que l'ensemble des I_ξ est cofinal dans I. Quitte à remplacer I par I_ξ, on peut supposer $I_\xi = I$, i.e. que tous les x_i sont égaux à un même élément ξ. Quitte à remplacer C par la sous-catégorie pleine $C_0 = \{\xi\}$, on peut supposer C réduite à un seul élément. (Car si on prouve que F, en tant qu'objet de $\mathrm{Ind}_{\pi_0}(C_0)$, est facteur direct d'un objet de C_0 (i.e. de ξ), il en sera de même de F en tant qu'objet de $\mathrm{Ind}\,C$). Donc on peut supposer [page 215]

$$C \;=\; \{\xi\} \;,$$

donc C donné par le monoïde

$$M \;=\; \mathrm{End}_C(\xi) \;, \qquad \mathrm{card}\, M \;\leqslant\; \pi \;,$$

et la donnée du système inductif $(x_i)_{i\in I}$ revient à la donnée d'un système d'éléments

$$\alpha_{ji} \;\in\; M \qquad (i,j \in I,\; i \leqslant j)$$

satisfaisant p. 77

$$\alpha_{ii} \;=\; 1 \;, \qquad \alpha_{kj}\alpha_{ji} \;=\; \alpha_{ki} \;\text{ si } i \leqslant j \leqslant k.$$

On a

$$F(\xi) \;=\; \varinjlim_{i\in I} M_i \qquad \left\{ \begin{array}{l} \text{où } M_i = M \;\forall\, i \in I, \text{ et } M_i \longrightarrow M_j \\ \text{est donné par} \\ \qquad\qquad u \longmapsto \alpha_{ji} u \;. \end{array} \right.$$

J'ai pu me ramener, par des arguments similaires ([92]), au cas où le monoïde $M = \mathrm{End}(\xi)$ est un monoïde de monomorphismes, i.e. [page 216]

$$uv \;=\; uv' \;\;\Longrightarrow\;\; v \;=\; v' \qquad \text{si } u, v, v' \in \mathcal{M} \;,$$

ce qui implique que les flèches de transition dans le système inductif des $M_i = M$ sont des monomorphismes. Il s'ensuit que l'on ne peut avoir $\mathrm{card}\, F(\xi) \leqslant \pi_0$ (I étant grand devant π_0) que si α_{ji_0} est un isomorphisme pour $j \geqslant i_0$, et i_0 assez grand, i.e. si le système inductif induit pour $j \geqslant i_0$ est constant, a fortiori que le système inductif envisagé est essentiellement constant. Mais je viens de passer près de quatre heures pour essayer de prouver ce point, sans y être arrivé ! Cela semble plus délicat à prouver que je ne le prévoyais, mais je crois toujours que c'est bel et bien vrai.

[page 217]

Commentary · Present state [ms. 216]

The small-category theorem and its boundary

Grothendieck's intended conclusion is that enough filteredness forces a diagram in a small category to become constant up to splitting an idempotent. The reduction to a one-object category is valid. If a π_0^+-directed poset is the union of at most π_0 subsets, at least one subset is cofinal: otherwise choose one obstruction to cofinality for each subset and take a common upper bound, contradicting the union. The same subset, with its inherited order, remains π_0^+-directed. Applying this to the fibres of the object function gives a cofinal presentation whose values are one fixed object c; its remaining data lie in $\mathrm{End}_C(c)$.

92. Pour ces réductions, cf. 4.15.8 (p. 453-463). L'ultime réduction se trouve dans 4.15.8.9 (p. 461), et son corollaire 4.15.10.

The cancellation reduction and eventual-stationarity assertion on page 216 are not proved in these pages. Nor does the later annotation establish the exact endpoint printed in 4.8.13. The official continuation, 4.15.10–4.15.11, proves the conclusion under the strict inequality $\pi_0 > \operatorname{card}\operatorname{réd} C$ and explicitly describes it as a weaker form of 4.8.13 (Grothendieck, 1990–1991n). We use that strict-bound theorem for the applications here. It proves Corollary 4.8.14, because an essentially small category allows the cardinal to be enlarged. Thus an essentially small category is accessible exactly when it is idempotent complete; an accessible category with a common presentability bound on all objects is essentially small. The higher-categorical counterpart is Lurie (2009, Corollaries 5.4.3.5–5.4.3.6).

The equality case $\pi_0 = \operatorname{card}\operatorname{réd} C$ is deliberately kept separate in the audit. The checked forward reference and the general small-category result do not settle that fixed-cardinal assertion. We do not describe it as a currently open problem merely because its proof is absent here. What is established for this reading is the strict-bound result, the consequent small-category characterization, and the exact remaining endpoint in the printed proposition.

4.9 Le théorème de représentation indicielle pour $\mathrm{Ind}_\pi(C)$

4.9.1 ([93]). Soient C une catégorie équivalente à une petite catégorie, π_0 un cardinal infini,

$$\mathcal{M} \;=\; \mathrm{Ind}_{\pi_0}(C) \;\subset\; C^\wedge \;, \tag{4.9.1}$$

J une catégorie équivalente à une petite catégorie. Considérons l'inclusion pleinement fidèle $C \hookrightarrow \mathcal{M}$, et l'inclusion correspondante de $\mathfrak{U}$-catégories

$$\underline{\mathrm{Hom}}(J, C) \;\hookrightarrow\; \underline{\mathrm{Hom}}(J, \mathcal{M}) \qquad \text{(pleinement fidèle)}. \tag{4.9.2}$$

On sait, comme $C \subset \mathcal{M}_{\pi_0}$, que les objets de $\underline{\mathrm{Hom}}(J, C)$ donnent des objets π_0-*accessibles* de $\underline{\mathrm{Hom}}(J, \mathcal{M})$, du moins si on suppose

$$\operatorname{card}\operatorname{réd} J \;\leqslant\; \pi_0 \;, \tag{4.9.3}$$

ce que nous ferons désormais. (Cf. 4.5.8, 2°, p. 119.) Comme le deuxième membre de (4.9.2) satisfait L_{π_0} ($\mathcal{M}$ y satisfait), il s'ensuit que ce foncteur (4.9.2) se prolonge en

$$\mathrm{Ind}_{\pi_0}(\underline{\mathrm{Hom}}(J, C)) \;\hookrightarrow\; \underline{\mathrm{Hom}}(J, \underbrace{\mathcal{M}}_{=\mathrm{Ind}_{\pi_0}(C)}) \;, \tag{4.9.3}$$

et ce foncteur est *pleinement fidèle* grâce au résultat d'accessibilité qu'on vient d'énoncer. Je m'intéresse à établir des cas où ce foncteur est essentiellement surjectif, i.e. est une *équivalence* de catégories. Notons que pour que p. 78

$$\varphi \;:\; J \longrightarrow \mathcal{M}$$

appartienne à l'image essentielle, il faut et il suffit qu'il existe un foncteur

$$\Phi \;:\; I \;\longrightarrow\; \underline{\mathrm{Hom}}(J, C) \;,\; I \text{ grande devant } \pi_0 \text{ (et on peut supposer } I \text{ ordonnée)} \;, \tag{4.9.4}$$

tel qu'on ait

$$\varphi \;\xleftarrow{\sim}\; \varinjlim_{i \in I} \Phi(i) \;, \tag{4.9.5}$$

[page 218]

ou ce qui revient au même, tel qu'on ait

$$\varphi(j) \;\xleftarrow{\sim}\; \varinjlim_{i \in I} \Phi(i, j) \;, \qquad \text{pour } j \in J \;, \tag{4.9.6}$$

93. [Les numéros 4.9.1 à 4.9.6 sont utilisés deux fois, 4.9.3 trois fois.]

où on a posé

$$\Phi(i,j) \;=\; \Phi(i)(j)\ ,$$

interprétant donc Φ comme un foncteur

$$\Phi \;:\; I\times J \;\longrightarrow\; C\ ; \tag{4.9.7}$$

la loi fonctorielle de $\varphi(j)$ donnée par (4.9.6) étant évidente. En d'autres termes, les φ dans l'image essentielle de (4.4.3) sont ceux qui admettent une *représentation indicielle* par un foncteur Φ sous forme (4.9.4), ou sous forme (4.9.7), avec *de plus* I grand devant π_0. Je rappelle a ce sujet la

Proposition 4.9.2. *Sous les conditions précédentes sur C, π_0, J (notamment* $\operatorname{card}\operatorname{réd} J \leqslant \pi_0$*), si $\varphi : J \longrightarrow \mathcal{M} \overset{déf}{=} \operatorname{Ind}_{\pi_0}(C)$, pour que φ appartienne à l'image essentielle du foncteur pleinement fidèle (4.9.3), il faut et il suffit qu'elle satisfasse les deux conditions suivantes :*

[page 219]

Commentary · Exposition [ms. 218]

A coherent diagram needs a common index

Grothendieck's aim is to present an entire diagram by diagrams in the small category, so that its arrows and relations are visible before taking the colimit. Write $[J,C]$ for $\underline{\mathrm{Hom}}(J,C)$ and assume $|\mathrm{Mor}\,J| \le \pi_0$. For $A : J \to C$ and a π_0^+-filtered diagram (X_i) in $[J,\mathcal{M}]$, the set of natural transformations is the equalizer

$$\mathrm{Nat}(A,X) = \mathrm{Eq}\left(\prod_{j\in \mathrm{Ob}\,J} \mathrm{Hom}(Aj, Xj) \rightrightarrows \prod_{u:j\to k} \mathrm{Hom}(Aj, Xk)\right).$$

Both products have at most π_0 factors. The defining commutation theorem in sets therefore proves that A is π_0^+-presentable. The usual Hom formula for ind-objects then gives full faithfulness of

$$\mathrm{Ind}_{\pi_0}([J,C]) \longrightarrow [J, \mathrm{Ind}_{\pi_0}(C)].$$

This argument proves uniqueness of morphisms between already indexed presentations. It does not produce the presentation of an arbitrary diagram.

For a diagram φ, let $K = [J,C]/\varphi$. If K is π_0^+-filtered and each evaluation $K \to C/\varphi(j)$ is final, the tautological diagram in $[J,C]$ has colimit φ, because colimits in the target functor category are computed objectwise. Conversely, suppose $\varphi = \varinjlim_{i\in I} A_i$ is already an indexed presentation. Any family of at most π_0 objects of K, together with at most π_0 relations, factors through one stage A_i by the presentability just proved. Any equality between those factorizations holds at a further common stage. Thus K is π_0^+-filtered and $I \to K$ is final. The same factorization-and-equality argument applied at a single j shows that $I \to C/\varphi(j)$ is final. Since its factorization through K has final first factor, evaluation from K is final as well. This proves the two directions of 4.9.2 with the size condition in its precise place.

a) $\underline{\mathrm{Hom}}(J,C)/\varphi$ *est grande devant* π_0.

b) Pour tout $j \in J$*, le foncteur*

$$\underline{\mathrm{Hom}}(J,C)/\varphi \;\longrightarrow\; C/\varphi(j) \qquad \begin{cases} \textit{foncteur entre catégories filtrantes grandes devant } \pi_0, \textit{ en vertu de a),} \end{cases} \tag{4.9.2.1}$$

induit par le foncteur

$$\begin{cases} \underline{\mathrm{Hom}}(J,C) \;\longrightarrow\; C \\ F \;\longmapsto\; F(j)\ , \end{cases} \tag{4.9.2.2}$$

est cofinal.

Le résultat principal dans la présente section est le suivant :

Théorème 4.9.3. *Sous les conditions générales de 4.9.1 pour C, π_0, J (notamment* $\operatorname{card}\operatorname{réd} J \leqslant \pi_0$*), le foncteur pleinement fidèle (4.9.3) est une équivalence de catégories dans chacun des deux cas suivants :*

a) C est stable par $\varinjlim$ filtrantes dénombrables.

*b) Il existe un cardinal $\pi_0 < \pi$, et un cardinal $\pi_0' > \pi_0$ (***N.B.** *On peut supposer que π_0' est le successeur de π_0, donc $\pi_0' \leqslant \pi$), tels que C soit stable par limites inductives grandes devant π_0, et de cardinal π_0'.*

([94]).

Remarque 4.9.4.

a) Ce théorème, cas a), contient le théorème 4.4.13, partie b) (p. 95-96), où on suppose que C est stable par limites inductives de cardinal $\leqslant \pi_0$, l'hypothèse a) de 4.9.3 étant considérablement plus faible.

b) Je présume qu'en dehors d'une hypothèse restrictive du type a) ou b) ci-dessus, le foncteur pleinement fidèle (4.9.3) n'est pas toujours essentiellement surjectif, même dans le cas particulier où J est une catégorie finie, p.ex. $J = B_G$, $G = \{\pm 1\}$. Pour un contre-exemple dans le cas très voisin où on prend $\mathcal{M} = \operatorname{Ind}(C)$ (au lieu de $\operatorname{Ind}_{\pi_0}(C)$), et où on considère le foncteur (pleinement fidèle si J est une catégorie équivalent à une catégorie *finie*)

$$\operatorname{Ind}(\underline{\operatorname{Hom}}(J, C)) \longrightarrow \underline{\operatorname{Hom}}(J, \operatorname{Ind}(C)),$$

[page 220]

je renvoie à l'exercice SGA 4 I 8.8.8.

L'application principale du théorème 4.9.3 consiste en le

Corollaire 4.9.5. *Soient $\mathcal{M}$ une catégorie* accessible *(4.8.7), J une catégorie équivalente à une petite catégorie. Alors la catégorie $\mathcal{M}(J^\circ) = \underline{\operatorname{Hom}}(J, \mathcal{M})$ est accessible. Plus précisément, soient π_0 un cardinal* utile *pour $\mathcal{M}$ (i.e. tel que $\operatorname{Ind}_{\pi_0}(\mathcal{M}_{\pi_0}) \xrightarrow{\sim} \mathcal{M}$, i.e. un cardinal tel que $\mathcal{M}$ soit π_0-accessible), soit π un cardinal infini tel que $\pi^{\pi_0} = \pi \geqslant \operatorname{card}\operatorname{réd} J$ ([95]), i.e. $\pi = c^{\pi_0}$, où c est n'importe quel cardinal $c \geqslant \sup(\pi_0, \operatorname{card}\operatorname{réd} J)$, alors $\underline{\operatorname{Hom}}(J, \mathcal{M})$ est π-accessible, plus précisément on a une équivalence de catégories*

$$\underline{\operatorname{Hom}}(J, \mathcal{M}) \xleftarrow{\sim} \operatorname{Ind}_\pi(\underline{\operatorname{Hom}}(J, \mathcal{M}_\pi)) \ . \tag{4.9.5.1}$$

On sait en effet, avec les hypothèses faites sur π_0, π, que π est utile pour $\mathcal{M}$, i.e. que

[page 221]

$$\mathcal{M} \xleftarrow{\sim} \operatorname{Ind}_\pi(\mathcal{M}_\pi) \ ,$$

d'autre part, $\mathcal{M}_\pi$ est stable par $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$. On peut donc appliquer 4.9.3 b), en prenant $C = \mathcal{M}_\pi$, π et π_0 comme ici (donc $\pi_0 < 2^{\pi_0} \leqslant \pi$), et $\pi_0' = \pi$.

Commentary · Development (commentators') [ms. 220]

An involution that no stage can carry

Grothendieck expects the indexed-representation theorem to fail for a finite category with a nontrivial automorphism. His reference to SGA 4, I, 8.8.8 gives the ordinary filtered example. The complete chapter also uses a countable signed-chain category in 4.9.6.8(2), on manuscript page 236. The following transfinite adaptation proves the failure of indexed representation for every infinite cardinal used here. We checked both antecedents and the manuscript's indexed-representation criteria; the cardinal-scaled argument below is supplied for this reading, without a claim of priority.

94. Cas commun : il existe un ordinal limite α, tel que 1) $\operatorname{card}\alpha \leqslant \pi_0$. 2) Les limites inductives [de] type $I_\alpha = \{\beta \mid \beta < \alpha\}$ sont représentables dans C.

95. On a donc $\pi = \pi^{\pi_0} \geqslant 2^{\pi_0} > \pi_0$.

A bounded-filtered involution obstruction [ours]. For every infinite cardinal π, there is a small category C and a diagram $B(\mathbb{Z}/2) \to \mathrm{Ind}_\pi(C)$ outside the essential image of

$$\mathrm{Ind}_\pi\big([B(\mathbb{Z}/2), C]\big) \longrightarrow [B(\mathbb{Z}/2), \mathrm{Ind}_\pi(C)].$$

Proof. Put $\lambda = \pi^+$ and let the objects of C be the ordinals $\alpha < \lambda$. There are no maps $\alpha \to \beta$ when $\alpha > \beta$, just the identity when $\alpha = \beta$, and two maps, labelled $+1, -1$, when $\alpha < \beta$. Composition multiplies the labels. This is a small category, and its only endomorphisms are identities. The positive maps define a functor $A : \lambda \to C$. The ordinal λ is λ-filtered, since every set of fewer than λ ordinals has supremum less than λ. Therefore

$$F = \varinjlim_{\alpha<\lambda} y(A\alpha)$$

belongs to $\mathrm{Ind}_\pi(C)$. For a fixed β, the tail $\alpha > \beta$ is cofinal, and $\mathrm{Hom}_C(\beta, \alpha) = \{+1, -1\}$ with identity transition maps on these two labels. Hence $F(\beta) = \{+1, -1\}$. For a morphism labelled ϵ, the presheaf action is multiplication by ϵ. Multiplication by -1 consequently defines a natural involution $\sigma : F \to F$, and it has no fixed point in any $F(\beta)$.

A functor $B(\mathbb{Z}/2) \to C$ must have trivial action, because every endomorphism in C is an identity. A natural map from such an object β to (F, σ) would be an element of $F(\beta)$ fixed by σ. No such element exists. Thus

$$[B(\mathbb{Z}/2), C]/(F, \sigma) = \varnothing.$$

In particular condition a) of 4.9.2 fails, and no indexed presentation can exist. Equivalently, every ind-colimit of the trivial actions still has trivial action, whereas $\sigma \neq 1_F$. This proves the assertion.□

At the ordinary filtered level the construction is the signed-chain version of the unequal two-interval example in SGA 4 (Artin et al., 1972, I, Exercise 8.8.8); the signed-chain category itself also occurs later in this chapter (Grothendieck, 1990–1991n, 4.9.6.8(2)). The transfinite chain is essential here: replacing it by the countable chain would not produce an object of $\mathrm{Ind}_\pi(C)$ when π is infinite. The obstruction is therefore a direct answer to the cardinal version posed on manuscript page 220, rather than an appeal to a counterexample at the wrong filteredness rank.

p. 80

4.9.6 ([96]). Le reste de la présente section 4.9 est consacré à la démonstration de 4.9.3, i.e. à la vérification, pour $J \longrightarrow \mathcal{M}$, des conditions a), b) de 4.9.2. Dans toute la suite, on se fixe donc une

$$\varphi \ : \ J \longrightarrow \mathcal{M} \ = \ \mathrm{Ind}_\pi(C) \ . \tag{4.9.6.1}$$

On peut supposer J réduite, donc petite et $\mathrm{card}\, J \leqslant \pi_0$. On va considérer le foncteur déduit du foncteur (4.9.2.1)

$$\underline{\mathrm{Hom}}(J, C)/\varphi \longrightarrow \prod_{j \in \mathrm{Ob}\, J} C/\varphi(j) \ , \tag{4.9.6.2}$$

dont les foncteurs en question se déduisent en composant avec les foncteurs projection

$$\prod C/\varphi(j) \longrightarrow C/\varphi(j_0) \ . \tag{4.9.6.3}$$

Comme les catégories facteurs $C/\varphi(j)$ sont filtrantes (et même grandes devant π), leur produit est également filtrant, et même grand devant π (immédiat), et de même pour les produits partiels. Il s'ensuit aussitôt que les projections (4.9.6.3) sont cofinales, en vertu du [page 222]

Commentary · Exposition [ms. 221]

Why colimits inside the small category repair coherence

Grothendieck's sufficient hypothesis makes the successive approximations to a diagram converge to an actual diagram in C. The countable case has a particularly transparent proof. Fix $\varphi : J \to$

96. Résultats préliminaires (à la démonstration de 4.9.3).

$\mathrm{Ind}_\pi(C)$, with $|\mathrm{Mor}\, J| \le \pi$, and assume that C has colimits of countable chains. Begin with arbitrary maps $X_0(j) \to \varphi(j)$ from objects of C. Since each $C/\varphi(j)$ is π^+-filtered, one can choose $X_1(j)$ and, for every arrow $u : j \to k$, a lift

$$d_0(u) : X_0(j) \longrightarrow X_1(k)$$

of its composite to $\varphi(k)$. The identity arrows give the transition maps $t_0(j) = d_0(1_j)$. Repeat this construction, imposing at the next stage all relations

$$d_{n+1}(v)d_n(u) = t_{n+1}(\ell)d_n(vu) \qquad (j \xrightarrow{u} k \xrightarrow{v} \ell).$$

Before refinement the two sides have the same image in $\varphi(\ell)$, so they become equal at a further stage of its category of elements. There are at most π equations and objects to dominate, and a common refinement imposes all of them. Taking $u = 1_j$ gives compatibility of the $d_n(v)$ with the transition maps. Thus their colimits define arrows of a functor $X : J \to C$, with $X(j) = \varinjlim_n X_n(j)$; the displayed relation proves composition and the identity relation proves the identity law.

There is a subtle but necessary final step. Yoneda need not preserve these colimits in C. Instead, every $\varphi(j)$, being a π^+-filtered colimit of representables, carries any existing colimit in C indexed by at most π arrows to a limit of sets. Indeed each representable has that property and π^+-filtered colimits of sets commute with those limits. Consequently the compatible elements of $\varphi(j)(X_n(j))$ define an element of $\varphi(j)(X(j))$, hence a map $X(j) \to \varphi(j)$. These maps form a natural transformation. This proves F 1 of page 226.

To prove F 3_π, start with $X_0(j) = G(j)$ and the given pointwise maps $u_\alpha(j) : F_\alpha(j) \to G(j)$. Besides the composition equations, impose the equations making $G \to X$ natural and making each composite $F_\alpha \to G \to X$ natural. For example the two maps $d_0(v)u_\alpha(j)$ and $t_0(k)u_\alpha(k)F_\alpha(v)$ already agree after mapping to $\varphi(k)$, so they can be equalized at the next refinement. Their number is still at most π. The resulting $G \to X$ and $F_\alpha \to X$ have exactly the compatibility requested by F 3_π. The faithful-functor lemma below now proves 4.9.3(a).

The same construction works along any infinite limit ordinal δ of cardinal at most π for which the relevant chain colimits exist in C. At a limit stage $\beta < \delta$, choose a cone in each $C/\varphi(j)$ on the preceding chain. At a successor stage, impose the compatibility of the new arrow lifts with every earlier transition and all composition equations. At most π data are involved, so the same filteredness argument applies. At the final colimit the equations make the arrow maps independent of the chosen stage, and the preceding preservation argument supplies the map to φ. This proves the intended two-cardinal case: if $\mu < \pi$ and C has μ^+-filtered colimits of cardinal $\mu^+ \le \pi$, use $\delta = \mu^+$. The theorem's printed b) reuses π_0 with a different role from its headline; writing the ind-rank as π and the smaller rank as μ removes that ambiguity.

For Corollary 4.9.5 take $C = \mathcal{M}_\pi$, with $\pi^{\pi_0} = \pi$ and $|\mathrm{Mor}\, J| \le \pi$. This C is closed under the existing π_0^+-filtered colimits of cardinal at most π, and the argument applies. Thus the theorem gives the claimed accessibility at the stated larger cardinal. The later statement that a small diagram category in an accessible category is accessible is therefore a continuation of this precise coherence argument; its higher-categorical counterpart is Lurie (2009, Proposition 5.4.4.3).

Lemme 4.9.6.1. *Soient I, I' deux catégories avec I' 0-connexe (p.ex. filtrante), alors le foncteur projection $pr_1 : I \times I' \longrightarrow I$ est cofinal.*

En effet, pour $i' \in \mathrm{Ob}\, I'$ `[plutôt` $i \in \mathrm{Ob}\, I$`]`, on a

$$i\backslash(I \times I') \;\simeq\; (i\backslash I) \times I' \;,$$

or $i\backslash I$ et I' étant 0-connexe, il en est de même de leur produit.

Lemme 4.9.6.2 ([97]). *Soit $(I_\alpha)_{\alpha\in A}$ une famille de catégories* filtrantes *(resp. grandes devant π). Alors $I_A \overset{déf}{=} \prod_{\alpha\in A} I_\alpha$ est filtrante (resp. grande devant π), et pour toute partie $B \subset A$, la projection canonique $I_A \longrightarrow I_B$ est cofinal.*

([98]). La stabilité de la propriété "filtrante" ou "grande devant π" par AQT `[âne qui trotte]`. On a, si $B' = A\backslash B$, $I_A \simeq I_B \times I_{B'} \longrightarrow I_B$, et on applique le lemme 4.9.6.1 pour conclure que ce foncteur est cofinal, $I_{B'}$ étant filtrante, donc 0-connexe.

[page 223]

97. Attention, il n'est pas vrai qu'un produit infini de catégories 0-connexes est 0-connexe !
98. Cf. démonstration élégante ci-dessous, 4.9.6.6.

Le foncteur (4.9.6.3) étant cofinal, pour établir que (4.9.2.1) l'est, il suffit de prouver qu'il en est ainsi du foncteur (4.9.6.2), ce que nous ferons. Notons de plus que ledit foncteur est *fidèle*, car il s'insère dans le carré commutatif

$$\begin{array}{ccc} \underline{\mathrm{Hom}}(J,C)/\varphi & \longrightarrow & \prod C/\varphi(j) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Hom}}(J,C) & \longrightarrow & C^{\mathrm{Ob}\,J} \end{array} ,$$

où les flèches verticales et la deuxième flèche horizontale sont fidèles. En définitive, pour établir le théorème 4.9.3, nous allons étudier le foncteur *fidèle* (4.9.6.2) p. 81

$$(*) \qquad \begin{array}{l} f \ : \ \underline{\mathrm{Hom}}(J,C)/\Phi \ \longrightarrow \ \prod_{j\in J_0} C/\varphi(j) \\ (\text{où on a posé } J_0 = \mathrm{Ob}\,J,\ J_1 = \mathrm{Fl}\,J) \ , \end{array}$$

et nous allons prouver :

ⓐ Ce foncteur fidèle (∗) est *cofinal.*

ⓑ La catégorie source $\underline{\mathrm{Hom}}(J,C)/\varphi$ est grande devant π_0.

Nous allons pour ceci dégager un lemme auxiliaire sur la cofinalité des foncteurs *fidèles* :

Commentary · Development (commentators') [ms. 222]

Connected factors can require unbounded zigzags

Grothendieck's warning in footnote 97 explains why the product argument must use filteredness, not merely connectedness. We make the obstruction quantitative; this also gives a concrete test for an infinite-product argument elsewhere in the reader. We checked the product assertions in 4.9.6 and the standard filtered-category criteria in SGA 4, I, 8.1. The following exact component calculation is supplied here as a small development, without a priority claim.

Components of a product of fences[ours]. Let P_n have objects $0, 1, \dots, n$ and, besides identities, one arrow along each adjacent edge, always directed from the even vertex to the odd vertex. Then every P_n is connected, whereas two objects $a = (a_n)$ and $b = (b_n)$ of $\prod_{n\geq 1} P_n$ are connected if and only if

$$\sup_{n\geq 1} |a_n - b_n| < \infty.$$

Consequently the product has exactly $2^{\aleph_0}$ connected components.

Proof. There are no composable nonidentity arrows in P_n, so its underlying undirected graph is the path with n edges. A zigzag of length r in the product projects to a zigzag of length r in every factor; therefore $|a_n - b_n| \leq r$ for all n. Conversely, suppose all these distances are at most r. Choose the unique shortest path in each factor. Turn it into a zigzag with the fixed orientation pattern forward, backward, forward, backward, and so on, by inserting identity arrows when the next edge has the opposite direction. At most two positions are needed for each edge, and further identities pad every path to length $2r$. The resulting coordinatewise arrows are arrows of the product, so they give one finite zigzag from a to b.

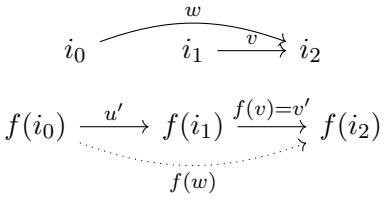
There are at most continuum many objects in the product. For every real $t \in [0,1]$, take $a_n(t) = \lfloor tn \rfloor$. If $s \neq t$, the distances $|a_n(s) - a_n(t)|$ are unbounded, hence these objects lie in distinct components. This gives the matching lower bound. □

Filtered categories avoid this defect because any finite family of objects has a common target, and any parallel pair can be equalized. For a product of π^+-filtered categories, choose a cocone coordinatewise for each diagram of at most π arrows. Choice assembles these cones into a cocone in the product, including the empty-diagram case. Every projection to a subproduct is final: its comma categories are products of a category with an initial object and the complementary filtered product. This proves 4.9.6.1–4.9.6.2 while accounting for the warning.

Lemme 4.9.6.3 ([99]). *Soit $f : I \longrightarrow I'$ un foncteur, et considérons les conditions :* [page 224]

99. Ce lemme fait partie du sorite général sur la cofinalité et les catégories filtrantes.

a) I filtrante, f cofinal, i.e. (en présence de I filtrante) f satisfait les conditions familières (F 1), (F 2).



b) I′ est filtrante, et les i′\I (pour i′ ∈ Ob I′) sont filtrantes.

b′) I′ 0-connexe, satisfait PF (2) ([100]) (égalisation des double-flèches).

b″) I′ est filtrante, les i′\I pseudo-filtrantes, i.e. satisfont à la condition PF 1′.

c) I′ filtrante, et f satisfait à F 1, ainsi que la condition suivante.

(F 3) *Pour tout couple (i_0, i_1) d'objets de I et toute flèche $f(i_0) \xrightarrow{u'} f(i_1)$, il existe un objet i_2 de I, et une flèche $v' : f(i_1) \longrightarrow f(i_2)$, tels que v' et $v'u'$ soient relevables en des flèches $i_1 \xrightarrow{v} i_2$ et $i_0 \xrightarrow{w} i_2$ (i.e. il existe i_2 et $v : i_1 \longrightarrow i_2$, $w : i_0 \longrightarrow i_2$ tels qu'on ait $f(v)u' = f(w)$).*

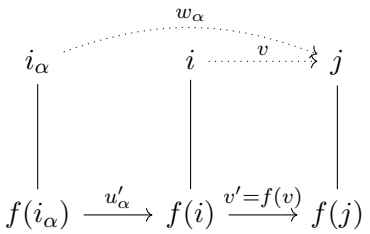
1) On a les implications

$$a \iff b \iff b' \implies b'' \iff c\ ,$$

et si f est fidèle *(p.ex. I ordonnée), les cinq conditions a), b), b′), b″), c) sont équivalentes.*

p. 82
[page 225]

2) Soit π un cardinal infini, et considérons les conditions :



a_π) I grande devant π, f cofinal, i.e. F 1, F 2.

b_π) I′ grande devant π, les i′\I (i′ ∈ Ob I′) aussi.

b_π'') I′ grande devant π, les i′\I (i′ ∈ Ob I′) sont π-pseudo-filtrantes, i.e. satisfont PS $1_\pi{}'$.

c_π) I′ grande devant π, et f satisfait F 1 et

(F 3_π) ([101]). *Pour toute famille $(i_\alpha)_{\alpha\in A}$ d'objets de I, avec* card $A \leqslant \pi$, *et $i \in \mathrm{Ob}\, I$, et une famille de flèches $u'_\alpha : f(i_\alpha) \longrightarrow f(i)$, existe $j \in \mathrm{Ob}\, I$ et une flèche $v' : f(i) \longrightarrow f(j)$, telle que v'* et *les $v'u'_\alpha$ proviennent de flèches de I, i.e. il existe des flèches $v : i \longrightarrow j$, $w_\alpha : i_\alpha \longrightarrow j$ telles que $f(v)u'_\alpha = f(w_\alpha)\ \forall\ \alpha \in A$.*

Ceci posé, on a

$$a_\pi \iff b_\pi \implies c_\pi \implies b_\pi{}''\ ,$$

et si f est fidèle, ou I ordonné, les quatre conditions a_π, b_π, $b_\pi{}''$, c_π sont équivalentes.

([102]).

4.9.6.4. N.B. Dans le cas qui nous intéresse, où f est le foncteur $(*)$ (p. 223), on sait que I' est grande devant π. On voudrait établir que I l'est et que f est cofinal, i.e. la condition a_π. On le prouvera en prenant b_π (qui implique a_π puisque f est fidèle). Il reste donc à prouver, sur le foncteur f dans $(*)$, p. 223, les deux conditions suivantes : [page 226]

100. p.ex. PF 2 est satisfaite si I' est *ordonnée*, sans avoir à supposer d'avance I' filtrante, seulement 0-connexe.
101. **N.B.** La condition F 3_π est tautologiquement satisfaite si f est *pleinement fidèle.*
102. Démonstration de la proposition donnée dans 4.9.6.7, page 227.

F 1) Pour tout système de flèches dans $\mathcal{M}$

$$X(j) \xrightarrow{p(j)} \varphi(j)\ , \qquad j \in J_0 = \mathrm{Ob}\, J,\ \text{les } X(j) \text{ dans } \mathrm{Ob}\, C\ ,$$

il existe un foncteur $F : J \longrightarrow C$ et $F \xrightarrow{q} \varphi$, enfin un système de flèches $X(j) \xrightarrow{u(j)} F(j)$ dans les $C/\varphi(j)$, i.e. rendant commutatif les diagrammes

$$\begin{array}{ccc} X(j) & \xrightarrow{\quad u(j) \quad} & F(j) \\ & {\scriptstyle p(j)}\searrow \quad \swarrow{\scriptstyle q(j)} & \\ & \varphi(j)\ . & \end{array}$$

F 3_π) Pour tout système $(F_\alpha)_{\alpha\in A}$ ($\mathrm{card}\, A \leqslant \pi$) d'éléments dans $\underline{\mathrm{Hom}}(C, J)$, et des flèches

$$F_\alpha \xrightarrow{p_\alpha} \varphi \qquad \text{dans } \underline{\mathrm{Hom}}(J, \mathcal{M}),$$

et pour G dans $\underline{\mathrm{Hom}}(J, C)$ et $G \xrightarrow{q} \varphi$ dans $\underline{\mathrm{Hom}}(J, \mathcal{M})$, étant donné un système de flèches $u_\alpha(j)$, p. 83

$$\begin{array}{ccc} F_\alpha(j) & \xrightarrow[\text{comm.}]{u_\alpha(j)} & G(j) \\ & {\scriptstyle p_\alpha(j)}\searrow \quad \swarrow{\scriptstyle q(j)} & \\ & \varphi(j)\ , & \end{array} \qquad u_\alpha(j) \text{ flèche dans } C/\varphi(j)\ ,$$

il existe $H \xrightarrow{q} \varphi$ dans $\underline{\mathrm{Hom}}(J, C)$ et une flèche $G \xrightarrow{v} H$ dans $\underline{\mathrm{Hom}}(J, C)/\varphi$, telle que pour tout $\alpha \in A$, le système de flèches composés [page 227]

$$\begin{array}{ccccc} F_\alpha(j) & \xrightarrow[\text{comm.}]{u_\alpha(j)} & G(j) & \xrightarrow[\text{comm.}]{v(j)} & H(j) \\ & {\scriptstyle p_\alpha(j)}\searrow & \downarrow{\scriptstyle q(j)} & \swarrow{\scriptstyle q(j)} & \\ & & \varphi(j) & & \end{array}$$

(pour $j \in J_0 \in \mathrm{Ob}\, J$) provienne d'un *foncteur* $w_\alpha : F_\alpha \longrightarrow H$.

Pour prouver 4.9.3, nous sommes donc ramené à prouver les deux propositions F 1), F 3_π) précédentes, sous l'une des deux conditions a) ou b) de 4.9.3.

Commentary · Exposition [ms. 225]

The faithful cofinality test, with its hypotheses restored

Grothendieck reduces the construction of a coherent presentation to the ability to lift a bounded family of arrows after one common refinement. Faithfulness then turns equations seen downstairs into actual equations upstairs. This is the precise role of F 3_π; the evaluation functor into the product of the categories of elements is faithful because a natural transformation is determined by its components.

The printed condition b′ in 4.9.6.3 is incomplete. It only says that I' is connected and equalizes parallel pairs, so it cannot imply an assertion about I or f. The functor $\varnothing \to 1$ satisfies it and is not final. The proof in the continuation uses, in addition, that every $(i' \downarrow f)$ is filtered; inserting that clause gives the intended b′. The assertions involving b) and the faithful test c) are correct. Here is a proof of the version needed in these pages.

Suppose $f : I \to I'$ is faithful, I' is π^+-filtered, F 1 holds, and F 3_π holds. Given a diagram $D : K \to I$ with at most π arrows, choose a cone $u_k : fDk \to z$ in I', and then a map $z \to f(i)$ by

F 1. F 3_π gives $v : i \to h$ and $w_k : Dk \to h$ whose images are the composites of those cone maps with $f(v)$. For an arrow $a : k \to \ell$ of K we have

$$f(w_\ell D(a)) = f(w_k).$$

Faithfulness gives $w_\ell D(a) = w_k$, so I is π^+-filtered. Its nonemptiness follows from F 1 and nonemptiness of I'.

Apply the same construction to a bounded diagram of objects $(i_k, p_k : z \to f(i_k))$ in $(z \downarrow f)$. In I' take a cone on its image together with z and all p_k. After F 1 and F 3_π, the maps w_k obtained above satisfy

$$f(w_k)p_k = p$$

for one map $p : z \to f(h)$. They are therefore a cone in the comma category. The empty case is F 1. Every comma category is π^+-filtered, hence nonempty and connected, so f is final. This proves $\mathrm{c}_\pi \Rightarrow \mathrm{b}_\pi \Rightarrow \mathrm{a}_\pi$ under faithfulness, including all quantifiers used in 4.9.6.4.

Faithfulness cannot simply be discarded. For a nontrivial group G, the functor $BG \to 1$ satisfies F 1 and every F 3_π, since all equations in the target are automatic and arbitrary arrows upstairs can be chosen. But BG is not filtered: distinct automorphisms cannot be equalized. This example identifies the exact step that fails when equality of images is substituted for equality of arrows.

Corollaire 4.9.6.5 (de 4.9.6.3). *Soit $(f_\alpha : I_\alpha \longrightarrow I'_\alpha)$ une famille de foncteurs cofinaux, les catégories source étant filtrantes. Alors le foncteur produit $f = \prod f_\alpha : I = \prod_\alpha I_\alpha \longrightarrow I' = \prod_\alpha I'_\alpha$ est cofinal.*

En effet, il faut vérifier que les catégories $i'\backslash I$, pour $i' \in \mathrm{Ob}\, I'$, sont 0-connexes. Or si $i' = (i'_\alpha)_{\alpha \in A}$, on a

$$i'\backslash I \;\simeq\; \prod_\alpha (i'_\alpha \backslash I_\alpha)\ ,$$

et par 4.9.6.3, 1°) a $\Longrightarrow$ c, les $i'_\alpha\backslash I_\alpha$ sont filtrantes, donc leur produit est filtrant (cf. 4.4.6.2), donc 0-connexe, q.e.d. [page 228]

Corollaire 4.4.6.6. *Soit π un cardinal infini. Tout produit de catégories grandes devant π est grand devant π.*

Soit $I = \prod_{\alpha \in A} I_\alpha$, soit B un ensemble de cardinal $\leqslant \pi$, il faut prouver que $I \xrightarrow{\mathrm{diag}_I} I^B$ est cofinal. Or ce foncteur s'identifie au produit des foncteurs similaires $I_\alpha \longrightarrow I_\alpha^B$, lesquels sont cofinaux, les catégories source étant de plus filtrantes. Donc on peut conclure par le corollaire 4.9.6.5.

4.9.6.7. Démonstration de 4.9.6.3. (Partie 1°.)

a $\Longrightarrow$ b. On sait déjà que a) implique que I' est filtrante (SGA 4 I 8.1.3 b). Reste à prouver que pour tout $i' \in \mathrm{Ob}\, I'$, $i'\backslash I$ est filtrante ([103]). Deux conditions PF 1′ et PF 2 à vérifier (en plus du fait que $i'\backslash I \neq \emptyset$, qui est connu par cofinalité de f, impliquant que $i'\backslash I$ est 0-connexe).

1) Soient (i, u'), (j, v') deux éléments de $i'\backslash I$, il faut voir qu'ils sont majorés par un troisième élément. Or I étant filtrante, i, j sont majorés par k. On aurait fini donc si on savait que $f(u_1)u' = f(v_1)v'$, soit w', car alors (k, w') ferait l'affaire.

Commentary · Exposition [ms. 228]

Completing the argument of manuscript page 228

On manuscript page 228 Grothendieck's proof has reached the point just before the two candidate arrows from i' are equalized. The remaining step is short once finality is used in the correct comma category. If I is filtered and f is final, every $(i' \downarrow f)$ is connected. Given two of its objects, join them by a finite zigzag. Project that zigzag to I and take a cone there. Commutativity along each arrow of the zigzag makes the composites from i' agree at its vertex, so that vertex is an object receiving maps from the two original comma objects. Parallel arrows in the comma category can

103. Court-circuit : on sait déjà que $i'\backslash I$ est 0-connexe, d'autre part elle est *localement* filtrante, car coétale sur I qui est filtrante, donc elle est filtrante.

be equalized by filteredness of I; the resulting arrow is still over i'. Hence the comma category is filtered. This finishes the particular step begun in 4.9.6.7.

For the stronger cardinal statement, begin with a diagram of at most π arrows in $(i' \downarrow f)$. Choose one object and a finite connecting zigzag to each of the others. The union of their projections and of the original diagram still has at most π arrows, because π is infinite. A cone in I simultaneously imposes all relations and all equalities of maps from i'. Thus every comma category is π^+-filtered. Likewise a bounded diagram in I' can be lifted object by object using F 1; connect, inside the appropriate comma categories, the two choices associated with each arrow. A cone on the resulting bounded diagram in I yields a cone in I'. This proves $\mathrm{a}_\pi \Rightarrow \mathrm{b}_\pi$.

Conversely, suppose I' and all $(i' \downarrow f)$ are π^+-filtered. Finality is immediate. First derive F 3_π. Given $u'_\alpha : f(i_\alpha) \to f(i)$, filteredness of $(f(i_\alpha) \downarrow f)$ supplies arrows $w_\alpha : i_\alpha \to k_\alpha$ and $v_\alpha : i \to k_\alpha$ with $f(w_\alpha) = f(v_\alpha)u'_\alpha$. Regard all v_α as arrows from $(i, 1)$ in $(f(i) \downarrow f)$. A cone on this bounded diagram supplies maps $h_\alpha : k_\alpha \to h$ with all $h_\alpha v_\alpha$ equal to one $v : i \to h$. The arrows $h_\alpha w_\alpha$ prove F 3_π.

Now choose a cone on fD in I', follow its vertex by a map to some $f(i)$, and apply F 3_π. This gives arrows $w_k : Dk \to h$ which satisfy all the cone equations after applying f. For each arrow $a : k \to \ell$, the two arrows $w_\ell D(a), w_k$ are parallel arrows in $(fDk \downarrow f)$. Filteredness there gives $e_a : h \to h_a$ equalizing them. In $(f(h) \downarrow f)$ take a cone on the bounded diagram consisting of $(h, 1)$ and these arrows e_a. Its map $e : h \to H$ factors through every e_a, so the maps ew_k satisfy every cone equation in I. This proves π^+-filteredness of I without faithfulness, and establishes $\mathrm{b}_\pi \Rightarrow \mathrm{a}_\pi$.

Finally, for final functors $f_\alpha : I_\alpha \to I'_\alpha$ with filtered sources, the comma category of the product functor is

$$((i'_\alpha)_\alpha \downarrow \prod_\alpha f_\alpha) \cong \prod_\alpha (i'_\alpha \downarrow f_\alpha).$$

Each factor is filtered by the argument just given; their product is filtered and therefore connected. This proves 4.9.6.5. Applying it to the diagonal functors $I_\alpha \to I_\alpha^B$ gives the diagonal proof of the next corollary, whose heading is misnumbered 4.4.6.6 in the edition. The direct coordinatewise cone proof gives the same result and avoids treating infinite products of merely connected categories as connected.

Overview · XVIII-b

These pages belong to the ordinary categorical foundations of the theory of derivators. Grothendieck is asking how a large category, and then its categories of diagrams, can be recovered from controlled small data. The recurring difficulty is that a bound on the size of a presentation is not yet an invariant of the object presented. The passage from one to the other requires both a factorization argument and an account of the relations which that argument introduces. Retracts, categories of elements, and changes of indexing category are therefore the central constructions of this part of Chapter XVIII.

There is a cardinal convention to fix at the outset. A category called *grande devant* π admits cocones on diagrams with at most π arrows. In the customary notation for regular cardinals it is π^+-filtered. An object called π-accessible in the manuscript is consequently π^+-presentable. The parameter π itself need not be regular. We retain the manuscript's indices, including its later adjective "regular" for a useful cardinal satisfying a particular presentation bound. That adjective is a separate definition, not a statement about the set-theoretic cofinality of π.

The opening, which continues Proposition 4.5.13 from the preceding pages, compares two bounded-presentation filtrations with the intrinsic filtration $\mathcal{M}_\pi$. In a cocomplete category the basic calculation is straightforward: a colimit indexed by a category with at most π arrows, of π-accessible objects, is again π-accessible, because a limit of that size in sets commutes with π^+-filtered colimits. The converse requires generation. When every object is a sufficiently filtered colimit of objects of a small subcategory, the identity of a presentable object factors through one stage. What follows is a retract of a stage. Lemma 4.5.14 suppresses this last distinction. The commentary gives the corrected implication and an explicit counterexample in sets to its unrestricted wording. Its later application to a subcategory closed under bounded colimits remains valid, since such a subcategory also contains the required idempotent splittings.

The discussion of universal strict epimorphic families has a different purpose. It seeks hypotheses under which one bounded presentation already contains the relations needed for descent. The printed direct-product example in groups is defective even after the accompanying footnote: the two coordinate subgroups of $C_2 \times C_2$ do not form a strict epimorphic family. Replacing the product by the free product gives the intended example, including failure of epimorphy after pullback. We distinguish this correction from the unresolved proof transition in Corollary 4.5.16, where a universal epimorphic hypothesis is used as though it were universally strictly epimorphic. The strengthened version has a complete proof. The argument given in these pages does not establish the weaker printed version or the entire deduction of case C of Proposition 4.5.13.

Section 4.6 builds a small category closed under the colimits needed for reconstruction. The qualitative transfinite construction is sound: at each stage there is a set of diagrams and hence a set of chosen colimits; regularity of the stopping ordinal ensures that every bounded diagram appears early enough to be treated. The numerical estimate for the number of new morphisms is a separate assertion. It is false for an arbitrary small starting category, as the source's own later footnotes suspect. A finitary variety with many binary idempotent operations provides a direct counterexample. Thus the existence of a small reconstruction category must be retained while the claimed sharp bound requires another argument. The normalization of a finite initial cardinal in Corollary 4.6.2 repairs an additional elementary edge case, but does not repair that proof.

The resulting cocomplete recognition theorem is the locally presentable theory: a π_0-paratopos is, with the stated hypotheses restored, locally π_0^+-presentable. The presheaf reflection and the small-category presentation explain why suitable filtered colimits commute with bounded limits. This places the discussion alongside Gabriel–Ulmer duality and the systematic accounts of accessible categories, without asserting that Grothendieck was drawing on those accounts here (Gabriel and Ulmer, 1971; Makkai and Paré, 1989; Adámek and

Rosický, 1994). His immediate reference is SGA 4. One of its assertions, that full faithfulness of a filtered-completion functor forces the original objects to be accessible, fails at the stated generality; the rigid real ring supplies the manuscript's counterexample. The intended Ind application instead follows by evaluation of presheaves.

Exactness does not fix the generating cardinal. To answer footnote 59, we construct, for every prescribed infinite π_0, a sheaf topos whose only π_0^+-presentable object is initial, although filtered colimits are exact and a small dense category exists. The construction uses a set of cardinal π_0^{++} with the topology of complements of subsets of smaller cardinality. Every nonempty support has an increasing π_0^+-indexed cover by proper opens; restricting a sheaf to this cover rules out presentability at the proposed rank. This is a supplied development of the question, with a complete proof and no claim of priority. The closing examples of §4.6 also separate the conditions on images, unions and pushouts of monomorphisms. Pointed sets satisfy all six conditions under discussion and give an example beyond abelian categories and topoi.

Section 4.7 removes the assumption of cocompleteness. Now $\mathcal{M} = \mathrm{Ind}_{\pi_0} C$, and the primed filtration denotes closure under repeated bounded filtered colimits; its meaning must not be imported from the preceding section. The cardinal equation $\pi^{\pi_0} = \pi$ pays for adjoining all the small witnesses needed to make a subcategory of an indexing category sufficiently filtered. We spell out this closure operation, including the old arrows and cone legs omitted from the printed construction. The resulting comparison of presentation size and presentability is the ordinary version of the modern change-of-cardinal arguments (Vasey, 2020, §3).

The retract question which Grothendieck leaves at the centre of this comparison has a positive answer in the literature. Chen's bounded closure theorem, and his formulation of the Makkai–Paré retract-removal result, show that iterating the specified bounded filtered colimits does not enlarge the resulting class (Chen, 2021, Corollaries 4.13 and 4.15). We also give an elementary retract argument which preserves the number of arrows. Consequently $\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi}$ at every permitted cardinal. At the initial cardinal the common value is $\mathrm{Kar}(C)$, not necessarily C: a two-arrow idempotent category is sufficiently filtered at every rank and realizes a nonrepresentable retract. This endpoint explains several otherwise misleading assertions in the text.

The generalized filtration axioms and their useful cardinals require an additional distinction. A filtered slice is a presentation only when its canonical cocone has the correct colimit. Density supplies that condition, but the axioms printed in 4.7.7 do not force it at every level. We exhibit a filtration of sets whose initial slices are terminal and whose initial realization nevertheless misses every nonempty set. This disproves the bare converse in 4.7.12 and identifies the missing hypothesis. Once usefulness is understood through the realization equivalence, every useful cardinal satisfies the quantitative "regularity" requirement of 4.7.13. The commentary proves this with a size-controlled cofinal directed poset, so no example of a useful but nonregular cardinal exists under that interpretation. Conversely, the category of nonempty $\aleph_1$-directed posets has unboundedly many nonuseful manuscript cardinals: every singular $\theta > \aleph_1$ of countable cofinality gives failure of θ^+-accessibility. We provide the complete argument, refining the rank choices in Vasey (2020, Example 3.8). This concerns the accessibility spectrum, rather than the presentability rank of one object (Lieberman et al., 2019).

Section 4.8 returns to density and gives the conceptual recognition of accessible categories. The author's initial doubt about enlargement of a dense subcategory is eventually withdrawn, correctly: naturality against the smaller dense category determines the missing components. The characterization of the smallest presentable part as an idempotent completion is likewise valid. Two other assertions need more substantial correction. First, Lemma 4.8.11 omits "pro" from the conclusion supplied by SGA 4, I, 8.13.2(b). An accessible finite-limit-preserving functor need only be prorepresentable. Locally constant functions from the Cantor space

give an explicit counterexample to representability; preservation of all small limits gives the intended representability theorem. Second, the conjecture in footnote 91 that accessibility of a category and its opposite forces essential smallness is false. Sets and partial injections form a self-dual accessible category with objects of every small cardinality (Heunen, 2013, §3.2); we prove the precise presentability criterion directly.

The small-category theorem requires a more restrained verdict. The argument in these pages does not establish the equality endpoint in 4.8.13. The later manuscript proves a strict cardinal inequality, sufficient for Corollary 4.8.14, and explicitly calls it a weaker result. The continuity result checked in Tendas (2022) also has a strict threshold. We therefore retain the theorem on essentially small accessible categories while leaving that exact endpoint uncertified; this is not a claim that the endpoint is an established open problem today.

Section 4.9 explains why a diagram of ind-objects need not come from diagrams at individual stages. Coherence can impose a genuine obstruction, even for a one-object category with an involution. We extend the SGA 4 counterexample to every infinite filtering bound using a transfinite signed-chain category. The resulting ind-object has an involution which no stage admits. Under the appropriate colimit hypotheses on C, Grothendieck's common-index construction repairs the obstruction. The final cofinality lemmas express that construction through simultaneous factorization and equalization. We restore the missing hypotheses in their printed alternatives and complete the particular proof under way on manuscript page 228.

The later homotopical setting preserves this architecture while replacing sets of maps by mapping spaces and strict diagrams by coherent diagrams. Lurie's recognition theorem characterizes presentable infinity-categories through accessibility, cocompleteness and accessible presheaf localization; his diagram-category theorem supplies the corresponding stability under small diagrams (Lurie, 2009, Theorem 5.5.1.1 and Proposition 5.4.4.3). These are structural counterparts of the constructions here. They explain the relevance of this long ordinary-categorical preparation to the work on derivators without identifying strict diagrams in a homotopy category with coherent diagrams in a homotopy theory.

Le résultat principal dans la présente section est le suivant : p. 79

Théorème 4.9.3. *Sous les conditions générales de 4.9.1 pour C, π_0, J (notamment* $\operatorname{card}\operatorname{réd} J \leqslant \pi_0$*), le foncteur pleinement fidèle (4.9.3) est une équivalence de catégories dans chacun des deux cas suivants :*

a) C est stable par $\varinjlim$ filtrantes dénombrables.

b) Il existe un cardinal $\pi_0 < \pi$, et un cardinal $\pi_0' > \pi_0$ (**N.B.** *On peut supposer que π_0' est le successeur de π_0, donc $\pi_0' \leqslant \pi$), tels que C soit stable par limites inductives grandes devant π_0, et de cardinal π_0'.*

([94]).

Remarque 4.9.4.

a) Ce théorème, cas a), contient le théorème 4.4.13, partie b) (p. 95-96), où on suppose que C est stable par limites inductives de cardinal $\leqslant \pi_0$, l'hypothèse a) de 4.9.3 étant considérablement plus faible.

b) Je présume qu'en dehors d'une hypothèse restrictive du type a) ou b) ci-dessus, le foncteur pleinement fidèle (4.9.3) n'est pas toujours essentiellement surjectif, même dans le cas particulier où J est une catégorie finie, p.ex. $J = B_G$, $G = \{\pm 1\}$. Pour un contre-exemple dans le cas très voisin où on prend $\mathcal{M} = \operatorname{Ind}(C)$ (au lieu de $\operatorname{Ind}_{\pi_0}(C)$), et où on considère le foncteur (pleinement fidèle si J est une catégorie équivalent à une catégorie *finie*) [page 220]

$$\operatorname{Ind}(\underline{\operatorname{Hom}}(J, C)) \longrightarrow \underline{\operatorname{Hom}}(J, \operatorname{Ind}(C)),$$

je renvoie à l'exercice SGA 4 I 8.8.8.

L'application principale du théorème 4.9.3 consiste en le

Corollaire 4.9.5. *Soient $\mathcal{M}$ une catégorie* accessible *(4.8.7), J une catégorie équivalente à une petite catégorie. Alors la catégorie $\mathcal{M}(J^\circ) = \underline{\operatorname{Hom}}(J, \mathcal{M})$ est accessible. Plus précisément, soient π_0 un cardinal* utile *pour $\mathcal{M}$ (i.e. tel que $\operatorname{Ind}_{\pi_0}(\mathcal{M}_{\pi_0}) \xrightarrow{\sim} \mathcal{M}$, i.e. un cardinal tel que $\mathcal{M}$ soit π_0-accessible), soit π un cardinal infini tel que $\pi^{\pi_0} = \pi \geqslant \operatorname{card}\operatorname{réd} J$ ([95]), i.e. $\pi = c^{\pi_0}$, où c est n'importe quel cardinal $c \geqslant \sup(\pi_0, \operatorname{card}\operatorname{réd} J)$, alors $\underline{\operatorname{Hom}}(J, \mathcal{M})$ est π-accessible, plus précisément on a une équivalence de catégories*

$$\underline{\operatorname{Hom}}(J, \mathcal{M}) \xleftarrow{\sim} \operatorname{Ind}_\pi(\underline{\operatorname{Hom}}(J, \mathcal{M}_\pi)) \ . \tag{4.9.5.1}$$

On sait en effet, avec les hypothèses faites sur π_0, π, que π est utile pour $\mathcal{M}$, i.e. que [page 221]

$$\mathcal{M} \xleftarrow{\sim} \operatorname{Ind}_\pi(\mathcal{M}_\pi) \ ,$$

d'autre part, $\mathcal{M}_\pi$ est stable par $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$. On peut donc appliquer 4.9.3 b), en prenant $C = \mathcal{M}_\pi$, π et π_0 comme ici (donc $\pi_0 < 2^{\pi_0} \leqslant \pi$), et $\pi_0' = \pi$.

Commentary · Exposition [ms. 220]

One indexing category for an entire diagram

Grothendieck wants an approximation of a diagram which remembers its arrows. Writing each value of $\varphi : J \to \operatorname{Ind}_\pi(C)$ as an ind-object separately does not provide this: an arrow can be represented only after enlarging the chosen indices, and a relation between arrows can require a further enlargement. The comparison functor therefore asks for one π-filtered system of genuine J-diagrams in C. Its essential surjectivity is a coherence assertion about presentations, not merely the existence of presentations of their values.

94. Cas commun : il existe un ordinal limite α, tel que 1) $\operatorname{card}\alpha \leqslant \pi_0$. 2) Les limites inductives [de] type $I_\alpha = \{\beta \mid \beta < \alpha\}$ sont représentables dans C.

95. On a donc $\pi = \pi^{\pi_0} \geqslant 2^{\pi_0} > \pi_0$.

We shall use a cardinal convention which removes a recurrent ambiguity in these pages. For an infinite cardinal ρ, "large before ρ" means that every diagram with at most ρ arrows has a cocone. This is modern ρ^+-filteredness. An object called ρ-accessible here is correspondingly ρ^+-presentable. We retain Ind_ρ for Grothendieck's completion, and reserve λ for a regular cardinal when using modern terminology. Thus $\mathrm{Ind}_\rho(C)$ is the completion under λ-filtered colimits with $\lambda = \rho^+$. This convention applies even when ρ itself is singular.

The precise sufficient condition established by the ensuing proof is as follows. Suppose C is essentially small, $|\operatorname{Mor} J| \le \rho$, and C admits colimits of chains of one nonzero limit ordinal α with $|\alpha| \le \rho$. Then

$$\mathrm{Ind}_\rho([J, C]) \longrightarrow [J, \mathrm{Ind}_\rho(C)]$$

is an equivalence. One may take $\alpha = \omega$ in case (a). For the intended case (b), take a smaller infinite cardinal $\theta < \rho$ and $\alpha = \theta^+$, assuming the stipulated θ^+-filtered colimits of size at most θ^+ exist in C. The printed statement moves between π_0 as the completion bound and π_0 as this smaller auxiliary cardinal. Corollary 4.9.5 and the formulation in 4.10 make the intended roles clear; the proof must keep the bound on $|\alpha|$ tied to the completion cardinal. Footnote 94 should be read with that same bound. This is a normalization of the statement, not an additional closure assumption on the intended theorem.

Full faithfulness has a short explanation which also identifies the cardinal restriction on J. For $A, B : J \to \mathcal{M}$,

$$\mathrm{Nat}(A, B) = \mathrm{Eq}\left(\prod_{j \in J} \mathrm{Hom}(A_j, B_j) \rightrightarrows \prod_{u : j \to k} \mathrm{Hom}(A_j, B_k) \right).$$

If every A_j is ρ^+-presentable, this expression commutes with ρ^+-filtered colimits: every product has at most ρ factors, and the equality conditions have the same bound. Consequently the objects of $[J, C]$ remain presentable in $[J, \mathrm{Ind}_\rho C]$, so extension under filtered colimits is fully faithful. The long construction which follows is needed only to produce enough such objects. Its antecedent is the indexed-presentation criterion of Artin et al. (1972, I, 8.8.2–8.8.3); the present cardinal accounting is what makes that criterion usable for accessible categories.

Commentary · Examples [ms. 220]

The involution obstruction at every cardinal

The reservation in Remark 4.9.4 has a concrete answer. The obstruction in SGA 4, I, Exercise 8.8.8 is an involution of an ind-object which cannot be reached equivariantly from any of the chosen approximating objects. The same construction works at every infinite completion bound; it is the case $I = B(\mathbf{Z}/2)$ of Henry (2025b, Example 1.4, Construction 3.1 and Section 3.2). We give the calculation because it distinguishes the theorem's actual hypothesis from the much weaker fact that $\mathrm{Ind}_\rho(C)$ is accessible.

Example (cardinal form of the involution obstruction). For every infinite cardinal ρ there is a small category C such that

$$\mathrm{Ind}_\rho([B(\mathbf{Z}/2), C]) \longrightarrow [B(\mathbf{Z}/2), \mathrm{Ind}_\rho(C)]$$

is not essentially surjective.

Proof. Put $\lambda = \rho^+$. The objects of C are the ordinals $\beta < \lambda$. There are no arrows $\beta \to \gamma$ when $\beta > \gamma$, there is only the identity when $\beta = \gamma$, and there are two arrows labelled $+1, -1$ when $\beta < \gamma$. Composition multiplies labels. These rules are associative and define a small category. Let $y : C \to \widehat{C}$ be Yoneda, and form

$$F = \operatorname*{colim}_{\beta < \lambda} y(\beta),$$

using the arrows labelled $+1$ as transitions. The ordinal λ is λ-filtered: a set of fewer than λ ordinals below λ has an upper bound below λ. Hence F belongs to $\mathrm{Ind}_\rho(C)$.

For a fixed $\gamma < \lambda$, evaluation gives

$$F(\gamma) = \operatorname*{colim}_{\beta < \lambda} C(\gamma, \beta) = \{+1, -1\}.$$

Indeed the terms for $\beta > \gamma$ are these two-element sets and all subsequent transition maps are identities. Precomposition with an arrow labelled ε multiplies by ε. Multiplication by -1 on every $F(\gamma)$ therefore defines a natural automorphism $s : F \to F$, with $s^2 = 1$. It defines an object (F, s) of the right-hand diagram category.

Every functor $B(\mathbf{Z}/2) \to C$ has trivial action, because every endomorphism in C is an identity. A map of actions $(y\gamma, 1) \to (F, s)$ would correspond by Yoneda to an element of $F(\gamma)$ fixed by multiplication by -1. There is no such element. If (F, s) were a filtered colimit of C-valued actions, each object of the nonempty indexing category would give exactly such an equivariant map to its colimit. This contradiction proves the assertion. □

For $\lambda = \omega$ the signed category is the abstract form of the asymmetric finite subsets used in SGA 4. The uncountable replacement supplies the stronger filteredness required here. Thus Grothendieck's question is settled affirmatively, and the same construction is now part of a general characterization of the indexing categories for which presentations always exist. The chosen category also explains the missing hypothesis: a strictly increasing countable chain has no colimit in C. Any cocone has an apex strictly above all its terms and one constant sign. Reversing that sign gives a second cocone to the same apex, which cannot factor through the first because the apex has only its identity endomorphism. This contradicts the universal property of a proposed colimit.

p. 80

4.9.6 ([96]). Le reste de la présente section 4.9 est consacré à la démonstration de 4.9.3, i.e. à la vérification, pour $J \longrightarrow \mathcal{M}$, des conditions a), b) de 4.9.2. Dans toute la suite, on se fixe donc une

$$\varphi \ : \ J \longrightarrow \mathcal{M} \ = \ \mathrm{Ind}_\pi(C) \ . \tag{4.9.6.1}$$

On peut supposer J réduite, donc petite et $\operatorname{card} J \leqslant \pi_0$. On va considérer le foncteur déduit du foncteur (4.9.2.1)

$$\underline{\mathrm{Hom}}(J, C)/\varphi \longrightarrow \prod_{j \in \mathrm{Ob}\, J} C/\varphi(j) \ , \tag{4.9.6.2}$$

dont les foncteurs en question se déduisent en composant avec les foncteurs projection

$$\prod C/\varphi(j) \longrightarrow C/\varphi(j_0) \ . \tag{4.9.6.3}$$

Comme les catégories facteurs $C/\varphi(j)$ sont filtrantes (et même grandes devant π), leur produit est également filtrant, et même grand devant π (immédiat), et de même pour les produits partiels. Il s'ensuit aussitôt que les projections (4.9.6.3) sont cofinales, en vertu du [page 222]

Commentary · Exposition [ms. 221]

Why the cardinal must grow with the diagram

Corollary 4.9.5 applies the representation theorem after enlarging the class of presentable objects. Its usefulness lies precisely in not claiming that an arbitrary diagram is assembled from the originally chosen presentability rank. The preceding involution example shows how that stronger assertion can fail. At a sufficiently large rank the subcategory $\mathcal{M}_\pi$ contains the intermediate colimits needed to enforce the diagram's equations.

The exponent condition has two separate jobs. If $\pi = c^{\pi_0}$ and $c \geq \max(\pi_0, |\operatorname{Mor} J|)$, then

$$\pi^{\pi_0} = (c^{\pi_0})^{\pi_0} = c^{\pi_0 \cdot \pi_0} = c^{\pi_0} = \pi, \qquad \pi \geq 2^{\pi_0} > \pi_0.$$

This gives enough room to carry out the accessibility enlargement established earlier in Chapter XVIII, and enough room to record all arrows and equations of J. Conversely, a cardinal satisfying the displayed fixed-point condition is of the indicated form by taking $c = \pi$. No generalized continuum hypothesis is being used.

For intuition take $\mathcal{M} = \mathbf{Set}$ and let π dominate the number of arrows of J. The sets of cardinal at most π are the π^+-presentable objects. Given at most π chosen elements of the values of a J-diagram,

96. Résultats préliminaires (à la démonstration de 4.9.3).

close them under its structure maps. At most $\pi \cdot \pi = \pi$ elements are added. The resulting subdiagram has pointwise cardinal at most π. The poset of these subdiagrams is π^+-filtered: the union of at most π of them still has that bound. Their union is the original diagram. Moreover the equalizer formula in the preceding block proves that every such bounded subdiagram is π^+-presentable in $[J, \mathbf{Set}]$. This is the elementary model for the corollary. In a general accessible category there are no underlying subsets on which to perform this closure; the comma categories and their cofinal functors provide the replacement.

Lemme 4.9.6.1. *Soient I, I' deux catégories avec I' 0-connexe (p.ex. filtrante), alors le foncteur projection $pr_1 : I \times I' \longrightarrow I$ est cofinal.*

En effet, pour $i' \in \mathrm{Ob}\, I'$ `[plutôt` $i \in \mathrm{Ob}\, I$`]`, on a

$$i\backslash(I \times I') \;\simeq\; (i\backslash I) \times I' \;,$$

or $i\backslash I$ et I' étant 0-connexe, il en est de même de leur produit.

Lemme 4.9.6.2 ([97]). *Soit $(I_\alpha)_{\alpha\in A}$ une famille de catégories* filtrantes *(resp. grandes devant π). Alors $I_A \overset{déf}{=} \prod_{\alpha\in A} I_\alpha$ est filtrante (resp. grande devant π), et pour toute partie $B \subset A$, la projection canonique $I_A \longrightarrow I_B$ est cofinal.*

([98]). La stabilité de la propriété "filtrante" ou "grande devant π" par AQT `[âne qui trotte]`. On a, si $B' = A\backslash B$, $I_A \simeq I_B \times I_{B'} \longrightarrow I_B$, et on applique le lemme 4.9.6.1 pour conclure que ce foncteur est cofinal, $I_{B'}$ étant filtrante, donc 0-connexe.

Le foncteur (4.9.6.3) étant cofinal, pour établir que (4.9.2.1) l'est, il suffit de prouver qu'il [page 223]
en est ainsi du foncteur (4.9.6.2), ce que nous ferons. Notons de plus que ledit foncteur est *fidèle*, car il s'insère dans le carré commutatif

$$\begin{array}{ccc} \underline{\mathrm{Hom}}(J,C)/\varphi & \longrightarrow & \prod C/\varphi(j) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Hom}}(J,C) & \longrightarrow & C^{\mathrm{Ob}\, J} \end{array} ,$$

où les flèches verticales et la deuxième flèche horizontale sont fidèles. En définitive, pour p. 81
établir le théorème 4.9.3, nous allons étudier le foncteur *fidèle* (4.9.6.2)

$$(*) \qquad \begin{array}{l} f \;:\; \underline{\mathrm{Hom}}(J,C)/\Phi \;\longrightarrow\; \prod_{j\in J_0} C/\varphi(j) \\ (\text{où on a posé } J_0 = \mathrm{Ob}\, J,\; J_1 = \mathrm{Fl}\, J) \;, \end{array}$$

et nous allons prouver :

ⓐ Ce foncteur fidèle $(*)$ est *cofinal.*

ⓑ La catégorie source $\underline{\mathrm{Hom}}(J,C)/\varphi$ est grande devant π_0.

Nous allons pour ceci dégager un lemme auxiliaire sur la cofinalité des foncteurs *fidèles* :

Commentary · Examples [ms. 222]

Products need bounds on witnesses

The product trick is the first way Grothendieck makes independent choices simultaneous. If each I_a is λ-filtered and $D : K \to \prod_a I_a$ has fewer than λ arrows, choose a cocone on each projected diagram D_a. These coordinate cocones give a cocone on D. The empty diagram supplies nonemptiness. Thus arbitrary small products of λ-filtered categories are λ-filtered, using the usual axiom of choice. No bound on the number of factors is needed: the same small diagram is being solved in every coordinate.

97. Attention, il n'est pas vrai qu'un produit infini de catégories 0-connexes est 0-connexe !

98. Cf. démonstration élégante ci-dessous, 4.9.6.6.

The projection to a subproduct is final because its comma category at (x_b) is

$$\left(\prod_{b\in B}(x_b\backslash I_b)\right)\times\left(\prod_{a\notin B} I_a\right).$$

Both factors are nonempty and filtered. This calculation includes the empty subproduct, where the target is the terminal category. For the simpler projection $I\times I'\to I$, only connectedness and nonemptiness of I' are needed, since $(i\backslash I)\times I'$ has the same connected components as I'.

Footnote 97 correctly warns against replacing filteredness by connectedness in an infinite product. Here is a full example. Let P_n be the finite fence poset on vertices $0,1,\dots,n$, with the successive relations

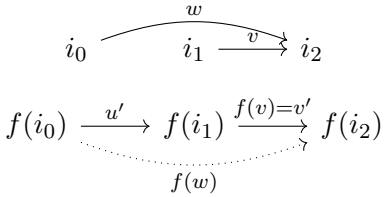
$$0<1>2<3>4<\cdots.$$

Its underlying undirected comparability graph is a path, so P_n is connected, and any zigzag from 0 to n has at least n nonidentity steps. Consider the two objects $a=(0)_n$ and $b=(n)_n$ of $\prod_{n\geq 1}P_n$. A zigzag with m steps between them would project to a zigzag with at most m steps from 0 to n in every coordinate. Taking $n>m$ is impossible. Thus the product is disconnected. Filteredness avoids this failure because two objects always have a common target, giving a uniformly two-step zigzag in every coordinate. The issue is a uniform finite witness, not merely the existence of coordinatewise witnesses.

[page 224]

Lemme 4.9.6.3 ([99]). *Soit $f: I\longrightarrow I'$ un foncteur, et considérons les conditions :*

a) I filtrante, f cofinal, i.e. (en présence de I filtrante) f satisfait les conditions familières (F 1), (F 2).



b) I' est filtrante, et les $i'\backslash I$ (pour $i'\in \mathrm{Ob}\, I'$) sont filtrantes.

b′) I' 0-connexe, satisfait PF (2) ([100]) (égalisation des double-flèches).

b″) I' est filtrante, les $i'\backslash I$ pseudo-filtrantes, i.e. satisfont à la condition PF $1'$.

c) I' filtrante, et f satisfait à F 1, ainsi que la condition suivante.

(F 3) *Pour tout couple (i_0,i_1) d'objets de I et toute flèche $f(i_0)\xrightarrow{u'}f(i_1)$, il existe un objet i_2 de I, et une flèche $v': f(i_1)\longrightarrow f(i_2)$, tels que v' et $v'u'$ soient relevables en des flèches $i_1\xrightarrow{v} i_2$ et $i_0\xrightarrow{w} i_2$ (i.e. il existe i_2 et $v: i_1\longrightarrow i_2$, $w: i_0\longrightarrow i_2$ tels qu'on ait $f(v)u'=f(w)$).*

1) On a les implications

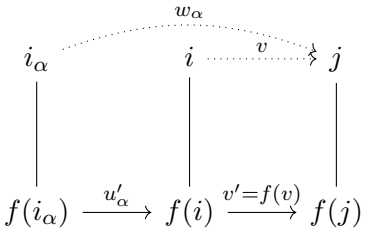
$$a \iff b \iff b' \implies b'' \iff c\,,$$

et si f est fidèle *(p.ex. I ordonnée), les cinq conditions a), b), b′), b″), c) sont équivalentes.*

p. 82
[page 225]

2) Soit π un cardinal infini, et considérons les conditions :

a_π) I grande devant π, f cofinal, i.e. F 1, F 2.



b_π) I' grande devant π, les $i'\backslash I$ ($i'\in \mathrm{Ob}\, I'$) aussi.

b_π'') I' grande devant π, les $i'\backslash I$ ($i'\in \mathrm{Ob}\, I'$) sont π-pseudo-filtrantes, i.e. satisfont PS $1_\pi{}'$.

c_π) I' grande devant π, et f satisfait F 1 et

99. Ce lemme fait partie du sorite général sur la cofinalité et les catégories filtrantes.
100. p.ex. PF 2 est satisfaite si I' est *ordonnée*, sans avoir à supposer d'avance I' filtrante, seulement 0-connexe.

F 3_π ([101]). *Pour toute famille $(i_\alpha)_{\alpha\in A}$ d'objets de I, avec* card $A \leqslant \pi$, *et $i \in \mathrm{Ob}\, I$, et une famille de flèches $u'_\alpha : f(i_\alpha) \longrightarrow f(i)$, existe $j \in \mathrm{Ob}\, I$ et une flèche $v' : f(i) \longrightarrow f(j)$, telle que v'* et *les $v'u'_\alpha$ proviennent de flèches de I, i.e. il existe des flèches $v : i \longrightarrow j$, $w_\alpha : i_\alpha \longrightarrow j$ telles que $f(v)u'_\alpha = f(w_\alpha)\ \forall\ \alpha \in A$.*

Ceci posé, on a

$$a_\pi \iff b_\pi \implies c_\pi \implies b_\pi{}'' ,$$

et si f est fidèle, ou I ordonné, les quatre conditions a_π, b_π, $b_\pi{}''$, c_π sont équivalentes.

([102]).

Commentary · Exposition [ms. 224]

What the cofinality lemma actually requires

Grothendieck has reduced a problem about natural transformations to a faithful functor into a product of comma categories. The new lemma is designed to exploit that faithfulness: one may arrange equality in the target and then reflect it back to the source. Keeping the two operations separate makes both the proof and its limitations transparent.

Write $D_d = (d \downarrow f)$ for $d \in I'$, and say explicitly that a category is *object-directed* if it is nonempty and any two objects admit maps to a common object. This is the particular property called "pseudo-filtrante" in this passage. It does not include equalization of parallel arrows and should not be confused with other uses of "pseudofiltered" in the literature. The coherent finite form of the lemma is

$$\begin{aligned} &I \text{ filtered and } f \text{ final} \iff I' \text{ filtered and every } D_d \text{ filtered,} \\ &I' \text{ filtered and every } D_d \text{ object-directed} \iff I' \text{ filtered, F1 and F3.} \end{aligned}$$

The first line implies the second. If f is faithful, the second also implies the first. F1 means that every d admits an arrow to some $f(i)$; F3 says that every arrow $f(i_0) \to f(i_1)$ becomes the image of an arrow out of i_0 after postcomposition with the image of an arrow out of i_1.

There is an actual omission in the printed condition b′: it requires only that I' be connected and satisfy PF2, without mentioning the comma categories. Taken literally it cannot be equivalent to a): the functor from a two-object discrete category to the terminal category is faithful and satisfies that printed b′, but its source is not filtered. The missing clause is "every D_d is filtered", as the proof and the explicit parenthesis on manuscript p. 236 confirm. With that clause restored, connectedness and PF2 for I' suffice; the argument below proves this slightly stronger formulation.

The nonempty requirement in b″ must likewise remain visible. If PF1′ is read only as a condition on pairs of objects, the empty category satisfies it vacuously, and $\varnothing \to 1$ disproves b″ ⇒c. Reading it as common upper bounds for all finite families, including the empty family, supplies precisely the required convention. The cardinal version explicitly quantifies over all families of cardinal at most π and therefore already includes the empty one. This is a clarification of the finite convention, not a counterexample to the intended criterion.

4.9.6.4. N.B. Dans le cas qui nous intéresse, où f est le foncteur $(*)$ (p. 223), on sait que I' est grande devant π. On voudrait établir que I l'est et que f est cofinal, i.e. la condition a_π. On le prouvera en prenant b_π (qui implique a_π puisque f est fidèle). Il reste donc à prouver, [page 226] sur le foncteur f dans $(*)$, p. 223, les deux conditions suivantes :

101. **N.B.** La condition F 3_π est tautologiquement satisfaite si f est *pleinement fidèle.*

102. Démonstration de la proposition donnée dans 4.9.6.7, page 227.

F 1) Pour tout système de flèches dans $\mathcal{M}$

$$X(j) \xrightarrow{p(j)} \varphi(j)\ , \qquad j \in J_0 = \mathrm{Ob}\, J,\ \text{les } X(j) \text{ dans } \mathrm{Ob}\, C\ ,$$

il existe un foncteur $F : J \longrightarrow C$ et $F \xrightarrow{q} \varphi$, enfin un système de flèches $X(j) \xrightarrow{u(j)} F(j)$ dans les $C/\varphi(j)$, i.e. rendant commutatif les diagrammes

$$\begin{array}{ccc} X(j) & \xrightarrow{\quad u(j) \quad} & F(j) \\ & {\scriptstyle p(j)}\searrow \quad \swarrow{\scriptstyle q(j)} & \\ & \varphi(j)\ . & \end{array}$$

F 3_π) Pour tout système $(F_\alpha)_{\alpha\in A}$ ($\mathrm{card}\, A \leqslant \pi$) d'éléments dans $\underline{\mathrm{Hom}}(C, J)$, et des flèches

$$F_\alpha \xrightarrow{p_\alpha} \varphi \qquad \text{dans } \underline{\mathrm{Hom}}(J, \mathcal{M}),$$

et pour G dans $\underline{\mathrm{Hom}}(J, C)$ et $G \xrightarrow{q} \varphi$ dans $\underline{\mathrm{Hom}}(J, \mathcal{M})$, étant donné un système de flèches $u_\alpha(j)$, p. 83

$$\begin{array}{ccc} F_\alpha(j) & \xrightarrow[\text{comm.}]{u_\alpha(j)} & G(j) \\ & {\scriptstyle p_\alpha(j)}\searrow \quad \swarrow{\scriptstyle q(j)} & \\ & \varphi(j)\ , & \end{array} \qquad u_\alpha(j) \text{ flèche dans } C/\varphi(j)\ ,$$

il existe $H \xrightarrow{q} \varphi$ dans $\underline{\mathrm{Hom}}(J, C)$ et une flèche $G \xrightarrow{v} H$ dans $\underline{\mathrm{Hom}}(J, C)/\varphi$, telle que pour tout $\alpha \in A$, le système de flèches composés [page 227]

$$\begin{array}{ccccc} F_\alpha(j) & \xrightarrow[\text{comm.}]{u_\alpha(j)} & G(j) & \xrightarrow[\text{comm.}]{v(j)} & H(j) \\ & {\scriptstyle p_\alpha(j)}\searrow & \downarrow{\scriptstyle q(j)} & \swarrow{\scriptstyle q(j)} & \\ & & \varphi(j) & & \end{array}$$

(pour $j \in J_0 \in \mathrm{Ob}\, J$) provienne d'un *foncteur* $w_\alpha : F_\alpha \longrightarrow H$.

Pour prouver 4.9.3, nous sommes donc ramené à prouver les deux propositions F 1), F 3_π) précédentes, sous l'une des deux conditions a) ou b) de 4.9.3.

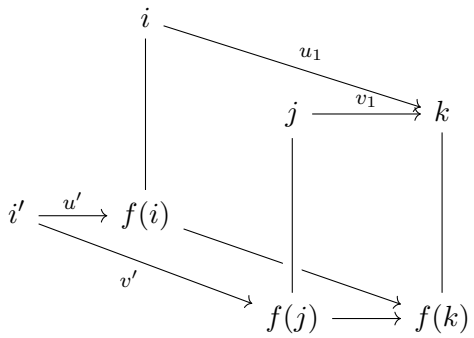
Corollaire 4.9.6.5 (de 4.9.6.3). *Soit $(f_\alpha : I_\alpha \longrightarrow I'_\alpha)$ une famille de foncteurs cofinaux, les catégories source étant filtrantes. Alors le foncteur produit $f = \prod f_\alpha : I = \prod_\alpha I_\alpha \longrightarrow I' = \prod_\alpha I'_\alpha$ est cofinal.*

En effet, il faut vérifier que les catégories $i'\backslash I$, pour $i' \in \mathrm{Ob}\, I'$, sont 0-connexes. Or si $i' = (i'_\alpha)_{\alpha\in A}$, on a

$$i'\backslash I \ \simeq\ \prod_\alpha (i'_\alpha \backslash I_\alpha)\ ,$$

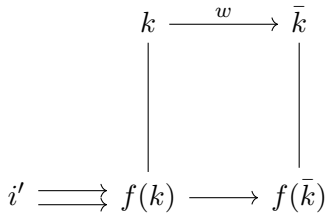
et par 4.9.6.3, 1°) a $\Longrightarrow$ c, les $i'_\alpha\backslash I_\alpha$ sont filtrantes, donc leur produit est filtrant (cf. 4.4.6.2), donc 0-connexe, q.e.d. [page 228]

Corollaire 4.4.6.6. *Soit π un cardinal infini. Tout produit de catégories grandes devant π est grand devant π.*



Soit $I = \prod_{\alpha\in A} I_\alpha$, soit B un ensemble de cardinal $\leqslant \pi$, il faut prouver que $I \xrightarrow{\mathrm{diag}_I} I^B$ est cofinal. Or ce foncteur s'identifie au produit des foncteurs similaires $I_\alpha \longrightarrow I_\alpha^B$, lesquels sont cofinaux, les catégories source étant de plus filtrantes. Donc on peut conclure par le corollaire 4.9.6.5.

4.9.6.7. Démonstration de 4.9.6.3. (Partie 1°.)



a $\Longrightarrow$ b. On sait déjà que a) implique que I' est filtrante (SGA 4 I 8.1.3 b). Reste à prouver que pour tout $i' \in \mathrm{Ob}\, I'$, $i'\backslash I$ est filtrante ([103]). Deux conditions PF 1′ et PF 2 à vérifier (en plus du fait que $i'\backslash I \neq \emptyset$, qui est connu par cofinalité de f, impliquant que $i'\backslash I$ est 0-connexe).

1) Soient (i, u'), (j, v') deux éléments de $i'\backslash I$, il faut voir qu'ils sont majorés par un troisième élément. Or I étant filtrante, i, j sont majorés par k. On aurait fini donc si on savait que $f(u_1)u' = f(v_1)v'$, soit w', car alors (k, w') ferait l'affaire.

p. 84

Mais on applique F 2 sur f à la double-flèche en question $i' \rightrightarrows f(k)$, on trouve $w : k \longrightarrow \bar{k}$, [page 229]

telle que

$$\underbrace{f(w)(f(u_1)u')}_{=f(wu_1)u'} = \underbrace{f(w)(f(v_1)v')}_{f(wv_1)v'},$$

et remplaçant k par $\bar{k}$, et u_1, v_1 par wu_1, wv_1, on trouve ce qu'on veut.

Commentary · Exposition [ms. 228]

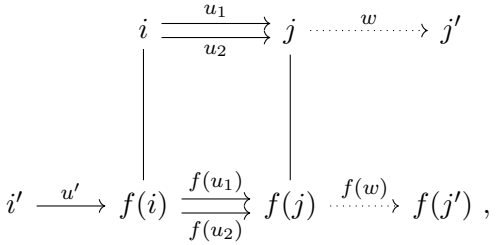
The finite proof, with the lifting equation in its proper order

The proof is a calculus of eventual equality. It is useful to complete it once because the same operations reappear, with a cardinal bound, in the construction of sections. We use "final" for Grothendieck's right-cofinal functors.

Suppose first that I is filtered and f is final. A basic consequence is the following form of F2: if $r, s : d \rightrightarrows f(i)$, there is $w : i \to k$ such that $f(w)r = f(w)s$. Indeed (i, r) and (i, s) are joined by a finite zigzag in $(d \downarrow f)$. A cocone in I on the finite underlying graph makes the two composites from d equal. The two resulting maps from i to its apex may differ; equalizing them in I gives the single map w asserted. Together with F1, this proves that I' is filtered: two objects first map into the image of f and then to a common target; a parallel pair first maps to an object $f(i)$ and is then equalized by F2.

The same argument proves that every D_d is filtered. For two of its objects, choose a common target for their underlying objects of I, and then use F2 to make the two maps from d agree. For parallel arrows in D_d, equalize their underlying arrows in I. The resulting arrow remains in the comma category because its structure map is obtained by composition. This proves a)⇒b), including the target-filteredness which is invoked from SGA 4 in the text.

103. Court-circuit : on sait déjà que $i'\backslash I$ est 0-connexe, d'autre part elle est *localement* filtrante, car coétale sur I qui est filtrante, donc elle est filtrante.



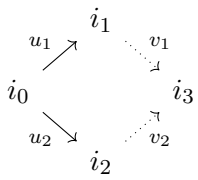
Now suppose only the corrected b′: I' is nonempty and connected, has right equalizers for parallel pairs, and each D_d is filtered. Finality follows immediately, hence I is nonempty and connected. First obtain F3 by taking a common target for $(i_0, 1)$ and (i_1, u') in $D_{f(i_0)}$. To equalize $a, b : i_0 \rightrightarrows i_1$, equalize $f(a), f(b)$ in I', use F1 to move the target into the image of f, and use F3 to replace that target arrow by an image $f(w)$. The resulting arrows wa, wb have the same image. They are parallel arrows in $D_{f(i_0)}$ from $(i_0, 1)$ to $(\operatorname{cod} w, f(wa))$, so filteredness of that comma category equalizes them in I.

For an outgoing span $i_1 \leftarrow i_0 \rightarrow i_2$, a common target in $D_{f(i_0)}$ supplies maps v_1, v_2 whose composites with the span have the same image. The equalization just proved makes the composites themselves equal. Thus every outgoing span completes to a commuting square. In a connected category this, together with parallel-pair equalization, gives filteredness: move along a finite zigzag between two objects and complete each successive outgoing span to keep a common target. This proves corrected b′)⇒a). The converse is immediate from b).

Finally suppose c). F1 makes each D_d nonempty. Given two objects of D_d, use filteredness of I' to form a common target for their maps from d, use F1 to put this target in the image of f, and apply F3 twice to lift both arrows after a further enlargement. Thus D_d is object-directed. Conversely, that property for $D_{f(i_0)}$ gives F3 from $(i_0, 1)$ and (i_1, u'), while nonemptiness gives F1. If f is faithful, a parallel pair in a comma category can be equalized in I', the equalizing arrow lifted by F3 after F1, and the resulting equality reflected by faithfulness. Hence b) follows.

The printed formula on p. 231, $f(w)v' = f(v)$, reverses the factors and is not typed: with $v : i_2 \to \bar{i}_2$, $w : i_1 \to \bar{i}_2$ and $v' : f(i_1) \to f(i_2)$ the correct equation is $f(v)v' = f(w)$. The proof above uses this order. This is an edition/source slip, not a failure of the argument. Its companion typo $\xi_1 = (i_0, v')$ must likewise be read as (i_1, v').

2) PF (2) pour $i'\backslash I$, i.e. on se donne un diagramme ci-contre `[ci-dessous]`,



avec $f(u_1)u' = f(u_2)u'$, soit v' (double-flèche dans $i'\backslash I$ de (i, u') dans (j, v')), on veut l'égaliser à droite. Or I étant filtrant, il existe $w : j \longrightarrow j'$ telle que $wu_1 = wu_2$, or cette flèche définit une flèche $(j, v') \longrightarrow (j', f(w')v')$, qui égalise la double-flèche donnée.

b $\Longrightarrow$ b′ est clair.

b) $\Longrightarrow$ a). Comme les $i'\backslash I$ sont filtrantes, donc 0-connexes, f est cofinal, il reste à prouver que I est filtrant, donc à vérifier PF 0 (I 0-connexe), PF 1, PF 2 pour I. I est 0-connexe, car I' l'est, et f cofinal, i.e. $\mathbf{W}_0$-coasphérique, d'où PF 0.

[page 230]

Prouvons PF 1, i.e. que si  est donné, on peut compléter en un carré commutatif.

$$\begin{array}{ccccc} & & f(i_1) & & \\ & \overset{f(u_1)}{\nearrow} & & \overset{f(v_1)}{\searrow} & \\ f(i_0) & & & & f(i_3) \\ & \underset{f(u_2)}{\searrow} & & \underset{f(v_2)}{\nearrow} & \\ & & f(i_2) & & \end{array}$$

Mais considérons les objets $\xi_1 = (i_1, f(u_1))$, $\xi_2 = (i_2, f(u_2))$ de $f(i_0)\backslash I$, et utilisant PF 1′ pour cette catégorie, on trouve $\xi_3 = (i_3, w')$ dans ladite catégorie, et des flèches de ξ_1, ξ_2 dans ξ_3, i.e. $v_1 : i_1 \longrightarrow i_3$, $[v_2 : i_2 \longrightarrow i_3,]$ telles que $\underbrace{f(v_1)f(u_1)}_{f(v_1u_1)} = w'$, $\underbrace{f(v_2)f(u_2)}_{f(v_2u_2)} = w'$, donc

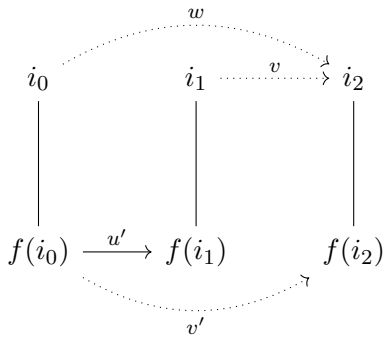
$$f(v_1u_1) \;=\; f(v_2u_2)\ .$$

Ainsi, on a une double-flèche $i_0 \overset{v_1u_1}{\underset{v_2u_2}{\rightrightarrows}} i_3$, égalisée par f. Si on prouve PF 2 sur I, on trouve $i_3 \xrightarrow{\alpha} \bar{i}_3$ telle que $\alpha(v_1u_1) = \alpha(v_2u_2)$, i.e. $(\alpha v_1)u_1 = (\alpha v_2)u_2$, et quitte à remplacer i_3 par $\bar{i}_3$, v_1, v_2 par αv_1, αv_2, on a gagné.

Reste à prouver PF 2 sur I, i.e. égaliser une double-flèche

$$i_0 \;\overset{v_1}{\underset{v_2}{\rightrightarrows}}\; i_1\ .$$

Or I' satisfaisant à PF 2, on peut égaliser la double-flèche $f(u_1)$, $f(u_2)$ par une flèche [page 231]
$f(i_1) \xrightarrow{v'} i'$ dans I', et comme $i'\backslash I$ non vide, on peut supposer que i' est de la forme $f(i_2)$.

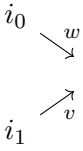


$$\begin{array}{ccccc} i_0 & \overset{u_1}{\underset{u_2}{\rightrightarrows}} & i_1 & \longrightarrow & i_2 \\ \Big| & & & & \\ f(i_0) & \overset{f(u_1)}{\underset{f(u_2)}{\rightrightarrows}} & f(i_1) & \xrightarrow{v'} & f(i_2) \end{array}$$

Admettons pour un instant la condition F 3 de c), que nous allons appliquer à (i_1, i_2, v'). Il existe donc $i_2 \xrightarrow{v} \bar{i}_2$, $w : i_1 \longrightarrow \bar{i}_2$ tels que l'on ait $f(w)v' = f(v)$. Il s'ensuit que $f(w)$ égalise $f(u_1)$ et $f(u_2)$, i.e. qu'on a $f(wu_1) = f(wu_2)$, i.e. la double-flèche initiale est remplacée par $(\bar{u}_1 = wu_1, \bar{u}_2 = wu_2)$, telle que $f(\bar{u}_1) = f(\bar{u}_2)$. En somme, on est ramené au cas d'une double-flèche (u_1, u_2) telle que $f(u_1) = f(u_2)$, soit v'. Mais alors soit $\xi_1 = (i_0, v')$, $\xi_0 = (i_0, \mathrm{id}_{f(i_0)})$, on a donc une double-flèche $(u_1, u_2) : \xi_0 \rightrightarrows \xi_1$ dans $f(i_0)\backslash I$. Cette catégorie est filtrante, donc [page 232]
cette double-flèche est égalisable à droite, ce qui implique aussitôt que la double-flèche (v_1, v_2) *dans* I est aussi égalisable à droite.

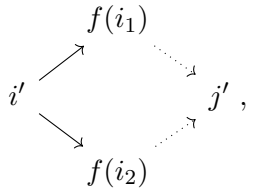
Donc il reste à prouver que b′) implique la condition F 3. Mais considérons les deux objets $\xi_0 = (i_0, \mathrm{id}_{f(i_0)})$, $\xi_1 = (i_1, u')$ de $f(i_0)\backslash I$, et utilisons la condition de filtration PF 1 sur cette catégorie, donc on trouve un objet $\xi_2 = (i_2, v')$, et deux flèches $\begin{array}{ccc} \xi_0 & \overset{w}{\searrow} & \\ & & \xi_2 \\ \xi_1 & \underset{v}{\nearrow} & \end{array}$, i.e. $i_0 \xrightarrow{w} i_2$ et

$i_1 \xrightarrow{v} i_2$ telles qu'on ait $f(w)\mathrm{id}_{i_0} = f(v)u' = v'$, d'où $f(w) = f(v)u'$, ce qui est la condition F p. 86



3.

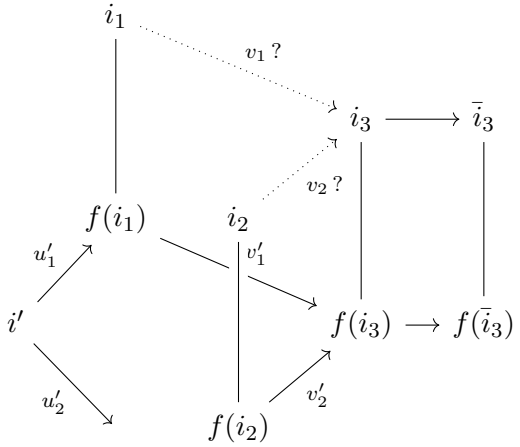
Ainsi on a établi



$$\text{a} \iff \text{b} \iff \text{b}' ,$$

prouvons maintenant

a $\Longrightarrow$ c. On sait déjà que a) implique I' filtrante, et il reste à établir F 3. Or I étant filtrante, il existe des flèches  . On n'a pas forcément $f(w) = f(v)u'$, on a là une double-flèche $f(i_0) = f(i_1)$ dans I'. Mais par la condition F 2 sur f, il existe $i_2 \xrightarrow{\alpha} \bar{i}_2$ dans I telle que $f(\alpha)$ égalise ladite double-flèche, donc $f(\underbrace{\alpha w}_{\bar{w}}) = f(\underbrace{\alpha v}_{\bar{v}})u'$, et quitte à remplacer i_2 par $\bar{i}_2$, et w, v par $\bar{w} = \alpha w$, $\bar{v} = \alpha v$, on gagne.

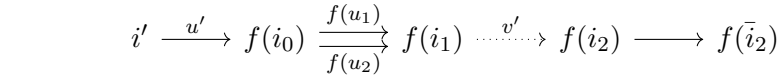


[page 233]

Reste à prouver (pour la partie 1°) que si f est *fidèle*, alors c) $\Longrightarrow$ b). Il reste donc à prouver que c) implique que pour i' dans I', $i'\backslash I$ est filtrante. On sait déjà par F 1 que $i'\backslash I$ est non vide, il reste à prouver les conditions PF 1′, PF 2 pour $i'\backslash I$. Comme I' filtrante, l'on peut compléter

et par F 1 on peut supposer j' de la forme $f(i_3)$.

p. 87



Appliquant F 3 à i_1, i_3, v'_1, on peut supposer (quitte à remplacer i_3 par $\bar{i}_3$) que v'_1 provient d'un $v_1 : i_1 \longrightarrow i_3$. Appliquant à nouveau F 3 à i_2, i_3, v'_2, on peut supposer que v'_2 également

[page 234]

provient d'un $v_2 : i_2 \longrightarrow i_3$. Alors $\xi_3 = (i_3, v_1'u_1' = v_2'u_2')$ est un majorant commun de $\xi_1 = (i_1, u_1')$, $\xi_2 = (i_2, u_2')$.

Prouvons enfin PF 2 pour $i'\backslash I$, donc on a un diagramme ci-contre [ci-dessous] avec $f(u_1)u' = f(u_2)u'$ (double-flèche dans $i'\backslash I$), on veut égaliser dans $i'\backslash I$.

Mais I' étant filtrante, on peut égaliser $(f(u_1), f(u_2))$ par $f(i_1) \longrightarrow j'$, et à cause de F 1 on peut supposer $j' = f(i_2)$. Appliquant encore F 3 à (i_1, i_2, v'), on trouve $i_1 \longrightarrow \bar{i}_2$ tel que $f(w)$ égalise $f(u_1)$, $f(u_2)$:

$$f(wu_1) \;=\; f(wu_2)\ .$$

Mais f étant *fidèle*, cela implique $wu_1 = wu_2$, et on a donc égalisé la double-flèche de $i'\backslash I$ par $w : (i_1, -) \longrightarrow (\bar{i}_2, -)$.

4.9.6.8. N.B.

1°) Si on ne suppose pas que f soit fidèle, on voit que c) implique pourtant que les $i'\backslash I$ satisfont PF 1′ (elles sont donc pseudo-filtrantes et 0-connexes). Donc f est cofinal.
On voit, par le même argument, que I satisfait PF 1′, i.e. est pseudo-filtrante. Ainsi, si on introduit la condition : [page 235]

(b″) I' est filtrante, les $i'\backslash I$ ($i \in \mathrm{Ob}\, I'$) sont pseudo-filtrantes (i.e. satisfont PF 1′) (donc f cofinal).

On trouve les implications

$$(\mathrm{a} \iff \mathrm{b} \iff \mathrm{b}') \implies (\mathrm{b}'' \iff \mathrm{c})\ ,$$

et les conditions équivalentes c), b″) impliquent que I est également pseudo-filtrante, et que pour toute double-flèche $\xi_0 \overset{u_1}{\underset{u_2}{\rightrightarrows}} \xi_1$ dans un $i'\backslash I$ ou dans I, il existe une flèche $\xi_1 \xrightarrow{v} \xi_2$ dans la même catégorie, telle que vu_1 et vu_2 : $\xi_0 \rightrightarrows \xi_2$ aient *même image dans* I'. Donc si f est fidèle, alors ces conditions c, c′ [plutôt b″] impliquent que I et les $i'\backslash I$ satisfont aussi la condition PF 2 de la double-flèche, donc sont filtrantes, donc dans ce cas les cinq conditions a) b) b′) c) c′) [plutôt b″)] sont équivalentes. Mais aussi lorsque I est ordonnée, on sait [?] que la condition de la double-flèche dans I est satisfaite automatiquement. p. 88

2°) Notons aussi que dans la condition b′), on ne peut supprimer l'hypothèse que I' satisfait PF 2 (en plus de I' 0-connexe et les $i'\backslash I$ filtrantes). Pour le voir, prenons $I' = I$, $f = \mathrm{id}$, donc l'hypothèse a ($\iff$ b $\iff$ b′) signifie que I est filtrante, f étant bien sûr cofinal. Mais b′ affaiblie signifie que I est 0-connexe et les $i\backslash I$ sont filtrantes, et on sait que ceci n'implique *pas* que I soit filtrante, même si on suppose I pseudo-filtrante. Un exemple simple est donné par I définie par [page 236]

$$\mathrm{Ob}\, I \;=\; \mathbf{N}\ , \qquad \mathrm{Hom}_I(i,j) \;=\; \begin{cases} \emptyset & \text{si } i > j \\ \{\mathrm{id}_i\} & \text{si } i = j \\ \{\pm 1\} & \text{si } i < j\ , \end{cases}$$

la composition des flèches se faisant par la multiplication des signes $\varepsilon_{k,j}\varepsilon'_{j,i} = (\varepsilon\varepsilon')_{k,i}$ (en posant $\mathrm{id}_i = (+1)_{i,i}$). Les catégories $i\backslash I$ sont isomorphes entre elles et sont *ordonnées* et pseudo-filtrantes, donc filtrantes, d'autre part, I est pseudo-filtrante, pourtant elle n'est pas filtrante, car ne satisfait pas PF 2.

3°) D'autre part, si f n'est pas fidèle, alors c) (équivalente à b'') n'implique pas a), comme on voit en prenant $I' = e$; alors b″) équivaut à I pseudo-filtrante, qui n'implique pas que I soit filtrante.

4.9.6.9. Démonstration de 4.9.6.3, partie 2°. [page 237]

Commentary · Examples [ms. 236]

Connected slices cannot replace equalization

Grothendieck's signed category measures exactly the part of filteredness lost when one retains only common upper bounds. Its objects are natural numbers, and for $n < m$ there are two arrows $n \to m$, labelled $+1$ and -1. Composition multiplies signs. Any two objects map to a larger integer, so the category is object-directed and connected. But two opposite-sign arrows can never be equalized on the right: multiplying both by the same sign leaves them opposite. It is therefore not filtered.

Fix n. The objects of $n\backslash I$ are 1_n and pairs (m, ε) for $m > n$. Between (m, ε) and (k, δ) with $m < k$ there is exactly one possible arrow, namely the arrow labelled $\delta\varepsilon^{-1}$. At equal levels the only arrows are identities between equal objects. Thus the slice is a poset, consisting of a bottom point followed by two points at each subsequent level, both below every point at a higher level. Two objects have an upper bound at any strictly larger level; hence the slice is filtered. Shifting levels shows that these slices are mutually isomorphic. Taking $f = 1_I$ gives exactly the counterexample promised on p. 236: connectedness of I' and filteredness of all D_d do not imply filteredness of I unless PF2 is retained for I'.

There is an even smaller illustration of the role of faithfulness. For a nontrivial group G, the functor $BG \to 1$ satisfies F1 and F3: there is only one target arrow, and one can choose both lifting arrows to be the identity. Its source is object-directed, but not filtered, since 1 and any $g \neq 1$ cannot be equalized by multiplying on the left by an invertible element. The functor is final because BG is connected. Finality alone is consequently weaker than having a filtered source. The same example works for every cardinal version of F3.

C'est essentiellement "la même" démonstration que pour la partie 1°).

$a_\pi) \Longrightarrow b_\pi)$. On peut court-circuiter la démonstration directe, en regardant, pour un ensemble A de cardinal $\leqslant \pi$, le diagramme

$$\begin{array}{ccc} I & \xrightarrow{\delta_A} & I^A \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f^A} \\ I' & \xrightarrow{\delta_{A'}} & I'^A \end{array}$$

[plutôt δ'_A]. Comme f est cofinal, I filtrante, f^A est aussi cofinal (4.9.8.5), d'autre part, I grande devant π signifie que δ_A est cofinal ($\forall$ A avec $\mathrm{card}\, A \leqslant \pi$). Donc $f^A\delta_A = \delta_{A'}f$ est cofinal, donc $\delta_{A'}f$ et f le sont, donc $\delta_{A'}$ aussi, ce qui signifie que I' est grande devant π.

Reste à prouver que pour i' dans I', $i'\backslash I$ est grande devant π. Cela résulte du fait que $i'\backslash I \xrightarrow{p} I$ est coétale, que $i\backslash I$ est 0-connexe, et du

Lemme 4.9.6.9.1. *Soit I une catégorie filtrante (resp. grande devant π). Alors pour toute J sur I coétale sur I et 0-connexe, J est filtrante (resp. grande devant π).*

Le cas filtrant est déjà connu (cf. II …). Pour le cas "grande devant π", on va utiliser le p. 89

Corollaire 4.9.6.9.2. *Soit J une catégorie. Pour que J soit grande devant π, il faut et il suffit qu'elle soit 0-connexe, et satisfasse PF_π 2 (cf. page 81), ainsi que la variante suivante de PF_π 1′.* [page 238]

PF_π 1) Pour tout objet x_0 de J, $x_0\backslash J$ satisfait PF_π 1′, i.e. pour toute famille de flèches $x_0 \xrightarrow{u_\alpha} y_\alpha$ ($\alpha \in A$, $\operatorname{card} A \leqslant \pi$), existe une flèche $x_0 \xrightarrow{v} z$ et des flèches $v_\alpha : y_\alpha \longrightarrow z$, avec $v_\alpha u_\alpha = v \ \forall\, \alpha \in A$.

Commentary · Exposition [ms. 237]

A connected category of elements inherits filteredness

The shortcut through a coétale functor expresses a useful structural fact. In modern language the functor $p : E \to I$ is a discrete opfibration: for every $e \in E$ and arrow $p(e) \to i$ there is a unique lift with source e. Equivalently, E is the category of elements of a covariant set-valued functor on I. The projection $(d \downarrow f) \to I$ is of this form, associated with $i \mapsto I'(d, f(i))$.

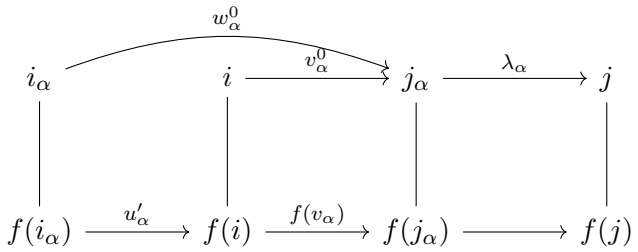
Assume I is λ-filtered and E is nonempty and connected. We give a direct proof that E is λ-filtered. Any finite zigzag in E has a common target: choose a cocone on its projected finite diagram in I and lift its legs. The lifted endpoint objects coincide along each edge by uniqueness of lifting, and hence along the entire zigzag. This proves that any two objects of E have a common target. A parallel pair in E is equalized by lifting an equalizing arrow in I; uniqueness of lifting identifies the resulting composites. Thus E is filtered.

For a family (e_a) of fewer than λ objects, choose a base object e_0 and, using the finite case, a common target z_a of e_0 and e_a. The projected arrows $p(e_0) \to p(z_a)$ have a common compatible target in I by λ-filteredness. Lift these arrows from the z_a. Their targets are all the same object, because the composites starting at e_0 are unique lifts of the same base arrow. It receives arrows from every e_a. A family of fewer than λ parallel arrows is equalized by the same lifting argument as before. Common upper bounds and simultaneous equalization now give cocones on arbitrary diagrams with fewer than λ arrows. This proves Lemma 4.9.6.9.1 completely.

The proof also explains Corollary 4.9.6.9.2. Connectedness plus the common-target condition for every family issuing from one object first gives the finite common-target property by following zigzags. For a larger family, join each member to a fixed base object and then apply the stipulated condition to those arrows from the base. Together with simultaneous equalization, this is exactly λ-filteredness. Connectedness cannot be discarded: a disjoint union of two terminal categories satisfies every condition localized at an individual object but has no cocone on the diagram consisting of one object in each component.

Démonstration. Si J est grande devant π, alors PF_π 1) résulte aussitôt de la conjonction de PF_π 1′ et PF_π 2, d'où le "il faut". Inversement, supposons que J satisfasse PF_π 1, PF_π 2, et soit 0-connexe, il faut prouver qu'elle satisfait PF_π 1′. Mais on sait déjà que les conditions en question, qui impliquent PF 1, PF 2, 0-connexe, impliquent que J est filtrante. Donc si on a une famille $(x_\alpha)_{\alpha\in A}$, $\operatorname{card} A \leqslant \pi$, choisissant un $x_0 \in \operatorname{Ob} J$, on peut pour tout α trouver y_α qui majore x_0 et x_α, d'où des flèches $\begin{array}{ccc} & & x_\alpha \\ & \searrow & \\ & & y_\alpha \\ & \nearrow & \\ x_0 & & \end{array}$, on peut leurs appliquer PF_π 1, d'où des flèches $y_\alpha \longrightarrow z$, et en composant des $x_\alpha \longrightarrow z$, q.e.d.

Prouvons maintenant le lemme. Il suffit (par le corollaire précédent) de prouver que J satisfait à PF_π 1 et PF_π 2. Or PF_π 1 est immédiat, puisque $\forall\, x_0$ dans J, $x_0\backslash J \xrightarrow{\sim} y_0\backslash I$, où y_0 est l'image de x_0 dans I. Quant à PF_π 2, si on a des $x_0 \overset{u_\alpha}{\rightrightarrows} x_1$ dans J, d'où des [page 239]
$g(x_0) \overset{g(u_\alpha)}{\rightrightarrows} g(x_1)$, on égalise dans I par $g(x_1) \xrightarrow{w} y$, mais comme g est coétale, $\exists\, x_1 \xrightarrow{v} x_2$ dans J telle que $g(v) = w$, donc on a $g(vu_\alpha) = g(vu_\beta)$ pour $\alpha, \beta \in A$, et comme g est fidèle, on en conclut $vu_\alpha = vu_\beta$, donc v égalise $(u_\alpha)_{\alpha\in A}$, q.e.d.



Prouvons $\mathrm{b}_\pi) \Longrightarrow \mathrm{a}_\pi)$: Si I' et les $i'\backslash I$ sont grandes devant π, alors I l'est aussi (et f est cofinal, les $i'\backslash I$ étant 0-connexes, car filtrantes). Comme on sait déjà que I est 0-connexe (I' l'étant et f cofinal), il reste, par 4.9.6.9.2, à vérifier PF_π 1 et PF_π 2.

La démonstration donnée dans 1° pour le cas similaire filtrant (implication $\mathrm{b}' \Longrightarrow \mathrm{a}$, pages [page 240]
231-232), s'applique mutatis mutandis. (La propriété F 3 a déjà été établie dans la partie 1°), comme conséquence de b, et peut donc être utilisée librement.)

Donc on a prouvé $a_\pi \iff b_\pi$. Prouvons $a_\pi \implies c_\pi$. On sait déjà que a_π implique que I' est grande devant π, et bien sûr la condition F 1, reste à établir la validité de la condition F 3_π. Par F 3, $\forall\, \alpha \in A$ on peut trouver j_α dans I et $w^0_\alpha : i_\alpha \longrightarrow j_\alpha$, $v^0_\alpha : i \longrightarrow j$ tels que

$$f(v_\alpha)u'_\alpha \;=\; f(w_\alpha)\ .$$

p. 90

Comme I satisfait PF 1_π (cf. 4.9.6.9.2), il existe h dans I et des $\lambda_\alpha : j_\alpha \longrightarrow j$, tels que $\lambda_\alpha v^0_\alpha = \lambda$ soit indépendant de α, alors on a pour tout $\alpha \in A$

$$f(\lambda)u'_\alpha \;\Big(\;=\; f(\lambda_\alpha)\underbrace{f(v_\alpha)u'_\alpha}_{f(w_\alpha)}\;\Big) \;=\; f(\underbrace{\lambda_\alpha w^0_\alpha}_{w_\alpha})\ ,$$

donc $\lambda : i \longrightarrow j$ et les $w_\alpha = \lambda_\alpha w^0_\alpha : i_\alpha \longrightarrow j$ satisfont aux conditions voulues.

$c_\pi \implies b''_\pi$. Il faut prouver que si c_π est satisfait, alors les $i'\backslash I$ satisfont PF $1'_\pi$.

Soit donc $\xi_\alpha = (i_\alpha, u'_\alpha)$ ($\alpha \in A$, $\operatorname{card} A \leqslant \pi$) une famille d'éléments de $i'\backslash I$, comme I' satisfait à PF 1_π (cf. 4.9.6.9.2), il existe j' dans I' et des flèches $u''_\alpha : f(i_\alpha) \longrightarrow j'$, telles que $u''_\alpha u'_\alpha = u'$ indépendant de α. Comme f satisfait F 1, on peut supposer que j' est de la forme $f(j)$. Appliquant F 3_π aux i_α, j, u''_α, on trouve $v : j \longrightarrow k$ et des $w_\alpha : i_\alpha \longrightarrow k$, tels que [page 241]

$$f(v)u''_\alpha \;=\; f(w_\alpha) \qquad \forall\, \alpha \in A\ ,$$

d'où

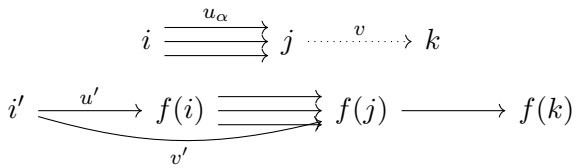
$$f(w_\alpha)u'_\alpha \;=\; f(v)\,\underbrace{u''_\alpha u'_\alpha}_{u'} \;=\; f(v)u' \qquad \text{indépendant de } \alpha,$$

soit w', donc les w_α définissent une flèche des ξ_α dans $\xi = (k, w')$, q.e.d.

Commentary · Exposition [ms. 240]

Simultaneous lifting at the cardinal bound

The cardinal proof requires one simultaneous enlargement. Repeating F3 separately for an infinite family would give unrelated targets, so the common-domain form of filteredness is essential. Put $\lambda = \pi^+$. For a functor $f : I \to I'$, with I' λ-filtered, let $F3_\pi$ have exactly the meaning stated on p. 225. Then F1 and $F3_\pi$ are equivalent to every $(d \downarrow f)$ being nonempty and admitting common targets for all families of at most π objects. The reverse implication, not displayed in the printed implication chain, follows by applying this property to $(i, 1)$ and the objects (i_a, u'_a) of $(f(i) \downarrow f)$. There are at most π of these objects because π is infinite.



For the forward implication, a family $(i_a, r_a : d \to f(i_a))$ first acquires a compatible target in I'. By F1 its target may be replaced by $f(j)$. Apply $F3_\pi$ to all arrows $f(i_a) \to f(j)$ at once. The resulting maps $i_a \to k$ make the composites from d equal, so they are a common target in the comma category. If f is faithful, a family of at most π parallel comma arrows is equalized by first equalizing their images in I', moving the target into the image of f, and lifting the resulting arrow by the ordinary F3. Faithfulness reflects the common image. The comma categories are therefore λ-filtered.

We also fill in the cardinal descent which the source leaves to "mutatis mutandis". Suppose I' and every $(d \downarrow f)$ are λ-filtered. For a diagram $D : K \to I$ with at most π arrows, choose a cocone $fD \to d$ in I' and then a map $d \to f(i)$ by F1. The resulting family $fD(k) \to f(i)$ lifts simultaneously by $F3_\pi$ to maps $w_k : D(k) \to j$. Their naturality equations hold after applying f. For each arrow $a : k \to l$ of K, the pair $w_k, w_l D(a)$ is therefore a parallel pair in $(fD(k) \downarrow f)$ with

target $(j, f(w_k))$. Each such pair can be equalized in I by filteredness of that comma category. There are at most π choices of an equalizing map out of j; filteredness of $(f(j) \downarrow f)$ gives a compatible common successor for them. Composing w_k with its map from j makes every naturality equation hold. This is the required cocone on D.

Finally, if I is λ-filtered and f final, its comma categories are connected discrete opfibrations over I, hence λ-filtered by the previous block. The target I' inherits λ-filteredness by choosing image targets for all objects of a small diagram, and then using the filtered comma categories to impose its at most π relations; equivalently, the diagonal argument printed on p. 237 applies. These arguments prove all intended cardinal implications, with no need to assume π regular. The only regular cardinal used in the modern formulation is π^+.

$\mathrm{b}''_\pi \Longrightarrow \mathrm{b}_\pi$ si f est fidèle. On est ramené à prouver que si b''_π est satisfait, f fidèle, alors les catégories $i'\backslash I$, dont on sait déjà qu'elles satisfont PF 1_π, satisfont également PF 2_π. Soient donc $\xi = (i, u')$, $\eta = (j, v')$ deux objets de $i'\backslash I$, et $(u_\alpha)_{\alpha\in A}$ une famille de flèches $\xi \longrightarrow \eta$ (avec $\operatorname{card} A \leqslant \pi$), donc des flèches dans I telles que $f(u_\alpha)u' = v' \ \forall\, \alpha \in A$.

Comme I' est grande devant π, on peut égaliser par $f(j) \longrightarrow k'$, et comme $k'\backslash I \neq \emptyset$, on peut supposer k' de la forme $f(k)$. Or d'après l'implication $\mathrm{b}'' \Longrightarrow \mathrm{a} \Longrightarrow \mathrm{c}$ de la partie 1°) (cf. page 235) et comme $\mathrm{b}''_\pi \Longrightarrow \mathrm{b}''$, on sait déjà que f satisfait à F 3. En l'appliquant à j, k et $f(j) \longrightarrow f(k)$, on peut supposer que $f(j) \longrightarrow f(k)$ provient de $v : j \longrightarrow k$. On aura donc $f(v)f(u_\alpha) = f(v)f(u_\beta)\ \forall\, \alpha, \beta \in A$, donc $f(vu_\alpha) = f(vu_\beta)$. Comme f est fidèle, cela implique que $vu_\alpha = vu_\beta$, i.e. v égalise les u_α. D'ailleurs, v peut être considérée comme une flèche *dans* $i'\backslash I$, de (j, v') dans $(k, f(v)v')$. Q.e.d. [page 242] p. 91

4.9.6.10. Quand I est *ordonné*, alors les quatre conditions a_π, b_π, c_π, b''_π sont équivalentes, car les $i'\backslash I$ sont ordonnés, et il est claire qu'alors $\mathrm{b}''_\pi \Longleftrightarrow \mathrm{b}_\pi$.

Commentary · Development (commentators') [ms. 242] [page 243]

Replacing faithfulness by eventual equality in its fibres

The proof isolates a weaker hypothesis than faithfulness. In approximation problems, two different arrows may become equal after applying the comparison functor, yet already become equal at a later stage of the source. That is sufficient for the same conclusion.

Proposition (relative eventual equalization). [ours] Let π be infinite, I' be π^+-filtered, and $f : I \to I'$ satisfy F1 and $\mathrm{F3}_\pi$. Then the following are equivalent: I is π^+-filtered; and every family $(a_t : x \to y)_{t\in T}$ with $|T| \leq \pi$ and with $f(a_t)$ independent of t is equalized by some arrow $y \to z$ in I. Under these conditions f is final and each $(d \downarrow f)$ is π^+-filtered.

Proof. Necessity follows immediately from filteredness. Conversely, the preceding simultaneous-lifting argument shows that every comma category is nonempty and has common targets for at most π objects. For a family of at most π parallel arrows in such a comma category, equalize their images in I', use F1 to move the target into the image of f, and apply F3 to replace the resulting arrow by an image $f(w)$. The composites wa_t now have identical images. The asserted eventual-equality condition gives a further arrow h equalizing them in I. It is also an arrow of the comma category when the new structure map is defined by composition. Thus the comma category is π^+-filtered. The cardinal descent proved above gives π^+-filteredness of I, and nonempty connected comma categories give finality. □

Faithfulness implies the extra condition with $y \to z$ the identity. A functor from an ordered category has the same property for the still simpler reason that any parallel arrows are already equal. The proposition describes exactly what the printed proof uses when neither simplification is available. We checked the cofinality criteria in SGA 4, I, 8.1 and the filtered-colimit criteria in The Stacks Project Authors (2026d, Section 4.19); we did not find this particular cardinal formulation with the relative kernel condition stated there. The argument is a rearrangement of Grothendieck's proof, offered as a usable extension rather than a priority claim.

4.10 Le théorème de représentation indicielle : démonstration

On va d'abord reformuler le théorème 4.9.3 sous forme plus générale, en termes de catégories *cofibrées*. Soit

$$\mathcal{D} \longrightarrow J \tag{4.10.1}$$

un foncteur cofibrant, où J est équivalent à une petite catégorie, et de même pour les catégories fibres $\mathcal{D}_j$ ($j \in \mathrm{Ob}\, J$). On se donne un cardinal infini π. Soit

$$\mathcal{M}_j \;=\; \mathrm{Ind}_\pi(\mathcal{D}_j) \qquad (j \in \mathrm{Ob}\, J)\ , \tag{4.10.2}$$

alors les $\mathcal{M}_j$ sont les fibres d'une catégorie cofibrée $\mathcal{N}$ sur J, que je désigne aussi par $\mathrm{Ind}_\pi(\mathcal{D}/J)$, donc on pose

$$\mathcal{N} \;=\; \mathrm{Ind}_\pi(\mathcal{D}/J)\ . \tag{4.10.3}$$

On a donc une inclusion pleinement fidèle de catégories cofibrées sur J

$$\mathcal{D} \hookrightarrow \mathcal{N}\ ,$$

d'où une inclusion

$$\underline{\Gamma}(\mathcal{D}/J) \longrightarrow \underline{\Gamma}(\mathcal{N}/J)\ . \tag{4.10.4}$$

Dans le cas où $\mathcal{D}$ est de la forme $C \times J$, alors $\mathcal{N}$ est de la forme $\mathcal{M} \times J$, avec $\mathcal{M} = \mathrm{Ind}_\pi(C)$, [page 244]
et l'inclusion (4.10.3) n'est autre (à isomorphisme près) que

$$\underline{\mathrm{Hom}}(J, C) \longrightarrow \underline{\mathrm{Hom}}(J, \mathcal{M})\ .$$

Revenant au cas général, on voit encore que :

1°) Le deuxième membre de (4.10.3) est stable par $\varinjlim$ grandes devant π, lesquelles se calculent fibre à fibre.

2°) Le premier membre de (4.10.3) est formé d'objets π-accessibles du second.

D'où un foncteur *pleinement* fidèle

$$\mathrm{Ind}_\pi(\underline{\Gamma}(\mathcal{D}/J)) \hookrightarrow \underline{\Gamma}(\mathcal{N}/J)\ . \tag{4.10.4}$$

([104]).

Commentary · Exposition [ms. 243]

Sections turn many approximation problems into one

Grothendieck now replaces a diagram in one category by a family of categories whose objects are transported along the arrows of the indexing category. The gain is substantial: a single theorem will approximate a diagram, a compatible family of objects, or a section of a fibred construction. His *cofibrant functor* means a Grothendieck opfibration, not a cofibration in a model category. For an arrow $a : i \to j$, choose transport $a_* : \mathcal{D}_i \to \mathcal{D}_j$. A section consists of objects X_i and maps $a_* X_i \to X_j$, satisfying unit and composition equations. These maps need not be invertible or cocartesian. The coherence isomorphisms of a cleavage are understood throughout.

To compare his cardinal conventions with current ones, put $\kappa = \pi^+$. A category "large before π" is κ-filtered: every diagram with at most π arrows admits a cocone. An object called π-accessible here is κ-presentable. Thus $\mathrm{Ind}_\pi \mathcal{D}_i$ in these pages is the usual $\mathrm{Ind}_\kappa \mathcal{D}_i$. This shift matters even when $\pi = \aleph_0$: Grothendieck is then asking for countable-diagram cocones, not merely finite-diagram cocones.

104. [Les numéros 4.10.1 à 4.10.4 sont utilisés deux fois.]

The completion of the opfibration is obtained by applying Ind_κ to every fibre and every transport functor. Its sections may be approximated pointwise without difficulty. The theorem asks whether those approximations can be made into sections before taking their colimit. The condition on one ordinal-shaped colimit supplies exactly the operation needed to turn successive approximations to the structure maps into an actual section.

There is a size qualification to the preliminary assertion on p. 244. Pointwise κ-presentable sections are κ-presentable when $|\operatorname{Mor} J| < \kappa$, as in the theorem immediately following. Without it the assertion is false. Take J discrete with $|J| \geq \kappa$ and fibres $\mathrm{Set} = \mathrm{Ind}_\kappa(\mathrm{Set}_{<\kappa})$. The constant singleton family is pointwise presentable. Index a diagram by the $< \kappa$-sized subsets $A \subset J$, putting a singleton in coordinates of A and the empty set elsewhere. This index is κ-filtered and the colimit is the constant singleton, but no stage receives a map from that family. The presentability claim therefore uses the forthcoming size bound; this does not affect Theorem 4.10.1 itself.

p. 92

Théorème 4.10.1. *Supposons qu'on ait*

$$\operatorname{card} \text{réd}\, J \leqslant \pi \,, \tag{4.10.1.1}$$

et qu'il existe un ordinal limite α, tel que :

1) $\operatorname{card} \alpha \leqslant \pi$.

2) Les limites inductives de type $I_\alpha = \{\beta \mid \beta < \alpha\}$ sont représentables dans les catégories $\mathcal{D}_j$ ($j \in \operatorname{Ob} J$), et pour toute flèche $\alpha : j \longrightarrow j'$ dans J [trop de α], $\alpha^* : \mathcal{D}_j \longrightarrow \mathcal{D}_{j'}$ commute auxdites limites. [page 245]

Alors le foncteur canonique pleinement fidèle (4.10.4) est une équivalence de catégories.

Ceci va être contenu dans le résultat un peu plus précis :

Corollaire 4.10.2. *Les hypothèses étant celles de 4.10.1, avec en plus*

$$\operatorname{card} J \leqslant \pi \tag{4.10.2.1}$$

(qui équivaut à (4.10.1.1) si J est réduite, cas auquel on peut évidemment se réduire dans 4.10.1). Soit $\varphi \in \operatorname{Ob} \underline{\Gamma}(\mathcal{N}/J)$, et considérons le foncteur canonique fidèle *:*

$$\underline{\Gamma}(\mathcal{D}/J)/\varphi \longrightarrow \prod_{j \in J} C_j/\varphi(j) \,. \tag{4.10.2.2}$$

Alors la catégorie source $\underline{\Gamma}(\mathcal{D}/J)/\varphi$ est grande devant π, et le foncteur envisagé est cofinal.

De ceci, le théorème résulte de façon essentiellement soritale, tout comme dans le cas particulier 4.9.3 précédent (cf. page 223) ([105]). [page 246]

Pour établir le corollaire, comme la catégorie but de (4.10.2.2) est grande devant π, comme produit de telles catégories (cf. 4.9.6.6, page 228), et le foncteur fidèle, il suffit en vertu de 4.9.6.3, 2°, de vérifier les conditions F 1 et F 3_π (page 225) pour le foncteur envisagé.

On va interpréter le foncteur (4.10.2.2) en termes d'une catégorie cofibrée

$$\mathcal{D}_\varphi \longrightarrow J \,, \tag{4.10.5}$$

dont les fibres sont les $\mathcal{D}_j/\varphi(j)$. On note que si $\alpha : j \longrightarrow j'$ est une flèche de J, alors on a

$$\begin{cases} \alpha_* : C_j \longrightarrow C_{j'} \\ \text{et} \quad \alpha_*(\varphi(j)) \longrightarrow \varphi(j') \,, \end{cases}$$

d'où un foncteur composé

p. 93
[page 247]

$$C_j/\varphi(j) \longrightarrow C_{j'}/\alpha^*(\varphi(j)) \longrightarrow C_{j'}/\varphi(j') \,,$$

105. Un peu court ! Il faudrait expliciter l'argument avec soin – il y en a pour deux ou trois pages !

avec transitivité à isomorphisme canonique près etc. On note que l'on a un isomorphisme canonique

$$\underline{\Gamma}(\mathcal{D}_\varphi/J) \;\simeq\; \underline{\Gamma}(\mathcal{D}/J)/\varphi\ ,$$

de sorte que le foncteur fidèle canonique (4.10.2.2) s'identifie au foncteur

$$\underline{\Gamma}(\mathcal{D}_\varphi/J) \longrightarrow \prod_{j\in \mathrm{Ob}\, J} (\mathcal{D}_\varphi)_j\ . \tag{4.10.6}$$

Commentary · Exposition [ms. 246]

From cofinal approximation to the equivalence

Grothendieck explicitly asks that the passage from the cofinality assertion to the representation theorem be written out. We do so because it also explains which information the section category retains. Let φ be a section of $\mathcal{N} = \mathrm{Ind}_\kappa(\mathcal{D}/J)$ and let

$$I = \Gamma(\mathcal{D}/J)/\varphi.$$

After replacing the fibres and J by small equivalent categories, this category is small: its objects comprise a small family of section data and maps in locally small fibres. Corollary 4.10.2 makes I κ-filtered and makes the evaluation functor $I \to \mathcal{D}_j/\varphi_j$ final for every j. Indeed it is the composite of the asserted final functor to the product and a final product projection. The canonical diagram $I \to \Gamma(\mathcal{D}/J)$ has a cocone to φ. At j its colimit is

$$\operatorname*{colim}_{(D\to\varphi)\in I} D_j \simeq \operatorname*{colim}_{(d\to\varphi_j)\in \mathcal{D}_j/\varphi_j} d \simeq \varphi_j.$$

These isomorphisms are compatible with every structure map, because the original cocone consists of section morphisms. Filtered colimits of sections are pointwise: the completed transport functors preserve them. Consequently the colimit section is φ, proving essential surjectivity.

For full faithfulness, let D be a section with values in $\mathcal{D}_j$. Maps from D to a section Y form the equalizer

$$\mathrm{Hom}_\Gamma(D,Y) \longrightarrow \prod_j \mathrm{Hom}(D_j, Y_j) \rightrightarrows \prod_{a:i\to j} \mathrm{Hom}(a_* D_i, Y_j).$$

Every object appearing on the left of these fibrewise hom functors belongs to the corresponding $\mathcal{D}_j$ and is therefore κ-presentable. Both products have fewer than κ factors. Since κ-filtered colimits of sets commute with κ-small limits, this equalizer preserves those colimits. The usual ind hom formula now gives full faithfulness of the comparison functor. This proves the omitted passage without assuming that arbitrary pointwise morphisms are natural.

The auxiliary opfibration $\mathcal{D}_\varphi$ records the same argument more economically. Its transport sends $(d \to \varphi_i)$ to $a_* d \to a_* \varphi_i \to \varphi_j$, and a section of it is precisely a section D together with $D \to \varphi$. A colimit of an ordinal chain in such a slice is computed in $\mathcal{D}_j$, with its induced map to φ_j. Lemma 4.10.4 ensures that this remains the same colimit after embedding in the ind-category. Thus no extra colimit hypothesis is lost in passing to the slices.

Le corollaire 4.10.2 sera alors une conséquence du résultat plus général suivant :

Corollaire 4.10.3. *Soit $\mathcal{E} \longrightarrow J$ un foncteur cofibrant, et π un cardinal infini. On suppose :*

a) $\mathrm{card}\, J \leqslant \pi$.

b) Les catégories fibres $\mathcal{E}_j$ sont équivalentes à des petites catégories, et grandes devant π.

c) Il existe un ordinal limite tel que :

1°) $\mathrm{card}\, \alpha \leqslant \pi$.

2°) Les limites inductives de type I_α sont représentables dans les catégories $\mathcal{E}_j$, et les foncteurs cochangement de base $\lambda_* : \mathcal{E}_j \longrightarrow \mathcal{E}_{j'}$ y commutent. (C'est le cas p.ex. si les limites inductives filtrantes dénombrables *sont représentables dans les $\mathcal{E}_j$, et si les α_* y commutent ; ou s'il existe un cardinal $\pi_0 \leqslant \pi$ et un cardinal $\pi_0' > \pi_0$, tel que les limites inductives grandes devant π_0 et de cardinal $\leqslant \pi_0'$ soient représentables dans les $\mathcal{E}_j$, et que les α_* y commutent.)* [page 248]

Sous ces conditions, le foncteur canonique fidèle

$$\underline{\Gamma}(\mathcal{E}/J) \longrightarrow \prod_{j\in \mathrm{Ob}\, J} \mathcal{E}_j \tag{4.10.3.1}$$

est cofinal, et la catégorie source est grande devant π.

Il est ± immédiat que les hypothèses de 4.10.1 impliquent que celles de 4.10.3 sont satisfaites pour $\mathcal{E} = \mathcal{D}_\varphi \longrightarrow J$ (4.10.5). Pour ceci, on utilise le [page 249]

Lemme 4.10.4. *Soient C une catégorie, et π un cardinal infini. Alors le foncteur d'inclusion $C \longrightarrow \mathcal{M} \overset{\text{déf}}{=} \mathrm{Ind}_\pi C$ commute aux $\varinjlim$ de cardinal $\leqslant \pi$.*

Soit en effet I telle que $\mathrm{card}\, I \leqslant \pi$, et $(x_i)_{i\in I}$ un système inductif sur C, y ayant une limite x. Soit d'autre part $X = \varinjlim_{I'} \xi_{i'}$ un objet de $\mathrm{Ind}_\pi C$, avec I' grande devant π. On a

donc p. 94

$$\begin{aligned}
\mathrm{Hom}_{\mathcal{M}}(x, X) &\simeq \varinjlim_{I'} \mathrm{Hom}(x, \xi_{i'}) \\
&\simeq \varinjlim_{I'} \varprojlim_{I} \mathrm{Hom}(x_i, \xi_{i'}) \\
&\overset{\text{SGA 4 I 9.8}}{\simeq} \varprojlim_{I} \underbrace{\varinjlim_{I'} \mathrm{Hom}(x_i, \xi_{i'})}_{\simeq \mathrm{Hom}(x_i, X)} \\
&\simeq \varprojlim_{I} \mathrm{Hom}(x_i, X)\ ,
\end{aligned}$$

ce qui prouve que x est aussi une $\varinjlim$ des x_i dans $\mathcal{M}$ tout entier.

Ainsi, on est réduit à prouver 4.10.3. Appliquant 4.9.6 2°, on est ramené à prouver, pour [250] le foncteur envisagé, les conditions F 1 et F 3_π (page 225).

Dans les arguments qui suivent, on va utiliser les conditions a), b) de 4.10.3, mais non, pour l'instant, la condition c.

Lemme 4.10.5. *Sous les conditions de 4.10.3 a) b) (à l'exclusion de c), pour que (4.10.3.1) soit cofinal et $\Gamma(\mathcal{E}/J)$ grande devant π, il faut et il suffit que le foncteur envisagé satisfasse à la condition F 1, rappelée ci-dessous, et à la variante F′ 1 de celle-ci énoncée ci-dessous :*

F 1) *Pour tout système $(X(j))_{j\in \mathrm{Ob}\, J}$ d'éléments $X(j) \in \mathrm{Ob}\, \mathcal{E}_j$, existe une* section *$G$ de $\mathcal{E}$ sur J, et un système de flèches*

$$X(j) \longrightarrow G(j) \qquad (j \in ObJ)\ . \tag{4.10.5.1}$$

F′1) *Sous les conditions de* F 1 *précédent, supposons de plus une section F de $\mathcal{E}$ sur J et un système de flèches* [251]

$$F(j) \longrightarrow X(j) \qquad (j \in \mathrm{Ob}\, J)\ ,$$

alors G et le système de flèches (4.10.5.1) peut être choisi de telle façon que les flèches composées

$$F(j) \longrightarrow X(j) \longrightarrow G(j)$$

définissent un homomorphisme de sections

$$F \longrightarrow G$$

(dans la catégorie $\underline{\Gamma}(\mathcal{E}/J)$).

([106]).

106. **N.B.** Les conditions F 1 et F′ 1 équivalent à dire que le foncteur envisagé satisfait aux conditions F1 et F3, vu encore (en vertu de 4.9.6.3, 1°) que $\underline{\Gamma}(\mathcal{E}/J)$ est *filtrante* sans plus, et le foncteur fidèle (4.10.3.1) cofinal. Cela implique déjà que $\underline{\Gamma}(\mathcal{E}/J)$ est grande devant π.

Commentary · Exposition [ms. 250]

Why one compatible family controls many families

The force of Lemma 4.10.5 is that a construction with one prescribed section suffices to establish the simultaneous lifting condition for at most π sections. The fibres supply enough room to remove all failures of naturality before the section construction starts.

Suppose sections F_a and F are given, together with arbitrary component maps $u_{a,j} : F_{a,j} \to F_j$, where $|A| \leq \pi$. For an arrow $b : i \to j$, compare the two maps from $b_*F_{a,i}$ to F_j: one uses the structure of F_a followed by $u_{a,j}$, the other uses $b_*u_{a,i}$ followed by the structure of F. There are at most π such pairs at each j. Since $\mathcal{E}_j$ is κ-filtered, they can all be equalized by one map $F_j \to X_j$. This use of transport is implicit in the source's arrows in the total category.

Apply F′1 to the section F and the maps $F_j \to X_j$. It produces a section G and maps $X_j \to G_j$ for which $F \to G$ is natural. Each $F_a \to G$ is now natural as well: its naturality square is the composite of the already equalized square ending at X_j and the naturality square for $F \to G$. Thus F3$_\pi$ holds. The faithful cofinality criterion gives both κ-filteredness of $\Gamma(\mathcal{E}/J)$ and finality of evaluation.

Conversely, suppose evaluation is final and its source is κ-filtered. F1 follows. Given $F_j \to X_j$, apply F1 to obtain $X_j \to H_j$ for some section H. The ordinary F3 condition for the resulting pointwise arrow $F \to H$ then gives a section map $H \to G$ whose composite from F is natural. This is F′1. The equivalence asserted in the lemma is therefore exact; it is special to this evaluation functor and the bound on the number of naturality equations.

Démonstration. Il faut voir que F 1 & F′ 1 équivaut à F 1 & F 3$_\pi$. L'implication $\Longleftarrow$ est ± immédiate, c'est de $\Longrightarrow$ que nous aurons besoin, donc

$$\text{F } 1 \;\&\; \text{F}' \; 1 \quad \Longrightarrow \quad \text{F } 3_\pi \; .$$

Pour ceci, réénonçons F 3$_\pi$ dans le contexte présent. On se donne une famille $(F_\alpha)_{\alpha \in A}$, p. 95
$\operatorname{card} A \leqslant \pi$, d'objets de $\underline{\Gamma}(\mathcal{E}/J)$, un objet F de la même catégorie, et pour tout j dans $\operatorname{Ob} J$, un système de flèches

$$F_\alpha(j) \xrightarrow{u_\alpha(j)} F(j) \; ,$$

mais sans supposer que pour α fixé, j variable

cela définisse un homomorphisme de sections $F_\alpha \longrightarrow F$. On cherche une section G de $\mathcal{E}$ sur [252]
J, et un homomorphisme de sections $F \longrightarrow G$, tels que pour tout α, le système des composés

$$F_\alpha(j) \longrightarrow F(j) \longrightarrow G(j)$$

définisse un homomorphisme de sections $F_\alpha \longrightarrow G_\alpha$. Soit donc $\lambda : j \longrightarrow j'$ une flèche de J, considérons les carrés (*non commutatifs*)

$$(*) \qquad \begin{array}{ccc} F_\alpha(j) & \xrightarrow{u_\alpha(j)} & F(j) \\ {\scriptstyle F_\alpha(\lambda)}\downarrow & ! & \downarrow{\scriptstyle F(\lambda)} \\ F_\alpha(j') & \xrightarrow{u_\alpha(j')} & F(j') \end{array}$$

(indexés par $\alpha \in A$). Pour j' fixé dans J, le nombre de ces carrés est majoré par $\operatorname{card} \operatorname{Ob}(J/j') \times \operatorname{card} A \leqslant \pi \cdot \pi = \pi$. Il s'ensuit, comme $\mathcal{E}_{j'}$ est grande devant π, qu'il existe un objet $X(j')$ de $\mathcal{E}_{j'}$, et une flèche $v(j') : F(j') \longrightarrow X(j')$ de telle façon que pour tout $\alpha \in A$, et tout $\lambda \in \operatorname{Ob} J/j'$, le carré déduit de $(*)$

en composant avec $F(j') \longrightarrow X(j')$ soit commutatif. On fait ce choix pour tout objet j' [253]
de J. Appliquons alors F′ 1 à F et au système de flèches $F(j) \xrightarrow{v(j)} X(j)$, on trouve G et un système de flèches

$$w(j) \; : \; X(j) \longrightarrow G(j)$$

de telle façon que les flèches composées

$$w(j)v(j): \qquad F(j) \longrightarrow G(j), \quad F(j) \to X(j) \to G(j)$$

définissent un homomorphisme de sections. Je dis que cet homomorphisme a la propriété voulue pour F 3_π, i.e. que pour tout $\alpha \in A$, le système des composés

$$F_\alpha(j) \longrightarrow F(j) \longrightarrow G(j)$$

(pour $j \in \mathrm{Ob}\, J$ variable) définit un homomorphisme de sections $F_\alpha \longrightarrow G$. En effet, il suffit pour cela de considérer, pour une flèche λ de J, le diagramme

p. 96 [254]

$$\begin{array}{ccccccc} F_\alpha(j) & \xrightarrow{u_\alpha(j)} & F(j) & \xrightarrow{v(j)} & X(j) & \xrightarrow{w(j)} & G(j) \\ \downarrow{\scriptstyle F_\alpha(\lambda)} & ! & \downarrow{\scriptstyle F(\lambda)} & & \text{comm.} & & \downarrow{\scriptstyle G(\lambda)} \\ F_\alpha(j') & \xrightarrow{u_\alpha(j')} & F(j') & \xrightarrow{v(j')} & X(j') & \xrightarrow{w(j')} & G(j') \,. \end{array}$$

Le lemme 4.10.5 étant prouvé, tout revient donc à prouver la condition F 1, et son complément F′ 1, qui se prouvera dans la même haleine.

4.10.6. On se donne donc le système d'objets

$$X(j) \in \mathrm{Ob}\, \mathcal{E}_j \qquad (j \in \mathrm{Ob}\, J)\,, \tag{4.10.6.1}$$

et le cas échéant, un objet F de $\underline{\Gamma}(\mathcal{E}/J)$, et un système de flèches

$$F(j) \xrightarrow{u_j} X(j)\,, \tag{4.6.10.2}$$

et on se propose de construire G de $\underline{\Gamma}(\mathcal{E}/J)$, et un système de flèches

$$X(j) \xrightarrow{w(j)} G(j)\,, \tag{4.10.6.3}$$

de telle façon que (si on a la donnée supplémentaire des $u(j)$) les flèches composées

$$F(j) \xrightarrow{u(j)} X(j) \xrightarrow{v(j)} G(j)$$

soient fonctorielles en j.

On va faire une construction transfinie sur les ordinaux α tels que [255]

$$\mathrm{card}\, \alpha \leqslant \pi$$

d'un système inductif

$$(X_\alpha(j))_\alpha$$

d'objets de $\prod_{j \in \mathrm{Ob}\, J} \mathcal{E}_j$. On va d'abord ignorer la donnée éventuelle (4.10.6.2). On posera

$$X_0(j) = X(j)\,, \tag{4.10.6.4}$$

et on va donner la prescription pour passer de X_α à $X_{\alpha+1}$. La construction inclura aussi, pour toute flèche $\lambda : j' \longrightarrow j$ de J et tout α, la donnée de

$$X_\alpha(j) \xrightarrow{t_\alpha(\lambda)} X_{\alpha+1}(j)\,, \qquad \text{flèche (dans } \mathcal{E}) \text{ au dessus de } \lambda, \tag{4.10.6.5}$$

et ces flèches, et les flèches de transition $X_\alpha(j) \xrightarrow{\tau_\alpha(j)} X_{\alpha+1}(j)$, doivent satisfaire aux trois conditions suivantes : p. 97 [256]

(i) Si λ est une flèche identique $\mathrm{id}_J : J \longrightarrow J$, alors $\boxed{t_\alpha(\lambda) = \tau_\alpha(j).}$

(ii) Dans le diagramme

$$\begin{array}{ccccccccc} X_\alpha(j') & \xrightarrow{\tau_\alpha(j')} & X_{\alpha+1}(j') & \longrightarrow & X_{\alpha+2}(j') & \longrightarrow & X_{\alpha+3}(j') & \longrightarrow \\ & \searrow^{t_\alpha(\lambda)} & \bullet & \searrow^{t_{\alpha+1}(\lambda)} & & \searrow & & \cdots\searrow \\ X_\alpha(j') & \longrightarrow & X_{\alpha+1}(j') & \xrightarrow{\tau_{\alpha+1}(j')} & X_{\alpha+2}(j') & \xrightarrow{\tau_{\alpha+2}(j')} & X_{\alpha+3}(j') & \longrightarrow \end{array},$$

$\tau_{\alpha+2}(j)$ "rend le carré $\bullet$ commutatif", i.e. égalise $t_{\alpha+1}(\lambda)\tau_\alpha(j')$ et $\tau_{\alpha+1}(j)t_\alpha(\lambda)$:

$$\boxed{\tau_{\alpha+2}(j)t_{\alpha+1}(\lambda)\tau_\alpha(j') \;=\; \tau_{\alpha+2}(j)\tau_{\alpha+1}(j)t_\alpha(\lambda)\;.}$$

(iii) Si on a deux flèches consécutives $\lambda : j'' \longrightarrow j'$, $\mu : j' \longrightarrow j$, on a donc le diagramme

$$\begin{array}{ccccccc} X_\alpha(j'') & \longrightarrow & X_{\alpha+1}(j'') & \longrightarrow & X_{\alpha+2}(j'') & \longrightarrow & X_{\alpha+3}(j'') \\ & \searrow^{t_\alpha(\lambda)} & & \searrow & & \searrow & \\ X_\alpha(j') & \xrightarrow{t_\alpha(\mu\lambda)} & X_{\alpha+1}(j') & \longrightarrow & X_{\alpha+2}(j') & \longrightarrow & X_{\alpha+3}(j') \\ & \searrow & & \searrow^{t_{\alpha+1}(\mu)} & & \searrow & \\ X_\alpha(j) & \longrightarrow & X_{\alpha+1}(j) & \xrightarrow{\tau_{\alpha+1}(j)} & X_{\alpha+2}(j) & \xrightarrow{\tau_{\alpha+2}(j)} & X_{\alpha+3}(j)\;, \end{array}$$

$$\boxed{\tau_{\alpha+2}(j)t_{\alpha+1}(\mu)t_\alpha(\lambda) \;=\; \tau_{\alpha+2}(j)\tau_{\alpha+1}(j)t_\alpha(\mu\lambda)}$$

Ainsi, pour définir les $X_{\alpha+1}(j)$, il faut tenir compte de toutes ces contraintes. Donc : [257]

1°) Pour j fixé, $X_{\alpha+1}(j)$ doit être but des flèches

$$X_\alpha(j') \xrightarrow{t_\alpha(\lambda)} X_{\alpha+1}(j)\;,$$

pour les $\lambda : j' \longrightarrow j$ dans $\mathrm{Ob}\, J/j$ – y compris pour $\lambda = \mathrm{id}_j$, auquel cas $t_\alpha(\lambda) : X_\alpha(j) \longrightarrow X_{\alpha+1}(j)$ jouera le rôle du morphisme de transition $\tau_\alpha(j)$.

2°) Si α est de la forme $\alpha' + 2$, i.e. s'il n'est ni ordinal limite, ni successeur d'un ordinal limite, alors on exige de plus, pour les morphismes de transition $\tau_\alpha(j)$, d'égaliser les couples de flèches prévus dans (ii) et (iii) ci-dessus.

Comme l'ensemble de ces données dans 1°), ou de ces contraintes dans 2°), est de cardinal $\leqslant \pi$, et que la catégorie $\mathcal{E}_j$ est grande devant π, on voit qu'on peut bel et bien trouver $X_{\alpha+1}(j)$ et des $t_\alpha(\lambda) : X_\alpha(j') \longrightarrow X_{\alpha+1}(j)$, de façon à satisfaire (si $\alpha = \alpha'+2$) aux contraintes rappelées dans 2°. Cela achève la description de la construction de $X_{\alpha+1}(\bullet)$, en termes de $X_\beta(\bullet)$ ($\beta \leqslant \alpha$) et des $t_\beta(\lambda)$ ($\beta < \alpha$). [258]

Il faut enfin définir $X_\alpha(\bullet)$ pour α un ordinal limite. Cette fois, on lui demande seulement de recevoir les $X_\beta(\bullet)$ pour $\beta < \alpha$. Comme l'ensemble I_α de ces β est de cardinal $\leqslant \pi$, et que les $\mathcal{E}_j$ sont grandes devant π, on peut bel et bien trouver les $X_\alpha(j)$.

On a donc prouvé l'essentiel du

p. 98 [259]

Commentary · Development (commentators') [ms. 258]

A transfinite compatibility condition must be added

Grothendieck's iterative construction has the right mechanism: add all needed arrows, and then move farther along the filtered system until the equations hold. At an internal limit ordinal, however, the displayed conditions on consecutive stages no longer compare the new arrows with all earlier ones. The inference on p. 262 from condition (ii) to a morphism of ind-objects needs a repair.

A counterexample to that inference. [ours] Let $J = B(\mathbb{Z}/2)$ and take the constant opfibration with fibre a small skeleton of countable sets. This fibre has a terminal object, hence is $\aleph_1$-filtered,

and it admits countable ordinal colimits. Set $X_\beta = \{0,1\}$ with identity transition maps for every countable ordinal β. For the nonidentity group element s, set $t_\beta(s) = \mathrm{id}$ when $\beta < \omega$, and set $t_\beta(s)$ equal to the transposition when $\beta \geq \omega$. Put $t_\beta(1) = \mathrm{id}$ throughout. Conditions (i)–(iii) hold: consecutive indices never cross from a finite ordinal to ω, and on either side the maps form a representation of $\mathbb{Z}/2$. But along the chain of length $\omega + \omega$ the induced maps from its constant stages would have to be both the identity and the transposition. They define no morphism of its ind-objects. This disproves the intermediate inference, not the section theorem.

Strengthened construction. [ours] Under 4.10.3(a),(b), fix a nonzero limit ordinal δ with $|\delta| \leq \pi$. Write $r_{\gamma\beta} : X_\beta \to X_\gamma$ for the transitions, and write a map above $a : i \to j$ as $t_\beta(a) : a_* X_\beta(i) \to X_{\beta+1}(j)$. The objects and maps can be chosen so that, for every $\beta < \gamma < \delta$,

$$t_\gamma(a)\, a_* r_{\gamma\beta} = r_{\gamma+1,\beta+1}\, t_\beta(a), \tag{B1}$$

and so that the unit condition holds and the composition equations become equal after a later transition. Prescribed maps $F_j \to X_0(j)$ from a section can also be made natural after the first step.

Here is the full induction. Having constructed the system through stage γ, first choose in each fibre a common target Y_j of $X_\gamma(j)$ and all $a_* X_\gamma(i)$ for arrows $a : i \to j$. This uses at most π objects. For every $\beta < \gamma$, the proposed two sides of (B1) are now parallel maps into Y_j. Postcompose the chosen maps by one equalizing arrow, simultaneously for every such pair. There are at most $\pi \cdot \pi = \pi$ pairs.

At this same step impose all previously formed composition equations. For $a : i \to j$, $b : j \to k$ and $\beta + 2 \leq \gamma$, compare, in $\mathcal{E}_k$, the maps obtained from

$$t_{\beta+1}(b)\, b_* t_\beta(a) \quad \text{and} \quad t_\beta(ba)$$

by transport to $X_\gamma(k)$ and then to Y_k. Again there are at most π pairs; add them to the equalizations already required. Coherence isomorphisms identify $(ba)_*$ with $b_* a_*$. Choose the identity transport map to be the transition itself. At the first step also equalize $t_0(a) a_* u_i$ and $r_{10}(j) u_j F(a)$ for every a, where $u_j : F_j \to X_0(j)$ is the optional datum. Filteredness supplies a single further target accommodating all these equations. Call it $X_{\gamma+1}(j)$.

At a limit stage $\gamma < \delta$, choose a cocone on the entire earlier chain in each fibre; this defines X_γ and the transitions $r_{\gamma\beta}$. Its diagram has at most π arrows. No colimit is required at this stage. At the next successor step (B1) is imposed for every earlier β, including those before this limit. This is precisely the additional condition absent from the printed construction. All equations already imposed survive postcomposition, so the induction is consistent.

Suppose now that the δ-chain colimits exist and transport preserves them. Put $G_j = \operatorname{colim}_{\beta<\delta} X_\beta(j)$. Equation (B1) makes the maps $a_* X_\beta(i) \to G_j$ a compatible cocone; preservation gives $a_* G_i \to G_j$. The composition equations hold on each stage after some further stage, and hence hold in G. The unit equations hold by construction. Thus G is a section receiving X_0, and the first-step equations make $F \to G$ natural when prescribed. This proves F1 and F′1, completing the general ordinal case of the theorem. For $\delta = \omega$, the source's consecutive-stage argument already suffices.

The parenthesis in 4.10.3(c) has a related endpoint issue. If $\pi_0 = \pi$, its hypotheses need not supply an ordinal of cardinal at most π. They still suffice for the conclusion: take $\delta = \pi_0^+$, which is at most π_0' and is large before π_0. Every proper initial segment has cardinal at most π, so the induction above runs through all stages below δ; only the final colimit has the larger size. Alternatively, imposing $\pi_0 < \pi$ makes the printed implication to condition (c) valid as stated.

We checked the related constructions in SGA 4, I, 9.21 and the modern limit results cited below. We did not find this particular defect in the displayed XVIII argument discussed there. The strengthened induction is supplied as a proof repair, with no claim of priority.

Lemme 4.10.7. *Sous les conditions de 4.10.3 a) b), et pour un système $X(\bullet) \in \mathrm{Ob} \prod_{j \in \mathrm{Ob}\, J} \mathcal{E}_j$ donné, on peut trouver un système inductif $(X_\alpha(i))_\alpha$ dans $\prod \mathcal{E}_j$, indexé par les ordinaux α telle que* $\operatorname{card} \alpha \leqslant \pi$, *et pour toute flèche $\lambda : j' \longrightarrow j$ dans J des flèches $t_\alpha(\lambda) : X_\alpha(j') \longrightarrow X_\alpha(j)$, de telle façon que l'on ait les conditions suivantes.*

1°) $X_0(\bullet) = X(\bullet)$.

2°) Les conditions (i) (ii) (iii) (p. 256).

3°) Si on se donne F dans $\operatorname{Ob}\underline{\Gamma}(\mathcal{E}/J)$, et des flèches $u(j) : F(j) \longrightarrow X(j) = X_0(j)$, on peut supposer que pour toute flèche $\lambda : j' \longrightarrow j$ dans J, on a

$$(*) \qquad \begin{array}{ccccc} F(j') & \xrightarrow{u(j')} & X_0(j') & & \\ {\scriptstyle F(\lambda)}\downarrow & & & \searrow^{t_0(\lambda)} & \\ F(j) & \xrightarrow{u(j)} & X_0(j) & \xrightarrow{\tau_0(j)} & X_1(j) \end{array} \qquad \text{commutatif.}$$

Il reste seulement à prouver ce dernier complément 3°. C'est une contrainte uniquement [260] sur la construction de $X_1(\bullet)$ et des $t_0(\lambda)$. Supposons donc que l'on ait construit $X_1(\bullet)$ sans tenir compte de cette contrainte. Pour j fixé, il faut donc "rendre commutatif" tous ces carrés, i.e. toutes ces double-flèches $(t_0(\lambda)u(j'), \tau_0(j)u(j)F(\lambda))$ de but $X_1(j)$. Comme l'ensemble de ces double-flèches est de cardinal $\operatorname{card}\operatorname{Ob}\mathcal{E}/j \leqslant \pi$, on peut trouver $X_1(j) \longrightarrow X_1'(j)$ dans $\mathcal{E}_j$, égalisant toutes ces double-flèches, donc quitte à remplacer $X_1(j)$ par $X_1'(j)$, on gagne.

Il est temps enfin de faire appel à l'hypothèse c) de 4.10.3. Soit donc α un ordinal limite, [261] comme stipulé dans cette condition. Comme $\operatorname{card}\alpha \leqslant \pi$, a fortiori $\operatorname{card}\beta \leqslant \pi$ si $\beta < \alpha$, on a donc un système inductif

$$(X_\beta(\bullet))_{\beta \in I_\alpha}$$

dans $\prod_{j\in J}\mathcal{E}_j$. Comme les $\varinjlim$ de type I_α existent dans $\mathcal{E}_j$, on peut donc considérer

$$G(j) \;=\; \varinjlim_{\beta\in I_\alpha} X_\beta(j) \;\in\; \operatorname{Ob}\mathcal{E}_j \;.$$

Si $\lambda : j' \longrightarrow j$ est une flèche de J, on en déduit une λ-flèche

$$G(\lambda) \;:\; G(j) = \varinjlim X_\beta(j) \longrightarrow G(j') \simeq \varinjlim X_{\beta+1}(j')$$

par $G(\lambda) = \varinjlim t_\beta(\lambda)$. Il faut faire attention que les $t_\beta(\lambda)$ ne définissent pas un homomorphisme [262] de systèmes projectifs, mais par la condition (ii), p. 256, ils définissent un homomorphisme d'ind-objets, donc

un homomorphisme sur les $\varinjlim$ ([106]). La condition (i) assure que $\lambda \longmapsto G(\lambda)$ transforme p. 99 identités en identités, et la condition (iii) que l'on a $G(\mu\lambda) = G(\mu)G(\lambda)$. Donc G apparaît comme une section de $\mathcal{E}$ sur J. On a d'autre part des flèches

$$X(j) \overset{\text{déf}}{=} X_0(j) \longrightarrow G(j) = \varinjlim_{\beta\in I_\alpha} X_\beta(j) \;,$$

ce qui prouve F (1). D'autre part, la condition 3°) du lemme prouve la validité de F′ (1). Cela achève la démonstration de 4.10.3, et par là de 4.10.1 et de 4.9.3.

[page 263]

Commentary · Examples [ms. 262]

A section is a module with an extra structure map

The section theorem becomes concrete over the walking arrow. Let $R \to S$ be a homomorphism of rings and let its transport functor be $S \otimes_R - : R\text{-Mod} \to S\text{-Mod}$. A section is a triple (M, N, θ) with $\theta : S \otimes_R M \to N$. A map of sections is a pair (f, g) satisfying $g\theta = \theta'(1 \otimes f)$. Thus the condition imposed by the section category is one familiar commutative square.

This category is equivalent to the category of left modules over

$$T = \begin{pmatrix} R & 0 \\ S & S \end{pmatrix},$$

106. Attention, c'est ici qu'on utilise tacitement le fait que le foncteur $\lambda_* : \mathcal{E}_{j'} \longrightarrow \mathcal{E}_j$ commute aux $\varinjlim$ de type I_α, ce qui implique que les inclusions $\mathcal{E}_j \hookrightarrow \mathcal{E}$ commutent à ce type de $\varinjlim$.

where the lower-left copy of S is the (S,R)-bimodule supplied by the ring map. The module corresponding to (M,N,θ) is $M \oplus N$, with action

$$\begin{pmatrix} r & 0 \\ s & t \end{pmatrix} (m,n) = (rm, \theta(s \otimes m) + tn).$$

Bilinearity of θ makes this action associative; conversely the two diagonal idempotents of T split any T-module into M and N, and its lower-left action recovers θ. These constructions are inverse on objects and maps.

Choose an infinite $\pi \geq |R|, |S|$ and put $\kappa = \pi^+$. A triple is the union of its subtriples whose two underlying sets have cardinal at most π. To construct one containing specified subsets of at most π elements, take the R-submodule M_0 they generate, then the S-submodule N_0 generated by the prescribed elements and the image of $S \otimes_R M_0$. Both sets still have cardinal at most π, since π is infinite. Any collection of at most π such subtriples is contained in another, by the same construction. Their poset is therefore κ-filtered and their colimit is the original triple.

Each small triple is κ-presentable. Indeed its T-module has at most π elements, hence a presentation with at most π generators and relations: use all its elements as generators and all relations in the free module, whose underlying set also has cardinal at most π. A map from this presentation into a κ-filtered colimit factors at one stage, and its relations and the equality of two such maps can be witnessed at one later stage. This directly verifies the presentability assertion. The construction illustrates both tasks in Grothendieck's proof: enlarge the objects enough to contain the structure map, then impose its equations.

Corollaire 4.10.8 (du théorème 4.10.1). *Soit $\mathcal{N} \longrightarrow J$ un foncteur cofibrant, tel que les fibres soient des catégories accessibles (4.8), les foncteurs cochangement de base $\lambda_* : \mathcal{N}_{j'} \longrightarrow \mathcal{N}_j$ accessibles, enfin J équivalente à une petite catégorie. Alors la catégorie $\mathcal{M} = \underline{\Gamma}(\mathcal{N}/J)$ est accessible. Plus précisément, soit π_0 un cardinal infini tel que les catégories $\mathcal{N}_j$ soient π_0-accessibles, et que les foncteurs λ_* soient π_0-accessibles, et soit π un cardinal infini tel que l'on ait :*

ⓐ $\pi^{\pi_0} = \pi$.

ⓑ $\forall\ \lambda : j' \longrightarrow j$ *dans* J, $\lambda_* : \mathcal{E}_j \longrightarrow \mathcal{E}_{j'}$ *applique* $(\mathcal{E}_j)_{\pi_0}$ *dans* $(\mathcal{E}_{j'})_{\pi_0}$.

ⓒ $\operatorname{card} \text{réd}\, J \leqslant \pi$.

Alors $\mathcal{M}$ est π-accessible, et plus précisément, on a

$$\mathcal{M} \ \simeq\ \operatorname{Ind}_\pi(\mathcal{M}_\pi)\ ,$$

où $\mathcal{M}_\pi$ est la sous-catégorie pleine de $\mathcal{M}$ formée des sections F de $\mathcal{M}$ sur J telles que l'on ait $F(j) \in (\mathcal{E}_j)_\pi\ \forall\ j \in \operatorname{Ob} J$, $(\mathcal{E}_j)_\pi$ désignant la sous-catégorie pleine de $\mathcal{E}_j$ formée des objets π-accessibles de $\mathcal{E}_j$. [page 264]

En effet, l'hypothèse au début implique l'existence de π_0 et de π satisfaisant les conditions dites. Les conditions a) et b) sur π, plus le fait que les foncteurs λ_* soient π_0-accessibles, impliquent que la sous-catégorie strictement pleine $\mathcal{N}_\pi$ de $\mathcal{N}$ dont les fibres sont les $(\mathcal{N}_j)_\pi$, est une sous-catégorie cofibrée, et que de plus $\mathcal{N}$ est J-équivalent à $\operatorname{Ind}_\pi(\mathcal{N}_\pi/J)$. D'autre part, les fibres de $\mathcal{N}_\pi/J$ sont stables par $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$, donc la condition "ordinale" de 4.10.1 est vérifiée (en y faisant $\mathcal{D} = \mathcal{N}_\pi$). Comme de plus $\operatorname{card} J \leqslant \pi$, on en conclut par 4.10.1 que $\mathcal{M} \simeq \operatorname{Ind}_\pi(\mathcal{M}_\pi)$.

[page 265]

Commentary · Context [ms. 264]

The earlier language of cardinal filtrations

Grothendieck is returning to a problem already treated in the foundations of SGA 4: how a category assembled from small objects retains a small supply of generators after one imposes compatible structure. Exposé I first develops ind-objects and simultaneous presentations in Section 8, then cardinal filtrations and categories of sections in Section 9. The concrete antecedents are

8.8.2–8.8.5 and 9.22–9.24 (Artin et al., 1972). The references to SGA in this chapter therefore identify specific constructions, not merely a historical affinity.

The present argument makes a useful separation within that method. One cardinal bounds the arrows, equations, and chosen approximations. Another colimit shape supplies the completion of the successive corrections. Once those two roles have been isolated, a theorem about ordinary diagrams becomes a theorem about sections, because the correction is performed fibre by fibre and then checked against transport. The distinction between the category of all sections and its cartesian or cocartesian part must survive that passage: invertibility of a structure map is additional structure to enforce, not a consequence of ordinary naturality.

This is also a way to read the source's repeated requests to write out apparently formal steps. The same filtered system must witness an object, its maps, and their relations. A proof which merely chooses representatives of the separate objects has not yet constructed that system. The cofinality criterion and the iteration are precisely the two parts which supply it. They remain ordinary categorical arguments here; the homotopical relevance comes from applying them to categories of diagrams, sections, and specified classes of arrows.

Corollaire 4.10.9. *Soit $\mathcal{N} \longrightarrow J$ une "cofibration en paratopos" ([107]), i.e. un foncteur cofibrant tel que les fibres soient des catégories paratopos, et les foncteurs cochangement de base soient des foncteurs images inverses (resp. images directes) pour des morphismes de paratopos, i.e. qu'ils commutent aux (petites) $\varinjlim$ (resp. aux petites $\varprojlim$). Supposons de plus J équivalente à une petite catégorie. Alors $\underline{\Gamma}(\mathcal{N}/J)$ est une catégorie paratopos.*

En effet, c'est une catégorie accessible en vertu de 4.10.8, d'autre part l'hypothèse sur les λ_* implique aussitôt que $\underline{\Gamma}(\mathcal{N}/J)$ est stable par petites $\varprojlim$ (resp. par petites $\varprojlim$ `[plutôt` $\varinjlim$ `?]`). Donc $\underline{\Gamma}(\mathcal{N}/J)$ est une catégorie paratopos en vertu de 4.8.9 b $\Longrightarrow$ a (resp. c $\Longrightarrow$ a). p. 100

Corollaire 4.10.10. *Soit $\mathcal{N} \longrightarrow J$ une catégorie* fibrée *(non cofibrée!), telle que les fibres soient des catégories paratopos et les foncteurs changement de base soient des foncteurs images directes pour des morphismes de paratopos (i.e. des foncteurs accessibles, commutant aux petites $\varprojlim$). Supposons de plus J équivalente à une petite catégorie. Alors $\underline{\Gamma}(\mathcal{N}/J)$ est une catégorie paratopos.* [page 266]

Commentary · Exposition [ms. 265]

Paratoposes and the direction of pointwise limits

The application to paratoposes uses the characterization established earlier in this chapter: an accessible category with all small limits, equivalently an accessible category with all small colimits, is locally presentable. "Paratopos" here should not be read as asserting the additional exactness properties of a Grothendieck topos. Module categories, including the preceding example, already lie in the intended range.

In the direct-image alternative we retain the words "for a morphism of paratoposes": the transports are actual right adjoints and are therefore accessible. Their bare preservation of limits, mentioned in the parenthesis, is not by itself the hypothesis needed to invoke 4.10.8. Indeed, to see accessibility of a right adjoint R, take a small strongly generating family of presentable objects a in its target. Choose a regular cardinal bounding the presentability ranks of both the a and their images La under its left adjoint. Testing the filtered-colimit comparison for R by $\mathrm{Hom}(a, R-) \simeq \mathrm{Hom}(La, -)$ now makes it a bijection for every a, hence an isomorphism. This gives one common rank. The next corollary explicitly includes accessibility.

For ordinary sections of an opfibration, limits are pointwise whenever the fibres have them, with no preservation requirement on transport. Given a diagram of sections X^d, put $L_j = \lim_d X^d_j$. For $a : i \to j$, the maps $a_*L_i \to a_*X^d_i \to X^d_j$ form a cone and therefore induce $a_*L_i \to L_j$. Their unit and composition equations follow after composing with each limit projection. A cone of sections factors uniquely through the L_j, and the same projections verify naturality of the factorization. This proves the limit universal property in the section category.

By contrast, constructing colimits pointwise uses preservation of those colimits by a_*, since the needed arrow is $a_* \operatorname{colim} X^d_i \to \operatorname{colim} X^d_j$. Thus the colimit-preserving case of 4.10.9 gives pointwise colimits as well as limits. In the limit-preserving case, pointwise limits suffice, together

107. terme ambigu, cf. la double explication.

with accessibility, for local presentability. Both printed occurrences of $\varinjlim$ in the proof are defensible. The editors' tentative replacement of the second by $\varprojlim$ is not needed and does not follow from the stated preservation hypothesis. We retain the printed text and its question rather than turning a tentative editorial suggestion into a mathematical correction.

For a fibration the directions reverse. A section carries maps $X_i \to a^* X_j$. Colimits are pointwise without a preservation condition, while pointwise limits require that a^* preserve them. Consequently 4.10.10 follows either from accessibility of sections and pointwise limits, or by replacing each right-adjoint inverse-image functor by its left adjoint, obtaining the equivalent description by an opfibration. The arrow labels in its printed proof are inconsistent with the direction $a : i \to j$; the adjunction is correctly $a_! : \mathcal{N}_i \rightleftarrows \mathcal{N}_j : a^*$.

En effet, l'hypothèse implique que pour toute flèche $\lambda : j' \longrightarrow j$ dans J, le foncteur $\lambda_* : \mathcal{N}_{j'} \longrightarrow \mathcal{N}_j$ admet un adjoint à gauche $\lambda^* : \mathcal{N}_j \longrightarrow \mathcal{N}_{j'}$, d'où s'ensuit que $\mathcal{N} \longrightarrow J$ est aussi cofibrant, les foncteurs de cochangement de base commutant aux petites $\varinjlim$. Donc on peut appliquer 4.8.9, qui donne le résultat voulu.

Question 4.10.11. *Soit $\mathcal{N} \longrightarrow J$ un foncteur* fibrant, *tel que les $\mathcal{N}_j$ soient des catégories accessibles, et les foncteurs λ^* de changement de base accessibles, J étant équivalente à une petite catégorie. Je conjecture que sous ces conditions, $\underline{\Gamma}(\mathcal{N}/J) \overset{\text{déf}}{=} \mathrm{Hom}(J, \mathcal{N})$ est accessible,* [page 267] *et qu'il en est de même de* $\mathrm{Hom}\ \underline{\mathrm{cart}}_J(J, \mathcal{N})$.

C'est ce qui est prouvé dans SGA 4 I 9.24 sous des hypothèses légèrement plus fortes (à l'aide de l'ancienne notion trop forte à mon gré, de filtrations cardinales). Je serais étonné que la démonstration (un peu longuette) de loc. cit. ne s'applique pas au cas général. Mais on aimerait avoir un énoncé qui coiffe celui-ci et 4.10.8, dans le cas d'un foncteur $\mathcal{N} \longrightarrow J$ qui ne serait supposé ni fibrant ni cofibrant, mais …(???).

4.11 Application à l'existence des limites dans une catégorie de la forme $\mathrm{Ind}_{\pi_0}(C)$.

Proposition 4.11.1. *Soit C une catégorie équivalente à une petite catégorie, π un cardinal infini, posons $\mathcal{M} = \mathrm{Ind}_\pi(C)$. Soit Φ un ensemble de catégories de cardinal réduit $\leqslant \pi$. On se propose d'examiner si $\mathcal{M}$ est "stable par $\varinjlim$ de type Φ" (i.e. stable par $\varinjlim$ de type I, quel que soit $I \in \Phi$). Il suffit pour cela que C est stable par $\varinjlim$ de type Φ, et que de plus il existe un ordinal limite α avec* $\mathrm{card}\,\alpha \leqslant \pi$ *et tel que C soit stable par $\varinjlim$ de type I_α (p.ex. tel que $I_\alpha \in \Phi$). Inversement, si $\mathcal{M}$ est stable par $\varinjlim$ de type Φ, et si on suppose de plus C karoubienne (i.e. stable par facteurs directs), alors C est stable par $\varinjlim$ de type Φ. Dans l'un et l'autre cas, le foncteur d'inclusion $C \hookrightarrow \mathcal{M}$ commute aux $\varinjlim$ envisagées.* [page 268]

Commentary · Present state [ms. 267]

The question about fibred sections is settled

Grothendieck asks for accessibility of ordinary and cartesian sections under accessible inverse-image functors. Both assertions are now proved. The first construction is an oplax limit of the pseudofunctor $J^{\mathrm{op}} \to \mathrm{Acc}$ classifying the fibration; the second is its pseudolimit. After the ranks have been enlarged uniformly, Positselski (2024, Theorems 8.1, 8.3 and Corollary 9.2) give these conclusions and pointwise descriptions of the presentable objects. The hypotheses on a common smaller chain-colimit cardinal and on preservation of presentables in the pseudolimit theorem are essential to that precise fixed-rank statement. This supplies a direct modern answer to 4.10.11, rather than merely an analogy with it.

Here is how the categorical construction encodes the question. Form the product $P = \prod_j \mathcal{N}_j$. For each $a : i \to j$, a potential section needs an arrow $X_i \to a^* X_j$. An inserter adds all these arrows to an object of P. Equifiers then impose the equations for identity arrows and composable pairs. The result is the category of ordinary sections. To obtain cartesian sections, add inverses to the structure maps and equify the two composites with the identity maps. The coherence isomorphisms of the

pseudofunctor occur in the composition equations. This accounts for the actual section category, rather than a category in which compatibility is imposed only up to an unspecified isomorphism.

The required common cardinals can be chosen because there are only set-many fibres and transport functors. First choose a regular λ for which all fibres are accessible and all transports preserve λ-filtered colimits. A λ-chain is itself λ-filtered, so these chain colimits exist and are preserved. Then choose a sufficiently large regular $\kappa > \lambda$, with the appropriate sharp cardinal inequality, so that all fibres are κ-accessible, J is κ-small, and all transports preserve κ-presentables when needed. The uniformization mechanism developed in 4.12 explains the last step.

SGA 4, I, 9.22–9.24 already treats ordinary and cartesian sections, using cardinal filtrations and stronger closure assumptions (Artin et al., 1972). The new formulation separates the smaller colimits used to construct compatible structure from the larger filtered colimits used to present arbitrary objects. The wish for an encompassing theorem is realized by closure of accessible categories under the relevant products, inserters, equifiers and pseudolimits. It does not assert closure under arbitrary strict equalizers of accessible functors, nor does it give a hypothesis-free theorem for an arbitrary functor to J.

([108]).

Démonstration. a) Condition suffisante. On applique 4.9.3 pour conclure que pour toute catégorie J de cardinal réduit $\leqslant \pi$ (en particulier pour $J \in \Phi$), tout foncteur $\varphi : J \longrightarrow \mathcal{M} = \mathrm{Ind}_\pi(C)$ admet une représentation indicielle $\Phi : J \times I \longrightarrow C$, avec I grande devant π. Ceci, plus la stabilité de C par $\varinjlim$ de type J, suffit à établir l'existence de la $\varinjlim$ de φ. p. 101 [page 269]

La réciproque provient du fait que si C est karoubienne, alors son image essentielle dans $\mathcal{M}$ n'est autre que $\mathcal{M}_\pi$, laquelle est stable dans $\mathcal{M}$ par toute $\varinjlim$ de cardinal $\leqslant \pi$ représentable dans $\mathcal{M}$. Si $\mathcal{M}$ est stable par $\varinjlim$ de type Φ, il en est de même de $\mathcal{M}_\pi$, donc de C, q.e.d.

Corollaire 4.11.2. *Pour que $\mathcal{M}$ soit stable par $\varinjlim$ filtrantes (resp. par petites $\varinjlim$), il suffit que C le soit par $\varinjlim$ filtrantes (resp. par $\varinjlim$)* de cardinal $\leqslant \pi$, *et c'est aussi nécessaire si C est karoubienne.*

Supposons C stable par $\varinjlim$ filtrantes (resp. par $\varinjlim$ de cardinal $\leqslant \pi$, alors par 4.11.1 $\mathcal{M}$ est stable par ce même type de limites inductives. D'autre part, il est stable par $\varinjlim$ grandes devant π. Il suffit donc de prouver le [page 270]

Commentary · Exposition [ms. 269]

Transporting colimits through an ind-presentation

The representation theorem pays for itself immediately. Once a diagram $X : J \to \mathrm{Ind}_\kappa C$ is written as $X_j = \mathrm{colim}_{i\in I} D_{i,j}$ with I κ-filtered and every D_i a genuine C-valued diagram, the candidate colimit is forced:

$$Q = \mathrm{colim}_{i\in I} \left(\mathrm{colim}^C_{j\in J} D_{i,j} \right).$$

The inner colimits are preserved by $C \to \mathrm{Ind}_\kappa C$ because $|\operatorname{Mor} J| < \kappa$; the outer one exists by definition of the completion. For any Y in the completion,

$$\mathrm{Hom}(Q, Y) \simeq \lim_i \lim_j \mathrm{Hom}(D_{i,j}, Y) \simeq \lim_j \mathrm{Hom}(X_j, Y).$$

The middle interchange is an interchange of two limits, so it needs no extra exactness hypothesis. This proves 4.11.1's sufficiency, including the prescribed cocone.

The preservation assertion of Lemma 4.10.4 is equally specific. If $c = \mathrm{colim}^C_{j\in J} c_j$ and $Y = \mathrm{colim}_{a\in A} y_a$, then

$$\mathrm{Hom}(c, Y) \simeq \mathrm{colim}_a \lim_j \mathrm{Hom}(c_j, y_a) \simeq \lim_j \mathrm{colim}_a \mathrm{Hom}(c_j, y_a).$$

Here the second interchange does use κ-filteredness of A and κ-smallness of J. This distinction explains why no general colimit-preservation property of the ordinary Yoneda embedding is being claimed.

For necessity, an existing κ-small colimit of κ-presentables is again κ-presentable: its hom functor is a κ-small limit of hom functors, and the same interchange applies. The κ-presentable objects

108. Expliciter ici les corollaires des types 4.13.20, 4.13.21 (p. 341).

of $\mathrm{Ind}_\kappa C$ are retracts of objects of C. To see the retract statement, express a presentable X as a filtered colimit of representables and factor id_X through one stage. If C is idempotent complete, that retract lies in C, proving the converse. Idempotent completeness is used at precisely this point, not in the construction of Q.

Lemme 4.11.3. *Soit $\mathcal{M}$ une catégorie, π un cardinal. Supposons que $\mathcal{M}$ soit stable par $\varinjlim$ filtrantes de cardinal $\leqslant \pi$ (resp. par $\varinjlim$ de cardinal $\leqslant \pi$, resp. par sommes des cardinal $\leqslant \pi$),* et *par $\varinjlim$ grandes devant π. Alors $\mathcal{M}$ est stable par petites $\varinjlim$ filtrantes (resp. par petites $\varinjlim$, resp. par petites sommes).*

Ce lemme se prouve comme 4.4.14, page 97.

Reste la réciproque dans 4.11.2, qui résulte de l'assertion similaire dans 4.11.1.

Corollaire 4.11.4. *Quand $\mathcal{M} = \mathrm{Ind}_\pi C$ est-il stable par sommes ? S'il existe un ordinal α tel que* $\mathrm{card}\,\alpha \leqslant \pi$, *et que C soit stable par $\varinjlim$ de type I_α, alors il suffit que C soit stable par sommes de cardinal $\leqslant \pi$. Cette condition est aussi nécessaire si C est karoubienne.*

([109]).

Se prouve comme 4.11.2, en utilisant 4.11.3.

[page 271]

Commentary · Exposition [ms. 270]

Building an arbitrary colimit from bounded pieces

The cardinal enlargement in Lemma 4.11.3 can be made quite explicit. Assume π is infinite, as it is in the application, and put $\kappa = \pi^+$. Every small category J is the union of its subcategories with at most π arrows. Their poset P is κ-filtered: the subcategory generated by the union of at most π such subcategories still has at most π arrows, since only finite composites are added. For a diagram $X : J \to \mathcal{M}$, suppose all the colimits $Q_K = \mathrm{colim}_K X$ exist for $K \in P$. A cocone from the diagram $K \mapsto Q_K$ to Y is exactly a cocone from X to Y. Every object and arrow of J occurs in some K, and two occurrences can be compared in a larger one. Thus $\mathrm{colim}_{K\in P} Q_K$ is the desired colimit over J.

When J is filtered and only filtered colimits are assumed for the bounded pieces, take instead its filtered subcategories of size at most π. Every set of at most π arrows is contained in one: repeatedly add cocones for pairs of objects and equalizers for parallel pairs, then close under composition. Countably many repetitions suffice; their union is filtered and still has at most π arrows. The same construction bounds a family of at most π such subcategories. Their indexing poset is therefore κ-filtered, and the preceding cocone argument applies unchanged. For coproducts use the poset of subsets of the indexing set of size at most π.

This also makes 4.11.4 stronger than its stated form. If C has coproducts indexed by sets of size at most π, then $\mathrm{Ind}_\kappa C$ has all small coproducts without an additional ordinal-colimit assumption. For a bounded family of ind-objects, take the product of their κ-filtered presentation categories, form the coproduct of the resulting objects of C at each index, and then take its filtered colimit. The hom universal property proves this is the coproduct. The preceding bounded-subset construction gives arbitrary coproducts. The converse under idempotent completeness follows from the presentability argument on p. 269. Thus the omission of the word "limit" before "ordinal" in 4.11.4 creates no counterexample to its conclusion.

Proposition 4.11.5 ([110]). *Soit Φ un ensemble de catégories I équivalentes à des catégories finies, et "rigides", i.e. pour tout $i \in \mathrm{Ob}\, I$, $\mathrm{Hom}_I(i,i) = \{\mathrm{id}_i\}$. Soient C une catégorie équivalente à une petite catégorie, π un cardinal infini, $\mathcal{M} = \mathrm{Ind}_\pi C$. Pour que $\mathcal{M}$ soit stable par $\varinjlim$ (resp. par $\varprojlim$) de type Φ, il* suffit *que C le soit. Dans le cas non respé, si C est karoubienne, cette condition est aussi nécessaire.*

Cette dernière assertion est contenue dans l'assertion similaire dans 4.11.1. Pour la première assertion, cela résulte de la façon habituelle du

Lemme 4.11.6 ([111]). *Soit J une catégorie équivalente à une catégorie finie, J rigide, C une catégorie équivalente à une petite catégorie, π un cardinal infini. Alors tout foncteur*

Commentary · Exposition [ms. 272]

Finite rigid diagrams really do admit simultaneous presentations

The hesitation attached to 4.11.6 concerns a true statement. After taking a skeleton, a finite category with only identity endomorphisms admits an ordering of its objects in which every nonidentity arrow increases the order. Indeed a cycle would produce an endomorphism, and the identity-only condition would make every arrow in the cycle invertible, contradicting skeletal distinctness. The finite induction in SGA 4, I, 8.8.5 therefore extends to the present cardinal bound (Artin et al., 1972).

We give the induction with the required simultaneous constraints. Fix $X : J \to \mathrm{Ind}_\kappa C$ and let $S = C^J/X$. To show that S is κ-filtered, take a diagram $H : K \to S$ with $|\operatorname{Mor} K| < \kappa$. Construct a cocone $H \to D$ one vertex of J at a time. At a vertex j, include in C/X_j every $H_k(j)$, with the arrows prescribed by K, and every previously chosen $D(i)$ indexed by an incoming nonidentity arrow $a : i \to j$, mapped to X_j through $X(a)$. Include also the maps $H_k(i) \to D(i)$ and $H_k(i) \to H_k(j)$, and, for composable incoming arrows, the maps between previously chosen $D(i)$'s. This is a diagram with fewer than κ arrows. A cocone in the κ-filtered category C/X_j gives $D(j)$, the arrows $D(a)$, and the components $H_k(j) \to D(j)$. The imposed relations say exactly that composition is respected and that every $H_k \to D$ is natural. Since no nonidentity arrow leaves j for an earlier vertex, subsequent choices cannot alter this work. The induction supplies the desired cocone, including nonemptiness when K is empty.

The same induction can begin with arbitrary objects $c_j \to X_j$, adding them as isolated objects to the diagrams at the corresponding vertices. It proves the object-lifting condition for evaluation $S \to \prod_j C/X_j$. To see the required connectedness, take two lifts of a fixed family. Repeat the induction with the two section diagrams and with the additional pairs of arrows from each c_j; equalizing these pairs in C/X_j gives a common successor in the relevant comma category. Evaluation is therefore final. The density argument already given on p. 246 proves the equivalence $\mathrm{Ind}_\kappa(C^J) \simeq (\mathrm{Ind}_\kappa C)^J$.

The modern sharp result is Henry (2025b, Theorem 1.3): for all categories C, this equivalence holds exactly when J is essentially κ-small and well-founded. Finite rigid categories are such shapes. Thus the source's further question about dropping rigidity has a negative answer in general; a finite category with a nonidentity endomorphism is already outside the universal statement. The condition concerns a theorem for every C, not the impossibility of successful representation for one particular C.

Corollaire 4.11.7 ([112]). *Pour que* $\mathcal{M} = \mathrm{Ind}_\pi C$ *soit stable par* $\varinjlim$ *(resp. par* $\varprojlim$ *)* finies, *il* suffit *que* C *le soit. Et c'est aussi nécessaire dans le cas non respé, lorsqu'on suppose* C *karoubienne.*

4.12 Foncteurs accessibles entre catégories accessibles

Proposition 4.12.1 ([113]). *Soient* $\mathcal{M}, \mathcal{N}$ *deux catégories accessibles (4.8), et* $f : \mathcal{M} \longrightarrow \mathcal{N}$ *un foncteur accessible. Alors il existe des cardinaux infinis* π_0*,* π_1 *tels que* $\pi_1 \geqslant \pi_0$ *et que pour tout cardinal* $\pi \geqslant \pi_1$*, on ait*

$$f(\mathcal{M}_\pi) \subset \mathcal{N}_{\pi^{\pi_0}} , \tag{4.12.1}$$

112. sous réserve de validité de 4.11.5.
113. Remonterait à 4.8.

et en particulier

(4.12.1.2) $$f(\mathcal{M}_\pi) \subset \mathcal{N}_\pi \qquad \textit{si } \pi = \pi^{\pi_0}.$$

De façon plus précise, on peut prendre pour π_0 un cardinal utile pour $\mathcal{M}$ et tel que f soit [page 274]
π_0-accessible (p.ex. le plus petit cardinal de ce type). Soit alors π_1 un cardinal tel qu'on ait $f(\mathcal{M}_{\pi_0}) \subset \mathcal{N}_{\pi_1}$, $\pi_1 \geqslant \operatorname{card} \operatorname{réd} \mathcal{M}_{\pi_0}$, et enfin tel que $\mathcal{N}_{\pi_1}$ soit [une] *sous-catégorie strictement génératrice de $\mathcal{N}$. Le couple (π_0, π_1) satisfait aux conditions énoncées.*

Commentary · Exposition [ms. 273]

Why the finite limit and colimit corollaries follow

The preceding representation establishes both clauses of 4.11.5, but they use different universal-property arguments. For colimits, the iterated-colimit calculation on p. 269 applies directly. For limits, the inclusion $C \to \mathrm{Ind}_\kappa C$ preserves every existing limit in C: the ordinary Yoneda embedding preserves limits, and the completion is a full subcategory of the presheaf category.

Let $D : J \to \mathrm{Ind}_\kappa C$ have a simultaneous presentation $D_j = \mathrm{colim}_{i \in I} D_{i,j}$, with J finite rigid. If C has J-limits, put $L_i = \lim_j^C D_{i,j}$ and $L = \mathrm{colim}_i L_i$. For a representable $c \in C$, compactness and filtered-limit commutation in sets give

$$\mathrm{Hom}(c, L) \simeq \mathrm{colim}_i \lim_j \mathrm{Hom}(c, D_{i,j}) \simeq \lim_j \mathrm{Hom}(c, D_j).$$

For an arbitrary ind-object $Z = \mathrm{colim}_a c_a$, apply $\lim_a$ to this identity and commute the two limits. This proves $\mathrm{Hom}(Z, L) \simeq \lim_j \mathrm{Hom}(Z, D_j)$, hence $L = \lim_j D_j$.

Although an arbitrary finite category need not be rigid, finite limits are generated by finite products and equalizers, and finite colimits by finite coproducts and coequalizers. The corresponding shapes are finite rigid categories. The empty shape provides the terminal or initial object, and the parallel-pair shape provides equalizers or coequalizers. This proves Corollary 4.11.7 without silently applying 4.11.6 to a finite category with endomorphisms. The converse for finite colimits uses idempotent completeness as before; no analogous converse for finite limits is asserted.

Démonstration. On aura en effet

$$\mathcal{N}_1 \xleftarrow{\sim} \mathrm{Ind}_{\pi_0}(\mathcal{M}_{\pi_0})$$

et f commutant aux $\varinjlim$ grandes devant π_0, sera connu (à isomorphisme unique près) par sa restriction à $\mathcal{M}_{\pi_0}$, laquelle se factorise par $\mathcal{N}_{\pi_1}$,

$$f|\mathcal{M}_{\pi_0} : \mathcal{M}_{\pi_0} \longrightarrow \mathcal{N}_{\pi_1} .$$

Pour prouver (4.12.1.1), posant $\pi' = \pi^{\pi_0} \geqslant \pi$, et notant que $\pi'^{\pi_0} = \pi_0$ [plutôt $\pi'^{\pi_0} = \pi'$],

$$f(\mathcal{M}_\pi) \subset f(\mathcal{M}_{\pi'}) \overset{?}{\subset} \mathcal{N}_{\pi'} ,$$

on voit qu'il suffit de prouver (4.12.1.2) (pour π'). Donc on peut supposer $\pi = \pi^{\pi_0}$ et prouver p. 103
(4.12.1.2). Mais comme $\pi_1 \geqslant \operatorname{card} \operatorname{réd} \mathcal{M}_{\pi_0}$, on sait que si π est tel que $\pi \geqslant \pi_1$, $\pi^{\pi_0} = \pi$, alors $\mathcal{M}_\pi$ est formé des $\varinjlim_I x_i$, les $x_i \in \mathcal{N}_{\pi_0}$, et I grande devant π_0, et $\operatorname{card} I \leqslant \pi$.

On a alors (f étant π_0-accessible) [page 275]

$$f(x) = \varinjlim_I f(x_i) ,$$

les $f(x_i)$ sont dans $\mathcal{N}_{\pi_1}$, donc dans $\mathcal{N}_\pi$, or $\mathcal{N}_\pi$ stable par $\varinjlim$ de cardinal $\leqslant \pi$ (puisque $\mathcal{N}$ est engendrée par $\mathcal{N}_{\pi_1}$, formée d'objets π_1-accessibles et a fortiori π-accessibles, cf. SGA 4 I 9.9). D'où $f(x) \in \mathcal{N}_\pi$, q.e.d.

Corollaire 4.12.2. *Supposons que π_0 soit aussi utile pour $\mathcal{N}$, et que $\pi_1 \geqslant \operatorname{card} \operatorname{réd} \mathcal{N}_{\pi_0}$. Soit π un cardinal $\geqslant \pi_1$, et tel que $\pi^{\pi_0} = \pi$. Alors f s'identifie, à équivalence de catégories et à isomorphisme de foncteurs près, au foncteur*

$$\operatorname{Ind}(f_\pi) \ : \ \operatorname{Ind}_\pi(\mathcal{M}_\pi) \ \longrightarrow \ \operatorname{Ind}_\pi(\mathcal{N}_\pi) \ ,$$

où $f_\pi : \mathcal{M}_\pi \longrightarrow \mathcal{N}_\pi$ est le foncteur induit par f.

Proposition 4.12.3 ([114]). *Soient C une catégorie équivalente à une petite catégorie, $\mathcal{N}$ une $\mathfrak{U}$-catégorie, π_0 un cardinal infini. On suppose que $\mathcal{N}$ satisfait L_{π_0} (stabilité par $\varinjlim$ grandes devant π_0). Soit $\mathcal{M} = \operatorname{Ind}_{\pi_0} C$, $\operatorname{Hom}_{!\,\pi_0}(\mathcal{M},\mathcal{N})$ la sous-catégorie strictement pleine de* [page 276] *$\operatorname{Hom}(\mathcal{M},\mathcal{N})$ formée des $f : \mathcal{M} \longrightarrow \mathcal{N}$ π_0-accessibles. Alors le foncteur restriction*

$$\operatorname{Hom}_{!\,\pi_0}(\mathcal{M},\mathcal{N}) \ \longrightarrow \ \operatorname{Hom}(C,\mathcal{N}) \tag{4.12.3.1}$$

est une équivalence de catégories. On trouve un foncteur quasi-inverse comme composé

$$\operatorname{Hom}(C,\mathcal{N}) \ \longrightarrow \ \operatorname{Hom}(\underbrace{\operatorname{Ind}_{\pi_0}(C)}_{\mathcal{M}}, \operatorname{Ind}_{\pi_0}(\mathcal{N})) \ \longrightarrow \ \operatorname{Hom}(\mathcal{M},\mathcal{N}) \ , \tag{4.12.3.2}$$

où la deuxième flèche est le foncteur composition $F \longmapsto L \circ F$ avec le foncteur limite inductive $L : \operatorname{Ind}_{\pi_0}\mathcal{N} \longrightarrow \mathcal{N}$. Le foncteur composé (4.11.3.2) a une image contenue dans $\operatorname{Hom}_{!\,\pi_0}(\mathcal{M},\mathcal{N})$ et induit une équivalence entre cette dernière catégorie et $\operatorname{Hom}(C,\mathcal{N})$.

Commentary · Exposition [ms. 275]

An accessible functor eventually respects a common size bound

The point of 4.12.1 is to replace the qualitative word "accessible" by a controlled estimate on the images of small objects. Choose a useful π_0 for $\mathcal{M}$ such that f preserves colimits indexed by categories large before π_0. The essentially small category $\mathcal{M}_{\pi_0}$ has only set-many images under f. Their accessibility ranks can therefore be bounded by one π_1, enlarged also to dominate the size of a skeleton and a generating rank for $\mathcal{N}$.

For $\pi \geq \pi_1$ satisfying $\pi^{\pi_0} = \pi$, the earlier presentation theorem expresses every $x \in \mathcal{M}_\pi$ as a colimit of objects $x_i \in \mathcal{M}_{\pi_0}$ over a category I large before π_0 with $|\operatorname{Mor} I| \leq \pi$. Since f preserves this colimit,

$$f(x) \simeq \operatorname{colim}_{i \in I} f(x_i).$$

Every $f(x_i)$ is π-accessible, and a colimit of at most π such objects is π-accessible. The latter assertion follows by writing its hom functor as a π-bounded limit and commuting it with the filtered colimits used to define π-accessibility. Thus $f(\mathcal{M}_\pi) \subset \mathcal{N}_\pi$. For general π, put $\rho = \pi^{\pi_0}$. Cardinal arithmetic gives $\rho^{\pi_0} = \rho$, and monotonicity gives $\mathcal{M}_\pi \subset \mathcal{M}_\rho$, proving the advertised bound $f(\mathcal{M}_\pi) \subset \mathcal{N}_\rho$.

The printed $\mathcal{N}_1 \simeq \operatorname{Ind}_{\pi_0}(\mathcal{M}_{\pi_0})$ on p. 274 must mean $\mathcal{M} \simeq \operatorname{Ind}_{\pi_0}(\mathcal{M}_{\pi_0})$, and the x_i later belong to $\mathcal{M}_{\pi_0}$, not $\mathcal{N}_{\pi_0}$. These are present in the edition and are retained as source slips. The proof itself is the familiar uniformization argument. Applied to a small family of functors, one first bounds all their required ranks, then chooses a common fixed point; this is the step used for sections and cartesian sections.

Once the same π is useful for both categories, preservation of the appropriate filtered colimits says that f is determined by $f_\pi : \mathcal{M}_\pi \to \mathcal{N}_\pi$. Corollary 4.12.2 identifies it with the ind-extension of that small functor. The identification includes natural transformations, as the following universal property makes precise.

En d'autres termes, on peut dire que le foncteur d'inclusion canonique

$$C \ \longrightarrow \ \operatorname{Ind}_{\pi_0} C \ = \ \mathcal{M} \tag{4.12.3.3}$$

[page 277]

est 2-universel *pour les foncteurs de C dans des catégories $\mathcal{N}$ satisfaisant L_{π_0}, celles-ci étant considérées comme* 0*-objets d'une* 2*-catégorie où les* 1*-objets sont les foncteurs $\mathcal{N} \longrightarrow \mathcal{N}'$ π_0-accessibles, i.e. commutent aux $\varinjlim$ grandes devant π_0.*

114. remonte à 4.7.

Cet énoncé est l'analogue, pour C petite quelconque, de 4.4.16 (page 101), valable pour C stable par $\varinjlim$ de cardinal $\leqslant \pi_0$. Il y a bien sûr d'autres variantes, en relation avec la commutation à d'autres types de $\varinjlim$ ($\varinjlim$ filtrantes, sommes, limites inductives finies etc.) envisagées dans la section 4.11 précédente.

La démonstration de 4.12.3 est soritale.

p. 104
[page 278]

Corollaire 4.12.4. *Soient $\mathcal{M}$ et $\mathcal{N}$ deux catégories accessibles, et soit π_0 un cardinal infini tel que $\mathcal{M}$ soit π_0-accessible, i.e. que π_0 soit un cardinal utile pour $\mathcal{M}$. Soit $\pi_1 = \sup(\pi_0, \operatorname{card} \text{réd}\, \mathcal{M}_{\pi_0})$. Alors pour tout cardinal $\pi \geqslant \pi_1$ utile pour $\mathcal{M}$ (et en particulier, pour tout $\pi \geqslant \pi_1$ tel que $\pi^{\pi_0} = \pi$), la catégorie des foncteurs $\mathcal{M} \longrightarrow \mathcal{N}$ qui sont π-accessibles est elle-même accessible.*

Commentary · Exposition [ms. 277]

The free filtered-colimit completion includes natural transformations

Grothendieck's "2-universal" formulation records more than existence of an extension. Given $g : C \to \mathcal{N}$, where $\mathcal{N}$ admits κ-filtered colimits, define

$$\overline{g}(X) = \operatorname{colim}_{(c \to X) \in C/X} g(c), \qquad X \in \operatorname{Ind}_\kappa C.$$

The category C/X is small and κ-filtered. A map $X \to Y$ induces $C/X \to C/Y$, and hence a map between the displayed colimits. Identity maps and composition are respected by uniqueness in the colimit universal property. For $X = c$ representable, (c, id) is terminal in C/c, so $\overline{g}(c) \simeq g(c)$.

This extension preserves κ-filtered colimits. For a κ-filtered diagram X_i with colimit X, consider pairs $(i, c \to X_i)$. Their category is κ-filtered: fewer than κ objects and equations can first be moved to a common index i, using presentability of the representables, and then bounded inside C/X_i. The functor sending a pair to $c \to X$ is final. Every such map factors through some X_i, and two factorizations become equal at a later index; the same argument with fewer than κ constraints verifies the required compatibility. Therefore the displayed formula for $\overline{g}(X)$ is the iterated colimit of the formulas for $\overline{g}(X_i)$, proving preservation.

If F already preserves these colimits, the canonical expression $X = \operatorname{colim}_{C/X} c$ forces $F(X) \simeq \overline{F|_C}(X)$. Finally a transformation $g \to h$ induces $\overline{g} \to \overline{h}$ by applying its components to each presentation. Conversely a transformation between colimit-preserving extensions is forced by its restriction to C, since the maps from the presentation objects are a colimit cocone. Restriction is consequently fully faithful and essentially surjective, exactly the equivalence of categories stated in 4.12.3. This is the cardinal-bounded counterpart of the ordinary ind universal property in SGA 4, I, 8.7 (Artin et al., 1972).

En effet, on aura $\mathcal{M} \simeq \operatorname{Ind}_\pi \mathcal{M}_\pi$, d'où par 4.12.3

$$\operatorname{Hom}_{!\,\pi}(\mathcal{M}, \mathcal{N}) \xrightarrow{\sim} \operatorname{Hom}(\mathcal{M}_\pi, \mathcal{N}),$$

or $\operatorname{Hom}(\mathcal{M}_\pi, \mathcal{N})$ est accessible par 4.9.5 (p. 220). On peut préciser d'ailleurs ce point. Supposons π_0 choisi tel que π_0 soit utile non seulement pour $\mathcal{M}$, mais pour $\mathcal{N}$ également. Rappelons que l'on a $\operatorname{card} \operatorname{Fl} \mathcal{M}_\pi \leqslant 2^\pi$ (cf. 4.7.7, page 173).

Posons donc [page 279]

$$\pi' = 2^\pi,$$

on a donc $\pi'^{\pi_0} = 2^{\pi\pi_0} = 2^\pi = \pi'$, et $\operatorname{card} \text{réd}\, \mathcal{M}_\pi \leqslant \pi'$. Donc 4.9.5 nous donne que

$$\operatorname{Hom}(\mathcal{M}_\pi, \mathcal{N}) \simeq \operatorname{Ind}_{\pi'}(\operatorname{Hom}(\mathcal{M}_\pi, \mathcal{M}_{\pi'})),$$

d'où :

Commentary · Exposition [ms. 278]

Fixing an accessibility rank before forming a functor category

Grothendieck first fixes the amount of colimit preservation demanded of a functor. This makes its domain effectively small: a functor preserving the relevant filtered colimits is determined, including

its natural transformations, by its values on a small category of presentable objects. Write $\lambda = \pi^+$ and $A = \mathcal{M}_\pi$. Whenever $\mathcal{N}$ admits λ-filtered colimits, restriction gives

$$\mathrm{Fun}_{\lambda\text{-filt}}(\mathcal{M},\mathcal{N}) \simeq \mathrm{Fun}(A,\mathcal{N}).$$

The inverse is the extension $F(x) = \varinjlim_{(a\to x)\in A/x} F(a)$. The same formula extends a natural transformation, and its uniqueness follows because the cocone $a \to x$ presents x. Thus the equivalence concerns categories of functors, rather than merely their isomorphism classes. This is the ordinary categorical form of the universal property of Ind; compare Chorny and Rosický (2012, Remark 2.3(1)).

There is one hypothesis to restore in the proof as printed. Proposition 4.12.3 assumes $\mathcal{N}$ satisfies L_π, whereas the first statement of 4.12.4 chooses π_0 using $\mathcal{M}$ alone. The displayed restriction equivalence does not follow without the required colimits in $\mathcal{N}$. Choosing π_0 useful for both categories supplies this hypothesis, exactly as Grothendieck does in the paragraph leading to 4.12.5. This repairs the proof and gives the form used subsequently; we do not infer a counterexample to the broader assertion merely from this omitted hypothesis.

The cardinal 2^π in 4.12.5 has a different job from π. The latter controls how a functor is extended; the former is large enough to control all the objects and arrows in its small domain simultaneously. If a skeleton of A has at most 2^π arrows and $\pi \geq \pi_0$, then

$$(2^\pi)^{\pi_0} = 2^{\pi\pi_0} = 2^\pi.$$

Corollary 4.9.5 therefore applies to $\mathrm{Fun}(A,\mathcal{N})$. The $\mathcal{M}_{\pi'}$ printed in the preliminary display on p. 279 must be read mathematically as $\mathcal{N}_{\pi'}$, as the following corollary confirms. Also, "under the conditions of 4.12.4" retains the requirement that π be useful for $\mathcal{M}$; the shorter inequality $\pi \geq \pi_1$ in 4.12.5 does not by itself replace that requirement.

Corollaire 4.12.5. *Sous les conditions de 4.12.4, si π_0 est utile pour $\mathcal{M}$* et *pour $\mathcal{N}$, alors pour $\pi \geqslant \pi_1$, $\mathrm{Hom}_{!\,\pi}(\mathcal{M},\mathcal{N})$ est π'-accessible, où $\pi' = 2^\pi$, de façon plus précise, on a une équivalence de catégories*

$$\mathrm{Hom}_{!\,\pi}(\mathcal{M},\mathcal{N}) \simeq \mathrm{Ind}_{\pi'}(\mathrm{Hom}(\mathcal{M}_\pi,\mathcal{N}_{\pi'})).$$

Remarque 4.12.6. Si $\mathcal{M}$, $\mathcal{N}$ sont accessibles, la catégorie $\mathrm{Hom}_{\mathrm{acc}}(\mathcal{M},\mathcal{N})$ des foncteurs accessibles n'est par toujours accessible. Si $\mathcal{N}$ satisfait L_{π_0}, cette catégorie satisfait L_{π_0}, et les $\varinjlim$ grandes devant π_0 se calculent argument par argument.

Si on pouvait trouver une sous-catégorie (équivalente à une petite catégorie) $\mathcal{H}_\pi$ de [page 280]
$\mathcal{H} = \mathrm{Hom}_{\mathrm{acc}}(\mathcal{M},\mathcal{N})$, pour un cardinal $\pi \geqslant \pi_0$ telle que tout objet F de $\mathcal{H}$ s'écrive $\varinjlim_I F_i$, les F_i dans $\mathcal{H}_\pi$, I grande devant π, alors si les objets de $\mathcal{H}_\pi$ sont des foncteurs π'-accessibles de $\mathcal{M}$ dans $\mathcal{N}$, il en serait de même de tout F dans $\mathcal{H}$. Donc il existerait un cardinal infini π' tel que tout foncteur accessible de $\mathcal{M}$ dans $\mathcal{N}$ soit π'-accessible. Mais sauf erreur, si p.ex. $\mathcal{M} = \mathcal{N} = \mathrm{Ens}$, il n'existe pas de tel cardinal. Je ne veux pas m'arrêter ici sur cette question, et faire un contre-exemple.

[page 281]

Commentary · Examples [ms. 280]

Accessible endofunctors of sets have no common bound

Grothendieck's hesitation on p. 280 can be settled by the most elementary representable functors. For each set B, consider

$$H_B(X) = \mathrm{Hom}(B,X) = X^B.$$

If λ is regular and $|B| < \lambda$, this functor preserves λ-filtered colimits. A map $B \to \varinjlim_i X_i$ is represented by choosing a representative for each of its fewer than λ values and then a common stage. If two representatives define the same map, fewer than λ equalities have to be witnessed, and filteredness places all their witnesses at a further common stage. These are respectively surjectivity and injectivity of the comparison map.

The bound cannot be made independent of B. Fix an infinite cardinal π, let $|B| > \pi$, and order the subsets $T \subseteq B$ of cardinal at most π by inclusion. Their poset is π^+-directed: the union of at most π such subsets still has cardinal at most π. Their colimit is B. But the image of

$$\varinjlim_{T \in [B]^{\leq \pi}} T^B \longrightarrow B^B$$

consists precisely of the maps with image of cardinal at most π. It omits id_B. Thus H_B is accessible, for example at the regular cardinal $|B|^+$, but is not π^+-accessible.

This proves the stronger assertion about the category of all accessible endofunctors. Suppose that category were μ-accessible and choose a small set $\mathcal{G}$ of μ-presentable generators. There is a regular cardinal λ such that every $G \in \mathcal{G}$ preserves λ-filtered colimits. Pointwise small colimits of accessible set-valued functors remain accessible: choose one common preservation rank for the small diagram, and interchange its colimit with a filtered colimit in Set. Consequently these pointwise colimits are also colimits in the full category of accessible functors. Every object, being a μ-filtered colimit of objects of $\mathcal{G}$, would therefore preserve λ-filtered colimits. The preceding example contradicts this conclusion. Natural transformations cause no size difficulty: between two accessible functors they are determined on a common small subcategory of sufficiently presentable sets.

This completes the counterexample requested by the source. The broader replacement of small generating sets by generating classes is the subject of Chorny and Rosický (2012, Definition 2.1 and Examples 2.2); that theory gives a context for the size obstruction, rather than making the ordinary accessibility assertion true.

4.13 Ensembles accessibles d'objets d'une catégorie accessible

Définition 4.13.1. Soient $\mathcal{M}$ une catégorie accessible, S une partie de $\mathrm{Ob}\,\mathcal{M}$, $\underline{S}$ la sous-catégorie pleine de $\mathcal{M}$ définie par S. On dit que S est une *partie accessible* de $\mathrm{Ob}\,\mathcal{M}$, ou encore que $\underline{S}$ est une *sous-catégorie "accessible dans $\mathcal{M}$"*, si p. 105

a) $\underline{S}$ est strictement pleine, i.e. pour x, y deux objets isomorphes de $\mathcal{M}$, $x \in S$ implique $y \in S$,

b) $\underline{S}$ est accessible,

c) le foncteur d'inclusion $\underline{S} \longrightarrow \mathcal{M}$ est accessible.

Soient π_0 un cardinal utile pour $\mathcal{M}$, i.e. tel que $\mathcal{M} \simeq \mathrm{Ind}_{\pi_0}(\mathcal{M}_{\pi_0})$, soit $\pi_1 = \sup(\pi_0, \mathrm{card\,réd}\,\mathcal{M}_{\pi_0})$. Soit d'autre part π_0' un cardinal tel que

$\underline{S}$ (supposé accessible dans $\mathcal{M}$) soit π_0-*accessible*, i.e. π_0'-utile pour $\underline{S}$, et de plus tel que $f : \underline{S} \hookrightarrow \mathcal{M}$ soit π_0'-accessible. Soit $\pi_1' \geqslant \pi_0'$ un cardinal tel que $\underline{S}_{\pi_0'} \subset \mathcal{M}_{\pi_1'}$, $\pi_1' \geqslant \mathrm{card\,réd}\,\underline{S}_{\pi_0'}$. [page 282]
Il résulte de 4.12.1 que pour tout cardinal

$$(*) \qquad \pi \geqslant \pi_1', \qquad \text{tel que } \pi^{\pi_0'} = \pi,$$

on doit avoir

$$\underline{S}_\pi \subset \mathcal{M}_\pi, \qquad \text{donc } \underline{S}_\pi \subset \mathcal{M}_\pi \cap \underline{S},$$

d'ailleurs, comme $\underline{S} \hookrightarrow \mathcal{M}$ est π_0'-accessible et a fortiori π-accessible, et pleinement fidèle, il s'ensuit aussitôt que $\mathcal{M}_\pi \cap S \subset S_\pi$, d'où

$$S_\pi = \mathcal{M} \cap S.$$

D'ailleurs, la condition $(*)$ implique que π est utile pour $\underline{S}$, donc

$$\underline{S} \xleftarrow{\sim} \mathrm{Ind}_\pi(\underline{S}_\pi). \qquad \text{[page 283]}$$

(D'ailleurs, *si* $\pi_0' \geqslant \pi_0$, la relation $\pi^{\pi_0'} = \pi$ implique a fortiori $\pi^{\pi_0} = \pi$, et si $\pi_1' \geqslant \pi_1$, on voit que $(*)$ implique que π est utile aussi pour $\mathcal{M}$, i.e.

$$\mathcal{M} \xleftarrow{\sim} \mathrm{Ind}_\pi(\mathcal{M}_\pi).$$

D'autre part, le foncteur d'inclusion $\underline{S} \hookrightarrow \mathcal{M}$ se déduit essentiellement de $\underline{S}_\pi \hookrightarrow \mathcal{M}_\pi$ en passant aux catégories Ind_π. ([116]).)

Commentary · Exposition [ms. 282]

Accessibility of a full subcategory is a relative assertion

Grothendieck now turns from functors to classes of objects specified by a property. His terminology "accessible in $\mathcal{M}$" includes three separate requirements: closure under isomorphism, accessibility of the full subcategory itself, and accessibility of its inclusion. In current language this is a replete, accessible, accessibly embedded full subcategory. Intrinsic accessibility alone does not control how its objects sit in the ambient category. This distinction will account for the extra bound needed in 4.13.2(c).

The equality of presentable objects on p. 282 is particularly useful. Let $i : \mathcal{S} \hookrightarrow \mathcal{M}$ be fully faithful and preserve λ-filtered colimits. If $s \in \mathcal{S}$ is λ-presentable in $\mathcal{M}$, then for every λ-filtered diagram D in $\mathcal{S}$,

$$\mathcal{S}(s, \varinjlim D) \cong \mathcal{M}(is, \varinjlim iD) \cong \varinjlim \mathcal{M}(is, iD) \cong \varinjlim \mathcal{S}(s, D).$$

Thus ambient presentability implies intrinsic presentability. The reverse implication requires the inclusion to preserve presentable objects as well as colimits. Uniformization supplies this after increasing the cardinal and bounding the ambient ranks of a small generating family. With those choices,

$$\mathcal{S}_\pi = \mathcal{S} \cap \mathcal{M}_\pi.$$

The missing subscript on the last $\mathcal{M}$ in the printed formula is therefore substantive notation, not a new description of S_π.

The subsequent correspondence between retract-closed subcategories of $\mathcal{M}_\pi$ and subcategories generated from them by π^+-filtered colimits follows from one familiar retract argument. If a π^+-presentable object s is a filtered colimit of objects a_i in the chosen small subcategory, its identity factors through some $a_i \to s$, so s is a retract of a_i. Conversely presentability is preserved by retracts. The natural closure in 4.13.3 is precisely the closure which makes this argument an equality of full subcategories. In 4.13.4 the printed words "non pleinement fidèle" contradict both 4.13.2 and this proof: the canonical functor under discussion is fully faithful.

Ceci prouve entre autres le "il faut" dans la proposition qui suit :

Proposition 4.13.2. *Soient $\mathcal{M}$ une catégorie accessible, π_0 un cardinal infini utile pour $\mathcal{M}$, S une partie de* $\mathrm{Ob}\,\mathcal{M}$, *$\underline{S}$ la sous-catégorie pleine de $\mathcal{M}$ correspondante.*

[page 284]

a) Pour que S soit accessible, il faut et il suffit qu'il existe un cardinal infini π et une partie $S(\pi)$ de $\mathcal{M}_\pi$, tels que S soit formé des objets de $\mathcal{M}$ qui sont isomorphes à un objet de la forme $\varinjlim_{i \in I} x_i$, avec les x_i dans $S(\pi)$ et I grande devant π. En d'autres termes, il faut et il suffit qu'il existe un cardinal infini π_1 et une sous-catégorie pleine $\underline{S}(\pi)$ de $\mathcal{M}_\pi$, tels que $\underline{S}$ soit l'image essentielle du foncteur canonique pleinement fidèle

$$\mathrm{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \mathcal{M} \qquad (\xleftarrow{\sim} \mathrm{Ind}_\pi(\mathcal{M}) \ ([117])), \tag{4.13.2.1}$$

prolongeant l'inclusion canonique $\underline{S}(\pi) \hookrightarrow \mathcal{M}$ (cf. 4.12.3).

p. 106

b) Si S est accessible, on peut trouver des cardinaux π_0', π_1' tels que $\pi_1' \geqslant \pi_0' \geqslant \pi_0$ (où π_0 est un cardinal donné utile pour $\mathcal{M}$) et tels que tout cardinal $\pi \geqslant \pi_1'$ avec $\pi^{\pi_0'} = \pi$ satisfasse aux conditions de c), en prenant $S(\pi) = S \cap \mathrm{Ob}\,\mathcal{M}_\pi$, i.e. $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$. Sous ces conditions, π est utile pour $\underline{S}$ et *pour $\mathcal{M}$, $S(\pi)$ est une sous-catégorie* strictement *pleine de $\mathcal{M}_\pi$, stable dans $\mathcal{M}_\pi$ par facteurs directs (ou ce qui revient au même, $\mathcal{M}_\pi$ étant karoubienne, une sous-catégorie karoubienne de $\mathcal{M}_\pi$).*

[page 285]

116. [Le contenu de cette parenthèse est] "facultatif".

117. si π utile pour $\mathcal{M}$.

c) On peut prendre π_0' le plus petit cardinal $\geqslant \pi_0$ utile pour $\underline{S}$ et tel que $\underline{S} \hookrightarrow \mathcal{M}$ soit π_0'-accessible, et $\pi_1' = \sup(\pi_0', \operatorname{card réd} \underline{S}_{\pi_0'})$.

La partie b) ainsi que c) a déjà été prouvée, ce qui implique le "il faut" dans la partie a). Il reste à prouver le "il suffit" dans a). Mais l'hypothèse implique que

$$\underline{S} \xleftarrow{\sim} \operatorname{Ind}_\pi(S_\pi),$$

ce qui implique que $\underline{S}$ est accessible et même π-accessible, et elle implique aussi que $\underline{S}$ est une sous-catégorie *strictement* pleine de $\mathcal{M}$. Il reste à voir

[que] le foncteur d'inclusion est accessible, en fait il est π-accessible, puisque (4.13.2.1) [page 286]
l'est (cf. 4.12.3).

Commentary · Development (commentators') [ms. 285]

The ambient rank cannot be omitted from the threshold

The purpose of 4.13.2(c) is to make the eventual comparison $\mathcal{S}_\pi = \mathcal{S} \cap \mathcal{M}_\pi$ effective. Its proposed threshold omits data which the preceding argument explicitly used. We give a small counterexample, so that the correction can be made without weakening the surrounding theory.

Counterexample to the threshold in 4.13.2(c). [ours] Let X be a set of cardinal greater than $2^{\aleph_0}$, let $\mathcal{M} = \mathcal{P}(X)$ ordered by inclusion, and let $\mathcal{S}$ be its full one-object subcategory $\{X\}$. Then $\mathcal{M}$ is $\aleph_0$-accessible in Grothendieck's convention, $\mathcal{S}$ is accessible at every infinite cardinal, and its inclusion preserves all nonempty filtered colimits. Nevertheless, for $\pi = 2^{\aleph_0}$, the sole object of $\mathcal{S}_\pi$ does not belong to $\mathcal{M}_\pi$.

Proof. Colimits in $\mathcal{P}(X)$ are unions. For every infinite ρ, a subset $Y \subseteq X$ is ρ^+-presentable precisely when $|Y| \leq \rho$. If this inequality holds and $Y \subseteq \bigcup_i Z_i$ for a ρ^+-directed family, select an index for each element of Y and then a common upper bound. This proves preservation of the relevant colimits by the representable, whose values are either empty or singleton. If $|Y| > \rho$, the diagram of its subsets of cardinal at most ρ is ρ^+-directed and has union Y, but none of its members contains Y. This proves the converse. Every subset is the union of its countable subsets, with an $\aleph_1$-directed indexing poset; hence $\mathcal{M}$ has the claimed accessibility. The corresponding assertions for the one-object category and its inclusion are immediate from constant diagrams. Finally $|X| > \pi$ gives the failure of ambient presentability. □

Here the cardinal prescribed in 4.13.2(c) is $\pi_0' = \aleph_0$ and $\sup(\pi_0', \operatorname{card}_{\mathrm{red}} \mathcal{S}_{\pi_0'}) = \aleph_0$, whereas $\pi^{\pi_0'} = \pi$. Thus its displayed numerical conditions hold and its proposed conclusion fails. The repair is to retain a cardinal θ such that

$$i(\mathcal{S}_{\pi_0'}) \subseteq \mathcal{M}_\theta$$

and to take π_1' at least θ, as well as the bounds already listed. To guarantee simultaneous usefulness for $\mathcal{M}$, also retain the ambient bound π_1 from p. 281. The existential assertion of 4.13.2(b) is unaffected.

This example is our explicit diagnostic of the printed estimate, not a claim of priority. We checked the uniformization discussion in Raptis (2020, §2.3), which explicitly separates preservation of filtered colimits from preservation of presentable objects, and the standard limits treatment in Positselski (2024); neither is being cited as a correction of this particular passage.

Définition 4.13.3. Soient $\mathcal{M}$, $S \subset \operatorname{Ob}\mathcal{M}$, $\underline{S} \subset \mathcal{M}$ comme dans 4.12.1, π un cardinal infini. On dit que S est une partie π-*accessible* de $\operatorname{Ob}\mathcal{M}$, ou que $\underline{S}$ est une sous-catégorie π-accessible dans $\mathcal{M}$, si S, π satisfont les conditions de 4.13.3 a), i.e. $\underline{S}$ est l'image essentielle de $\operatorname{Ind}_\pi(S(\pi))$, où $S(\pi)$ est une sous-catégorie pleine de $\mathcal{M}_\pi$.

Notons que, quitte à renforcer $S(\pi)$ par $S'(\pi) = \natural$-clôture de $S(\pi)$ dans $\mathcal{M}_\pi$, on peut supposer que $S(\pi)$ est une sous-catégorie *strictement pleine et karoubienne*

de $\mathcal{M}_\pi$. On sait alors que, $S(\pi)$ étant karoubienne, $S(\pi) \longrightarrow \underbrace{(\operatorname{Ind}_\pi(S(\pi)))}_{\pi}$ est une [page 287]

équivalence de catégories. Comme $\operatorname{Ind}_\pi(S(\pi)) \simeq \underline{S}$ et que $S(\pi)$ est strictement pleine dans $\mathcal{M}_\pi$, donc aussi dans $\mathcal{M}$ et a fortiori dans $\underline{S}$, que l'on a

(4.13.1) $\qquad \underline{S}(\pi) = \underline{S}_\pi, \qquad$ sous-catégorie de $\underline{S}$ des objets π-accessibles de S.

Je dis qu'on aura aussi

$$\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi. \tag{4.13.2}$$

Comme c est clair, il reste à voir que $\underline{S} \cap \mathcal{M}_\pi \subset \underline{S}(\pi)$, or il est immédiat que $\underline{S} \cap \mathcal{M}_\pi \subset S_\pi$, et on conclut par (4.13.1). On trouve ainsi :

Proposition 4.13.4. *Soit $\mathcal{M}$ une catégorie accessible, π un cardinal infini. Soit Σ_π l'ensemble des*

sous-catégories strictement pleines $\underline{S}(\pi)$ de $\mathcal{M}_\pi$ qui sont karoubiennes, ou ce qui revient au même, stables dans $\mathcal{M}_\pi$ par facteurs directs. Soit Σ'_π l'ensemble des sous-catégories de $\mathcal{M}$ qui sont π-accessibles dans $\mathcal{M}$. Considérons les applications [page 288] p. 107

$$\Sigma_\pi \underset{\beta_\pi}{\overset{\alpha_\pi}{\rightleftarrows}} \Sigma'_\pi \tag{4.13.4.1}$$

définies ainsi : Si $\underline{S}(\pi) \in \Sigma_\pi$, $\alpha_\pi(\underline{S}(\pi))$ est l'image essentielle du foncteur non pleinement fidèle $\mathrm{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \mathcal{M}$. Si $\underline{S} \in \Sigma'_\pi$, $\beta_\pi(\underline{S}) = \underline{S} \cap \mathcal{M}_\pi$. Les applications α_π, β_π sont des bijections, inverses l'une de l'autre.

On n'a pas eu à supposer que π soit utile pour $\mathcal{M}$, ni que π soit minoré par un cardinal utile pour $\mathcal{M}$, i.e. qu'on ait $\pi \geqslant \pi_0$, où π_0 est le plus petit cardinal utile pour $\mathcal{M}$.

4.13.5. Soit $\underline{S}$ une sous-catégorie *strictement pleine* de $\mathcal{M}$ (catégorie accessible), π'_0 un cardinal infini. Dire que $\underline{S}$ est π'_0-accessible dans $\mathcal{M}$ signifie que les conditions suivantes sont satisfaites. [page 289]

1) π'_0 est utile pour $\underline{S}$, i.e. $\underline{S} \xleftarrow{\sim} \mathrm{Ind}_{\pi'_0}(\underline{S}_{\pi'_0})$.
2) $\underline{S} \hookrightarrow \mathcal{M}$ est π'_0-accessible.
3) $\underline{S}_{\pi'_0} \hookrightarrow \mathcal{M}_{\pi'_0}$ (qui implique que $S_{\pi'_0}$ est équivalente à une petite catégorie).

Supposons ces conditions satisfaites, et soit π un cardinal $> \pi'_0$. Est-ce que $\underline{S}$ est π-accessible dans $\mathcal{M}$, i.e. les conditions similaires sont-elles satisfaites pour π ? C'est évident pour 2°), mais risque d'être faux pour 1°, 2° `[plutôt 3° ?]`. Mais faisons appel à 4.13.2 c). Posons

$$\pi'_1 = \sup(\pi'_0, \operatorname{card}\operatorname{réd} S_{\pi'_0}, \underbrace{\pi_0}_{\substack{\text{plus petit cardinal}\\ \text{infini utile}\\ \text{pour } \mathcal{M}}}).$$

Alors pour $\pi \geqslant \pi'_1$ tel que $\pi^{\pi'_0} = \pi$, $\underline{S}$ est π-accessible dans $\mathcal{M}$ (4.13.2 b et c). Supposons p.ex. [page 290]

$$\pi'_0 \geqslant \pi_0$$

(pratiquement ce sera toujours vérifié) et de plus

$$\pi'_0 \geqslant \operatorname{card}\operatorname{réd} \mathcal{M}_{\pi_0},$$

i.e. supposons

$$\pi'_0 \geqslant \sup(\pi_0, \operatorname{card}\operatorname{réd} \mathcal{M}_{\pi_0}) = \pi_1.$$

Alors

$$\pi'_1 = \sup(\pi'_0, \operatorname{card}\operatorname{réd} S_{\pi'_0}) \leqslant \sup(\pi'_0, \operatorname{card}\operatorname{réd} \mathcal{M}_{\pi'_0}) \leqslant 2^{(\pi'_0{}^{\pi_0})}$$

(4.7.7.1, p. 177). Donc on trouve ceci :

Corollaire 4.13.6. *Soit π'_0 un cardinal $\geqslant \pi_1 = \sup(\pi_0, \operatorname{card}\operatorname{réd} \mathcal{M}_{\pi_0})$ ([118]), et soit $\underline{S}$ une sous-catégorie π'_0-accessible dans $\mathcal{M}$. Alors pour tout cardinal π tel que $\pi \geqslant 2^{(\pi'_0{}^{\pi_0})}$, et tel que l'on ait $\pi^{\pi'_0} = \pi$ (i.e. π de la forme $c^{\pi'_0}$, avec c un cardinal $\geqslant 2^{(\pi'_0{}^{\pi_0})}$), $\underline{S}$ est π-accessible dans $\mathcal{M}$. (De plus, ces cardinaux sont réguliers pour $\underline{S}$ et pour $\mathcal{M}$, donc $\underline{S} \simeq \mathrm{Ind}_\pi(\underline{S}_\pi)$, $\mathcal{M} \simeq \mathrm{Ind}_\pi(\mathcal{M}_\pi)$).* p. 108 [page 291]

([119], [120]).

Proposition 4.13.7 ([121]). *Soient $\mathcal{M}$ une catégorie accessible, $(S_\alpha)_{\alpha\in A}$ une famille de parties de* $\mathrm{Ob}\,\mathcal{M}$, *indexée par un petit ensemble A, $(\underline{S}_\alpha)_{\alpha\in A}$ la famille des sous-catégories accessibles dans $\mathcal{M}$ correspondante. Soit $S=\bigcap_{\alpha\in A} S_\alpha$, $\underline{S}=\bigcap_{\alpha\in A}\underline{S}_\alpha$, de sorte que $\underline{S}$ est la sous-catégorie pleine de $\mathcal{M}$ définie par $S\subset \mathrm{Ob}\,\mathcal{M}$. Ceci posé, si les S_α sont accessibles, il en est de même de S – ou encore, si les $\underline{S}_\alpha$ sont accessibles dans $\mathcal{M}$, il en est de même de $\underline{S}$.*

Commentary · Later developments [ms. 290]

A homotopical use of accessible properties of arrows

The passage from accessible categories to accessible full subcategories is useful when the property under consideration belongs to a morphism. Regard a map as an object of the arrow category $\mathcal{M}^{[1]}$ and a commutative square as a morphism there. The phrase "the weak equivalences form an accessible subcategory" then has the same precise meaning as the relative accessibility discussed here: a suitable small family of weak equivalences presents every weak equivalence, and the inclusion preserves the specified filtered colimits.

A concrete later application is the treatment of weak equivalences in combinatorial model categories by Raptis and Rosický (2015, Section 2 and Proposition 2.2). After a functorial factorization, a map is a weak equivalence exactly when its fibration part is a trivial fibration. Their construction expresses the weak-equivalence category as a pseudopullback and obtains accessibility with an explicit enlarged rank. They then prove the sharper result that weak equivalences of simplicial sets form a finitely accessible category (Raptis and Rosický, 2015, Corollary 5.1). The finite conclusion is a further theorem, not a consequence of existence of some accessibility rank.

For the reader of these pages, the structural connection is the relevant one. A property is imposed by pulling back a suitable full subcategory along an accessible functor; several properties are imposed by intersection. The full subcategory retains its morphisms, so the resulting statement concerns coherent squares and their presentations, rather than only a set of admissible arrows. This is why bounds on the inclusion and on the images of presentable objects matter. It also explains why increasing the rank is a substantial part of the method: the homotopical construction may preserve filtered colimits long before it preserves the originally selected small objects. None of this identifies the ordinary cofinality arguments here with a theorem about homotopy colimits; their role is to provide the size control needed before those constructions are applied.

Cela résulte du résultat plus précis :

Corollaire 4.13.8 ([122]). *Avec les notations de 4.13.7 et 4.13.6, soit, pour tout $\alpha\in A$, π'_α un cardinal $\geqslant \pi_1$ tel que S_α soit π'_α-accessible. Soit*

$$\pi'_0=\sup_{\alpha\in A}\pi'_\alpha$$
$$\pi''_0=\sup(\operatorname{card} A,\sup_\alpha 2^{(\pi'^{\pi_0}_\alpha)})$$

et soit $\pi\geqslant\pi''_0$ un cardinal tel que $\pi^{\pi'_0}=\pi$, i.e. de la forme $c^{\pi'_0}$, avec $c\geqslant\pi'_0$. Alors S est π-accessible (i.e. $\underline{S}$ est π-accessible dans $\mathcal{M}$). En particulier, S est $2^{\pi''_0}$-accessible. ([123]).

Démonstration. Soit $\alpha\in A$. Comme $\pi'_\alpha\leqslant\pi'_0$ et $\pi^{\pi'_0}=\pi$, on a a fortiori [page 292]

$$\pi^{\pi'_\alpha}=\pi,\qquad \text{de plus } \pi\geqslant\pi''_0\geqslant 2^{(\pi^{\pi_0}_\alpha)},$$

donc en vertu de 4.13.6, $\underline{S}_\alpha$ est π-accessible dans $\mathcal{M}$. D'autre part, comme $\underline{S}_\alpha$ est π'_α-accessible, il est stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π'_α, a fortiori par $\varinjlim$ grandes devant π'_0 ($\geqslant\pi'_\alpha$). D'ailleurs, $\pi^{\pi'_0}=\pi$ implique $\pi\geqslant 2^{\pi_0}>\pi_0$. Donc 4.13.8 résulte du

118. **N.B.** π_0 est le plus petit cardinal utile pour $\mathcal{M}$.
119. Enchaîner ici avec 4.13.23 etc.
120. Mettre ici le lemme 4.16.7.11 signalé en marge p. 292.
121. Le rejeter après 4.13.23.
122. Cf. reformulation plus raisonnable et plus correcte page 302, 302 bis.
123. Ça a l'air un peu abracadabrant ! Il faut de plus supposer que π n'est pas cardinal limite !

Commentary · Later developments [ms. 291]

Intersections and the later theory of accessible subcategories

Grothendieck wants a class of admissible properties of objects which is closed under imposing several conditions at once. Proposition 4.13.7 supplies exactly that operation. Its force is that a small intersection still has a small generating family, although the generating families for its separate conditions need not intersect in a useful way at the initial cardinal. The proof therefore raises the cardinal first and then constructs approximations which satisfy all the conditions.

This is now a standard stability theorem. In the higher categorical setting, Lurie (2009, Definition 5.4.7.8 and Proposition 5.4.7.10) uses the same relative notion and proves closure under small intersections by a homotopy pullback involving the diagonal and a product of inclusions. The ordinary categorical counterpart belongs to the limit theory of accessible categories. A class-sized generalization, with the stronger embedding hypothesis needed there, is Chorny and Rosický (2012, Corollary 3.3). For explicit preservation ranks, Positselski (2024, Corollary 5.1 and Theorem 9.1) retains a smaller ordinal-colimit hypothesis while controlling the larger presentability rank.

These formulations illuminate the calculation which follows. The objects of $\mathcal{M}_\pi/x$ are small approximations equipped with a map to x. If x satisfies one of the properties, the approximations satisfying that property form a cofinal full subcategory. The problem is therefore to show that a small family of such cofinal subcategories has cofinal intersection. Cofinality alone does not suffice: in $\mathbb{N}$ the even and odd subsets are both cofinal and disjoint. Closure under a suitable family of colimits is the additional input which turns repeated approximation into simultaneous approximation.

Corollaire 4.13.9. *Soit $\pi > \pi_0$ un cardinal tel que $\underline{S}_\alpha$ soit π-accessible dans $\mathcal{M}$ pour tout $\alpha \in A$, et tel que* $\operatorname{card} A \leqslant \pi$. *Supposons de plus qu'il existe un cardinal π_0' tel que $\pi_0 \leqslant \pi_0' < \pi$, tel que les $\underline{S}_\alpha$ soient stables dans $\mathcal{M}$ par $\varinjlim$ grandes devant π_0'. Alors $\underline{S} = \bigcap_{\alpha\in A} \underline{S}_\alpha$ est π-accessible dans $\mathcal{M}$.*

([124]).

Posons, pour tout $\alpha \in A$,

$$\underline{S}_\alpha(\pi) \overset{\text{déf}}{=} \underline{S}_\alpha \cap \mathcal{M}_\pi$$
$$\underline{S}(\pi) \overset{\text{déf}}{=} \underline{S} \cap \mathcal{M}_\pi = \bigcap \underline{S}_\alpha(\pi).$$

Chaque $\underline{S}_\alpha(\pi)$ est stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π_0' et de cardinal $\leqslant \pi$ (puisqu'il en est ainsi de $\underline{S}_\alpha$ et de $\mathcal{M}_\pi$) (donc il en est de même de leur intersection

$\underline{S}(\pi)$. A fortiori, $\underline{S}(\pi)$ est une sous-catégorie strictement pleine et karoubienne de $\mathcal{M}_\pi$.) [page 293]

D'autre part, chaque $\underline{S}_\alpha$ étant stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π_0', il en est de même p. 109
de leur intersection $\underline{S}$. A fortiori, celle-ci est stable par $\varinjlim$ grandes devant π, donc le foncteur pleinement fidèle canonique $\operatorname{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \mathcal{M}$ se factorise par S en

$$\operatorname{Ind}_\pi \underline{S}(\pi) \hookrightarrow \underline{S}\ ,$$

il faut prouver que ce foncteur est essentiellement surjectif. Soit donc $x \in S = \operatorname{Ob} \underline{S}$, tout revient à prouver que

$$(*) \qquad \varinjlim_{i\in \underline{S}(\pi)/x} x_i \xrightarrow{\sim} x\ ,$$

et que $\underline{S}(\pi)/x$ est grande devant π.

Notons que, comme $\pi_0' \geqslant \pi_0$, et $\pi^{\pi_0'} = \pi$, on aura $\pi^{\pi_0} = \pi$, donc π est cardinal utile pour $\mathcal{M}$, donc $I = \mathcal{M}_\pi/x$ est grande devant x, et on a

$$(**) \qquad \varinjlim_{i\in I=\mathcal{M}_\pi/x} x_i \xrightarrow{\sim} x\ .$$

Donc, si on admet que $\underline{S}(\pi)/x$ est grande devant π, le fait que $(*)$ soit un isomorphisme

124. Ce serait le moment de formuler ici le Lemme 4.16.7.11 (p. 488), qui devrait même remonter avec les premières généralités sur les parties π-accessibles dès avant 4.13.7 (immédiat après 4.13.6). [page 294]

équivaut à dire que le foncteur canonique

$$J \overset{\text{déf}}{=} \underline{S}(\pi)/x \longrightarrow \mathcal{M}_\pi \;=\; I$$

est *cofinal* (cf. 4.4.2, p. 79). Mais on voit tout de suite que ce foncteur est un foncteur d'inclusion d'une sous-catégorie strictement pleine (stable par $\varinjlim$ grandes devant π_0', de cardinal $\leqslant \pi$).

Notons maintenant que la flèche $(**)$ similaire à $(*)$, avec $\underline{S}(\pi)$ remplacée par $\underline{S}_\alpha(\pi)$, est bel et bien un isomorphisme, puisque $x \in \operatorname{Ob} \underline{S} \subset \operatorname{Ob} \underline{S}_\alpha$, et que $\underline{S}_\alpha$ est π-accessible. Cela s'interprète par le fait que le foncteur d'inclusion

$$J_\alpha \overset{\text{déf}}{=} \underline{S}_\alpha(\pi)/x \longrightarrow \mathcal{M}_\pi/x \;=\; I$$

est cofinal. C'est encore une inclusion d'une sous-catégorie J_α strictement pleine de I, stable par $\varinjlim$ grandes devant π_0' et de cardinal $\leqslant \pi$, et on a

$$J \;=\; \bigcap J_\alpha \,.$$

Donc la condition voulue résultera du

Lemme 4.13.10 ([125], [126]). *Soient π_0' et $\pi > \pi_0'$ des cardinaux infinis, I une catégorie équivalente à une petite catégorie, $(J_\alpha)_{\alpha\in A}$ une famille de sous-catégories J_α de I. On suppose :* [page 295]

ⓐ *I est grande devant π ([127]).*

ⓑ *I est stable par $\varinjlim$ de cardinal $\leqslant \pi$, et grandes devant π_0' ([128]).*

ⓒ *$\forall\, r \in A$, J_r est stable dans I par les limites inductives envisagés dans b) (en particulier, J_r est une sous-catégorie* strictement pleine *de I).* p. 110

ⓓ *$\forall\, r \in A$, J_r est une sous-catégorie* cofinale *de I (*grande devant π*).*

ⓔ $\operatorname{card} A \leqslant \pi$.

Soit $J = \bigcap_{r\in A} J_r$. Alors J est encore cofinale dans I, et grande devant π (et de plus stable dans I par $\varinjlim$ de cardinal $\leqslant \pi$ et grandes devant π_0').

En d'autres termes, si I est grande devant π, l'intersection J d'une famille $(J_\alpha)_{\alpha\in A}$ de sous-catégories strictement pleines cofinales et grandes devant π, est encore cofinale et grande devant π, *pourvu que* $\operatorname{card} A \leqslant \pi$, et que l'on postule une propriété de stabilité de I et des J_α dans I, pour les limites inductives de cardinal $\leqslant \pi$ et grandes devant un cardinal convenable $\pi_0' < \pi$ donné. [page 296]

4.13.10.1. Notons d'ailleurs que si $f : J \longrightarrow I$ est un foncteur cofinal *pleinement fidèle*, avec I grande devant π, alors J est automatiquement grande devant π. Cela résulte p.ex. de 4.9.6.3 2° (p. 225) par le critère c_π (vu que pour f pleinement fidèle, la condition F 3_π est tautologiquement satisfaite). On peut aussi le voir ainsi : Soit B un ensemble avec $\operatorname{card} B \leqslant \pi$, il faut prouver que $J \longrightarrow J^B$ est cofinal, or on a

$$\begin{array}{ccc} J & \xrightarrow{\text{cof. ?}} & J^B \\ {\scriptstyle\text{cof.}}\downarrow & & \downarrow{\scriptstyle\text{cof.}} \\ I & \xrightarrow{\text{cof.}} & I^B \,, \end{array}$$

où trois des quatre flèches du carré sont cofinales, $J^B \longrightarrow I^B$ l'étant comme produit de foncteurs cofinaux entre catégories *filtrantes* (cf. 4.9.6.5, page 227) – on sait en effet déjà que J est filtrante.

125. Il faut supposer que π ne soit pas un cardinal limite, pour pouvoir conclure que I est stable par $\varinjlim$ de type I_{α_π}, et les J_r stables dans I par ces limites.

126. Cf. forme plus générale du lemme dans 4.13.10.2, p. 302. [page 297]

127. Il suffit que I soit grande devant tout $\pi' < \pi$.

128. Il suffit ici la stabilité par $\varinjlim$ de type I_{α_π}, cf. page 302 [?].

Donc le composé

$$J \longrightarrow J^B \xrightarrow{\text{cof.}} I^B$$

est cofinal. Mais comme le deuxième foncteur $J^B \longrightarrow I^B$ est pleinement fidèle, il s'ensuit aussitôt que $J \longrightarrow J^B$ est cofinal (car $\xi\backslash J$ pour $\xi \in \mathrm{Ob}\, J^B$ est le même, à isomorphisme près, qu'on considère ξ comme objet de J^B, ou de I^B).

Ainsi dans l'énoncé de la condition d) du lemme, il est inutile de spécifier que J_α est grande devant π, et de même dans la conclusion sur J.

Comme $J \hookrightarrow I$ est pleinement fidèle, pour voir que ce foncteur est cofinal, il suffit de voir qu'il satisfait F 1, i.e. que pour tout $i \in \mathrm{Ob}\, I$, existe $j \in J$ avec $i \longrightarrow j$. On va construire j comme limite d'un système inductif ordinal d'objets i_α de I, indexé par les ordinaux α tels que $\mathrm{card}\,\alpha < \pi$. Désignons par α_π le plus petite ordinal tel que $\mathrm{card}\,\alpha_\pi = \pi$. L'ensemble p. 111 ordonné I_{α_π} des ordinaux $\alpha < \alpha_\pi$ étant grande devant π'_0 ([129]) et de cardinal π, on pourra [page 298] donc prendre la limite $\varinjlim_{\alpha \in I_{\alpha_0}} i_\alpha$ dans I.

Construction de $(i_\alpha)_{\alpha \in I_{\alpha_0}}$. Soit

$$\alpha_\pi \;=\; \text{plus petit ordinal } \alpha \text{ tel que } \mathrm{card}\,\alpha = \pi, \tag{1}$$

donc c'est l'ordinal caractérisé par

$$\begin{cases} \mathrm{card}\,\alpha_\pi \;=\; \pi \\ \alpha < \alpha_\pi \;\Longrightarrow\; \mathrm{card}\,\alpha \;<\; \pi\ , \end{cases} \tag{2}$$

ou encore par le fait que l'ensemble ordonné I_{α_π} des ordinaux $\alpha < \alpha_\pi$ est *parfaitement bien ordonné*. Ainsi, I_{α_π} *est grande devant* π' *pour tout cardinal* $\pi' < \pi$ ([130]). Dans les conditions b) c) de 4.3.10, il suffira de supposer I stable par $\varinjlim$ de type I_{α_π}, et les J_r ($r \in A$) stables dans I par ce type de limites.

Lemme 4.13.10.1. *Soit π un cardinal infini, A un ensemble non vide tel que* $\mathrm{card}\,A \leqslant \pi$. *Alors il existe une application* [page 299]

$$\varphi \;:\; I_{\alpha_\pi} \longrightarrow A$$

telle que pour tout $r \in A$, $\varphi^{-1}(\{r\})$ soit une partie cofinale de I_{α_π}, ou ce que est plus précis, $\mathrm{card}\,\varphi^{-1}(\{r\}) = \pi$.

Commentary · Exposition [ms. 298]

The ordinal calculation needs cofinality, not cardinality alone

Grothendieck chooses an ordinal long enough to revisit every condition, and then takes its colimit. Two distinct size arguments enter this construction. An ordinal β below the initial ordinal of cardinal π has cardinal less than π, so filteredness supplies a cocone at that stage. By contrast, the whole initial ordinal π is large before ρ precisely when

$$\mathrm{cf}(\pi) > \rho.$$

Indeed a subset of size at most ρ has an upper bound exactly when it is not cofinal. The statement on p. 298 that the ordinal is large before every cardinal below π is therefore equivalent to regularity of π. For $\pi = \aleph_\omega$, the countable sequence of initial ordinals $\aleph_n$ is a counterexample. The marginal warning is justified, but "limit cardinal" is too broad: a regular limit cardinal would cause no such failure.

There is a useful qualification for 4.13.8. Its equation $\pi^\rho = \pi$ already forces $\mathrm{cf}(\pi) > \rho$. To see this directly, suppose $\delta = \mathrm{cf}(\pi) \leq \rho$ and enumerate all maps $\delta \to \pi$ by indices below π. Partition those indices into δ sets E_ξ, each of cardinal less than π. At coordinate ξ, choose a value different from the values of all maps indexed by E_ξ. The resulting map differs from every map in the enumeration,

129. faux si π est un cardinal limite.

130. Faux si π est cardinal limite.

a contradiction. Thus the particular filtration needed in 4.13.8 follows from its fixed-point equation; the extra successor-cardinal requirement in footnote 123 is unnecessary there.

The ordinal lemma restated in 4.13.10.2 has an independent valid proof under its explicitly stated chain-colimit hypothesis. Partition the initial ordinal π into at most π subsets, each of cardinal π, and assign one part to each J_r. Every such part is cofinal and, with its induced order, has order type π. Recursively choose a compatible chain which, at the assigned stages, belongs to the corresponding J_r; at a limit stage take a cocone, then extend into the required cofinal subcategory. Start by extending the prescribed object into the first assigned subcategory, rather than requiring an arbitrary $i_0 = i$ already to belong to it. The final colimit is the colimit of its restriction to each assigned part, hence belongs to every J_r. This proves cofinality. If I is only large before every cardinal below π, the full subcategory inherits precisely those filtration bounds; inheritance of the stronger bound π requires that bound for I itself.

En effet, il suffit de considérer un ensemble A' de cardinal π (p.ex. $A' = I_{\alpha_\pi}$), l'application

$$\psi \;=\; \mathrm{pr}_1 \;:\; A \times A' \longrightarrow A\;,$$

et de se donner une bijection

$$A \times A' \xrightarrow{\sim} I_{\alpha_\pi}$$

laquelle existe puisque

$$\mathrm{card}\,(A \times A') \;=\; \mathrm{card}\,A \cdot \mathrm{card}\,A' \;=\; \mathrm{card}\,A' \;=\; \pi \;=\; \mathrm{card}\,I_{\alpha_\pi}\;,$$

puisque $0 \neq \mathrm{card}\,A \leqslant \mathrm{card}\,A' = \pi$ et π infini. On suppose choisie φ comme dans 4.13.10.1, et on construira le système inductif $(i_\alpha)_{\alpha \in I_{\alpha_\pi}}$ de telle façon qu'on ait

$$i_\alpha \;\in\; J_{\varphi(\alpha)}\;.$$

Posant

$$j \;=\; \varinjlim_{\alpha \in I_{\alpha_\pi}} i_\alpha\;,$$

pour tout r, comme p. 112 [page 300]

$$I_r \overset{\text{déf}}{=} \varphi^{-1}(r) \;\subset\; I_{\alpha_\pi}$$

est cofinal dans I_{α_π}, on aura donc

$$j \;=\; \varinjlim_{\alpha \in I_r} i_\alpha\;,$$

et en vertu de $(*)$, les i_α pour $\alpha \in I_r$ sont dans J_r, donc par passage à la limite, utilisant l'hypothèse c), on trouve que $j \in J_r$, donc

$$j \;\in\; \bigcap_{r \in A} J_r \;=\; J\;,$$

et comme on choisira

$$(**) \qquad i_0 \;=\; i\;,$$

on aura bien trouvé $i \longrightarrow j$ avec $i \in J$. Donc il suffit de construire le système inductif (i_α) satisfaisant $(*)$ et $(**)$.

Si le système inductif est construit jusqu'au cran $i_\alpha \in \mathrm{Ob}\,J_{\varphi(\alpha)}$, on continue par

$$i_\alpha \longrightarrow i_{\alpha+1} \;\in\; \mathrm{Ob}\,J_{\varphi(\alpha+1)}\;,$$

ce qui est possible puisque $J_{\varphi(\alpha+1)}$ est cofinale. Donc il reste à construire i_α pour α ordinal limite. Or l'ensemble des i_β pour $\beta < \alpha$ est de cardinal $< \pi$, et comme par a) I est grande [page 301]

devant π (il suffit qu'il le soit devant tout cardinal $< \pi$), il existe un $i \in \mathrm{Ob}\, I$ qui majore tous les i_β. Choisissons des

$$i_\beta \xrightarrow{v_\beta} i\ .$$

On n'aura pas a priori commutativité dans

$$i_{\beta'} \xrightarrow{\tau_{\beta,\beta'}} i_\beta \underset{v_{\beta'}}{\overset{v_\beta}{\rightrightarrows}} i\ ,$$

mais comme l'ensemble des double-flèches $i_{\beta'} \underset{v_{\beta'}}{\overset{v_\beta\tau_{\beta,\beta'}}{\rightrightarrows}} i$ est de cardinal $< \pi$, I étant grande devant π, il existe $i \longrightarrow i'$ qui les égalise tous. Comme $J_{\varphi(\alpha)}$ est cofinal dans I, il existe $i'' \in J_{\varphi(\alpha)}$, et $i \longrightarrow i''$. On prend $i_\alpha = i''$, avec les homomorphismes composés

$$i_\beta \xrightarrow{v_\beta} i \longrightarrow i' \longrightarrow i''$$
$$\tau_{\alpha,\beta}$$

comme morphismes de transition. Cela achève la démonstration de 4.13.10 et par là de 4.13.9, 4.13.8. p. 113 [page 302]

Remarque 4.13.10.2. Voici ce qu'on a eu à utiliser vraiment, pour établir la conclusion de 4.13.10, en termes de I, π, $(J_r)_{r\in A}$ (et sans introduire de π'_0).

(a′) I est grande devant tout cardinal $\pi' < \pi$.

(b′) I est stable par $\varinjlim$ de type I_{α_π}.

(c′) $\forall\, r \in A$, J_r est stable dans I par les $\varinjlim$ de type I_{α_π}.

(d′) $\forall\, r \in A$, J_r est cofinale dans I.

(e′) $\mathrm{card}\, A \leqslant \pi$.

(**N.B.** d′) et e′) ne sont autres que d) et e) de 4.3.10, tandis que a′), b′), c′) sont des versions affaiblies de a), b), c) respectivement.)

Commentary · Development (commentators') [ms. 302]

Simultaneous refinement removes the regularity restriction

The intersection argument can be arranged so that the number of conditions and the length of the construction play separate roles. This gives the conclusion of 4.13.10 for the hypotheses in its main text, without imposing the extra cofinality restriction introduced in its footnotes.

Simultaneous cofinal intersection lemma. [ours] Let $\rho < \pi$ be infinite cardinals. Suppose I is π^+-filtered and admits all ρ^+-filtered colimits indexed by categories with at most π arrows. Let $(J_r)_{r\in A}$, where $|A| \le \pi$, be replete full cofinal subcategories closed under these colimits in I. Then $\bigcap_r J_r$ is cofinal in I, is π^+-filtered, and is closed under the same colimits.

Proof. The empty family is immediate. Put $\kappa = \rho^+$, a regular cardinal with $\kappa \le \pi$, and fix $x_0 \in I$. Construct a chain $(x_\beta)_{\beta<\kappa}$. After choosing x_β, choose, for every r, an arrow

$$a_{\beta r} : x_\beta \longrightarrow y_{\beta r}, \qquad y_{\beta r} \in J_r.$$

The star consisting of these arrows has at most π arrows. Filteredness therefore supplies a cocone with vertex $x_{\beta+1}$ and arrows $b_{\beta r} : y_{\beta r} \to x_{\beta+1}$ satisfying

$$b_{\beta r} a_{\beta r} = t_{\beta+1,\beta} \quad \text{for every } r.$$

At a limit $\gamma < \kappa$, choose a cocone on the entire already constructed x-chain; its size is less than $\kappa \le \pi$. The resulting transition arrows $t_{\gamma\beta}$ are compatible by construction. No intermediate colimit is required.

For a fixed r define, when $\beta < \gamma$,

$$y_{\beta r} \xrightarrow{b_{\beta r}} x_{\beta+1} \xrightarrow{t_{\gamma,\beta+1}} x_\gamma \xrightarrow{a_{\gamma r}} y_{\gamma r}.$$

These maps compose correctly: the equality $b_{\gamma r}a_{\gamma r} = t_{\gamma+1,\gamma}$ reduces composition to the transition identity for the x-chain. The maps a and b consequently give mutually inverse maps between the colimits of the two chains; their composites are the maps induced by a shift of the indexing ordinal, hence the identities on those colimits. The ordinal κ is ρ^+-filtered and has at most π arrows. Thus $x = \varinjlim_{\beta<\kappa} x_\beta$ exists, and closure of J_r shows that the isomorphic colimit of the $y_{\beta r}$ lies in J_r. Repleteness gives $x \in J_r$ for every r. The map $x_0 \to x$ proves the first cofinality condition.

For completeness, a full subcategory of a filtered category which receives a map from every ambient object is cofinal: any two objects in a comma category have a common successor by taking a cocone in the ambient category and then extending into the subcategory; parallel arrows are equalized in the same way. The same argument for diagrams with at most π arrows shows that the intersection is π^+-filtered. Closure under the specified colimits is inherited from each J_r. □

Applied to $I = \mathcal{M}_\pi/x$, this also repairs 4.13.9 without its unstated fixed-point equation, for a nonempty family. Choose one r: since $x \in \mathcal{S}_r$ and $\mathcal{S}_r$ is π-accessible in $\mathcal{M}$, a π^+-filtered presentation of x inside $\mathcal{S}_r$ uses objects presentable in $\mathcal{M}$. Factoring any at-most-π diagram of maps from presentable objects through a common stage shows directly that $\mathcal{M}_\pi/x$ is π^+-filtered and presents x. Global usefulness of π for $\mathcal{M}$ is therefore unnecessary for these particular slices. For an empty family the fixed-rank assertion requires π useful for $\mathcal{M}$, since the intersection is then $\mathcal{M}$ itself.

We checked the intersection and pseudopullback formulations in Lurie (2009); Chorny and Rosický (2012); Positselski (2024); we did not find this exact simultaneous-star repair of the printed ordinal argument there. The lemma is recorded as an explicit completion of Grothendieck's method, without a priority claim. It uses the full π^+-filteredness of I for the stars. The weaker hypothesis suggested in footnote 127 does not support this proof when $|A| = \pi$.

4.13.8 (reformulation). *Soit pour $r \in A$, $\pi''_r \geqslant \pi'_r \geqslant \pi_0$ (= cardinal utile pour $\mathcal{M}$ donné) comme spécifié dans 4.13.2 b) (et c), soit $\pi' = \sup_{r\in A} \pi'_r$, $\pi'' = \sup_{r\in A} \pi''_r$, de sorte que pour tout cardinal π avec $\pi^{\pi'_0} = \pi \geqslant \pi''$, $\underline{S}_r$ soit π-accessible dans $\mathcal{M}$ (et π utile pour $\underline{S}_r$* et *pour $\mathcal{M}$). Soit c un cardinal* non limite *tel que $c \geqslant \operatorname{card} A$ et $c > \pi'$ (p.ex. le successeur de* $\sup(\operatorname{card} A, \pi')$*). Prenons π tel que*

$$\pi^{\pi'} \;=\; \pi \;\geqslant\; \sup(\pi'', c)\ .$$

Alors $\underline{S} = \bigcap_{r\in A} \underline{S}_r$ est π-accessible.

En effet, si α_c est le premier ordinal de cardinal c, comme c n'est pas limite, I_{α_c} est grande devant tout cardinal $c' < c$, en particulier devant π'. Or pour tout $x \in \operatorname{Ob}\mathcal{M}$, $I = \mathcal{M}_\pi/x$ et les $J_r = \underline{S}_r/x$ sont stables par $\varinjlim$ grandes devant π' et de cardinal $\leqslant \pi$, et les J_r stables dans I pour ces limites, donc il en est en particulier ainsi pour les $\varinjlim$ de type I_{α_c}. On peut donc appliquer le résultat 4.13.10.2 pour conclure que si les J_r sont cofinaux dans I (qui est grande devant π, π étant utile pour $\mathcal{M}$), alors $J = \underline{S}/x$ l'est également. Cela implique alors, comme on a vu, que $\underline{S}$ est π-accessible dans $\mathcal{M}$. [page 302 bis]

4.13.10.3. On peut reformuler la reformulation précédente, en utilisant la terminologie introduite plus bas (4.13.23) :

Soit c un cardinal, α_c le plus petit ordinal α tel que $\operatorname{card}\alpha = c$, *$\pi$ un cardinal $\geqslant c$. On suppose*

(∗) *π est utile pour $\mathcal{M}$, et $\mathcal{M}$ est stable par $\varinjlim$ de type I_{α_c}. (Cette deuxième condition est le cas p.ex. si c est* non limite *et $c > \pi_0$, π_0 étant un cardinal tel que $\mathcal{M}$ satisfait 2_{π_0}, p.ex. un cardinal* utile *pour $\mathcal{M}$ ([131])).*

Alors l'ensemble des sous-catégories $\underline{S}$ de $\mathcal{M}$ qui sont α_c-π-accessible dans $\mathcal{M}$ (i.e. qui sont π-accessibles et stables dans $\mathcal{M}$ par $\varinjlim$ de type I_{α_c}) est stable par intersection de cardinal $\leqslant c$. Plus généralement, si Φ est un ensemble de catégories telles que

131. Car alors I_{α_c} est grande devant π_0.

1°) $I \in \Phi \Longrightarrow \operatorname{card} I \leqslant \pi$ *et*

2°) $I_{\alpha_c} \in \Phi$,

alors l'ensemble des sous-catégories de $\mathcal{M}$ *qui sont* Φ-π*-accessibles dans* $\mathcal{M}$*, est stable par intersection de cardinal* $\leqslant c$.

Définition 4.13.11 ([132]). Soient $\mathcal{M}$ une catégorie accessible, π_0 un cardinal utile pour $\mathcal{M}$, $\pi > \pi_0$ un cardinal. Une catégorie I est dite π_0-π-*adaptée* si p. 114 [page 303]

a) I est équivalente à une petite catégorie,

b) I est grande devant π, et

c) I est stable par $\varinjlim$ de cardinal $\leqslant \pi$, et grandes devant π_0 ([133]).

Un système inductif $(x_i)_{i\in I}$ de type I dans $\mathcal{M}$ est dit π_0-π-*adapté*, si I est π_0-π-adaptée, i.e. satisfait les conditions a) b) c), et si de plus on a

d) le foncteur $i \longmapsto x_i : I \longrightarrow \mathcal{M}$ commute aux $\varinjlim$ (grandes devant π_0 et de cardinal $\leqslant \pi$) envisagées dans c), et

e) les x_i sont dans $\mathcal{M}_\pi$.

Proposition 4.13.12. *Soient* $\mathcal{M}$ *une catégorie* π_0*-accessible, et* $\pi > \pi_0$ *un cardinal utile pour* $\mathcal{M}$*. Alors tout* $x \in \operatorname{Ob}\mathcal{M}$ *admet une représentation comme* $x \xleftarrow{\sim} \varinjlim_{j\in J} x_j$*, où le système inductif* $(x_j)_{j\in J}$ *dans* $\mathcal{M}$ *est* π_0*-*π*-adapté. De façon précise, on peut prendre* $J = \mathcal{M}_\pi/x$.

En effet, la vérification des propriétés a) à d) pour le système inductif canonique, de $\varinjlim$ isomorphe à x, est immédiate. [page 304]

La proposition précédente ne dit pas si on peut prendre pour J un ensemble ordonné. Dans ce cas, la condition c) signifie que pour toute partie J' de J grande devant π_0 et de cardinal $\leqslant \pi$, J admet une borne supérieure i_J dans J, et la condition d) que l'on a alors $x_{i_J} \xleftarrow{\sim} \varinjlim_{i\in J'} x_i$.

L'idée naturelle, pour construire un système inductif π_0-π-adapté $(x_j)_{j\in J}$, avec J ordonnée, en partant de celui qu'on a canoniquement, avec $J = \mathcal{M}_\pi/x$, est de prendre pour I l'ensemble, ordonné par inclusion, des sous-catégories J' de J_0 (sous-catégorie pleine petite de J équivalente à J) qui sont de cardinal $\leqslant \pi$ et grandes devant π_0. (Comparer (4.7.3.3), page 165). Cet ensemble ordonné est bel et bien (petit et) *grand devant* π, si on suppose que $\pi^{\pi_0} = \pi$ (cf. démonstration 4.7.5, p. 168-171).

Lemme 4.13.13. *Soient* π_0*,* $\pi > \pi_0$ *des cardinaux infinis tels que* $\pi^{\pi_0} = \pi$*, et* J *une petite catégorie, grande devant* π*. Soit* I *l'ensemble des sous-catégories* J' *de* J *qui sont grandes devant* π_0*, et de cardinal* $\leqslant \pi$*. Alors* I *est* π_0*-*π*-adaptée.* [page 305]

Il reste à voir que pour tout ensemble ordonné A grand devant π_0 et de cardinal $\leqslant \pi$, si $r \longmapsto J_r$ est une famille croissante d'éléments de I indexée par A, alors

$$J \overset{\text{déf}}{=} \bigcup_{r\in A} J_r \;=\; \varinjlim_{r\in A} J_r$$

est dans I, i.e. est une sous-catégorie de I de cardinal $\leqslant \pi$ (ce qui est clair) et *grande devant* π_0. Cela va résulter du

Lemme 4.13.13.1. *Soit* $(J_r)_{r\in A}$ *un système inductif de catégories grandes devant* π_0*, indexé par un ensemble ordonné* A *grand devant* π_0*. Alors* $J = \varinjlim_{r\in A} J_r$ *est grande devant* π_0. p. 115

Il faut voir que si B est un ensemble de cardinal $\leqslant \pi_0$, alors le foncteur diagonal [page 306]

$$(*) \qquad \delta \;:\; J \longrightarrow J^B$$

132. Refondre avec 4.13.23 etc.

133. **N.B.** Si $\pi = \pi_0$, la condition c) équivaut à dire que I est stable par facteurs directs.

est cofinal. Or comme A est grande devant π_0, $\operatorname{card} B \leqslant \pi_0$, les produits indexés par B commutent aux $\varinjlim$ de type A (SGA 4 I 9.8 appliqué à Cat et à π_0). Donc la flèche $(*)$ s'interprète comme limite inductive des flèches similaires

$$(**) \qquad \delta_r \ : \ J_r \longrightarrow J_r^B \ ,$$

lesquelles sont cofinales, donc δ est cofinal comme limite inductive de foncteurs cofinaux.

Commentary · Exposition [ms. 305]

Replacing a presentation by a continuous poset of presentations

The adapted presentations are designed to retain more than a filtered colimit expression. They remember colimits of smaller filtered diagrams inside the indexing category, and require the diagram itself to preserve those colimits. This continuity is what will allow a property of x to be detected in any sufficiently well-behaved presentation of x.

For the canonical presentation $\mathcal{M}_\pi/x \to \mathcal{M}$, the verification is concrete. A diagram with at most π arrows has a colimit in $\mathcal{M}$ when it is large before π_0. Its colimit carries the induced map to x. Moreover it remains π^+-presentable: its representable functor is an at-most-π limit of representables, and those limits of sets commute with π^+-filtered colimits. Thus the colimit is still an object of $\mathcal{M}_\pi/x$ and is computed there as claimed.

To replace this indexing category by a poset, one must close small sets of arrows under enough cocone choices. Here is the size argument behind 4.13.13. Start with at most π arrows of a small π^+-filtered category J, adjoin identities and composites, and, for every diagram of size at most π_0 in the resulting subcategory, adjoin a chosen cocone in J. There are at most $\pi^{\pi_0} = \pi$ such diagrams. Repeat the operation along π_0^+ stages, which is permissible because $\pi_0^+ \leq \pi$. The union still has at most π arrows. Every diagram of size at most π_0 in the union occurs at one stage, since π_0^+ is regular, so a subsequent stage contains its cocone. This gives a subcategory large before π_0.

Applying the construction to the union of at most π prescribed subcategories proves that the poset I in 4.13.13 is large before π. Its smaller directed suprema are literal unions. If A is π_0^+-directed, $|A| \leq \pi$, and $J_r \subseteq J_s$ for $r \leq s$, then $\bigcup_r J_r$ has at most π arrows. A diagram of size at most π_0 in this union is contained in one J_r, where it has a cocone. The union is therefore again an object of I.

This also proves 4.13.13.1 without relying on an unstated stability theorem for final functors. For general transition functors, rather than inclusions, lift the objects and arrows of a small diagram in $\varinjlim_r J_r$ to a common stage. There are at most π_0 composition and identity equations to impose, so a further common stage realizes them all. Take a cocone there. Hence the filtered colimit category is again π_0^+-filtered.

Finally the transition maps between $x_{J'} = \varinjlim_{j \in J'} x_j$ are induced by inclusions of subcategories. For a directed union $J' = \bigcup_r J_r$, a cocone on $x|_{J'}$ is exactly a compatible family of cocones on the restrictions $x|_{J_r}$. This proves

$$\varinjlim_r x_{J_r} \cong x_{\bigcup_r J_r}$$

by the universal property, and gives the continuity asserted in 4.13.13.2. Every object and arrow of J is contained in one of these subcategories; the same cocone argument gives $\varinjlim_{J' \in I} x_{J'} \cong \varinjlim_{j \in J} x_j$. This is the precise reason the replacement preserves the object being presented.

Lemme 4.13.13.2. *Sous les hypothèses de 4.13.13, soient $\mathcal{M}$ une catégorie satisfaisant L_{π_0}, et $(x_j)_{j \in J}$ (où $J \longrightarrow \mathcal{M}$) un système inductif dans $\mathcal{M}$, indexé par J. Pour toute $J' \in I$, posons*

$$x_{J'} \ = \ \varinjlim_{j \in J'} x_j$$

(qui existe dans $\mathcal{M}$, puisque $\mathcal{M}$ satisfait à L_{π_0}). Alors les $(x_{J'})_{J' \in I}$ forment un système inductif dans $\mathcal{M}$, et $I \longrightarrow \mathcal{M}$ commute aux limites inductives grandes devant π_0 et de cardinal $\leqslant \pi$. Si $\mathcal{M}$ est π_0-accessible, et les x_j ($j \in \operatorname{Ob} J$) sont dans $\mathcal{M}_\pi$, alors $(x_{J'})_{J' \in I}$ est un système inductif π_0-π-adapté dans $\mathcal{M}$. [page 307]

Tout ceci est essentiellement trivial, et donne :

Corollaire 4.13.14 (de 4.13.12). *Sous les conditions de 4.13.12, si $\pi^{\pi_0} = \pi$, on peut pour tout $x \in \mathrm{Ob}\,\mathcal{M}$ trouver une représentation $x \simeq \varinjlim_{i\in I} x_i$, où $(x_i)_{i\in I}$ est un système inductif π_0-π-adapté avec I* ensemble ordonné. *De plus, si $\pi' > \pi$ et si $x \in \mathcal{M}_{\pi'}$, on peut prendre I tel qu'on ait*

$$\mathrm{card}\, I \ \leqslant\ \pi'^{\pi}\ .$$

Ce dernier complément est immédiat, via les majorations habituelles. [page 308]

Commentary · Examples [ms. 307]

Adapted systems in a powerset category

The ordered version becomes especially transparent in a powerset category. Let $\mathcal{M} = \mathcal{P}(X)$ and let $Y \subseteq X$. For any infinite π, take

$$I = [Y]^{\leq \pi}, \qquad D(T) = T.$$

The poset I is π^+-directed and its colimit is Y. A directed family of at most π members has supremum their union, again of cardinal at most π, and D preserves that supremum. Every value T is π^+-presentable. Thus this is an adapted presentation, with no cardinal exponent calculation needed in this example.

Fix $Z \subseteq X$ with $|Z| \leq \pi$ and let $\mathcal{S}$ consist of the subsets containing Z. Then

$$I_{\mathcal{S}} = \{T \subseteq Y : |T| \leq \pi,\ Z \subseteq T\}$$

is cofinal in I exactly when $Z \subseteq Y$. If $Z \subseteq Y$, the extension $T \subseteq T \cup Z$ proves cofinality. Conversely a single object of $I_{\mathcal{S}}$ implies $Z \subseteq Y$. This calculates the recognition condition of 4.13.15 in full: an eventual supply of small approximations satisfying the property is equivalent to the colimit satisfying it. The word "eventual" means cofinality, not that every sufficiently large index must work; in more general diagrams the good indices need not form a final segment.

Théorème 4.13.15 ([134]). *Soient $\mathcal{M}$ une catégorie π_0-accessible, et $\pi > \pi'_0 \geqslant \pi_0$ tels que $\pi^{\pi_0} = \pi$ ([135]). Soit $\underline{S}$ une sous-catégorie strictement pleine de $\mathcal{M}$, et soit $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$. Les conditions suivantes sont équivalentes.*

ⓐ *$\underline{S}$ est π-accessible dans $\mathcal{M}$ (4.13.3) et $\underline{S}$ est stable dans $\mathcal{M}$ par limites inductives grandes devant π'_0.*

p. 116

a′) *$\underline{S}$ est π-accessible dans $\mathcal{M}$, et $\underline{S}(\pi)$ est stable dans $\mathcal{M}_\pi$ par limites inductives grandes devant π'_0 et de cardinal $\leqslant \pi$ ([136]).*

b) *Pour tout objet x de $\mathcal{M}$, on a ceci : la sous-catégorie strictement pleine $\underline{S}(\pi)/x$ de $J = \mathcal{M}_\pi/x$ est cofinale dans $\mathcal{M}_\pi/x$ si et seulement si $x \in \mathrm{Ob}\,\underline{S}$. De plus, $\underline{S}(\pi)$ est stable dans $\mathcal{M}_\pi$ pour $\varinjlim$ grandes devant π'_0 et de cardinal $\leqslant \pi$.*

ⓒ *Pour tout objet x de $\mathcal{M}$ et pour toute représentation $x \simeq \varinjlim_{i\in I} x_i$, où $(x_i)_{i\in I}$ est un système inductif π'_0-π-adapté, (4.13.11), on a ceci : la sous-catégorie strictement pleine $I_{\underline{S}}$ de I formée des $i \in \mathrm{Ob}\, I$ tels que $x_i \in \mathrm{Ob}\,\underline{S}$, est cofinale dans I si et seulement si $x \in \mathrm{Ob}\,\underline{S}$. De plus, $S(\pi)$ est stable dans $\mathcal{M}_\pi$ par $\varinjlim$ grandes devant π'_0 et de cardinal $\leqslant \pi$.*

[page 309]

c′) *Comme d)* `[plutôt c)]`*, avec I ensemble ordonné.*

Corollaire 4.13.16. *Les hypothèses sur $\mathcal{M}$, π_0, $\underline{S}$ étant celles de 4.13.15, pour qu'il existe des cardinaux $\pi > \pi'_0 \geqslant \pi_0$ satisfaisant les conditions $\pi^{\pi'_0} = \pi$ (a fortiori $\pi^{\pi_0} = \pi$) et les conditions*

134. Cf. version plus générale et plus symétrique du théorème 4.13.15 dans 4.13.22.

135. On peut se borner à supposer π utile pour $\mathcal{M}$ (au lieu de $\pi^{\pi_0} = \pi$), alors on trouve que a, a′, b, c sont équivalentes et impliquent c′, mais ne sont peut-être pas équivalentes à c′.

136. donner un nom à cette dernière condition, soit $\mathrm{L}(\pi'_0, \pi)$ (pour $\underline{S}(\pi)$ dans $\mathcal{M}_\pi$).

équivalentes a) à d′) [plutôt c′)] *de 4.13.15, il (faut et il) suffit que* $\underline{S}$ *soit accessible dans* $\mathcal{M}$*. De façon plus précise, si* $\underline{S}$ *est accessible dans* $\mathcal{M}$*, soit* $\pi_0' \geqslant \pi_0$ *un cardinal tel que* $\underline{S}$ *soit* π_0'*-accessible dans* $\mathcal{M}$*, et soit* π *un cardinal* $> \pi_0'$ *tel que* $\pi^{\pi_0'} = \pi$*. Alors* $(\underline{S}, \pi_0', \pi)$ *satisfait aux conditions équivalentes de 4.13.15.*

En effet, le "il faut" est évident sur la condition a) de 4.13.15. Pour le "il suffit" on note que $\underline{S}$ π_0'-accessible dans $\mathcal{M}$ implique que $\underline{S}$ est stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π_0'. Donc pour vérifier a), il suffit de vérifier que $\underline{S}$ est π-accessible dans $\overrightarrow{\mathcal{M}}$. Or comme $\underline{S}$ est [page 310]
π_0'-accessible et que $\pi > \pi_0'$ satisfait $\pi^{\pi_0'} = \pi$, on en conclut que $\underline{S}$ est $\underline{S}_\pi$-accessible, i.e. $\underline{S} \xleftarrow{\sim} \mathrm{Ind}_\pi(\underline{S}_\pi)$. Donc en vertu de 4.13.3, il reste à voir que $\underline{S}_\pi \subset \mathcal{M}_\pi$, ou ce qui revient au même, que $\underline{S}_\pi \subset \underline{S}(\pi) \overset{\text{déf}}{=} \underline{S} \cap \mathcal{M}_\pi$. (En fait, on aura même égalité, car il est clair que $\underline{S}(\pi) \subset \underline{S}_\pi \ldots$). Or $\underline{S}(\pi)$ est une sous-catégorie de $\underline{S}$ stable par $\varinjlim$ grandes devant π_0' et de cardinal $\leqslant \pi$ (puisque $\underline{S}$ et $\mathcal{M}_\pi$ sont stables par ces limites *dans* $\overrightarrow{\mathcal{M}}$, et que ces limites dans $\underline{S}$ et dans $\mathcal{M}$ sont itou), et $\underline{S}(\pi)$ contient $S_{\pi_0'}$. Donc $\underline{S}(\pi)$ contient $\underline{S}_\pi$, en vertu de 4.7.1 (page 161), implication c) $\Longrightarrow$ b′), appliquée à $\underline{S}$, π_0', π au lieu de $\mathcal{M}$, π_0, π. Cela prouve donc le corollaire 4.13.16.

Commentary · Development (commentators') [ms. 309]

The small-colimit condition does not imply the unbounded one

Theorem 4.13.15 attempts to recognize stability under all ${\pi_0'}^+$-filtered colimits from stability of the presentable objects under those of size at most π. This passage requires a relation between π and π_0', whereas the printed hypothesis controls only π_0. The distinction has mathematical consequences: the implication a′ $\Rightarrow$ a is false under the displayed hypotheses.

Counterexample to a′ $\Rightarrow$ a. [ours] Put $\rho = \aleph_1$, $\pi = \beth_{\omega_1}$, $\kappa = \rho^+$, and $\lambda = \pi^+$. The cardinal π is a strong limit of cofinality ρ. In particular $\pi^{\aleph_0} = \pi$: a countable sequence of ordinals below π is bounded, and for every $\theta < \pi$ one has $\theta^{\aleph_0} \leq 2^{\theta\aleph_0} < \pi$. Let

$$P = [\pi]^{\leq \rho}, \qquad \mathcal{M} = \mathcal{P}(P),$$

with both categories ordered by inclusion. Let A be the full subcategory of $\mathcal{M}$ consisting of subsets $Y \subseteq P$ with $|Y| \leq \pi$ which are nonempty and κ-directed in their induced order. Let $\mathcal{S}$ be the essential image of $\mathrm{Ind}_\pi(A)$ in $\mathcal{M}$.

The powerset calculation above shows that $\mathcal{M}$ is $\aleph_0$-accessible in the source convention and that its π-accessible objects are exactly its subsets of cardinal at most π. The inclusion of A consequently extends fully faithfully to $\mathrm{Ind}_\pi(A)$: for $Y \in A$, a map $Y \subseteq \bigcup_i Z_i$ into a λ-directed union factors through one Z_i. Thus $\mathcal{S}$ is π-accessible in $\mathcal{M}$. Its π-accessible objects are exactly A, since a λ-presentable object of an Ind-category is a retract of a generator, and a retract in a poset is the same object.

A κ-directed union of at most π members of A is again in A. Its cardinal is at most π. Any at-most-ρ family of its elements lies in one member of the diagram, where it has an upper bound. Hence A is closed under every κ-filtered colimit of cardinal at most π in $\mathcal{M}$. This proves condition a′ with $\pi_0 = \aleph_0$ and $\pi_0' = \rho$.

For each $z \in P$, the principal ideal $\downarrow z \subseteq P$ already belongs to A: it has largest element z and cardinal $2^{|z|} \leq 2^\rho < \pi$, since π is a strong limit. But the diagram

$$P \longrightarrow \mathcal{S}, \qquad z \longmapsto \downarrow z$$

is κ-directed and has union P, which does not lie in $\mathcal{S}$. To prove the last assertion, suppose P were a λ-directed union of members of A. The π-element subset $\{\{\alpha\} : \alpha < \pi\} \subseteq P$ would then lie in a single $Y \in A$. Its κ-directedness would make Y cofinal in P: bound the singletons belonging to any given at-most-ρ subset of π.

No cofinal subset of P has cardinal at most π. If $(y_\alpha)_{\alpha<\pi}$ were one, choose increasing cardinals $\pi_\xi < \pi$, $\xi < \rho$, cofinal in π. For each ξ choose

$$a_\xi \in \pi \setminus \bigcup_{\alpha < \pi_\xi} y_\alpha,$$

which is possible since the union has cardinal less than π. Then $\{a_\xi : \xi < \rho\} \in P$ is contained in none of the y_α, a contradiction. This proves failure of a. □

A sufficient repair is to strengthen the cardinal equation to $\pi^{\pi_0'} = \pi$, exactly the equation imposed in Corollary 4.13.16. Here is the missing unbounded-colimit argument under that repair. Write $A = \mathcal{S} \cap \mathcal{M}_\pi$. The bounded colimits assumed in a′ include chains of length $(\pi_0')^+ \leq \pi$. The simultaneous presentation theorem 4.9.3 therefore represents every diagram of cardinal at most π in $\mathrm{Ind}_\pi(A)$ by a π^+-filtered system of diagrams in A. For a ${\pi_0'}^+$-filtered such shape, take its colimit in A and then the filtered colimit; interchange of colimits proves that the inclusion $\mathcal{S} \hookrightarrow \mathcal{M}$ preserves the result.

For an arbitrarily large ${\pi_0'}^+$-filtered indexing category K, the closure construction of 4.13.13, now with π_0' in place of π_0, expresses K as the union of a π^+-directed system of ${\pi_0'}^+$-filtered subcategories of cardinal at most π. The equation $\pi^{\pi_0'} = \pi$ is precisely what bounds that construction. Compute the diagram's colimit first on these subcategories and then along their directed system. Both operations preserve membership in $\mathcal{S}$, proving a.

We checked the source's continuation: p. 337 calls a′ ⇒ a "sorital", and 4.13.19–21, pp. 340–341, states the bounded-to-unbounded extension without resolving this cardinal issue. Our counterexample concerns the printed theorem and those uses of that extension, not the valid existential recognition statement at sufficiently enlarged cardinals. We did not find this particular counterexample in the primary references checked; it is presented as a repair of the argument, without a priority claim.

Démonstration de 4.13.15. Voici les implications ± tautologiques,

(∗)
$$\mathrm{a} \Longrightarrow \mathrm{a}' \overset{\bullet}{\Longrightarrow} \mathrm{c} \rightrightarrows \begin{matrix} \mathrm{c}' \\ \mathrm{b}\ , \end{matrix}$$

que je vais expliciter un peu. On a a $\Longrightarrow$ a′ puisque si a est satisfait, $\underline{S}$ *et* $\mathcal{M}_\pi$ sont stables *dans* $\mathcal{M}$ par $\varinjlim$ grandes devant π_0' et de cardinal $\leqslant \pi$, donc aussi leur intersection $\underline{S}(\pi)$, qui est donc aussi stable dans $\mathcal{M}_\pi$ par lesdites limites. L'implication c $\Longrightarrow$ c′ est une tautologie, et c $\Longrightarrow$ b aussi, compte tenu de 4.13.12, qui nous dit que le système inductif canonique $(x_i)_{i\in I}$, avec $I = \mathcal{M}_\pi/x$, de limite x est π_0-π-adapté. (**N.B.** Comme $\pi^{\pi_0'} = \pi$ et $\pi_0' \geqslant \pi_0$, on a aussi $\pi^{\pi_0} = \pi$, donc π est utile pour $\mathcal{M}$, de sorte que 4.13.12 s'applique.) [page 311] p. 117

Reste à prouver la "± tautologie" a′ $\Longrightarrow$ c. Soit donc une représentation π_0-π-adaptée

$$x \ \simeq\ \varinjlim_{i\in I} x_i\ ,$$

prouvons que

$$x \ \in\ \mathrm{Ob}\,\underline{S} \qquad \Longleftrightarrow \qquad I_{\underline{S}} \text{ cofinal dans } I.$$

L'implication $\Longleftarrow$ provient du fait que, $\underline{S}$ étant π-accessible dans $\mathcal{M}$, est stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π ([137]). Reste à prouver que si $x \in \mathrm{Ob}\,\underline{S}$, alors $I_{\underline{S}}$ est cofinal dans I. [page 312] Considérons donc le diagramme de catégories

$$\begin{array}{ccc} I & \xrightarrow{\ \varphi\ } & J = \mathcal{M}_\pi/x \\ \uparrow & & \uparrow{\scriptstyle \alpha} \\ I' = I_{\underline{S}} & \xrightarrow{\ \varphi'\ } & J' = \underline{S}(\pi)/x\ , \end{array}$$

c'est un carré cartésien ($I' = I_{\underline{S}}$ est l'image inverse par $\varphi : I \longrightarrow J$ de la sous-catégorie strictement pleine J' de J). On a les propriétés suivantes

1) I est grande devant π, et φ cofinal ($\Longrightarrow$ J grande devant π).
2) I stable par $\varinjlim$ grandes devant π_0' et de cardinal $\leqslant \pi$, et φ commute à ces $\varinjlim$.

137. On n'utilise ici, pour $\Longleftarrow$, de l'hypothèse $(x_i)_{i\in I}$ π_0-π-adapté, que le seul fait que I soit grande devant π.

3) J' est stable par $\varinjlim$ du type précédent et α y commute ([138]).

4) J' cofinal dans J.

On vient de conclure que $I' = \varphi^{-1}(J')$ est cofinale dans I. Comme c'est une sous-catégorie pleine (et même strictement pleine), il suffit de prouver la propriété F 1, i.e. que pour tout $i \in \mathrm{Ob}\, I$, existe $i' \in \mathrm{Ob}\, I'$ et une flèche $i \longrightarrow i'$. [page 313]

Commentary · Exposition [ms. 312]

What must be pulled back is a closed cofinal subcategory

The difficult implication in the recognition theorem is a′ ⇒ c. The canonical map from a presentation of x to $\mathcal{M}_\pi/x$ is cofinal because its values are presentable: maps from at most π presentable objects and their compatibility equations factor through a common stage. For $x \in \mathcal{S}$, the subcategory $\mathcal{S}(\pi)/x$ is cofinal for the same reason. One must then show that its inverse image in the chosen presentation is cofinal.

A strict inverse image of a cofinal subcategory need not be cofinal without further hypotheses. The inclusions of the even and odd natural numbers into $\mathbb{N}$ again give a counterexample. Grothendieck's extra continuity conditions are therefore doing real work: after alternating between the presentation and the good approximations, a colimit makes their two chains agree.

The elementary lifting fact used on pp. 321–325 is this. If $F : I \to J$ is final and I is filtered, an arrow $F(i) \to F(k)$ becomes the image of an arrow of I after postcomposition by some $F(k \to k')$. To prove it, put i and k over a common object of I. The two resulting arrows out of $F(i)$ become equal after a further transition by the filtered finality criterion. That equality is the required lift. The same criterion equalizes any prescribed small family of parallel arrows after first equalizing them in J and then lifting the resulting transition. This is how the construction corrects commutativity while retaining actual arrows in I.

The four compatibility conditions on pp. 316–318 should be read as two factorization identities and naturality for two transformations, one of them shifted by one index. Once the two factorization identities hold at a successor stage, naturality of u with the immediately preceding stage is automatic:

$$(u_{\alpha+1}v_\alpha)u_\alpha = u_{\alpha+1}(v_\alpha u_\alpha).$$

Thus the additional equalization proposed on p. 323 is harmless but redundant. Naturality of v with all earlier stages still has to be imposed, especially after a limit stage; this is the substantive correction performed on pp. 324–326. The final block gives the complete construction, including the step taken up on manuscript p. 329.

On va construire encore i' par construction transfinie, sur l'intervalle ordinal I_{α_π}, en construisant un système inductif

$$(i_\alpha)_{\alpha \in I_{\alpha_\pi}}\ , \qquad i_\alpha \in \mathrm{Ob}\, I\ ,$$

d'objets de I, et un système inductif $(j_\alpha)_{\alpha \in I_{\alpha_\pi}}$, $j_\alpha \in \mathrm{Ob}\, J'$, flèches de transition notées $\tau_{\beta,\alpha} : i_\alpha \longrightarrow i_\beta$, $\tau'_{\beta,\alpha} : j_\alpha \longrightarrow j_\beta$, enfin pour tout α dans I_{α_π} des flèches

(∗)
$$\varphi(i_\alpha) \xrightarrow{u_\alpha} j_\alpha \underset{\varphi(\tau_{\alpha+1,\alpha})}{\overset{v_\alpha}{\rightrightarrows}} \varphi(i_{\alpha+1}) \ (\ \overset{u_{\alpha+1}}{\dashrightarrow}\ j_{\alpha+1}\ )$$
(with $\tau'_{\alpha+1,\alpha} : j_\alpha \dashrightarrow j_{\alpha+1}$)

dans J, telles que

(∗∗)
$$\begin{cases} v_\alpha u_\alpha &= \varphi(\tau_{\alpha+1,\alpha}) \\ u_{\alpha+1}v_\alpha &= \tau'_{\alpha+1,\alpha} \end{cases} \qquad ([139])\ .$$ p. 118

138. C'est ici qu'intervient l'hypothèse de stabilité faite dans b), car d'après b), $\underline{S}$ est π-accessible dans $\mathcal{M}$.

139. cf. aussi (∗ ∗ ∗∗), page suivante. [page 314]

Montrons comment la construction d'un tel système d'objets et de flèches avec

$$(***) \qquad i_0 \;=\; i$$

va impliquer l'existence de $i' \in \mathrm{Ob}\, I'$ et de $i \longrightarrow i'$. En effet, comme I_{α_π} est grande devant π'_0 (il est grand devant tout cardinal $< \pi$), il existe

$$i' \overset{\text{déf}}{=} \varinjlim_{i \in I_{\alpha_\pi}} i_\alpha$$

dans I, et on a une flèche de transition

$$i \;=\; i_0 \longrightarrow i' \;,$$

donc il reste à prouver que $i' \in \mathrm{Ob}\, I'$, i.e. $\varphi(i') \in \mathrm{Ob}\, J'$. Or φ commutant aux $\varinjlim$ de type I_{α_π}, on aura

$$\varphi(i) \;=\; \varinjlim \varphi(i_\alpha) \;.$$

Il me faut encore des compatibilités

$$(****) \qquad \begin{array}{ccc} \varphi(i_\alpha) & \xrightarrow{u_\alpha} & j_\alpha \\ {\scriptstyle \varphi(\tau_{\beta,\alpha})}\downarrow & & \downarrow{\scriptstyle \tau'_{\beta,\alpha}} \\ \varphi(i_\beta) & \xrightarrow{u_\beta} & j_\alpha \end{array} \quad \text{et} \quad \begin{array}{ccc} j_\alpha & \xrightarrow{v_\alpha} & \varphi(i_{\alpha+1}) \\ {\scriptstyle \tau'_{\beta,\alpha}}\downarrow & & \downarrow{\scriptstyle \varphi(\tau_{\beta+1,\alpha+1})} \\ j_\beta & \xrightarrow{v_\beta} & \varphi(i_{\beta+1}) \end{array}$$

oubliées tantôt.
Les compatibilités $(****)$ impliquent qu'on a des homomorphismes [page 315]

$$\varphi(i) \underset{v}{\overset{u}{\rightleftarrows}} j \qquad \text{où } j \overset{\text{déf}}{=} \varinjlim_{\alpha \in I_{\alpha_\pi}} j_\alpha \quad \text{(limite } \textit{dans } J', \text{ donc dans } J) \;,$$

et les compatibilités $(**)$ impliquent que

$$vu \;=\; \mathrm{id}_{\varphi(i)} \;, \qquad uv = \mathrm{id}_J \;,$$

donc que u, v sont des isomorphismes inverses l'un de l'autre. Comme J' est une sous-catégorie *strictement* pleine de J, il s'ensuit bien que $\varphi(i) \in J'$, i.e. $i \in I'$, q.e.d.

Donc tout revient à construire les

$$\underbrace{i_\alpha}_{\in \mathrm{Ob}\, I} \;,\; \tau_{\beta,\alpha} \;, \qquad \underbrace{j_\alpha}_{\in \mathrm{Ob}\, J'} \;,\; \tau'_{\beta,\alpha} \;, \qquad u_\alpha \;,\; v_\alpha \;,$$

satisfaisant aux contraintes $(**)$, $(***)$, $(****)$. On va faire la construction en trois étapes. p. 119

① Départ :

$$i_0 \;=\; i \;.$$

Comme J' est cofinal dans J, existe $j_0 \in \mathrm{Ob}\, J'$ et

$$\varphi(i_0) \xrightarrow{u_0} j_0 \;.$$

② Supposons que les i_β, j_β soient construits pour $\beta < \alpha$, ainsi que les $\tau_{\beta',\beta} : i_\beta \longrightarrow i_{\beta'}$, $\tau'_{\beta',\beta} : j_\beta \longrightarrow j_{\beta'}$ pour $\beta, \beta' < \alpha$, enfin les $u_\beta : \varphi(i_\beta) \longrightarrow j_\beta$, $v_\beta : j_\beta \longrightarrow \varphi(i_{\beta+1})$ pour $\beta < \alpha$ [page 316]

resp. pour $\beta+1<\alpha$, de façon à satisfaire aux contraintes $(**)$, $(***)$, i.e. commutativités dans

$$\left\{\begin{array}{ll}
\textcircled{1}\quad \varphi(i_\beta)\xrightarrow{u_\beta} j_\beta \xrightarrow{v_\beta}\varphi(i_{\beta+1}),\ \varphi(i_\beta)\xrightarrow{\varphi(\tau_{\beta+1,\beta})}\varphi(i_{\beta+1}) & \\
\textcircled{2}\quad j_\beta\xrightarrow{v_\beta}\varphi(i_{\beta+1})\xrightarrow{u_{\beta+1}} j_{\beta+1},\ j_\beta\xrightarrow{\tau'_{\beta+1,\beta}} j_{\beta+1} & \left.\begin{array}{l}\\\\\end{array}\right\}\ si\ \beta+1<\alpha \\
\textcircled{3}\quad \begin{array}{ccc}\varphi(i_\beta)&\xrightarrow{u_\beta}& j_\beta\\ {\scriptstyle\varphi(\tau_{\beta',\beta})}\downarrow & & \downarrow{\scriptstyle\tau'_{\beta',\beta}}\\ \varphi(i_{\beta'})&\xrightarrow{u_{\beta'}}& j_{\beta'}\end{array} & \text{si } \beta<\beta'<\alpha \\
\textcircled{4}\quad \begin{array}{ccc} j_\beta&\xrightarrow{v_\beta}&\varphi(i_{\beta+1})\\ {\scriptstyle\tau'_{\beta',\beta}}\downarrow & & \downarrow{\scriptstyle\varphi(\tau_{\beta'+1,\beta+1})}\\ j_{\beta'}&\xrightarrow{v_{\beta'}}&\varphi(i_{\beta'+1})\end{array} & \text{si } \beta<\beta' \text{ et } \beta'+1<\alpha\ ,
\end{array}\right.$$

il faut construire [page 317]

1) $i_\alpha\in\operatorname{Ob} I$, et un homomorphisme $(i_\beta)_{\beta\in I_\alpha}\longrightarrow i_\alpha$, i.e. des $\tau_{\alpha,\beta}: i_\beta\longrightarrow i_\alpha$ $(\beta\in I_\alpha)$, compatibles aux translations $\tau_{\beta',\beta}$ pour $\beta<\beta'<\alpha$. p. 120
2) $j_\alpha\in\operatorname{Ob} J'$, et un homomorphisme $(j_\beta)_{\beta\in I_\alpha}\longrightarrow j_\alpha$, i.e. des $\tau'_{\alpha,\beta}: j_\beta\longrightarrow j_\alpha$ $(\beta\in I_\alpha)$, compatibles aux translations $\tau'_{\beta',\beta}$ pour $\beta<\beta'<\alpha$.
3) Une flèche
$$u_\alpha:\varphi(i_\alpha)\longrightarrow j_\alpha\ .$$
4) Si α n'est pas ordinal limite, i.e. $\alpha=\alpha_0+1$, une flèche
$$v_{\alpha_0}: j_{\alpha_0}\longrightarrow\varphi(i_{\alpha_0+1})=\varphi(i_\alpha)\ ;$$

et ceci de façon à satisfaire aux contraintes ①②③④ quand on y suppose $\beta+1\leqslant\alpha$ (au lieu de $\beta'<\alpha$) dans ① et ②, et $\beta'\leqslant\alpha$ (au lieu de $\beta'<\alpha$) dans ③, et $\beta'+1\leqslant\alpha$ (au lieu de $\beta'+1<\alpha$) dans ④. Donc pour les contraintes 1°, 2°, 4°, il n'y a en tenir compte *que* si α n'est pas ordinal limite, donc $\alpha=\alpha_0+1$, et en y faisant

$$\beta'\ =\ \alpha_0\ .$$

Quant à la contrainte 3°, il faut en tenir compte pour $\beta'=\alpha$. Donc au total, il faut exiger [page 318]

$$(3_\alpha)(\beta)\qquad \begin{array}{ccc}\varphi(i_\beta)&\xrightarrow{u_\beta}& j_\beta\\ {\scriptstyle\varphi(\tau_{\alpha,\beta})}\downarrow & & \downarrow{\scriptstyle\tau'_{\alpha,\beta}}\\ \varphi(i_\alpha)&\xrightarrow{u_\alpha}& j_\beta\end{array}\qquad \text{commutatif pour } \beta<\alpha\ (^{140}),$$

(par restriction sur α), et si $\alpha=\alpha_0+1$ est ordinal non limite, il faut exiger de plus

$$(4_\alpha)(\beta)\qquad \begin{array}{ccc} j_\beta&\xrightarrow{v_\beta}&\varphi(i_{\beta+1})\\ {\scriptstyle\tau'_{\alpha_0,\beta}}\downarrow & & \downarrow{\scriptstyle\varphi(\tau_{\alpha,\beta+1})}\\ j_{\alpha_0}&\xrightarrow{v_{\alpha_0}}&\varphi(i_{\alpha_0+1})=\varphi(i_\alpha)\end{array}\qquad \beta<\alpha_0$$

140. **N.B.** Il suffit de l'exiger pour $\beta=\alpha_0$, dans le cas $\alpha=\alpha_0+1$, cf. ci-dessous, p. 323.

$$(1_\alpha) \qquad \varphi(i_{\alpha_0}) \xrightarrow{u_{\alpha_0}} j_{\alpha_0} \xrightarrow{\textcircled{v_{\alpha_0}}} \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \quad \text{(}\varphi(\textcircled{\tau_{\alpha,\alpha_0}})\text{)}$$

$$(2_\alpha) \qquad j_{\alpha_0} \xrightarrow{\textcircled{v_{\alpha_0}}} \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \xrightarrow{\textcircled{u_\alpha}} j_\alpha \ . \quad (\textcircled{\tau'_{\alpha,\alpha_0}})$$

p. 121

Dans ces compatibilités, j'ai cerclé les flèches $\tau_{\alpha,\beta}$, $\tau'_{\alpha,\beta}$ $(\beta < \alpha)$, $\Big(\ \tau_{\alpha,\beta+1}\ (\beta+1<\alpha)\ \Big)$, v_{α_0}, $\Big(\ \tau_{\alpha,\alpha_0}\ \Big)$, u_α, $\Big(\ \tau'_{\alpha,\alpha_0}\ \Big)$, qui ont été introduites dans les donnés 1) 2) 3) 4), page 317.

On va distinguer donc les deux cas. [page 319]

2 A) $\alpha = \alpha_0 + 1$.

Pour construire i_α et les $\tau_{\alpha,\beta} : i_\beta \longrightarrow i_\alpha$, il suffit de construire i_α et

$$\textcircled{\tau_{\alpha,\alpha_0}} \ : \ i_{\alpha_0} \ \longrightarrow \ i_\alpha = i_{\alpha_0+1} \ .$$

De même pour j_α et les $\tau'_{\alpha,\beta}$, il suffit de construire

$$\textcircled{\tau'_{\alpha,\alpha_0}} \ : \ j_{\alpha_0} \ \longrightarrow \ j_\alpha \ .$$

Il faut de plus se donner

$$j_{\alpha_0} \xrightarrow{\textcircled{v_{\alpha_0}}} \varphi(\underbrace{i_\alpha}_{=i_{\alpha_0+1}}) \xrightarrow{\textcircled{u_\alpha}} j_\alpha \ ,$$

donc en tout deux objets i_α, j_α (dans I et dans J' respectivement) et quatre flèches τ_{α,α_0}, τ'_{α,α_0}, v_{α_0}, u_α. Il faut quatre compatibilités (page 318), où les deux dernières $3_\alpha(\beta)$, $4_\alpha(\beta)$ dépendent d'un paramètre $\beta < \alpha$, i.e. $\beta \leqslant \alpha_0$, ou de $\beta < \alpha_0$.

On va d'abord s'occuper de deux premières compatibilités 1_α, 2_α, en termes de la donnée de [page 320 biffé] [page 321]

$$i_{\alpha_0} \ \in \ \mathrm{Ob}\, I \ , \qquad j_{\alpha_0} \ \in \ \mathrm{Ob}\, J' \ , \qquad u_{\alpha_0} \ : \ \varphi(i_{\alpha_0}) \ \longrightarrow \ j_{\alpha_0} \ .$$

Les deux compatibilités voulues pour les deux objets i_α, j_α et les quatre flèches τ_{α,α_0}, τ'_{α,α_0}, v_{α_0}, u_α sont indiquées dans le diagramme

$$(*) \qquad \varphi(i_{\alpha_0}) \xrightarrow{u_{\alpha_0}} j_{\alpha_0} \xrightarrow{v_{\alpha_0}\ ?} \varphi(\underbrace{i_\alpha}_{?}) \xrightarrow{u_\alpha\ ?} j_\alpha \ , \quad \tau'_{\alpha,\alpha_0} \text{ (}?\text{)}, \quad \varphi(\tau_{\alpha,\alpha_0})$$

On note que comme φ est cofinal, $\exists\ i_\alpha = i \in \mathrm{Ob}\, I$ et $j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i)$. Mais on veut que le composé

$$w \ : \ \varphi(i_{\alpha_0}) \xrightarrow{u_{\alpha_0}} j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i)$$

soit de la forme $\varphi(\tau)$, où $\tau = \tau_{\alpha,\alpha_0} : i_{\alpha_0} \longrightarrow i_\alpha$ est une flèche dans I. Comme φ est un foncteur cofinal de catégories filtrantes, on sait qu'on peut trouver $i \xrightarrow{\rho} i'$ dans I, tel que la flèche composée $\varphi(i_{\alpha_0}) \xrightarrow{w} \varphi(i) \xrightarrow{\varphi(\rho)} \varphi(i')$ soit de la forme $\varphi(\tau)$. Donc quitte à remplacer i par i', et v_{α_0} par le composé $v'_{\alpha_0} : j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i) \xrightarrow{\varphi(\rho)} \varphi(i')$, on peut supposer que $v_{\alpha_0} u_{\alpha_0}$ est de la p. 122 [page 322]

forme $\varphi(\tau)$. Cela nous donne donc en principe l'objet $i = i_\alpha$, et les flèches $v_{\alpha_0} : j_{\alpha_0} \longrightarrow \varphi(i)$ et $\tau_{\alpha,\alpha_0} : i_{\alpha_0} \longrightarrow i_\alpha$, de façon à satisfaire à la première compatibilité dans $(*)$. Il reste à construire j_α, τ'_{α,α_0}, u_α de façon à satisfaire à la deuxième compatibilité $(*)$. Or J' étant cofinal dans J, il existe j_α dans J' et une flèche $u_\alpha : \varphi(i_\alpha) \longrightarrow j_\alpha$. D'autre part, comme $J' \longrightarrow J$ est pleinement fidèle, la flèche composée $j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i_\alpha) \xrightarrow{u_\alpha} j_\alpha$ dans J, entre objets de J', provient d'une unique flèche $\tau'_{\alpha,\alpha_0} : j_{\alpha_0} \longrightarrow j_\alpha$ dans J'.

Ainsi, on a construit les deux objets et les quatre flèches voulues, de façon à satisfaire [page 323] aux contraintes 1_α, 2_α de la page 318. Les contraintes $3_\alpha(\beta)$, $4_\alpha(\beta)$ sont-elles alors satisfaites automatiquement ?

$$\begin{array}{ccc} \varphi(i_\beta) & \xrightarrow{u_\beta} & j_\beta \\ \downarrow & & \downarrow \\ \varphi(i_{\alpha_0}) & \xrightarrow{u_{\alpha_0}} & j_{\alpha_0} \\ {\scriptstyle \varphi(\tau_{\alpha,\alpha_0})}\downarrow & & \downarrow{\scriptstyle \tau'_{\alpha,\alpha_0}} \\ \varphi(i_\alpha) & \xrightarrow{u_\alpha} & j_\alpha \end{array} \qquad \beta < \alpha, \text{ i.e. } \beta \leqslant \alpha_0 \ .$$

Le carré supérieur est commutatif par hypothèse de récurrence, pour que le carré total (composé) soit commutatif, il suffit que le carré inférieur le soit. On a donc une double-flèche $(\tau'_{\alpha,\alpha_0} u_{\alpha_0}, u_\alpha \varphi(\tau_{\alpha,\alpha_0})) : \varphi(i_\alpha) \rightrightarrows j_\alpha$, elle n'est peut-être pas triviale, mais on sait, J' étant filtrante, qu'on peut l'égaliser par une flèche $j_\alpha \longrightarrow \bar{j}_\alpha$ dans J'. Donc quitte à remplacer j_α par $\bar{j}_\alpha$, u_α par le composé $\bar{u}_\alpha : \varphi(i_0) \longrightarrow j_\alpha \longrightarrow \bar{j}_\alpha$ et τ'_{α,α_0} par le composé $\bar{\tau}'_{\alpha,\alpha_0} : j_{\alpha_0} \longrightarrow j_\alpha \longrightarrow \bar{j}_\alpha$ [page 324] (sans toucher à i_α, v_{α_0}, $\tau_{\alpha_0,\alpha}$), on peut obtenir la commutativité, d'où $3_\alpha(\beta)$.

Reste la contrainte $4_\alpha(\beta)$. Pour ceci, considérons le diagramme composite

$$\begin{array}{ccc} j_\beta & \xrightarrow{v_\beta} & \varphi(i_{\beta+1}) \\ {\scriptstyle \tau'_{\alpha_0,\beta}}\downarrow & & \downarrow{\scriptstyle \varphi(\tau_{\alpha,\beta+1})} \\ j_{\alpha_0} & \xrightarrow{v_{\alpha_0}} & \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \ . \end{array}$$

Si α_0 n'est pas un ordinal limite, mais de la forme $\alpha_1 + 1$, on peut encore se ramener au cas où $\beta = \alpha_1$, en procédant comme ci-dessus. Mais on peut procéder dans tous les cas, sans un tel artifice (!), en considérant les double-flèches

$$(*) \qquad j_\beta \underset{v_{\alpha_0}\tau'_{\alpha_0,\beta}}{\overset{\varphi(\tau_{\alpha,\beta+1})v_\beta}{\rightrightarrows}} \varphi(i_\alpha)$$

déduites du carré précédent. Comme l'ensemble de ces double-flèches est de cardinal $\operatorname{card} \alpha < \pi$, p. 123 et que J est grande devant π (il suffirait qu'il le soit pour les cardinaux $\pi' < \pi$), on peut [page 325] trouver une flèche $\varphi(i_\alpha) \xrightarrow{u} j$ dans J qui égalise toutes ces double-flèches. Comme φ est cofinal, on peut supposer que j est de la forme $\varphi(i)$. Comme φ est un foncteur cofinal de catégories filtrantes, il existe alors $i \xrightarrow{\rho} i'$ dans I, tel que le composé $\varphi(i_\alpha) \xrightarrow{u} \varphi(i) \xrightarrow{\varphi(\rho)} \varphi(i')$ soit de la forme $\varphi(\sigma)$, pour $\sigma : i_\alpha \longrightarrow i'$. Au total, on a trouvé $\sigma : i_\alpha \longrightarrow i'$, tel que $\varphi(\sigma)$ $(= \varphi(\rho)u) : \varphi(i_\alpha) \longrightarrow \varphi(i')$ égalise toutes les double-flèches envisagées dans $(*)$, p. 324. Donc il s'impose de remplacer i_α par $\bar{i}_\alpha = i'$, v_{α_0} par le composé $j_{\alpha_0} \longrightarrow \varphi(i_\alpha) \xrightarrow{\varphi(\sigma)} \varphi(\bar{i}_\alpha)$, τ_{α,α_0} par le composé $\bar{\tau}_{\alpha,\alpha_0} : i_{\alpha_0} \xrightarrow{\tau_{\alpha,\alpha_0}} i_\alpha \xrightarrow{\sigma} \bar{i}_\alpha$. [page 326]

Pour résumer, voici la recette pour construire, d'abord $\boxed{i_\alpha,\ v_{\alpha_0},\ \tau_{\alpha,\alpha_0},}$ et *ensuite* $\boxed{j_\alpha,\ u_\alpha,\ \tau'_{\alpha,\alpha_0}}$.

On procède d'abord comme page 321, 322 pour construire le premier triple, de façon à satisfaire à la première compatibilité $(*)$ (p. 321), i.e. à 1_α. On "corrige" ensuite ce choix

de i_α, v_{α_0}, τ_{α,α_0}, en remplaçant i_α par $\bar{i}_\alpha$ pour $\sigma : i_\alpha \longrightarrow \bar{i}_\alpha$, v_{α_0} par $\bar{v}_{\alpha_0} = \varphi(\sigma)v_{\alpha_0}$, et τ_{α,α_0} par $\bar{\tau}_{\alpha,\alpha_0} = \sigma\tau_{\alpha,\alpha_0}$, de sorte à obtenir les compatibilités $4_\alpha(\beta)$ pour $\beta < \alpha_0$, comme on vient de l'indiquer. On ne touchera plus à ces choix de i_α, v_{α_0}, τ_{α,α_0}, dans la suite de la construction. On construit $(j_\alpha, u_\alpha, \tau'_{\alpha,\alpha_0})$ de façon à satisfaire à la deuxième compatibilité $(*)$ (p. 321), comme indiqué page 322. Ensuite, on corrige ce choix, en remplaçant j_α par $\bar{j}_\alpha$, [page 327]
avec $\rho : j_\alpha \longrightarrow \bar{j}_\alpha$, et u_α par $\bar{u}_\alpha = \rho u_\alpha$, τ'_{α,α_0} par $\bar{\tau}'_{\alpha,\alpha_0} = \rho\tau'_{\alpha,\alpha_0}$, de façon à satisfaire aux contraintes $3_\alpha(\beta)$ de la page 318.

Cela achève la construction dans le cas où $\alpha = \alpha_0 + 1$.

Cas 2 B : α est ordinal limite.

Il faut donc construire les données 1) 2) 3) de la page 317 (à l'exclusion de la donnée 4), de façon à satisfaire à la seule contrainte $3_\alpha(\beta)$.

On commence à construire i_α et les $\tau_{\beta,\alpha}$ dans I. C'est possible, car $I_\alpha = \{\beta \mid \beta < \alpha\}$ est de cardinal $\pi_\alpha < \pi$ – il suffit donc de supposer I grande devant les cardinaux $\pi' < \pi$.

On construit ensuite de même J_α dans J' et les $\tau'_{\beta,\alpha}$ $(\beta < \alpha)$, en utilisant le fait que J' est [page 328]
grande devant $\operatorname{card}\alpha = \operatorname{card} I_\alpha$. On doit de plus construire une flèche

$$u_\alpha \ : \ \varphi(i_\alpha) \ \longrightarrow \ j_\alpha \ .$$

C'est possible, car J' étant cofinale dans J, il existe j' dans J' et $\varphi(i_\alpha) \longrightarrow J'$, et J' étant filtrante, il existe $\bar{j}_\alpha$ et des flèches $j_\alpha \longrightarrow \bar{j}_\alpha$, $j' \nearrow \bar{j}_\alpha$, donc quitte à remplacer j_α par $\bar{j}_\alpha$, les $\tau'_{\alpha,\beta}$ par des $\bar{\tau}'_{\alpha,\beta}$, on trouve bien une flèche $u_\alpha : \varphi(i_\alpha) \longrightarrow j_\alpha$. Il faut ensuite s'occuper des

Commentary · Exposition [ms. 328]

Completing the alternating construction at the page boundary

Grothendieck is finishing a construction which makes a closed cofinal class visible in every continuous presentation. These pages end on manuscript p. 328, before the last naturality equations have been equalized. The complete chapter continues on manuscript p. 329 and states the result as Lemma 4.13.17 on pp. 329–330. We give a proof here with a suitable regular ordinal in place of the possibly singular ordinal π. This is a completion of his proof, not an additional assertion of originality.

Let $F : I \to J$ be final, with I π^+-filtered, and let $J' \subseteq J$ be replete, full, and final. Let $\rho < \pi$ be infinite. Assume that I and J' admit κ-indexed chain colimits for $\kappa = \rho^+$, and that both F and the inclusion $J' \to J$ preserve them. Then $I' = F^{-1}(J')$ is final in I. These assumptions hold in the application on p. 312, taking $\rho = \pi'_0$; no equation $\pi^{\pi'_0} = \pi$ is needed for this implication.

Fix $i_0 \in I$. We construct chains $i_\alpha \in I$, $j_\alpha \in J'$ for $\alpha < \kappa$, with arrows

$$F(i_\alpha) \xrightarrow{u_\alpha} j_\alpha \xrightarrow{v_\alpha} F(i_{\alpha+1})$$

and transition maps $t_{\beta\alpha}$, $s_{\beta\alpha}$. Require

$$v_\alpha u_\alpha = F(t_{\alpha+1,\alpha}), \qquad u_{\alpha+1}v_\alpha = s_{\alpha+1,\alpha},$$

and naturality of $u_\alpha : F(i_\alpha) \to j_\alpha$ and $v_\alpha : j_\alpha \to F(i_{\alpha+1})$. Choose j_0, u_0 using finality of $J' \to J$.

At a successor stage, finality of F gives $j_\alpha \to F(k)$. The lifting fact explained above allows us to enlarge k and arrange that its composite with u_α is $F(t)$ for an actual $t : i_\alpha \to k$. For each $\beta < \alpha$, compare the two arrows

$$j_\beta \rightrightarrows F(k) : \quad F(t\, t_{\alpha,\beta+1})v_\beta, \qquad v_\alpha s_{\alpha\beta}.$$

There are at most π of them. The category J is π^+-filtered, as follows by applying finality to diagrams in I or the criterion 4.9.6.3. Equalize this family in J, then use finality and the lifting fact to replace the equalizing transition by $F(k \to \bar{k})$. Set $i_{\alpha+1} = \bar{k}$ and postcompose the already chosen arrows. This imposes naturality of v without disturbing its factorization identity. Choose $u_{\alpha+1} : F(i_{\alpha+1}) \to j_{\alpha+1}$ with $j_{\alpha+1} \in J'$, and define $s_{\alpha+1,\alpha} = u_{\alpha+1}v_\alpha$. Naturality of u follows from the first identity and earlier naturality; the remaining transition maps are composites.

At a nonzero limit $\gamma < \kappa$, choose compatible cocones $i_\beta \to i_\gamma$ and $j_\beta \to j_\gamma$ on the two preceding chains. This is possible by filteredness, since $|\gamma| \leq \rho < \pi$. Extend j_γ inside J' if necessary to obtain $u_\gamma : F(i_\gamma) \to j_\gamma$. For each $\beta < \gamma$, the two composites

$$F(i_\beta) \rightrightarrows j_\gamma : \quad s_{\gamma\beta} u_\beta, \qquad u_\gamma F(t_{\gamma\beta})$$

need not yet coincide. Equalize them simultaneously in J and then extend the target into J'. Postcomposition corrects u_γ and the whole j-cocone, preserving all its transition identities. This is exactly the operation begun on p. 328 and completed on p. 329. There is no v-naturality condition with target index γ at this step: its target is the shifted index $\alpha + 1$, so the new conditions are imposed at the next successor stage.

Take $i_* = \varinjlim_{\alpha<\kappa} i_\alpha$ and $j_* = \varinjlim_{\alpha<\kappa} j_\alpha$. Preservation and naturality give arrows $F(i_*) \rightleftarrows j_*$. Their composites are identities because they are induced by the transition maps of the two chains. Hence $F(i_*) \cong j_* \in J'$, and repleteness gives $i_* \in I'$. The map $i_0 \to i_*$ proves the first finality condition; fullness and filteredness imply full finality as above.

The source's i in the colimit identities on pp. 314–315 must mean this final i_*, not the initial object i_0. That distinction is essential: otherwise the proof would assert that the starting object already lies in I'. With the corrected notation, the construction proves a$'$ ⇒ c. The continuation of the complete chapter also derives b and c$'$ ⇒ a$'$ using the same lemma. The separate implication a$'$ ⇒ a has the cardinal defect described in the preceding development block; completing the alternating construction does not repair that different step.

Overview · XVIII-c

Presentations which retain structure. These pages turn the existence of small approximations into a method for handling objects with structure. An accessible category supplies filtered presentations of its objects; a diagram requires compatible presentations of its arrows and their equations. A section of a fibred category adds transport between different fibres. A full subcategory defined by a property requires approximations which already possess that property. The successive arguments address these problems with the same operations: choose a common stage, impose a bounded family of equations, and take a suitably long colimit. The cardinal estimates specify when this process can still be carried out among the chosen small objects.

These pages begin with Theorem 4.9.3 and end during the proof of Theorem 4.13.15, on manuscript page 328 (Grothendieck, 1990–1991n). They are printed pages 79–123 of the edition; the manuscript labels run from an opening continuation before 220 through 328, including 302 bis and the cancelled page 320. These systems should not be identified with one another. The complete chapter was consulted where it supplies the opening hypotheses or the continuation of an unfinished proof. The end of these pages is not itself a mathematical gap.

The cardinal convention. Grothendieck's phrase "grande devant π" means modern π^+-filteredness: every diagram with at most π arrows has a cocone. His π-accessible objects are therefore π^+-presentable objects, and his $\mathrm{Ind}_\pi C$ is the completion under π^+-filtered colimits. This translation matters even for $\pi = \aleph_0$, where countable constraints, rather than only finite constraints, are admitted. It also prevents an unnoticed assumption that π is regular. The adjective "regular" applied to a category's filtration elsewhere in the chapter denotes a separate categorical condition.

A second distinction concerns a full subcategory $\mathcal{S} \subseteq \mathcal{M}$. Intrinsic accessibility, accessibility of the inclusion, and preservation of presentable objects by that inclusion are different requirements. The source's fixed-rank notion of accessibility *in* $\mathcal{M}$ requires the last comparison as well. We keep the intrinsic notation $\mathcal{S}_\pi$ separate from $\mathcal{S} \cap \mathcal{M}_\pi$ until the hypotheses identify them.

Cofinality and simultaneous presentation. The first task is to show that a small diagram in $\mathrm{Ind}_\pi C$ comes from a filtered system of diagrams in C. Full faithfulness follows from expressing natural transformations as an equalizer of products of hom sets, provided the indexing category has at most π arrows. Essential surjectivity is the substantial part. The source supplies it when C has colimits of one suitable limit-ordinal shape. In the ensuing section theorem, that colimit turns approximately compatible structure maps into actual structure maps.

The cofinality discussion 4.9.6 isolates the mechanism. We use "final" for right-cofinal functors. A faithful functor can reflect an equality once the requisite arrows have been lifted after enlargement. Without faithfulness, eventual equalization of arrows having the same image suffices; the commentary proves this relative variant explicitly. It also completes the cardinal descent and the discrete-opfibration lemma. Common upper bounds, connectedness, and equalization are kept distinct, with worked examples showing why none can silently replace another.

One clause is missing from the printed Lemma 4.9.6.3(b′): filteredness of the comma categories. The faithful functor from a two-object discrete category to the terminal category disproves the formulation as printed. The proof on page 236 specifies the missing condition. The possible empty-category issue in b″ is instead a convention to clarify: its cardinal version already includes the empty family among the families to be bounded.

The finite-diagram question now has a definitive answer. The comparison works for every C exactly for essentially small enough well-founded shapes, in the sense of Henry (2025b, Theorem 1.3). The finite rigid case in 4.11.6 is included. A nontrivial finite group supplies an

obstruction, and the commentary calculates the signed-ordinal involution example at every infinite completion bound. This is a known construction, with its antecedent in SGA 4, I, 8.8.8, not a result claimed for the commentators (Artin et al., 1972).

Sections and the transfer of colimits. In 4.10 "cofibrant" describes a Grothendieck opfibration. Its sections are families X_i with maps $a_*X_i \to X_j$ for $a : i \to j$; those maps need not be cocartesian. The approximation category of sections over a given section maps finally to the product of the fibrewise approximation categories. Evaluating its canonical colimit therefore recovers the original section. We write out this passage, which the source asks to have made explicit, and prove full faithfulness separately.

The transfinite construction has a coherence defect as displayed. Compatibility of consecutive stages does not compare choices across an internal limit ordinal. A constant two-point diagram whose involution changes at ω satisfies the displayed conditions but gives no induced map on its constant colimit. The repair imposes compatibility with every earlier stage when constructing a new stage; there are still at most π equations. The completed induction proves the intended section theorem. A separate endpoint adjustment handles the parenthesis allowing an auxiliary cardinal equal to π.

The application to paratoposes concerns locally presentable categories, without an additional assertion of topos exactness. Ordinary sections of an opfibration have pointwise limits whenever the fibres have them: their structure maps are induced by the limit projections. Preservation by transport is needed for pointwise colimits. This distinction vindicates the printed limit argument in 4.10.9 and prevents the editors' tentative alternative from becoming an unwarranted correction.

Question 4.10.11 about ordinary and cartesian sections is settled by the later theory of accessible limits. Products, inserters, and equifiers encode arbitrary sections; requiring invertible structure maps gives the pseudolimit describing cartesian sections. After choosing common ranks, Positselski (2024, Theorems 8.1, 8.3 and Corollary 9.2) apply. Their fixed-rank conclusions retain hypotheses about a smaller chain-colimit cardinal, close to the distinction Grothendieck is already exploiting.

Section 4.11 transfers bounded colimits from C to $\mathrm{Ind}_\pi C$ by first presenting the entire diagram. The universal-property argument interchanges two limits of hom sets. The separate assertion that $C \to \mathrm{Ind}_\pi C$ preserves existing bounded colimits uses filtered-colimit/limit commutation in sets. Idempotent completeness enters in the converse, through the description of presentable ind-objects as retracts of objects of C. We also give the finite rigid induction and the reduction of finite limits and colimits to products and equalizers, or coproducts and coequalizers.

Accessible functors and accessible properties. Uniformization in 4.12 bounds the ranks of the images of a small generating family. At a sufficiently large fixed point $\pi^{\pi_0} = \pi$, an accessible functor carries π-accessible objects to π-accessible objects. Fixing a preservation rank reduces the functor category to one with small domain. The proof of 4.12.4 invokes the ind universal property without explicitly securing the required colimits in the target. Choosing the rank useful for both categories repairs the proof, as in 4.12.5. We distinguish this verified form from the broader first assertion rather than manufacture a counterexample from an omitted hypothesis.

There is no common rank for all accessible endofunctors of sets: the representables $X \mapsto X^B$ prove this as $|B|$ grows. Small colimits of accessible set-valued functors are pointwise, so the same example rules out a small accessible generating family for their entire category. This supplies the counterexample sought in Remark 4.12.6.

The existential theorems about accessible full subcategories and their small intersections remain valid. A later higher-categorical counterpart is Lurie (2009, Proposition 5.4.7.10). The effective threshold in 4.13.2(c), however, omits the ambient ranks of the generators. The

singleton subcategory $\{X\} \subseteq \mathcal{P}(X)$ gives a complete counterexample to that estimate. The repair retains the missing bound already used on page 282.

For intersections, an ordinal of cardinality π need not have cofinality greater than the smaller bound. We prove a replacement construction which attends to all the subcategories at each stage of a chain of regular length $\rho^{+} \leq \pi$. Its colimit belongs to every subcategory. This proves the main cofinal-intersection lemma without an unnecessary regularity restriction on π. A related argument repairs the cofinal-pullback construction in the final proof.

Theorem 4.13.15 needs a more substantial correction. Under its printed hypothesis $\pi^{\pi_0} = \pi$, condition a′ need not imply a): closure of the presentable part under $\pi_0'^{+}$-filtered colimits of size at most π need not give unrestricted closure. We construct a counterexample with $\pi_0 = \aleph_0$, $\pi_0' = \aleph_1$, and $\pi = \beth_{\omega_1}$, proving both the bounded closure and the failure of unrestricted closure. Strengthening the hypothesis to $\pi^{\pi_0'} = \pi$ gives a sufficient repair: the indexing categories can then be exhausted by suitably filtered subcategories of size at most π. The bounded membership criteria and the accessible-intersection theorem survive this failed implication.

satisfaisant aux contraintes (∗∗), (∗ ∗ ∗), (∗ ∗ ∗∗). On va faire la construction en trois étapes. p. 119

① Départ :

$$i_0 \;=\; i\ .$$

Comme J' est cofinal dans J, existe $j_0 \in \mathrm{Ob}\, J'$ et

$$\varphi(i_0) \xrightarrow{u_0} j_0\ .$$

\end{cases}$$

[page 317]

Commentary · Exposition [ms. 316]

The size convention and the purpose of the zigzag

Grothendieck is trying to recognize a large object by the small pieces of a chosen presentation. The difficulty is that two cofinal presentations need not have any pieces in common. The construction begun on the preceding manuscript pages supplies a common piece by alternately passing from one presentation to the other, and then taking a limit of the resulting process. This is the technical engine of the membership criterion in 4.13.22.

We first fix the translation of the cardinal notation. In this chapter a category is *grande devant* the infinite cardinal π when every diagram having at most π arrows admits a cocone. In present terminology it is λ-filtered, where $\lambda = \pi^+$. Accordingly, a π-accessible object is λ-presentable: its represented functor preserves λ-filtered colimits. A useful cardinal for $\mathcal{M}$ says that $\mathcal{M}$ is generated under these colimits by its essentially small full subcategory $\mathcal{M}_\pi$. We shall retain π in quotations and use λ when the regular-cardinal convention makes a statement easier to compare with modern literature. Replacing π by a regular cardinal with the same name would lose the distinction between diagrams of size $\leq \pi$ and diagrams of size $< \pi$.

Here $\varphi : I \longrightarrow J$ is final, I is filtered, and $J' \subset J$ is a full, isomorphism-closed, final subcategory. The desired conclusion is that the strict inverse image $I' = \varphi^{-1}(J')$ is final in I. It will be enough to reach an object of I' from each prescribed $i \in I$: a full subcategory of a filtered category with this property is itself filtered and final. This familiar criterion is the one recorded in The Stacks Project Authors (2026d, Lemma 4.19.3); throughout these pages cofinality has this ordinary categorical meaning.

Finality alone is insufficient. Let $J = \mathbb{N}$ with its usual order, take I to be the even natural numbers, and take J' to be the odd natural numbers. Both inclusions are final, but I' is empty. The additional hypothesis in 4.13.17 is therefore doing real work: there is a nonzero limit ordinal θ such that the relevant θ-chains have colimits, those colimits are preserved by φ and $J' \hookrightarrow J$, and the shorter initial segments admit enough cocones. The even–odd example has no colimit for its unbounded countable chain.

Starting at i, the displayed maps have the form

$$\varphi(i_\beta) \xrightarrow{u_\beta} j_\beta \xrightarrow{v_\beta} \varphi(i_{\beta+1}).$$

They do not assert that any intermediate $\varphi(i_\beta)$ belongs to J'. Instead, the two composites are required to be the transition maps of the two chains. At the final limit stage the chains consequently have isomorphic colimits in J. One colimit comes from I, the other belongs to J'; isomorphism-closure then puts the former in J'. This explains both the alternation and the insistence on a strictly full subcategory.

il faut construire

p. 120

1) $i_\alpha \in \mathrm{Ob}\, I$, et un homomorphisme $(i_\beta)_{\beta\in I_\alpha} \longrightarrow i_\alpha$, i.e. des $\tau_{\alpha,\beta} : i_\beta \longrightarrow i_\alpha$ $(\beta \in I_\alpha)$, compatibles aux translations $\tau_{\beta',\beta}$ pour $\beta < \beta' < \alpha$.
2) $j_\alpha \in \mathrm{Ob}\, J'$, et un homomorphisme $(j_\beta)_{\beta\in I_\alpha} \longrightarrow j_\alpha$, i.e. des $\tau'_{\alpha,\beta} : j_\beta \longrightarrow j_\alpha$ $(\beta \in I_\alpha)$, compatibles aux translations $\tau'_{\beta',\beta}$ pour $\beta < \beta' < \alpha$.
3) Une flèche
$$u_\alpha : \varphi(i_\alpha) \longrightarrow j_\alpha \ .$$
4) Si α n'est pas ordinal limite, i.e. $\alpha = \alpha_0 + 1$, une flèche
$$v_{\alpha_0} : j_{\alpha_0} \longrightarrow \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \ ;$$

et ceci de façon à satisfaire aux contraintes ①②③④ quand on y suppose $\beta + 1 \leqslant \alpha$ (au lieu de $\beta' < \alpha$) dans ① et ②, et $\beta' \leqslant \alpha$ (au lieu de $\beta' < \alpha$) dans ③, et $\beta' + 1 \leqslant \alpha$ (au lieu de $\beta' + 1 < \alpha$) dans ④. Donc pour les contraintes 1°, 2°, 4°, il n'y a en tenir compte *que* si α n'est pas ordinal limite, donc $\alpha = \alpha_0 + 1$, et en y faisant

$$\beta' \ = \ \alpha_0 \ .$$

Quant à la contrainte 3°, il faut en tenir compte pour $\beta' = \alpha$. Donc au total, il faut exiger [page 318]

$(3_\alpha)(\beta)$
$$\begin{array}{ccc} \varphi(i_\beta) & \xrightarrow{u_\beta} & j_\beta \\ {\scriptstyle \varphi(\tau_{\alpha,\beta})}\downarrow & & \downarrow{\scriptstyle \tau'_{\alpha,\beta}} \\ \varphi(i_\alpha) & \xrightarrow{u_\alpha} & j_\beta \end{array}$$
commutatif pour $\beta < \alpha$ ([140]),

(par restriction sur α), et si $\alpha = \alpha_0 + 1$ est ordinal non limite, il faut exiger de plus

$(4_\alpha)(\beta)$
$$\begin{array}{ccc} j_\beta & \xrightarrow{v_\beta} & \varphi(i_{\beta+1}) \\ {\scriptstyle \tau'_{\alpha_0,\beta}}\downarrow & & \downarrow{\scriptstyle \varphi(\tau_{\alpha,\beta+1})} \\ j_{\alpha_0} & \xrightarrow{v_{\alpha_0}} & \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \end{array}$$
$\beta < \alpha_0$

(1_α)
$$\varphi(i_{\alpha_0}) \xrightarrow{u_{\alpha_0}} j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha)$$
$$\varphi(\tau_{\alpha,\alpha_0})$$

p. 121

$$(2_\alpha) \qquad j_{\alpha_0} \xrightarrow{\textcircled{v_{\alpha_0}}} \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \xrightarrow{\textcircled{u_\alpha}} j_\alpha \ .$$
$$\qquad\qquad\qquad\qquad\qquad\qquad \underset{\textcircled{\tau'_{\alpha,\alpha_0}}}{\curvearrowright}$$

Dans ces compatibilités, j'ai cerclé les flèches $\tau_{\alpha,\beta}$, $\tau'_{\alpha,\beta}$ $(\beta < \alpha)$, $\Big($ $\tau_{\alpha,\beta+1}$ $(\beta+1 < \alpha)$ $\Big)$, v_{α_0}, $\Big($ τ_{α,α_0} $\Big)$, u_α, $\Big($ τ'_{α,α_0} $\Big)$, qui ont été introduites dans les donnés 1) 2) 3) 4), page 317.

On va distinguer donc les deux cas. [page 319]

2 A) $\alpha = \alpha_0 + 1$.

Pour construire i_α et les $\tau_{\alpha,\beta} : i_\beta \longrightarrow i_\alpha$, il suffit de construire i_α et

$$\textcircled{\tau_{\alpha,\alpha_0}} \ : \ i_{\alpha_0} \ \longrightarrow \ i_\alpha = i_{\alpha_0+1} \ .$$

De même pour j_α et les $\tau'_{\alpha,\beta}$, il suffit de construire

$$\textcircled{\tau'_{\alpha,\alpha_0}} \ : \ j_{\alpha_0} \ \longrightarrow \ j_\alpha \ .$$

Il faut de plus se donner

$$j_{\alpha_0} \xrightarrow{\textcircled{v_{\alpha_0}}} \varphi(\underbrace{i_\alpha}_{=i_{\alpha_0+1}}) \xrightarrow{\textcircled{u_\alpha}} j_\alpha \ ,$$

donc en tout deux objets i_α, j_α (dans I et dans J' respectivement) et quatre flèches τ_{α,α_0}, τ'_{α,α_0}, v_{α_0}, u_α. Il faut quatre compatibilités (page 318), où les deux dernières $3_\alpha(\beta)$, $4_\alpha(\beta)$ dépendent d'un paramètre $\beta < \alpha$, i.e. $\beta \leqslant \alpha_0$, ou de $\beta < \alpha_0$.

On va d'abord s'occuper de deux premières compatibilités 1_α, 2_α, en termes de la donnée de [page 320 biffé] [page 321]

$$i_{\alpha_0} \ \in \ \mathrm{Ob}\, I \ , \qquad j_{\alpha_0} \ \in \ \mathrm{Ob}\, J' \ , \qquad u_{\alpha_0} \ : \ \varphi(i_{\alpha_0}) \ \longrightarrow \ j_{\alpha_0} \ .$$

Les deux compatibilités voulues pour les deux objets i_α, j_α et les quatre flèches τ_{α,α_0}, τ'_{α,α_0}, v_{α_0}, u_α sont indiquées dans le diagramme

$$(*) \qquad \varphi(i_{\alpha_0}) \xrightarrow{u_{\alpha_0}} j_{\alpha_0} \underset{v_{\alpha_0}\ ?}{\overset{\tau'_{\alpha,\alpha_0}}{\rightrightarrows}} \varphi(\underbrace{i_\alpha}_{?}) \xrightarrow{u_\alpha\ ?} j_\alpha \ .$$
$$\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \underset{\varphi(\tau_{\alpha,\alpha_0})}{\curvearrowright}$$

On note que comme φ est cofinal, $\exists\ i_\alpha = i \in \mathrm{Ob}\, I$ et $j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i)$. Mais on veut que le composé

$$w \ : \ \varphi(i_{\alpha_0}) \ \xrightarrow{u_{\alpha_0}} \ j_{\alpha_0} \ \xrightarrow{v_{\alpha_0}} \ \varphi(i)$$

soit de la forme $\varphi(\tau)$, où $\tau = \tau_{\alpha,\alpha_0} : i_{\alpha_0} \longrightarrow i_\alpha$ est une flèche dans I. Comme φ est un foncteur cofinal de catégories filtrantes, on sait qu'on peut trouver $i \xrightarrow{\rho} i'$ dans I, tel que la flèche composée $\varphi(i_{\alpha_0}) \xrightarrow{w} \varphi(i) \xrightarrow{\varphi(\rho)} \varphi(i')$ soit de la forme $\varphi(\tau)$. Donc quitte à remplacer i par i', et v_{α_0} par le composé $v'_{\alpha_0} : j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i) \xrightarrow{\varphi(\rho)} \varphi(i')$, on peut supposer que $v_{\alpha_0} u_{\alpha_0}$ est de la forme $\varphi(\tau)$. Cela nous donne donc en principe l'objet $i = i_\alpha$, et les flèches $v_{\alpha_0} : j_{\alpha_0} \longrightarrow \varphi(i)$ et $\tau_{\alpha,\alpha_0} : i_{\alpha_0} \longrightarrow i_\alpha$, de façon à satisfaire à la première compatibilité dans $(*)$. Il reste à construire j_α, τ'_{α,α_0}, u_α de façon à satisfaire à la deuxième compatibilité $(*)$. Or J' étant cofinal dans J, il existe j_α dans J' et une flèche $u_\alpha : \varphi(i_\alpha) \longrightarrow j_\alpha$. D'autre part, comme [page 323]

p. 122 [page 322]

$J' \longrightarrow J$ est pleinement fidèle, la flèche composée $j_{\alpha_0} \xrightarrow{v_{\alpha_0}} \varphi(i_\alpha) \xrightarrow{u_\alpha} j_\alpha$ dans J, entre objets de J', provient d'une unique flèche $\tau'_{\alpha,\alpha_0} : j_{\alpha_0} \longrightarrow j_\alpha$ dans J'.

Commentary · Exposition [ms. 322]

Finality supplies eventual lifting, not fullness

The successor construction needs to turn a map between images into the image of a map, after moving farther along the indexing category. Grothendieck invokes this several times. Writing out the small lemma makes clear why fullness of φ is unnecessary.

Suppose I is filtered and $\varphi : I \to J$ is final. Given $w : \varphi(a) \to \varphi(b)$, there exist arrows $r : b \to c$ and $t : a \to c$ in I such that

$$\varphi(r)w = \varphi(t).$$

Indeed, the objects $(a, 1_{\varphi(a)})$ and (b, w) of the comma category $(\varphi(a) \downarrow \varphi)$ are connected by a finite zigzag. Forgetting to I, choose a cocone on that finite zigzag. After applying φ, the equations defining its comma morphisms say that every composite from $\varphi(a)$ to the common target is the same. The two endpoints give t and r. This is a direct use of the connected-comma definition of finality, rather than a lifting property for individual arrows; compare The Stacks Project Authors (2026a, Definition 4.17.1).

Apply the lemma after first choosing $j_{\alpha_0} \to \varphi(b)$ by finality. Its composite with u_{α_0} then becomes $\varphi(t)$ after a further transition. This constructs i_α, v_{α_0} and τ_{α,α_0} with

$$v_{\alpha_0} u_{\alpha_0} = \varphi(\tau_{\alpha,\alpha_0}).$$

Finality of J' now supplies $u_\alpha : \varphi(i_\alpha) \to j_\alpha$ with $j_\alpha \in J'$. Fullness of $J' \hookrightarrow J$ permits us to define its transition arrow by

$$\tau'_{\alpha,\alpha_0} = u_\alpha v_{\alpha_0}.$$

Only this last passage uses fullness. It is useful to separate it from the earlier use of finality, since the proof would otherwise appear to assume that φ were fully faithful.

Ainsi, on a construit les deux objets et les quatre flèches voulues, de façon à satisfaire aux contraintes 1_α, 2_α de la page 318. Les contraintes $3_\alpha(\beta)$, $4_\alpha(\beta)$ sont-elles alors satisfaites automatiquement ?

$$\begin{array}{ccc} \varphi(i_\beta) & \xrightarrow{u_\beta} & j_\beta \\ \downarrow & & \downarrow \\ \varphi(i_{\alpha_0}) & \xrightarrow{u_{\alpha_0}} & j_{\alpha_0} \\ {\scriptstyle \varphi(\tau_{\alpha,\alpha_0})}\downarrow & & \downarrow{\scriptstyle \tau'_{\alpha,\alpha_0}} \\ \varphi(i_\alpha) & \xrightarrow{u_\alpha} & j_\alpha \end{array} \qquad \beta < \alpha, \text{ i.e. } \beta \leqslant \alpha_0 \ .$$

Le carré supérieur est commutatif par hypothèse de récurrence, pour que le carré total (composé) soit commutatif, il suffit que le carré inférieur le soit. On a donc une double-flèche $(\tau'_{\alpha,\alpha_0} u_{\alpha_0}, u_\alpha \varphi(\tau_{\alpha,\alpha_0})) : \varphi(i_\alpha) \rightrightarrows j_\alpha$, elle n'est peut-être pas triviale, mais on sait, J' étant filtrante, qu'on peut l'égaliser par une flèche $j_\alpha \longrightarrow \bar{j}_\alpha$ dans J'. Donc quitte à remplacer j_α par $\bar{j}_\alpha$, u_α par le composé $\bar{u}_\alpha : \varphi(i_0) \longrightarrow j_\alpha \longrightarrow \bar{j}_\alpha$ et τ'_{α,α_0} par le composé $\bar{\tau}'_{\alpha,\alpha_0} : j_{\alpha_0} \longrightarrow j_\alpha \longrightarrow \bar{j}_\alpha$ (sans toucher à i_α, v_{α_0}, $\tau_{\alpha_0,\alpha}$), on peut obtenir la commutativité, d'où $3_\alpha(\beta)$. [page 324]

Reste la contrainte $4_\alpha(\beta)$. Pour ceci, considérons le diagramme composite

$$\begin{array}{ccc} j_\beta & \xrightarrow{v_\beta} & \varphi(i_{\beta+1}) \\ {\scriptstyle \tau'_{\alpha_0,\beta}}\downarrow & & \downarrow{\scriptstyle \varphi(\tau_{\alpha,\beta+1})} \\ j_{\alpha_0} & \xrightarrow{v_{\alpha_0}} & \varphi(i_{\alpha_0+1}) = \varphi(i_\alpha) \ . \end{array}$$

140. **N.B.** Il suffit de l'exiger pour $\beta = \alpha_0$, dans le cas $\alpha = \alpha_0 + 1$, cf. ci-dessous, p. 323.

Si α_0 n'est pas un ordinal limite, mais de la forme $\alpha_1 + 1$, on peut encore se ramener au cas où $\beta = \alpha_1$, en procédant comme ci-dessus. Mais on peut procéder dans tous les cas, sans un tel artifice (!), en considérant les double-flèches

$$(*) \qquad j_\beta \underset{v_{\alpha_0}\tau'_{\alpha_0,\beta}}{\overset{\varphi(\tau_{\alpha,\beta+1})v_\beta}{\rightrightarrows}} \varphi(i_\alpha)$$

déduites du carré précédent. Comme l'ensemble de ces double-flèches est de cardinal $\operatorname{card}\alpha < \pi$, et que J est grande devant π (il suffirait qu'il le soit pour les cardinaux $\pi' < \pi$), on peut trouver une flèche $\varphi(i_\alpha) \xrightarrow{u} j$ dans J qui égalise toutes ces double-flèches. Comme φ est cofinal, on peut supposer que j est de la forme $\varphi(i)$. Comme φ est un foncteur cofinal de catégories filtrantes, il existe alors $i \xrightarrow{\rho} i'$ dans I, tel que le composé $\varphi(i_\alpha) \xrightarrow{u} \varphi(i) \xrightarrow{\varphi(\rho)} \varphi(i')$ soit de la forme $\varphi(\sigma)$, pour $\sigma : i_\alpha \longrightarrow i'$. Au total, on a trouvé $\sigma : i_\alpha \longrightarrow i'$, tel que $\varphi(\sigma)$ $(= \varphi(\rho)u) : \varphi(i_\alpha) \longrightarrow \varphi(i')$ égalise toutes les double-flèches envisagées dans $(*)$, p. 324. Donc il s'impose de remplacer i_α par $\bar{i}_\alpha = i'$, v_{α_0} par le composé $j_{\alpha_0} \longrightarrow \varphi(i_\alpha) \xrightarrow{\varphi(\sigma)} \varphi(\bar{i}_\alpha)$, τ_{α,α_0} par le composé $\bar{\tau}_{\alpha,\alpha_0} : i_{\alpha_0} \xrightarrow{\tau_{\alpha,\alpha_0}} i_\alpha \xrightarrow{\sigma} \bar{i}_\alpha$.

p. 123 [page 325] [page 326]

Pour résumer, voici la recette pour construire, d'abord $\boxed{i_\alpha,\ v_{\alpha_0},\ \tau_{\alpha,\alpha_0},}$ et *ensuite* $\boxed{j_\alpha,\ u_\alpha,\ \tau'_{\alpha,\alpha_0}}$.

On procède d'abord comme page 321, 322 pour construire le premier triple, de façon à satisfaire à la première compatibilité $(*)$ (p. 321), i.e. à 1_α. On "corrige" ensuite ce choix de i_α, v_{α_0}, τ_{α,α_0}, en remplaçant i_α par $\bar{i}_\alpha$ pour $\sigma : i_\alpha \longrightarrow \bar{i}_\alpha$, v_{α_0} par $\bar{v}_{\alpha_0} = \varphi(\sigma)v_{\alpha_0}$, et τ_{α,α_0} par $\bar{\tau}_{\alpha,\alpha_0} = \sigma\tau_{\alpha,\alpha_0}$, de sorte à obtenir les compatibilités $4_\alpha(\beta)$ pour $\beta < \alpha_0$, comme on vient de l'indiquer. On ne touchera plus à ces choix de i_α, v_{α_0}, τ_{α,α_0}, dans la suite de la construction. On construit $(j_\alpha, u_\alpha, \tau'_{\alpha,\alpha_0})$ de façon à satisfaire à la deuxième compatibilité $(*)$ (p. 321), comme indiqué page 322. Ensuite, on corrige ce choix, en remplaçant j_α par $\bar{j}_\alpha$, avec $\rho : j_\alpha \longrightarrow \bar{j}_\alpha$, et u_α par $\bar{u}_\alpha = \rho u_\alpha$, τ'_{α,α_0} par $\bar{\tau}'_{\alpha,\alpha_0} = \rho\tau'_{\alpha,\alpha_0}$, de façon à satisfaire aux contraintes $3_\alpha(\beta)$ de la page 318.

[page 327]

Cela achève la construction dans le cas où $\alpha = \alpha_0 + 1$.

Cas 2 B : α est ordinal limite.

Il faut donc construire les données 1) 2) 3) de la page 317 (à l'exclusion de la donnée 4), de façon à satisfaire à la seule contrainte $3_\alpha(\beta)$.

On commence à construire i_α et les $\tau_{\beta,\alpha}$ dans I. C'est possible, car $I_\alpha = \{\beta \mid \beta < \alpha\}$ est de cardinal $\pi_\alpha < \pi$ – il suffit donc de supposer I grande devant les cardinaux $\pi' < \pi$.

On construit ensuite de même J_α dans J' et les $\tau'_{\beta,\alpha}$ $(\beta < \alpha)$, en utilisant le fait que J' est grande devant $\operatorname{card}\alpha = \operatorname{card} I_\alpha$. On doit de plus construire une flèche

[page 328]

$$u_\alpha \ : \ \varphi(i_\alpha) \ \longrightarrow \ j_\alpha \ .$$

C'est possible, car J' étant cofinale dans J, il existe j' dans J' et $\varphi(i_\alpha) \longrightarrow J'$, et J' étant filtrante, il existe $\bar{j}_\alpha$ et des flèches $j_\alpha \longrightarrow \bar{j}_\alpha$, $j' \nearrow \bar{j}_\alpha$, donc quitte à remplacer j_α par $\bar{j}_\alpha$, les $\tau'_{\alpha,\beta}$ par des $\bar{\tau}'_{\alpha,\beta}$, on trouve bien une flèche $u_\alpha : \varphi(i_\alpha) \longrightarrow j_\alpha$. Il faut ensuite s'occuper des

Commentary · Development (commentators') [ms. 327]

The successor compatibilities are already forced

Grothendieck checks the four displayed compatibilities by successive corrections. His objective is sound, but once the two adjacent composites have been fixed, the remaining squares at a successor stage already commute. The following calculation shortens the construction without changing its hypotheses.

Successor simplification. [ours] Let $\alpha = \delta + 1$, assume all preceding transition maps and u's satisfy the stated compatibilities, and choose

$$v_\delta u_\delta = \varphi(\tau_{\alpha,\delta}), \qquad u_\alpha v_\delta = \tau'_{\alpha,\delta}.$$

Extend the transition maps to earlier indices by composition. Then both $(3_\alpha)(\beta)$ and $(4_\alpha)(\beta)$ hold automatically.

For the first square, the old naturality relation for $\beta < \delta$, and the identity relation when $\beta = \delta$, give

$$\begin{aligned}\tau'_{\alpha,\beta} u_\beta &= u_\alpha v_\delta \tau'_{\delta,\beta} u_\beta \\ &= u_\alpha v_\delta u_\delta \varphi(\tau_{\delta,\beta}) \\ &= u_\alpha \varphi(\tau_{\alpha,\beta}).\end{aligned}$$

For the second, let $\beta < \delta$. Since $\beta + 1 \le \delta$, the earlier second compatibility and naturality give

$$\begin{aligned}v_\delta \tau'_{\delta,\beta} &= v_\delta \tau'_{\delta,\beta+1} u_{\beta+1} v_\beta \\ &= v_\delta u_\delta \varphi(\tau_{\delta,\beta+1}) v_\beta \\ &= \varphi(\tau_{\alpha,\beta+1}) v_\beta.\end{aligned}$$

The same equations cover $\beta + 1 = \delta$, using the identity transition. This proves the assertion.

Thus the extra equalizations at manuscript pages 323–327 can be omitted at successor stages. They are not a counterexample to the construction: applying them to an already equal pair causes no harm, provided the later choices are made in the order specified on page 326. In particular, the phrase suggesting that the pair on page 323 may differ should not be read as evidence of an unresolved obstruction.

At a genuine limit stage there is no preceding last object, and a simultaneous equalization still has a purpose. One chooses cocones on the two earlier chains, adds a map $\varphi(i_\alpha) \to j_\alpha$ after enlarging j_α, and equalizes the resulting family of parallel pairs. The arrows have sources in J, not necessarily in J', so this equalization is first performed in J; finality of J' then moves its target back into J'. The required filteredness of J follows from that of I and finality of φ.

We checked the cofinality and eventual-equality lemmas in The Stacks Project Authors (2026a,d), and Grothendieck's complete construction. We did not locate this particular simplification as a separately stated result. The marking records our proof in this commentary, without a claim of priority.

compatibilités $3_\alpha(\beta)$, donc des double-flèches p. 124

$$\varphi(i_\beta) \underset{u_\alpha \varphi(\tau_{\alpha,\beta})}{\overset{\tau'_{\alpha,\beta} u_\beta}{\rightrightarrows}} j_\alpha \ .$$

Comme l'ensemble de ces double-flèches est de cardinal $\operatorname{card} \alpha < \pi$, et que J' est grande devant ledit cardinal, on trouve donc une flèche [page 329]

$$\rho : j_\alpha \longrightarrow j$$

dans J qui les égalise toutes. Comme J' est cofinal, on peut supposer j dans J', soit $\bar{j}_\alpha$. Donc quitte à remplacer j_α par $\bar{j}_\alpha$, et les $\tau'_{\alpha,\beta}$ par $\bar{\tau}'_{\alpha,\beta} = \rho \tau'_{\alpha,\beta}$, enfin $u_\alpha : \varphi(i_\alpha) \longrightarrow j_\alpha$ par $\bar{u}_\alpha = \rho u_\alpha : \varphi(i_\alpha) \longrightarrow \bar{j}_\alpha$, on satisfait à toutes les contraintes voulues.

Je résume le résultat ("± tautologique"!) prouvé dans les pages 313-329.

Lemme-clef 4.13.17. *Considérons un carré cartésien dans* Cat

$$\begin{array}{ccc} I & \xrightarrow{\varphi} & J \\ \uparrow & & \uparrow \psi \\ I' & \longrightarrow & J' \ . \end{array}$$

On fait les hypothèses suivantes : [page 330]

1) φ et ψ sont cofinaux, ψ est l'inclusion d'une sous-catégorie strictement pleine J' de J, I est filtrant (donc J et J' aussi).

On cherche des conditions pour que l'inclusion de la sous-catégorie strictement pleine $I' \longrightarrow I$ soit cofinale (auquel cas on voit tout de suite que I' est filtrante, et $I' \longrightarrow J'$ est aussi cofinal). Pour ceci, on suppose qu'il existe un ordinal limite α_0 *ayant les propriétés supplémentaires suivantes :*

2) I et J' sont stables par $\varinjlim$ de type I_{α_0} $(= \{\beta \mid \beta$ ordinal $< \alpha_0\})$, et les foncteurs φ, ψ commutent à ces limites.

3) Pour tout $\alpha \in I_{\alpha_0}$, I est grande devant $\operatorname{card}\alpha$*. (Donc, φ étant cofinal, J est également grande devant* $\operatorname{card}\alpha$*, et de même, ψ étant pleinement fidèle, et cofinal, J' est grande devant* $\operatorname{card}\alpha$*.)*

Sous ces conditions, I' est cofinal dans I (donc aussi grande devant $\operatorname{card}\alpha$*, pour tout $\alpha \in I_{\alpha_0}$).*

La démonstration est celle donnée ci-dessus. On n'a pas eu à utiliser que l'ordinal $\alpha_0 = \alpha_\pi$ était de cette espèce particulière, seulement que c'était un cardinal limite.

p. 125

Commentary · Exposition [ms. 330] [page 331]

Taking the final colimit completes the cofinality proof

The statement of 4.13.17 collects exactly the ingredients needed to finish the alternating construction. It is useful to make the last passage explicit, because it is the point where approximate membership becomes actual membership.

Write θ for the limit ordinal in that lemma. For $\beta < \theta$, the preceding construction gives compatible chains (i_β) in I and (j_β) in J', with i_0 prescribed. At each limit stage $\alpha < \theta$ there are at most $|\alpha|$ objects and compatibility equations to accommodate. The filteredness assumption for this cardinal supplies their cocones and simultaneous equalizations. At successor stages the preceding block gives all the compatibilities. Transfinite recursion therefore constructs the entire two chains.

Take their colimits,

$$\bar{i} = \varinjlim_{\beta<\theta} i_\beta \quad \text{in } I, \qquad \bar{j} = \varinjlim_{\beta<\theta} j_\beta \quad \text{in } J'.$$

Both exist by hypothesis. The functors to J preserve them. The maps u_β induce $U : \varphi(\bar{i}) \to \bar{j}$. The maps v_β induce $V : \bar{j} \to \varphi(\bar{i})$: compatibility (4) is precisely what is needed to define this map. The composite VU agrees on $\varphi(i_\beta)$ with the transition to $\varphi(i_{\beta+1})$ and hence with the colimit structure map. Therefore $VU = 1$. Likewise $UV = 1$ by compatibility (2). There is always a next index because θ is a limit ordinal; the successor indices are cofinal in θ.

We have proved $\varphi(\bar{i}) \simeq \bar{j}$. Since J' is closed under isomorphisms, $\bar{i} \in I'$, and the first colimit map gives $i_0 \to \bar{i}$. As i_0 was arbitrary and I' is full in the filtered category I, the required finality follows. A full final subcategory of a category admitting cocones on diagrams of a specified size again admits such cocones: form a cocone in the ambient category, then move its vertex into the subcategory. This also proves the final parenthesis of 4.13.17.

There is a similarly direct verification that $I' \to J'$ is final. The composite $I' \to I \to J$ is final. For each $j' \in J'$, its comma category with that composite is identical to $(j' \downarrow (I' \to J'))$, because $J' \subset J$ is full. Its nonemptiness and connectedness give the assertion.

A cardinal remark in the subsequent application requires correction. The initial ordinal of cardinality π is not large before every smaller cardinal when π is singular: a cofinal subset of size $\operatorname{cf}(\pi) < \pi$ has no upper bound. There is a repair which does not enlarge π: use instead the initial ordinal $\theta = (\pi_0')^+$. Since $\pi > \pi_0'$, its cardinality is at most π, it is large before π_0', and the hypotheses of adaptedness and $\mathrm{L}(\pi_0', \pi)$ provide exactly the θ-colimits needed. Every shorter segment has size at most π_0', so the remaining hypotheses of the lemma hold. If one insists on using the initial ordinal of π, it suffices to assume $\operatorname{cf}(\pi) > \pi_0'$, for example by imposing $\pi^{\pi_0'} = \pi$. The stronger sentence on manuscript page 336 is false at singular cardinals, but the argument has the smaller-ordinal repair just given.

Ce lemme implique, comme on l'a vu à la page 312, l'implication b $\Longrightarrow$ d dans le diagramme d'implications $(*)$ page 310, lequel est donc à présent prouvé.

Pour achever de prouver le théorème 4.13.15, il reste à prouver les implications

$$\begin{array}{ccc} \mathrm{c}' & & \\ & \searrow & \\ & & \mathrm{a}' \Longrightarrow \mathrm{a}\ . \\ & \nearrow & \\ \mathrm{b} & & \end{array}$$

Démontrons donc (b ou c′) $\Longrightarrow$ a′. Il reste à prouver que $\underline{S}$ est π-accessible dans $\mathcal{M}$, i.e. que le foncteur pleinement fidèle

$$(*) \qquad \mathrm{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \mathcal{M}$$

a pour image essentielle $\underline{S}$. Donc il faut prouver que si $x \in \mathrm{Ob}\,\mathcal{M}$, alors

$$(*) \qquad x \in \mathrm{Ob}\,\underline{S} \quad \overset{(?)}{\Longleftrightarrow} \quad \begin{array}{l} x \text{ est dans l'image essentielle de } \mathrm{Ind}_\pi(\underline{S}(\pi)), \text{ i.e. } x \\ \text{est isomorphe à } \varinjlim_{i\in I} x_i, \text{ les } x_i \text{ dans } \mathrm{Ob}\,\underline{S}(\pi),\ I \text{ grande} \\ \text{devant } \pi. \end{array}$$

(Supposons d'abord que $\underline{S}$ satisfasse b) ([141]). Donc on sait que [page 332]

$$(**) \qquad x \in \mathrm{Ob}\,\underline{S} \qquad \Longleftrightarrow \qquad \underline{S}/x \text{ est cofinale dans } \mathcal{M}_\pi/x\ .$$

Nous voulons déduire l'équivalence $(*)$ de l'équivalence $(**)$.

Prouvons $\Longrightarrow$ dans $(*)$, i.e. supposons $x \in \mathrm{Ob}\,\underline{S}$, et prouvons que x est dans l'image essentielle de $\mathrm{Ind}_\pi\,\underline{S}(\pi)$. En vertu de $(**)$, $\underline{S}(\pi)/x$ est une sous-catégorie (strictement pleine) cofinale dans $\mathcal{M}_\pi/x$, donc comme $\mathcal{M}_\pi/x$ est grande devant π, $\underline{S}(\pi)/x$ l'est aussi. Comme on sait que

$$x \ = \varinjlim_{i\in\mathcal{M}_\pi/x} x_i$$

(π étant cardinal utile pour $\mathcal{M}$), il s'ensuit par cofinalité qu'on a aussi

$$x \ = \varinjlim_{i\in\underline{S}(\pi)/x} x_i\ ,$$

et comme $\underline{S}(\pi)/x$ est grande devant π, cela implique que x appartient à l'image essentielle de $\mathrm{Ind}_\pi(\underline{S}(\pi))$.

Prouvons $\Longleftarrow$ dans $(*)$, i.e. supposons que x soit dans l'image essentielle de $\mathrm{Ind}_\pi(\underline{S}(\pi))$,

$$x \ = \varinjlim_{i\in I} x_i\ , \qquad \text{les } x_i \text{ dans } \underline{S}(\pi),\ I \text{ grande devant } \pi. \qquad \begin{array}{r}\text{p. 126}\\ \text{[page 333]}\end{array}$$

Alors le foncteur composé $i \longmapsto x_i$,

$$I \ \longrightarrow\ \underline{S}(\pi)/x \ \hookrightarrow\ \mathcal{M}_\pi/x$$

est cofinal (cf. 4.4.2, page 79), donc $\underline{S}(\pi)/x \longrightarrow \mathcal{M}_\pi/x$ satisfait la condition F 1 (puisque le composé le satisfait), et comme $\underline{S}(\pi)/x \longrightarrow \mathcal{M}_\pi/x$ est pleinement fidèle, cela implique déjà que ce foncteur est cofinal. Donc par $(**)$ on en conclut $x \in \mathrm{Ob}\,\underline{S}$, q.e.d.

Supposons maintenant que S satisfasse c′ (au lieu de b), et prouvons encore l'équivalence $(*)$. Pour ceci, écrivons

$$\square \qquad x \ = \varinjlim_{i\in I} x_i \qquad \begin{cases} \text{les } x_i \in \mathrm{Ob}\,\mathcal{M}_\pi,\ I \textit{ ensemble ordonné},\ (x_i)_{i\in I} \\ \text{est } \pi_0\text{-}\pi\text{-adaptée } ([142]). \end{cases}$$

141. Maladroit, on peut traiter les deux cas b) et c) en même temps, cf. bas de page 333.

ce qui est possible puisque π est utile pour $\mathcal{M}$ $\Big)$. Définissons $I_{\underline{S}}$ comme dans l'énoncé de c), donc comme image inverse de $\underline{S}(\pi)/x \hookrightarrow \mathcal{M}_\pi/x$ par $I \longrightarrow \mathcal{M}_\pi$. Par hypothèse d′) [plutôt c′)], on a

$$(**') \qquad x \in \operatorname{Ob} \underline{S} \qquad \Longleftrightarrow \qquad I_{\underline{S}} \text{ est cofinal dans } I \ .$$

En utilisant $(**')$, prouvons encore $(*)$ (page 331). En fait, on utilisera seulement qu'on a l'isomorphisme $\square$, avec I grande devant π, et qu'on a l'équivalence $(**')$, sans avoir à utiliser que I est ordonnée. Donc la démonstration vaut aussi dans le cas c). [page 334]

Prouvons $\Longrightarrow$ dans $(*)$, i.e. supposons $x \in \operatorname{Ob} \underline{S}$, prouvons que x est dans l'image essentielle de $\operatorname{Ind}_\pi(\underline{S}(\pi))$. En vertu de $(**')$, $I_{\underline{S}}$ est cofinale dans I, et comme $I_{\underline{S}} \longrightarrow I$ est une inclusion pleinement fidèle, il s'ensuit que $I_{\underline{S}}$ est également grande devant π, d'autre part on aura par cofinalité

$$x \ = \ \varinjlim_{i \in I_{\underline{S}}} x_i \ ,$$

où cette fois les x_i sont dans $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$, d'où résulte que x est dans l'image essentielle de $\operatorname{Ind}_\pi(\underline{S}(\pi))$.

Prouvons $\Longleftarrow$ dans $(*)$, i.e. supposons que l'on ait

$$x \ = \ \varinjlim_{j \in J} x_j \ , \qquad \text{les } x_j \text{ dans } \underline{S}(\pi), \ J \text{ grande devant } \pi \ .$$

p. 127

Commentary · Examples [ms. 334] [page 335]

A divisible group recognized through countable subgroups

The criterion is easiest to see when the small pieces are actual subobjects. Consider $\mathcal{M} = \mathrm{Ab}$ and $\pi = \aleph_0$, so that the modern regular cardinal is $\lambda = \aleph_1$. The objects of $\mathcal{M}_\pi$ are the countable abelian groups. A countable group has a presentation with countably many generators and relations, and a map from it into an $\aleph_1$-filtered colimit factors at one stage, with all relations and all equalities satisfied at one further stage. Conversely every group is the $\aleph_1$-filtered union of its countable subgroups; presentability then makes its identity factor through one countable subgroup, forcing the group itself to be countable.

Let $\mathcal{D} \subset \mathrm{Ab}$ be the full subcategory of divisible groups. For an abelian group X, put

$$I_X = \{A \leq X : |A| \leq \aleph_0\},$$

ordered by inclusion. This poset is $\aleph_1$-filtered: a countable family has a countable subgroup containing its union. It has colimits of countable chains, given by unions, and the inclusion into Ab preserves them. Its colimit is X.

If X is divisible, every countable subgroup A_0 is contained in a countable divisible subgroup. Having chosen A_n, choose for each $a \in A_n$ and each positive integer m one mth root of a in X, and let A_{n+1} be the subgroup generated by A_n and these roots. There are countably many choices, so A_{n+1} remains countable. The union $D = \bigcup_{n<\omega} A_n$ is divisible: an element belongs to some A_n and each required root belongs to A_{n+1}. Thus the countable divisible subgroups form a cofinal subposet of I_X.

Conversely, if that subposet is cofinal, any $x \in X$ lies in a countable divisible subgroup, by applying cofinality to $\langle x \rangle$. Every equation $my = x$ with $m \geq 1$ then has a solution in X. Hence

$$X \text{ divisible} \quad \Longleftrightarrow \quad \{A \in I_X : A \text{ divisible}\} \text{ cofinal in } I_X.$$

Divisibility is preserved by filtered colimits: represent an element at a stage, choose a root there, and take its image. The countable divisible groups form a set of isomorphism classes and are $\aleph_1$-presentable in $\mathcal{D}$, since the inclusion preserves these colimits. The preceding cofinal presentation

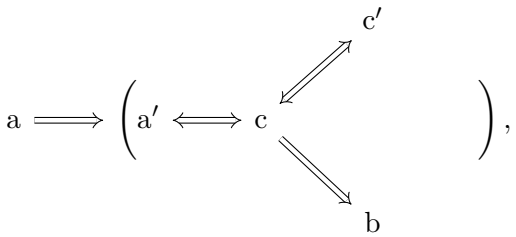
142. **N.B.** Ça existe, grâce à 4.13.14.

therefore proves that $\mathcal{D}$ is $\aleph_1$-accessible and accessibly embedded, with the indicated presentable objects. This establishes all the ingredients of the example, without invoking the classification of divisible groups.

The adaptedness condition cannot be discarded even here. The sequence

$$\mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{4} \cdots$$

has colimit $\mathbb{Q}$, using the maps $m \mapsto m/(n+1)!$ at stage n. None of its stages is divisible. Its indexing poset ω is filtered but is not $\aleph_1$-filtered, and does not contain the colimit of its own unbounded countable chain. The countable-subgroup presentation has exactly the additional closure which permits the membership criterion to work.



En invoquant à nouveau 4.4.2, on trouve que $J \longrightarrow \mathcal{M}_\pi/x$ est cofinal, et comme ce foncteur se factorise par le foncteur d'inclusion pleinement fidèle $\underline{S}(\pi)/x \hookrightarrow \mathcal{M}_\pi/x$, il s'ensuit comme tantôt que ce dernier est cofinal. Nous allons admettre pour un moment que ceci implique que l'image inverse $I_{\underline{S}}$ de cette sous-catégorie strictement pleine, par le foncteur également cofinal $I \longrightarrow \mathcal{M}_\pi/x$, est cofinal dans I. Ceci étant, l'équivalence $(**')$ (p. 333) implique $x \in \mathrm{Ob}\,\underline{S}$, ce qu'on voulait.

Donc il reste à prouver que si

$$J' \;=\; \underline{S}(\pi)/x \hookrightarrow \mathcal{M}_\pi/x \;=\; J$$

est cofinal, alors $I' = I_{\underline{S}} \longrightarrow I$ l'est aussi. Il semble qu'il faille bel et bien à nouveau invoquer les conditions de stabilité $\mathrm{L}(\pi_0, \pi)$ faites dans d$'$) `[plutôt c')]` ce qui n'avait pas été nécessaire pour le cas c) et le lemme-clef (un peu) vache 4.13.17, où on prendra (comme dans la démonstration écrite avant l'énoncé de cet lemme) $\alpha = \alpha_\pi \overset{\text{déf}}{=}$ plus petit ordinal α tel que $\mathrm{card}\,\alpha = \pi$. Donc I_α est de cardinal π, et grande devant tout cardinal $\pi' < \pi$, et en particulier devant π'_0. L'hypothèse 2°) de 4.13.17 est vérifiée pour I, par définition d'un système inductif π_0-π-adapté, et pour J', grâce à l'hypothèse $\mathrm{L}(\pi_0, \pi)$ sur $\underline{S}(\pi)$. De même, l'hypothèse 3°) (I grande devant tout cardinal $< \pi$) est satisfaite par définition des systèmes π_0-π-adaptés – I est même grande devant π. L'hypothèse 1°) a déjà été vue. [page 336]

On a donc prouvé (par voie circulaire)

`[et aussi b` $\Longrightarrow$ `c,]` en ayant à invoquer le lemme-clef vache pour les *deux* implications

$$\mathrm{a}' \implies \mathrm{c} \qquad \text{et} \qquad \mathrm{c}' \implies \mathrm{a}'$$

(donc pour deux implications *en sens inverses*, chose étrange …).

Il reste seulement encore à prouver l'implication [page 337]

$$\mathrm{a}' \implies \mathrm{a}\,,$$

ce qui est essentiellement sorital.

Cela achève la démonstration du critère d'accessibilité 4.13.15 d'une sous-catégorie pleine $\underline{S}$ de $\mathcal{M}$.

On va donner une variante un peu décantée de 4.13.15, qui (avec des hypothèses un peu plus faibles) capte l'essentiel de sa substance. L'énoncé 4.13.15 en est une conséquence quasi immédiate : p. 128 [page 338]

Corollaire 4.13.18 (de 4.13.15). *Soient $\mathcal{M}$ une catégorie accessible, π un cardinal utile pour $\mathcal{M}$, α_0 un* ordinal limite *tel que l'on ait* $\operatorname{card}\alpha_0 \leqslant \pi$. *Soit $I_{\alpha_0} = \{\alpha \mid \alpha < \alpha_0\}$, et supposons que $\mathcal{M}$ soit stable par $\varinjlim$ de type I_{α_0}.*

Soit alors $\underline{S}$ une sous-catégorie strictement pleine de $\mathcal{M}$, $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$. Désignons par $L(\alpha_0)$ la condition : $\underline{S}(\pi)$ est stable dans $\mathcal{M}_\pi$ (ou ce qui revient au même, dans $\mathcal{M}$) par $\varinjlim$ de type I_{α_0}. Alors les conditions suivantes sont équivalentes.

a) $\underline{S}$ est π-accessible dans $\mathcal{M}$, et est stable dans $\mathcal{M}$ par $\varinjlim$ de type I_{α_0}.

a′) $\underline{S}$ est π-accessible et $\underline{S}(\pi)$ satisfait $L(\alpha_0)$.

b) $\underline{S}(\pi)$ satisfait $L(\alpha_0)$, et pour tout $x \in \operatorname{Ob}\mathcal{M}$, on a ceci : $x \in \operatorname{Ob}\underline{S}$ si et seulement si la sous-catégorie strictement pleine $\underline{S}(\pi)/x$ de $\mathcal{M}(\pi)/x$ est cofinale dans $\mathcal{M}(\pi)/x$ `[lire` *$\mathcal{M}_\pi/x$*`]`.

c) $\underline{S}(\pi)$ satisfait $L(\alpha_0)$, de plus pour tout $x \in \operatorname{Ob}\mathcal{M}$, et toute représentation

$$x \;\simeq\; \varinjlim_{i\in I} x_i$$

qui est "α_0-π-adaptée", i.e. telle que [page 339]

1°) I équivalente à une petite catégorie, et grande devant π,

2°) les $\varinjlim$ de type I_{α_0} existent dans I,

3°) le foncteur $I \longrightarrow \mathcal{M}$, $i \longmapsto x_i$, commute aux $\varinjlim$ de type I_{α_0}, et enfin

4°) les $x_i \in \operatorname{Ob}\mathcal{M}_\pi$

(comparer 4.13.11), on a ceci (où on désigne par $I_{\underline{S}}$ la sous-catégorie strictement pleine de I formée des i tels que $x_i \in \operatorname{Ob}\underline{S}$) : on a $x \in \operatorname{Ob}\underline{S}$ si et seulement si $I_{\underline{S}}$ est cofinale dans I.

*c′) (*Si *I_{α_0} est grande devant π_0, et $\pi^{\pi_0} = \pi$, pour pouvoir invoquer 4.13.14, cf. p. 335.) Comme c), mais en supposant I ordonnée.*

([143]).

Commentary · Exposition [ms. 338]

The canonical presentation and an arbitrary adapted one

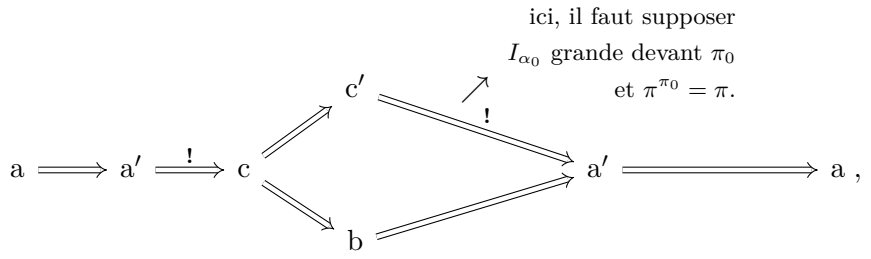
Grothendieck's criterion compares two ways of saying that the small objects of $\underline{S}$ suffice to build x. In the canonical presentation, this means that $\underline{S}(\pi)/x$ is final in $\mathcal{M}_\pi/x$. In a chosen presentation it means that the indices already lying in $\underline{S}$ are final. The first description is intrinsic; the second can be used in calculations.

For a useful π, the canonical diagram $\mathcal{M}_\pi/x \to \mathcal{M}$ is λ-filtered and has colimit x, where $\lambda = \pi^+$. If $\underline{S}(\pi)/x$ is final, it supplies a λ-filtered presentation of x using objects of $\underline{S}(\pi)$, so x lies in the essential image of $\mathrm{Ind}_\lambda(\underline{S}(\pi))$. Conversely, a presentation $x = \varinjlim_i x_i$ by such objects gives a final functor $I \to \mathcal{M}_\pi/x$. For example, an arrow $a \to x$ with a presentable factors at a stage, and equality of two such factorizations holds at a later stage; these are the two required comma-category conditions. Its factorization through the full subcategory $\underline{S}(\pi)/x$ makes that subcategory final.

This equivalence alone does not permit pulling the subcategory back along every final presentation. That was precisely the failure in the even–odd example. Conditions on Φ, and on the preservation of its colimits by the indexing diagram, supply the hypotheses of 4.13.17. They transfer finality to

$$I_{\underline{S}} = \{i \in I : x_i \in \underline{S}\}.$$

The converse direction is then immediate from the closure of $\underline{S}$ under the filtered colimits in question.



Here being π-accessible *in* $\mathcal{M}$ carries more information than abstract accessibility of $\underline{S}$. It identifies $\underline{S}$ with the full image of the Ind-completion of $\underline{S} \cap \mathcal{M}_\pi$ and ensures that the inclusion preserves the chosen filtered colimits. In particular, its small objects are measured in the ambient

143. **N.B.** Si on ne suppose par I_{α_0} grande devant π_0 et $\pi^{\pi_0} = \pi$, alors toutes les conditions de a) à c) (a, a′, b, c) sont équivalentes et *impliquent* c, mais ne lui sont peut-être pas équivalentes.

category. This distinction is made explicit in 4.13.26. It prevents one from treating any abstractly accessible full subcategory as if it automatically had the canonical presentations needed here.

The optional restriction to ordered indexing categories introduces a separate existence problem. The exponentiation hypotheses in c′ are used to construct sufficiently closed ordered presentations of controlled cardinality. They are not part of the elementary argument with the canonical slice. Thus the text correctly distinguishes the unconditional equivalence of a), a′), b), c) from the stronger assertion involving c′; the missing prime in footnote 143 is a typographical slip in the edition.

Démonstration. Elle se fait suivant le même diagramme logique que celle de 4.13.15,

où on a marqué du signe ! les deux implications qui sont "vaches", en ce sens qu'elles font appel au lemme-clef 4.13.17 (pages 329-330), qui se prouve par une construction transfinie un peu vissée. La démonstration des sept implications du diagramme est essentiellement celle donné dans les pages précédentes 311-337,

à l'exception de $a' \Longrightarrow a$, qui est un peu plus simple dans le cas actuel. On va la dégager sous forme de lemme un peu plus général. (**N.B.** La démonstration de $a' \Longrightarrow a$ dans 4.13.15 avait été omise comme "soritale" !, cf. page 337 …) p. 129 [page 340]

Lemme 4.13.19. *Soient $\mathcal{M}$ une catégorie accessible dans $\mathcal{M}$, π un cardinal utile pour $\mathcal{M}$ et tel que $\underline{S}$ soit π-accessible, i.e. $\underline{S}$ est l'image essentielle de $\mathrm{Ind}_\pi(\underline{S}(\pi))$ par le foncteur pleinement fidèle canonique $\mathrm{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \mathcal{M}$, où $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$. On suppose qu'il existe un ordinal limite α, tel que $\operatorname{card} \alpha \leqslant \pi$ et tel que $\mathcal{M}_\pi$ et $\underline{S}(\pi)$ $(= \underline{S}_\pi)$ soient stables par $\varinjlim$ de type I_α soient stables par $\varinjlim$ de type I_α, et que le foncteur d'inclusion $\underline{S}(\pi) \longrightarrow \mathcal{M}_\pi$ y commute. Soit Φ un ensemble de catégories telles que $\forall\ I \in \Phi$, on ait $\operatorname{card} \text{réd}\, I \leqslant \pi$, et supposons que $\mathcal{M}_\pi$ soit stable par $\varinjlim$ de type Φ, et que $\underline{S}(\pi)$ soit stable dans $\mathcal{M}_\pi$ par lesdites limites (ou ce qui revient au même, qu'il soit stable en lui-même par ces $\varinjlim$, et que le foncteur d'inclusion y commute). Alors $\mathcal{M}$ et $\underline{S}$ sont stables par $\varinjlim$ de type Φ, et le foncteur d'inclusion $\underline{S} \longrightarrow \mathcal{M}$ y commute, i.e. $\mathcal{M}$ est stable par ces limites, et $\underline{S}$ stable dans $\mathcal{M}$ par ces mêmes limites.*

Démonstration. On applique 4.11.1 (p. 267-268) séparément à $\mathcal{M} \simeq \mathrm{Ind}_\pi \mathcal{M}_\pi$ et à $\underline{S} \simeq \mathrm{Ind}_\pi \underline{S}(\pi)$, pour conclure que $\mathcal{M}$ et $\underline{S}$ sont stables séparément par $\varinjlim$ de type Φ. Il reste à voir que le foncteur $\underline{S} \longrightarrow \mathcal{M}$ y commute. Cela se voit comme dans la démonstration de 4.11.1, on obtient plus généralement ceci : [page 341]

Lemme 4.13.20 (cor. à 4.11.1). *Soient $f_0 : C \longrightarrow C'$ un foncteur entre catégories équivalentes à des petites catégories, π un cardinal infini, $f : \mathcal{M} \overset{\text{déf}}{=} \mathrm{Ind}_\pi C \longrightarrow \mathcal{M}' \overset{\text{déf}}{=} \mathrm{Ind}_\pi C'$ l'extension canonique $\mathrm{Ind}_\pi(f_0)$ de f_0. Soient Φ et α comme dans 4.11.1, et supposons que $I_\alpha \in \Phi$ et que f_0 commute aux $\varinjlim$ de type Φ. Alors f commute à ces mêmes limites inductives.* ([144]).

Corollaire 4.13.21. *Sous les conditions de 4.13.20, supposons que Φ contienne les catégories de cardinal $\leqslant \pi$ (resp. les catégories filtrantes de cardinal $\leqslant \pi$, resp. les catégories filtrantes grandes devant π_0 de cardinal $\leqslant \pi$, resp. les catégories discrètes de cardinal $\leqslant \pi$). Alors f commute aux petites $\varinjlim$ (resp. aux petites $\varinjlim$ filtrantes, resp. aux petites $\varinjlim$ filtrantes grandes devant π_0, resp. aux petites sommes). (Réciproque claire et "laissée au lecteur".)*

[page 342]

Se voit comme 4.4.14 et 4.4.14.1 (p. 97, 98).
Voici enfin, il me semble, la forme définitive (?) de 4.13.15, 4.13.18.

Commentary · Exposition [ms. 341]

Why a colimit calculation on small objects extends

The passage from a′ to a) requires more than saying that large objects are filtered colimits of small ones. A diagram of large objects also has arrows and relations; the small presentations must realize them simultaneously. The earlier representation theorem, used in 4.11.1, supplies this compatibility under the limit-ordinal hypothesis.

Let C and C' be the essentially small categories of 4.13.20 and put $\lambda = \pi^+$. For a diagram $D : J \to \mathrm{Ind}_\lambda(C)$ of one of the allowed shapes, its simultaneous presentation is a functor

$$X : J \times A \longrightarrow C$$

with A λ-filtered and $D(j) \simeq \varinjlim_{a\in A} X(j,a)$ naturally in j. The assumptions ensure that the J-colimits of $X(-,a)$ exist in C and represent the corresponding colimits in its Ind-completion. Consequently

$$\varinjlim_{j\in J} D(j) \simeq \varinjlim_{a\in A} \left(\varinjlim_{j\in J} X(j,a) \right).$$

This interchange uses only the universal property of colimits: both sides represent the set of cocones from the two-variable diagram to a prescribed target. It is not an interchange of a limit and a colimit.

If $f = \mathrm{Ind}_\lambda(f_0)$ and f_0 preserves these J-colimits, then

$$\begin{aligned} f\left(\varinjlim_{j} D(j) \right) &\simeq \varinjlim_{a} f_0 \left(\varinjlim_{j} X(j,a) \right) \\ &\simeq \varinjlim_{a} \varinjlim_{j} f_0 X(j,a) \\ &\simeq \varinjlim_{j} f(D(j)). \end{aligned}$$

All comparisons are natural, since they are induced by the same cocones. Apply this to the inclusion $\underline{S}(\pi) \hookrightarrow \mathcal{M}_\pi$ to obtain 4.13.19, including preservation by $\underline{S} \hookrightarrow \mathcal{M}$. This fills in the proof that page 337 calls sorital, while retaining the nontrivial simultaneous-presentation input rather than silently assuming it.

For the arbitrary-small-colimit assertion of 4.13.21, one can also see the size reduction directly. A small category is the directed union of its subcategories generated by at most π arrows. The poset of these subcategories is λ-filtered; each has at most π arrows because π is infinite. The colimit of a diagram over the whole category is the colimit, over this poset, of its restricted colimits. Preservation of the bounded colimits and of λ-filtered colimits therefore gives preservation of all small colimits. The versions with filtered shapes use filtered envelopes of the small subcategories; the later construction in 4.13.37–39 makes that step explicit.

For the variant restricted to categories large before π_0, that bounded-envelope argument is verified below with the sufficient additional hypothesis $\pi^{\pi_0} = \pi$. The bare formulation of 4.13.21 does not display this hypothesis. We have not established that its one ordinal-colimit assumption suffices to remove it, so we do not certify that particular fixed-rank inference in its full printed generality. This qualification concerns the third variant, not the explicit interchange calculation above.

The underlying extension principle already occurs in Artin et al. (1972, Exposé I, 8.7.2–8.7.3): a functor on C extends uniquely, up to canonical isomorphism, to a functor on $\mathrm{Ind}(C)$ preserving filtered colimits. Here the additional work controls the cardinal and the extra colimit shapes. It belongs to the same mathematical setting as the accessible-category theory of Makkai and Paré (1989), which predates these manuscript pages; it should not be described as a later discovery of that theory.

144. Il vaut mieux prendre des foncteurs $f_0 : C \longrightarrow \mathcal{N}$, et $\mathcal{N}$ [?] que f_0 commute aux $\varinjlim$ de type Φ, donc il en est de même de son extension $\mathrm{Ind}_\pi(C,\mathcal{N}) \longrightarrow \mathcal{N}$. (**N.B.** On suppose que $\mathcal{N}$ satisfait $\overrightarrow{L}_\pi$.)

Théorème 4.13.22 ([145]). *Soient $\mathcal{M}$ une catégorie accessible, π un cardinal infini, utile pour $\mathcal{M}$, et Φ un ensemble de catégories satisfaisant les deux conditions :*

1°) $J \in \Phi$ implique card réd $J \leqslant \pi$.

2°) Il existe un ordinal limite α_0 *avec* $I_{\alpha_0} \in \Phi$.

On suppose $\mathcal{M}$ stable par $\varinjlim$ de type Φ. Soient $\underline{S}$ une sous-catégorie strictement pleine *de $\mathcal{M}$, et $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$. Désignons par $L(\varphi)$ la condition sur $\underline{S}(\pi)$: $\underline{S}(\pi)$ est stable dans $\mathcal{M}$ (où* p. 130
ce qui revient au même, dans $\mathcal{M}_\pi$) par $\varinjlim$ de type Φ. Ceci posé, les conditions suivantes sur $\underline{S}$ sont équivalentes :

ⓐ *$\underline{S}$ est π-accessible dans $\mathcal{M}$, et stable dans $\mathcal{M}$ par $\varinjlim$ de type Φ.*

a′) *$\underline{S}$ est π-accessible dans $\mathcal{M}$, et $\underline{S}(\pi)$ satisfait à $L(\Phi)$.*

b) *$\underline{S}(\pi)$ satisfait à $L(\Phi)$, et pour tout $x \in \mathrm{Ob}\,\mathcal{M}$, on a ceci : $x \in \mathrm{Ob}\,\underline{S}$ si et seulement si la sous-catégorie strictement pleine $\underline{S}(\pi)/x$ de $\mathcal{M}(\pi)/x$ est cofinale dans $\mathcal{M}(\pi)/x$* `[lire` *$\mathcal{M}_\pi/x$*`]`. [page 343]

ⓒ *$\underline{S}(\pi)$ satisfait à $L(\Phi)$, et pour tout $x \in \mathrm{Ob}\,\mathcal{M}$ et toute représentation $x \simeq \varinjlim_{i \in I} x_i$ qui est Φ-π-adaptée (cf. définition plus bas), on a ceci : $x \in \mathrm{Ob}\,\underline{S}$ si et seulement si $I_{\underline{S}}$ est cofinale dans I, où $I_{\underline{S}}$ est la sous-catégorie strictement pleine de I formée des $i \in \mathrm{Ob}\,I$ tels que $x_i \in \mathrm{Ob}\,\underline{S}$ (ou encore, $x_i \in \mathrm{Ob}\,\underline{S}(\pi)$).* **N.B.** *On dit qu'un système inductif $(x_i)_{i \in I}$ dans $\mathcal{M}$ est Φ-π-adapté si*

1) I équivalente à une petite catégorie, et I grande devant π,

2) les $\varinjlim$ de type Φ existent dans I,

3) le foncteur $i \longmapsto x_i$ de I dans $\mathcal{M}$ commute aux $\varinjlim$ de type Φ, et enfin

4) les $x_i \in \mathrm{Ob}\,\mathcal{M}_\pi$.

c′) *(Si $\pi^{\pi_0} = \pi$, où π_0 est un cardinal $\leqslant \pi$ utile pour $\mathcal{M}$, et si $J \in \Phi$ implique que J est grande devant π_0.) Comme c), avec I* ordonnée.

([146], [147]).

Définition 4.13.23 ([148]). Soient $\mathcal{M}$ une catégorie accessible, π un cardinal, Φ un ensemble de catégories, satisfaisant les deux conditions :

a) $J \in \Phi \Longrightarrow$ card réd $J \leqslant \pi$.

b) Il existe un ordinal limite α_0, tel que $I_{\alpha_0} \in \Phi$ ([149]).

Soit S une partie de $\mathrm{Ob}\,\mathcal{M}$, $\underline{S}$ la sous-catégorie pleine qu'elle définit. On dit que S est une [page 344]
partie Φ-π-accessible de $\mathrm{Ob}\,\mathcal{M}$, ou que $\underline{S}$ est une *sous-catégorie Φ-π-accessible dans $\mathcal{M}$*, si les conditions suivantes sont satisfaites.

1°) π est utile pour $\mathcal{M}$, $\mathcal{M}$ est stable par $\varinjlim$ de type Φ ([150]).

2°) $\underline{S}$ est une sous-catégorie π-accessible dans $\mathcal{M}$.

3°) $\underline{S}$ est stable dans $\mathcal{M}$ par $\varinjlim$ de type Φ.

([151]).

N.B. Quand la condition préliminaire 1°) *sur* $\mathcal{M}$ est satisfaite, la validité des conditions 2°) 3°) équivaut donc à la condition que $\underline{S}$ soit *strictement* pleine dans $\mathcal{M}$, et que de plus $\underline{S}$ p. 131

145. cf. variante 4.13.36, page 358.

146. **N.B.** Quand les conditions restrictives ci-contre `[parenthèse dans c′)]` ne sont pas satisfaites, alors a, a′, b, c sont encore équivalentes, et impliquent c′, mais ne sont peut-être pas équivalentes à c′).

147. **N.B.** Il faudrait réénoncer les conditions annexes [?] (Si …), cf. p. 359-360.

148. **N.B.** Il y aurait intérêt à remonter cette définition (*sans* b), dès avant 4.13.15.

149. Si c'est pour poser une définition, on peut se passer de la condition b).

150. Condition préliminaire sur $\mathcal{M}$.

151. **N.B.** Quand $\Phi = \{I_{\alpha_0}\}$, on dit aussi que $\underline{S}$ est α_0-π-accessible dans $\mathcal{M}$. Si Φ est formé des catégories de cardinal $\leqslant \pi$ et grandes devant π_0, on dit que $\underline{S}$ est π_0-π-accessible dans $\mathcal{M}$.

satisfasse la condition a) du théorème 4.13.22. D'autre part, cette condition est équivalente à chacune des conditions a′, b, c de ce même théorème, et aussi à la dernière condition c′, sous réserve qu'on ait $\pi^{\pi_0} = \pi$ (pour un cardinal $\pi_0 < \pi$ utile pour $\mathcal{M}$) et que $J \in \Phi$ implique que J est grande devant π_0.

Conceptuellement, c'est la définition donnée dans 4.13.23, i.e. la condition ⓐ de 4.13.22, qui paraît la plus claire, ou sa variante immédiate a′. Mais du point de vue pratique, du travail avec les parties accessibles, c'est par propriété ⓒ qui paraît la plus commode. Le poids principal du théorème 4.13.22 est bien l'implication a $\Longrightarrow$ c (via a $\Longrightarrow$ a′ $\overset{!}{\Longrightarrow}$ c). Donc il faut [page 345]
surtout voir ce théorème comme donnant un critère remarquable d'appartenance à $\mathrm{Ob}\,\underline{S}$ d'un objet x de $\mathcal{M}$ qui est présenté par un système inductif Φ-π-adapté :

$$(*) \qquad x \in \mathrm{Ob}\,\underline{S} \qquad \Longleftrightarrow \qquad I_{\underline{S}} \text{ cofinal},$$

et dans cette équivalence, c'est l'implication $\Longrightarrow$ qui est la partie non soritale, et remarquable.

Proposition 4.13.24. *Soient $\mathcal{M}$, π, Φ comme dans 4.13.23 ([152]), on suppose que la condition 1° de 4.13.23 est satisfaite (π utile pour $\mathcal{M}$, $\mathcal{M}$ stable par $\varinjlim$ de type Φ). Soit Σ'^{Φ}_{π} l'ensemble des sous-catégories $\underline{S}$ de $\mathcal{M}$ qui sont Φ-π-accessibles dans $\mathcal{M}$, et Σ^{Φ}_{π} l'ensemble des sous-catégories $\underline{S}(\pi)$ de $\mathcal{M}_\pi$ qui sont strictement pleines, et stables dans $\mathcal{M}_\pi$ par $\varinjlim$ de type Φ. (Ces sous-catégories sont forcément karoubiennes, car stables par $\varinjlim$ de type I_{α_0}, donc aussi par facteurs directs.) Alors les bijections (4.13.4.1) (page 288) induisent des bijections inverses l'une à l'autre*

$$\Sigma^{\Phi}_{\pi} \;\underset{\longleftarrow}{\longrightarrow}\; \Sigma'^{\Phi}_{\pi} \quad .$$

Commentary · Development (commentators') [ms. 345]

Retracts are essential in the small-subcategory correspondence

Grothendieck wants to replace a large accessible subcategory by its small part, so that operations on the former can be performed inside an essentially small category. Proposition 4.13.24 gives this correspondence when the small part is closed under the stated colimits and under retracts. The parenthetical observation supplies retract closure from an ordinal colimit. Its footnote, however, says that the ordinal hypothesis is unnecessary, without replacing it by a retract hypothesis.

Counterexample to the footnote as stated. [ours] Take $\mathcal{M} = \mathrm{Set}$, $\pi = \aleph_0$ and $\Phi = \varnothing$. Let C be the strictly full subcategory of $\mathcal{M}_\pi$ consisting of the two-element sets. It satisfies all the stated Φ-closure requirements, vacuously. Nevertheless the filtered-colimit closure of C contains a singleton, so taking its small part does not recover C.

For completeness, fix a two-element set B and an idempotent constant map $e : B \to B$. Index a diagram by the ordinal ω_1, put B at each index, and put e on every strict transition and the identity on identity transitions. This is a functor because $e^2 = e$. The ordinal ω_1 is $\aleph_1$-filtered: every countable set of its indices is bounded. Its colimit in sets is the image of e, a singleton. The singleton is also $\aleph_1$-presentable, hence belongs to the small part of the Ind-image, but not to C. This proves the failure of the asserted inverse correspondence under the footnote's weakened hypotheses.

The exact repair is to require C to be closed under retracts, or to retain a nonzero limit-ordinal shape among the closure assumptions. To verify the latter option, take any idempotent $e : x \to x$ in C and form the constant-object diagram along that ordinal, with e on strict transitions. If its colimit is $q : x \to y$, the compatible maps $e : x \to x$ induce $s : y \to x$ with $sq = e$. Since $qe = q$ and the colimit maps jointly determine a morphism out of y, one has $qs = 1_y$. Thus y splits e, and closure under this colimit puts its splitting object in C.

Conversely, when $C \subset \mathcal{M}_\pi$ is full and retract closed, every λ-presentable object of its Ind-image is a retract of an object of C: factor its identity through one stage of a λ-filtered presentation. Hence the small part of that image is exactly C. Combined with 4.13.19, this gives the stated correspondence with the intended additional-colimit closure.

The general role of idempotent completion in Ind-constructions is standard. Our contribution here is the explicit diagnosis and counterexample for the particular footnote, checked against the edition and the surrounding propositions. We have not found a published discussion of this manuscript slip.

152. **N.B.** La condition $I_{\alpha_0} \in \Phi$ n'est pas utile.

Proposition 4.13.25. *Soient $\mathcal{M}$, π, Φ comme dans 4.13.23, avec $I_{\alpha_\pi} \in \Phi$ (α_π étant le plus petit ordinal de cardinal Φ* [plutôt π]*). Alors l'ensemble Σ'^{Φ}_{π} des sous-catégories de $\mathcal{M}$ Φ-π-accessibles dans $\mathcal{M}$ est stable par intersection de familles de cardinal $\leqslant \pi$* ([153]). [page 346]

(**N.B.** La bijection $\Sigma^{\Phi}_{\pi} \xrightarrow{\sim} \Sigma'^{\Phi}_{\pi}$ de 4.13.24 respecte les relations d'ordre naturelles d'inclusion, donc transforme intersections en intersections.)

Se voit comme 4.13.7 (qui est contenu dans l'énoncé actuel), en utilisant le lemme 4.13.10.

4.13.26. Soient $\mathcal{M}$, π, Φ comme dans 4.13.23, et soit $\underline{S}$ une sous-catégorie *strictement pleine* de $\mathcal{M}$, $f : \underline{S} \longrightarrow \mathcal{M}$ le foncteur d'inclusion. La condition que $\underline{S}$ soit Φ-π-accessible dans $\mathcal{M}$ se décompose en :

1) π est utile pour $\mathcal{M}$ *et* pour $\underline{S}$.
2) $\mathcal{M}$ et $\underline{S}$ sont stables par $\varinjlim$ de type Φ.
3) f commute auxdites limites.
4) f est π-accessible.
5) $f(\underline{S}_\pi) \subset \mathcal{M}_\pi$.

Soit alors $\pi' > \pi$ un autre cardinal, quand peut-on assurer que si $\underline{S}$ est Φ-π-accessible dans $\mathcal{M}$, il soit aussi Φ-π'-accessible ? Les conditions 2) 3) 4) sont visiblement stables par passage de π à π'. Restent les conditions 1) et 5). On sait que si $\pi'^{\pi} = \pi'$, alors la condition 1) reste valable pour π'. Plus généralement, si π_0 est un cardinal $\leqslant \pi$ tel que π_0 soit utile pour $\mathcal{M}$ et pour $\underline{S}$, alors si $\pi' > \pi_0$ est tel que $\pi'^{\pi_0} = \pi'$, alors π' est aussi utile pour $\mathcal{M}$ et pour $\underline{S}$. Si on admet l'HCG (hypothèse du continu généralisée), il en est ainsi pour tout $\pi' > \pi_0$, donc pour tout $\pi' > \pi$. p. 132 [page 347]

Commentary · Exposition [ms. 346]

Changing the rank without changing the condition

Grothendieck wants a calculus of conditions on objects which remains usable when several constructions have to be carried out together. An accessible subcategory comes with a size bound, whereas an intersection, an inverse image, or a category of diagrams will usually require a larger common bound. The point of 4.13.26–27 is to arrange that enlargement once, including its effect on the compact generators, before using the calculus.

There are two sizes in the notation. Here "grande devant π" means that diagrams with at most π arrows have cocones; in the usual convention this is π^+-filteredness. Thus $\mathcal{M}_\pi$ is the subcategory of π^+-presentable objects, and a useful π supplies an essentially small family of these objects generating $\mathcal{M}$ under π^+-filtered colimits. The five conditions on the inclusion $f : \underline{S} \hookrightarrow \mathcal{M}$ separate preservation of colimits from preservation of presentability. The former becomes easier as the filteredness bound increases. The latter is a genuine uniformity requirement: sufficiently small generators of the source must have sufficiently small images in the target. It is this requirement which accounts for the cardinal of $\underline{S}_{\pi_0}$ in 4.13.27.

The explicit enlargement $\pi' = 2^c$ is particularly convenient. If c bounds π, the generating data, and π_0, then

$$(\pi')^{\pi_0} = (2^c)^{\pi_0} = 2^{c\cdot\pi_0} = 2^c = \pi'.$$

The argument therefore provides arbitrarily large usable bounds without a continuum hypothesis. In modern accounts this belongs to uniformization: accessible functors preserve presentable objects at suitable sufficiently large ranks, not at an arbitrarily prescribed larger rank. The distinction is visible in the rank comparison recalled in Brooke-Taylor and Rosický (2017, Section 2).

The proposed GCH shortcut requires a correction. Even under GCH, $\lambda > \mu$ need not imply $\lambda^\mu = \lambda$. Take $\mu = \aleph_0$ and $\lambda = \aleph_\omega$. To see the obstruction directly, partition a set of cardinal λ into countably many pieces A_n of cardinal less than λ. If all functions $\mathbf{N} \to \lambda$ could be enumerated as $(f_\alpha)_{\alpha<\lambda}$, choose $g(n)$ outside $\{f_\alpha(n) : \alpha \in A_n\}$. This is possible because $|A_n| < \lambda$. For every α, the coordinate corresponding to the piece containing α gives $g(n) \neq f_\alpha(n)$, contradicting the enumeration. Hence $\lambda^{\aleph_0} > \lambda$.

153. Si π n'est pas cardinal limite. Sinon, il faut dire : familles de cardinal $< \pi$. Cf. 4.13.10.3, où je donne un énoncé rectifié légèrement plus général.

A correct GCH version adds $\mathrm{cf}(\lambda) > \mu$. Every map $\mu \to \lambda$ then has bounded image. For an infinite $\nu < \lambda$, GCH gives $\nu^\mu \leq 2^{\max(\nu,\mu)} \leq \lambda$, so the union over all bounds still has cardinal at most λ; constant functions give the reverse inequality. This repairs the arithmetic statement. It does not require us to reject the category-theoretic conclusions obtained by choosing the larger bound freely: the power-of-two construction already supplies what their proofs need.

Reste la condition 5), pour laquelle une réponse est donnée par 4.12.1 (p. 273). Si $\pi_0 \leqslant \pi$ est choisi de façon que f soit π_0-accessible (p.ex. $\pi_0 = \pi$), et si

$$\pi'_1 = \mathrm{card\,réd}\,\underline{S}_{\pi_0} \qquad (\leqslant \mathrm{card\,réd}\,\underline{S}(\pi))$$
$$\pi''_1 = \sup(\pi'_1, \pi)\ ,$$

on voit que si $\pi' \geqslant \pi''_1$ (i.e. $\pi' \geqslant \pi'_1, \pi$) est tel que $\pi'^{\pi_0} = \pi'$, alors on a bien

$$f(\underline{S}_{\pi'}) \ \subset\ \mathcal{M}_{\pi'}\ .$$

Si donc de plus $\pi' > \pi \geqslant \pi_0$ (comme supposé au début), et si on suppose l'HCG, alors la [page 348]
condition $\pi'^{\pi_0} = \pi'$ est automatique, et il reste la seule condition $\pi' \geqslant \pi''_1$, i.e. en définitive $\pi' \geqslant \mathrm{card\,réd}\,\underline{S}_{\pi_0}$. Pour résumer :

Proposition 4.13.27. *Sous les conditions de 4.13.23 (sans condition b) sur Φ), soit $\underline{S}$ une sous-catégorie de $\mathcal{M}$ qui est Φ-π-adaptée. Soit $\pi_0 \leqslant \pi$ un cardinal qui est utile pour $\underline{S}$ et pour $\mathcal{M}$, et tel que $f : \underline{S} \longrightarrow \mathcal{M}$ soit π_0-accessible, i.e. tel que $\underline{S}$ soit stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π_0 (on peut p.ex. prendre $\pi_0 = \pi$). Alors pour tout cardinal $\pi' > \pi$ tel que*

a) $\pi'^{\pi_0} = \pi'$ et

b) $\pi' \geqslant \mathrm{card\,réd}\,\underline{S}_{\pi_0}$,

$\underline{S}$ est Φ-π'-accessible dans $\mathcal{M}$. Donc si $\pi' > \pi$ est tel que $\pi'^{\pi} = \pi'$, $\pi' > \mathrm{card\,réd}\,\underline{S}_{\pi}$, alors $\underline{S}$ est Φ-π'-accessible. (Il suffit p.ex. de prendre $\pi' = 2^c$, avec $c \geqslant \sup(\pi, \mathrm{card\,réd}\,\underline{S}(\pi))$.) Si on admet l'HCG, il suffit donc qu'on ait $\pi' > \sup(\pi, \mathrm{card\,réd}\,\underline{S}(\pi))$.

Proposition 4.13.28 ([154]). *Soient $\mathcal{M}$, π, Φ comme dans 4.13.23. Supposons de plus que* [page 349]
$J \in \Phi$ implique que J est filtrante. *Alors l'ensemble $\tilde{\Sigma}^\Phi_\pi$ des sous-ensembles Φ-π-accessibles de $\mathcal{M}$ est stable par réunions finies. Plus généralement, soit λ un cardinal $< \pi$ tel que $\forall\ J \in \Phi$, J soit grande devant λ. Alors l'ensemble $\tilde{\Sigma}^\Phi_\pi$ est stable par réunions $(S_r)_{r\in A}$, indexées par des ensembles A de cardinal $\leqslant \lambda$.*

Corollaire 4.13.29. *L'ensemble des parties accessibles de $\mathrm{Ob}\,\mathcal{M}$ est stable par "petites" réunions – i.e. si $(S_r)_{r\in A}$ est une petite famille de parties accessibles de $\mathrm{Ob}\,\mathcal{M}$, alors $\bigcup_{r\in A} S_r$ est aussi accessible.*

La démonstration de 4.13.28 repose sur le lemme suivant (je n'explicite par la démonstration) :

Lemme 4.13.30. *Soit I une catégorie grande devant π, et $(J_r)_{r\in A}$ une famille des sous-* p. 133
catégories pleines telles que $\mathrm{card}\,A \leqslant \pi$, telle que $\bigcup_{r\in A} \mathrm{Ob}\,J_r$ soit cofinal dans $\mathrm{Ord}(I)$, i.e. [page 350]
pour tout $i \in \mathrm{Ob}\,I\ \exists\ j \in \bigcup_{r\in A} \mathrm{Ob}\,J_r$, et une flèche $i \longrightarrow j$. Alors il existe $r \in A$ tel que J_r soit cofinal dans I.

Théorème 4.13.31. *Soient $\mathcal{M}$, $\mathcal{N}$ des catégories accessibles, $f : \mathcal{M} \longrightarrow \mathcal{N}$ un foncteur accessible, $T \subset \mathrm{Ob}\,\mathcal{N}$ une partie de $\mathcal{N}$, $\underline{T} \subset \mathcal{N}$ la sous-catégorie strictement pleine correspondante de $\mathcal{N}$, $S = f^{-1}(T)$, $\underline{S} = f^{-1}(\underline{T})$ la sous-catégorie pleine de $\mathcal{M}$ associée. Si T est accessible, alors S est accessible ; en d'autres termes, si $\underline{T}$ est accessible dans $\mathcal{N}$, $\underline{S}$ est accessible dans $\mathcal{M}$.*

Cela résulte de l'énoncé plus précis :

Corollaire 4.13.32. *Soient π_0 et $\pi > \pi_0$ des cardinaux ayant les propriétés suivantes :* [page 351]

154. À rejeter plus bas, après 4.13.31, qui est la première application importante de 4.13.22, alors que 4.13.28 se prouve sans avoir à utiliser 4.13.22 ou ses variantes.

a) $\underline{T}$ *est* π_0*-*π*-accessible dans* $\mathcal{N}$ *(4.13.23).*

b) π_0 *est utile pour* $\mathcal{M}$ *(il l'est pour* $\mathcal{N}$*, à cause de a)).*

c) $f(\mathcal{M}_\pi) \subset \mathcal{N}_\pi$*.*

d) $\mathcal{M}$ *satisfait à* L_{π_0}*, et* f *est* π_0*-accessible.*

(L'existence d'un tel couple (π_0, π) *résulte aussitôt de 4.13.16 et de 4.12.1.) Alors* $\underline{S}$ *est* π_0*-*π*-accessible dans* $\mathcal{N}$*.*

Commentary · Exposition [ms. 350]

A calculus of object conditions

Grothendieck's accessible parts are intended to behave like manageable predicates on the objects of a large category. The two operations now needed are disjunction and substitution: a small union combines alternative conditions, while an inverse image expresses a condition after applying a functor. These are not statements merely about the number of objects. They say that the resulting full subcategory again has compact generators and that its sufficiently filtered colimits are computed in the ambient category.

The omitted proof of Lemma 4.13.30 explains why disjunction works. Let I be π^+-filtered and suppose that no J_r is objectwise cofinal. Choose $i_r \in I$ for which no arrow $i_r \to j$ exists with $j \in J_r$. Since there are at most π indices r, choose a common upper bound i of the i_r. Cofinality of the union supplies an arrow $i \to j$ with $j \in J_s$ for some s. Its composite with $i_s \to i$ contradicts the choice of i_s. Consequently some J_s is objectwise cofinal.

For a full subcategory of a filtered category, objectwise cofinality supplies the usual categorical finality. Any finite diagram in J_s first has a cocone in I; an arrow from its vertex to an object of J_s gives a cocone in J_s, because the subcategory is full. The same argument in each comma category $(i \downarrow J_s)$ supplies a nonempty filtered category. This proves finality and justifies using J_s to compute colimits. Applied to the indices at which an adapted presentation belongs to a given member of a family, the lemma says that a sufficiently filtered colimit lying in their union can be computed wholly inside one member. Enlarging the common cardinal to bound a small family gives Corollary 4.13.29.

The inverse-image argument uses the stronger cofinal-presentation criterion established earlier. For $x \in f^{-1}(\underline{T})$, present x by the compact objects over it. The image presentation consists of compact objects of $\mathcal{N}$, once the common bound has been chosen to make f preserve presentability. Since its colimit lies in $\underline{T}$, the criterion supplies cofinally many stages already lying in $\underline{T}$. Their preimages are the desired compact generators of $f^{-1}(\underline{T})$. The argument proves essential surjectivity of

$$\mathrm{Ind}_\pi\big(f^{-1}(\underline{T}) \cap \mathcal{M}_\pi\big) \longrightarrow f^{-1}(\underline{T}).$$

Full faithfulness follows from compactness in $\mathcal{M}$.

There is a small rank omission in the quantitative formulation 4.13.32. Its proof uses that π is useful for $\mathcal{M}$, whereas condition b) literally says that π_0 is useful. The safe formulation includes the former condition, obtained, for example, by imposing $\pi^{\pi_0} = \pi$. This is harmless for the qualitative theorem, where the common rank is free to increase. The conclusion of the corollary also prints $\mathcal{N}$ where it must say $\mathcal{M}$; that is a source slip, not an error of transcription.

The present categorical formulation packages the same mechanism as a pseudopullback. Its objects are triples (x, t, θ) with $\theta : f(x) \xrightarrow{\sim} t$ and $t \in \underline{T}$. Because $\underline{T}$ is replete and full, forgetting t, θ is an equivalence with the strict full inverse image. The accessible pseudopullback theorem therefore applies. This is one instance of the limit theorem of Makkai and Paré (1989, Theorem 5.1.6); its precise relation to products, inserters and equifiers is discussed in Positselski (2024, Introduction and Section 5). The repleteness assumption is what permits passage from an isomorphism to literal membership, and should remain visible in either proof.

Comme f commute aux $\varinjlim$ grandes devant π_0 en vertu de d), et que $\underline{T}$ est stable par ces limites par a) (cf. 4.13.23, 3°), il en est donc de même de $\underline{S}$, i.e. le 3° de la définition 4.13.23 est satisfait. D'autre part, la condition 1° (π utile pour $\mathcal{M}$, $\mathcal{M}$ stable par $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$) est vérifiée par b) et d). Donc il reste à vérifier la condition 2°, i.e. que

$\underline{S}$ est π-accessible. Posons

$$\underline{T}(\pi) = \underline{T} \cap \mathcal{N}_\pi$$
$$\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi \quad \underbrace{\subset}_{\text{grâce à c)}} \quad f^{-1}(\underline{T}(\pi)) \ .$$

Comme $\underline{S}$ est stable dans $\mathcal{M}$ par $\varinjlim$ grandes devant π_0 (lesquelles existent dans $\mathcal{M}$ par d), et a fortiori par $\varinjlim$ grandes devant π, on a un foncteur canonique pleinement fidèle

$$\mathrm{Ind}_\pi \underline{S}(\pi) \longrightarrow \underline{S} \ .$$

D'ailleurs, $\underline{T}$ étant strictement pleine dans $\mathcal{N}$, $\underline{S}$ est strictement pleine dans $\mathcal{M}$, et il reste [page 352] à vérifier que le foncteur précédent est essentiellement surjectif. Soit donc $x \in \mathrm{Ob}\,\underline{S}$. On aura, grâce à b),

$$x = \varinjlim_I x_i \ , \qquad x_i \in \mathcal{M}_\pi, \ I = \mathcal{M}_\pi/x \ .$$

D'ailleurs, le système inductif précédent est π_0-π-adapté, i.e. (p. 339) :

1) I équivalente à une petite catégorie, I grande devant π (résulte du fait que π est utile pour $\mathcal{M}$, cf. ⓑ).
2) Les limites inductives grandes devant π_0 est de cardinal $\leqslant \pi$ existent dans I (résulte de L_{π_0} sur $\mathcal{M}$ (cf. ⓓ)). p. 134
3) Le foncteur $\xi : I \longrightarrow \mathcal{M}$ y commute.
4) Les x_i sont dans $\mathcal{M}_\pi$.

Comme f commute aux $\varinjlim$ grandes devant π_0 (cf. ①), a fortiori à celles grandes devant π, on a donc

$$f(x) \simeq \varinjlim_I f(x_i) \ ,$$

je dis que le système inductif $(f(x_i))_{i\in I}$ dans $\mathcal{N}$ est π_0-π-adapté. Les conditions 1), 2) sont *ne varietur* (ne concernent que I), le foncteur $I \longrightarrow \mathcal{N}$ est le composé $I \xrightarrow{\xi} \mathcal{M} \xrightarrow{f} \mathcal{N}$, donc commute aux $\varinjlim$ grandes devant π_0 et de cardinal $\leqslant \pi$ ([155]), puisqu'il en est ainsi de ξ et de f, enfin les $f(x_i)$ sont dans $\mathcal{N}_\pi$ puisque par ⓒ $f(\mathcal{M}_\pi) \subset \mathcal{N}_\pi$.

Par ailleurs $f(x) \in \mathrm{Ob}\,\underline{T}$ (puisque $x \in \mathrm{Ob}\,\underline{S}$, où $\underline{S} \overset{\text{déf}}{=} f^{-1}(\underline{T})$). Donc on peut appliquer [page 353] 4.13.22 a $\Longrightarrow$ c à la situation $(\mathcal{N}, \pi_0, \pi, \underline{S})$ et au système inductif $(f(x_i))_{i\in I}$, pour conclure que la sous-catégorie I' de I formée des i tels que $f(x_i) \in \mathrm{Ob}\,\underline{S}$ `[plutôt Ob` $\underline{T}$`]`, i.e. tels que $x_i \in \underline{S}$, donc $x_i \in \underline{S}(\pi)$, est *cofinale* dans I. Donc on a

$$x \simeq \varinjlim_{i\in I'} x_i \ ,$$

avec cette fois les x_i dans $\underline{S}(\pi)$, et I' grande devant π (car cofinale et pleine dans I, qui est grande devant π), ce qui prouve que x est dans l'image essentielle de $\mathrm{Ind}_\pi(\underline{S}(\pi))$, q.e.d.

Question 4.13.33. On vient de voir que si $f : \mathcal{M} \longrightarrow \mathcal{N}$ est un foncteur accessible entre catégories accessibles, alors l'image inverse d'une partie accessible de $\mathrm{Ob}\,\mathcal{N}$ est une partie accessible de $\mathrm{Ob}\,\mathcal{M}$. Je conjecture que l'énoncé similaire, non pas pour les images directes, mais pour les *images essentielles*, est vraie, i.e. que pour toute sous-catégorie $\underline{S}$ [page 354] de $\mathcal{M}$ accessible dans $\mathcal{M}$, son image essentielle dans $\mathcal{N}$ est accessible dans $\mathcal{N}$ ([156]). Dans cette question, on peut supposer que $\underline{S} = \mathcal{M}$, et la question revient à celle-ci : tout foncteur accessible $f : \mathcal{M} \longrightarrow \mathcal{N}$ entre catégories accessibles se factorise-t-il en un foncteur (accessible)

155. cette commutation devrait avoir un nom, condition $\mathrm{L}(\pi_0, \pi)$ sur un foncteur.
156. Faux, même si on prend la $\natural$-clôture de l'image essentielle ("image $\natural$-essentielle").

essentiellement surjectif, et un foncteur accessible pleinement fidèle $\mathcal{M} \longrightarrow \underline{T} \longrightarrow \mathcal{N}$ (où $\underline{T}$ est elle-même accessible) ([157]) ? Si oui, cela me paraîtrait peut-être le résultat le plus profond (peut-être le seul véritablement profond) en théorie des catégories.

Commentary · Examples [ms. 353]

Why forgetting a retraction destroys the image theorem

The hope behind 4.13.33 is that an accessible construction might be followed by forgetting all its choices, while its essential image still retained a compact description. The footnotes reject that hope, including the attempted repair by closing under retracts. The following example makes both failures explicit. It is the split-monomorphism example of Rosický (2009, Example 3.5(1), author manuscript); the retract-closed formulation appears in Brooke-Taylor and Rosický (2017, Remark 3.3(2), accepted version).

Let R be the small category with two objects a, b, arrows $i : a \to b$ and $p : b \to a$, and relation $pi = 1_a$. The category Pos^R consists of split inclusions of posets with chosen retractions and maps preserving both pieces of data. Restriction along the walking arrow gives

$$F : \mathrm{Pos}^R \longrightarrow \mathrm{Pos}^{[1]}, \qquad (i, p) \longmapsto i.$$

These are accessible categories and F is accessible. One can check this without a general model theorem. A poset is the filtered union of its finite subposets. A finite collection of elements in an R-diagram generates a finite subdiagram, since R has only finitely many morphisms. The inherited orders are finite, and all operations and their equations restrict. Such finite diagrams are finitely presentable: maps and the finitely many order relations factor, and are eventually identified, in a filtered colimit. The same argument applies to the arrow category. Filtered colimits are computed pointwise, so restriction preserves them.

The replete full image $\mathcal{L}$ consists of split monomorphisms of posets, with every commutative square allowed as a morphism. Fix any infinite regular cardinal λ. For $\alpha < \lambda$, put

$$A_\alpha = \{\beta : \beta \leq \alpha\}, \qquad B_\alpha = A_\alpha \amalg \{\top\},$$

where $\top$ lies above every element, and let $j_\alpha : A_\alpha \hookrightarrow B_\alpha$ be the inclusion. It splits by sending $\top$ to α. The inclusions of initial segments, together with $\top \mapsto \top$, define a λ-chain in $\mathcal{L}$. Its index ordinal is λ-filtered. In the arrow category its colimit is

$$j : \lambda \hookrightarrow \lambda \amalg \{\top\}.$$

A monotone retraction would have to send $\top$ to an ordinal dominating every $\beta < \lambda$. No such ordinal belongs to λ. Thus j does not split. Since this construction works for every regular λ, the full image is not accessibly embedded.

Closing the image under retracts changes nothing. Suppose an arrow $j : A \to B$ is a retract of a split arrow $i : X \to Y$, with arrow-category maps $(u, v) : j \to i$ and $(r, s) : i \to j$ satisfying $ru = 1_A$, $sv = 1_B$. If $p : Y \to X$ retracts i, then

$$(rpv)j = rp(iu) = ru = 1_A.$$

Hence j already splits. This proves directly the stronger rejection recorded in footnote 156.

The reason the diagram above does not lift to Pos^R is concrete: the chosen retraction of the new top changes from α to β as the index increases. The squares preserve the inclusions but not their chosen retractions. Fullness of the essential image permits exactly these additional morphisms. In contrast, an Ind-completion of compact objects embeds fully faithfully before any choices are forgotten; this is why the image used in 4.13.34 behaves well.

Voici une question qui me paraît très voisine. Soient $\mathcal{M}$ une catégorie accessible, A une sous-catégories pleine petite. Supposons que $\mathcal{M}$ satisfasse à L_{π_0} (p.ex. π_0 utile pour $\mathcal{M}$), et soit $\underline{S}$ la plus petite sous-catégorie strictement pleine de $\mathcal{M}$ contenant A, et stable par limites grandes devant π_0. Je conjecture que $\underline{S}$ est accessible dans $\mathcal{M}$.

[page 355]

157. Il faut se borner tout au moins à essentiellement ♮-surjectif – mais même cela est trop optimiste.

De même, si Φ est un petit ensemble de petites catégories, tel que $\mathcal{M}$ soit stable par $\varinjlim$ de type Φ, on peut prendre l'enveloppe $\underline{S}$ de A pour les $\varinjlim$ grandes devant π_0 *et* les $\varinjlim$ de type Φ, et je conjecture encore que $\underline{S}$ est accessible. Dans cette direction, on a du moins le résultat très partiel suivant. p. 135

Proposition 4.13.34. *Soit $\mathcal{M}$ une catégorie accessible stable par petites $\varinjlim$ filtrantes, et soit $\underline{S}$ une sous-catégorie strictement pleine de $\mathcal{M}$. Conditions équivalentes :*

a) $\underline{S}$ est accessible dans $\mathcal{M}$, et stable dans $\mathcal{M}$ par petites $\varinjlim$ filtrantes.

b) Il existe une petite sous-catégorie pleine A de $\mathcal{M}$, telle que $\underline{S}$ soit la plus petite sous-catégorie strictement pleine de $\mathcal{M}$ contenant A et stable par petites $\varinjlim$ filtrantes.

[page 356]

Commentary · Development (commentators') [ms. 355]

The small-envelope conjectures at a fixed threshold

Grothendieck separates the false assertion about arbitrary essential images from a more controlled construction: start with a small collection of objects and close it under specified colimits already available in the ambient category. His proof of 4.13.34 treats all filtered colimits. The same method, combined with bounded completion of index categories, answers the two preceding envelope questions at a fixed filteredness threshold. We give the argument because the role of the size bound is otherwise easy to miss.

Proposition (small colimit envelopes). [ours] Let κ be an infinite regular cardinal. Let $\mathcal{M}$ be accessible, admitting all small κ-filtered colimits and the colimits of a small family Φ of small categories. If $A \subset \mathcal{M}$ is small, then its smallest replete full envelope closed under these colimits is accessible and accessibly embedded in $\mathcal{M}$.

We use the Ind extension result proved in 4.13.19: a small replete subcategory of $\mathcal{M}_\pi$, closed under a family of colimits of size at most π including a nonzero limit-ordinal shape, has a fully faithfully embedded Ind_π-completion closed under the same colimits. The closure under a limit-ordinal shape supplies the retract closure needed in applying that result.

Proof. Choose an infinite cardinal π which is useful for $\mathcal{M}$, with

$$\kappa \le \pi, \qquad \pi^{<\kappa} = \pi, \qquad A \subset \mathcal{M}_\pi, \qquad |\operatorname{Fl} I| \le \pi \quad (I \in \Phi).$$

Such a bound exists. Start above a usefulness bound for $\mathcal{M}$, above the presentability ranks of the small family A, and above the sizes of the shapes; then take a sufficiently large power 2^c. The exponentiation identity gives the displayed closure condition and the usual enlargement of usefulness.

Let Φ_π consist of the shapes in Φ and one representative of each κ-filtered category having at most π arrows. There is a set of such representatives. The subcategory $\mathcal{M}_\pi$ is closed under these colimits: a colimit with at most π arrows of π^+-presentable objects remains π^+-presentable, because π^+-filtered colimits of sets commute with limits indexed by at most π arrows. Let B be the smallest replete full subcategory of $\mathcal{M}_\pi$ containing A and closed under Φ_π-colimits. It is essentially small, being contained in $\mathcal{M}_\pi$.

We make its retract closure explicit. The ordinal κ is κ-filtered and has at most π arrows. For an idempotent $e : b \to b$, the diagram constant at b with transition e for every strict inequality has a colimit which splits e. Indeed, if $q : b \to c$ is its colimit map, then $qe = q$, while the compatible maps $e : b \to b$ induce $u : c \to b$ with $uq = e$; the colimit universal property gives $qu = 1_c$. Thus $c \in B$, and repleteness includes every ambient retract of b.

Consequently the canonical functor $\mathrm{Ind}_\pi B \to \mathcal{M}$ is fully faithful. Write $\mathcal{S}'$ for its replete image. It is accessible, its π^+-filtered colimits are computed in $\mathcal{M}$, and 4.13.19 shows that it is closed there under Φ_π-colimits. In particular it is already closed under the additional shapes Φ. It remains to pass from bounded κ-filtered diagrams to arbitrary small ones.

Here is the index-category argument with its cardinal estimate. If I is small and κ-filtered, every subcategory $K \subset I$ with at most π arrows is contained in a κ-filtered subcategory $\overline{K} \subset I$ with at most π arrows. For each diagram with fewer than κ arrows in the current subcategory, choose a cocone in I, adjoin its arrows and vertex, and close under finite composition. There are at most $\pi^{<\kappa} = \pi$ diagrams to treat, including their possible small shapes, so each stage still has at most π arrows. Iterate through κ stages, taking unions at limit stages. Since κ is regular, every diagram with fewer than κ arrows in the final union is contained in one earlier stage and acquires its cocone at the next. The final union is the required $\overline{K}$. The empty diagram is included, so nonemptiness is also assured.

Let P be the poset of all κ-filtered subcategories $J \subset I$ with at most π arrows. It is a set and is π^+-filtered. Indeed, the union of at most π such subcategories generates a subcategory with at most π arrows, and the preceding construction supplies an upper bound in P. Every object and arrow of I belongs to some member of P. These are actual subcategories, not full subcategories; taking full closure could add too many arrows.

Now let $D : I \to \mathcal{S}'$ be any small κ-filtered diagram. Each inner colimit below exists in $\mathcal{S}'$ by bounded closure, and the outer one exists by π^+-accessibility:

$$y = \varinjlim_{J \in P} \left(\varinjlim_{j \in J} D(j) \right).$$

Both are computed in $\mathcal{M}$. A compatible family of cocones on the restrictions $D|_J$ gives a unique cocone on D: to define its component at i, choose a J containing i; the result is independent of this choice because two such J have a common upper bound. Naturality follows by choosing a J containing the arrow in question. Conversely any cocone on D restricts compatibly. Hence y is the colimit of D, and $\mathcal{S}'$ is closed under all small κ-filtered colimits in $\mathcal{M}$.

Finally let $\mathcal{S}$ denote the envelope in the proposition. Every object of B belongs to $\mathcal{S}$ by its construction. Every π^+-filtered category is κ-filtered, so every object of $\mathcal{S}'$, being a π^+-filtered colimit of objects of B, belongs to $\mathcal{S}$. The reverse inclusion follows from the closure properties just proved for $\mathcal{S}'$. Therefore $\mathcal{S} = \mathcal{S}'$, proving the assertion. □

For the manuscript's two questions take $\kappa = \pi_0^+$, first with Φ empty and then with its specified additional shapes. The proof follows Grothendieck's own Ind and bounded-colimit method. We checked the cited primary papers on accessible constructions and images, together with the publisher descriptions of Makkai and Paré (1989) and Adámek and Rosický (1994); we did not locate this exact envelope formulation in the material inspected. The marker records the proof developed for this commentary, without asserting priority for the theorem.

On a a) $\Longrightarrow$ b), car si $\underline{S}$ est π-accessible dans $\mathcal{M}$, il est immédiat (sans autre condition de stabilité sur $\underline{S}$) que $\underline{S}$ est la plus petite sous-catégorie strictement pleine de $\mathcal{M}$ contenant $\underline{S}(\pi) \overset{\text{déf}}{=} \underline{S} \cap \mathcal{M}_\pi$ et stable par $\varinjlim$ grandes devant π. Si donc on sait déjà que $\underline{S}$ est même stable par *toutes* $\varinjlim$ filtrantes petites, il s'ensuit que $\underline{S}$ est la plus petite sous-catégorie de $\mathcal{M}$ ayant cette propriété de stabilité plus forte, et contenant A.

Prouvons b $\Longrightarrow$ a. Soit π un cardinal utile pour $\mathcal{M}$, et tel que $A \subset \mathcal{M}_\pi$. Soit B la plus petite sous-catégorie strictement pleine de $\mathcal{M}$ contenant A et stable par $\varinjlim$ filtrantes de cardinal $\leqslant \pi$. On a donc $B \hookrightarrow \mathcal{M}_\pi$ et $B \subset \underline{S}$, et $\underline{S}$ est aussi la L-enveloppe de B. D'ailleurs B est stable par facteurs directs. Considérons alors l'image essentielle $\underline{S}'$ de $\mathrm{Ind}_\pi(B)$ dans $\mathcal{M}$. On [page 357]
a $\underline{S}' \subset \underline{S}$, et tout revient à prouver que $\underline{S}' = \underline{S}$, d'où résultera en effet que $\underline{S}$ est π-accessible dans $\mathcal{M}$, a fortiori accessible dans $\mathcal{M}$, d'où a). Pour prouver que $\underline{S}' = \underline{S}$, par définition de $\underline{S}$ comme la L-enveloppe de A, il suffit de voir que $\underline{S}'$ est stable par petites $\varinjlim$ filtrantes. Or cela résulte du fait que $B \subset \mathcal{M}_\pi$ est stable dans $\mathcal{M}_\pi$ par $\varinjlim$ filtrantes de cardinal $\leqslant \pi$, et de 4.13.19, qui implique tout au moins, comme $B = \underline{S}' \cap \mathcal{M}_\pi$ (en vertu de 4.13.4) que $\underline{S}'$ est stable par $\varinjlim$ filtrantes *de cardinal* $\leqslant \pi$. Qu'il soit même stable par petites $\varinjlim$ filtrante quelconques, résulte de ceci, et du fait qu'il l'est par $\varinjlim$ grandes devant π. (Cf. 4.13.21 …)

Définition 4.13.35. Soient $\mathcal{M}$ une catégorie accessible, stable par petites $\varinjlim$ filtrantes, [page 358]
S une partie de $\mathrm{Ob}\,\mathcal{M}$, $\underline{S}$ la sous-catégorie pleine correspondante dans $\mathcal{M}$. On dit que S est *L-accessible*, ou que $\underline{S}$ est L-accessible dans $\mathcal{M}$, si $\underline{S}$ est accessible dans $\mathcal{M}$, et de plus stable par petites $\varinjlim$ filtrantes ([158]).

Proposition 4.13.36. *Soient $\mathcal{M}$, S, $\underline{S}$ comme dans 4.13.35, et soit π un cardinal utile pour $\mathcal{M}$. Supposons $\underline{S}$ stable dans $\mathcal{M}$ par petites $\varinjlim$ filtrantes, ou seulement $\underline{S}(\pi) \overset{déf}{=} \underline{S} \cap \mathcal{M}_\pi$ stable par petites $\varinjlim$ filtrantes de cardinal $\leqslant \pi$. Conditions équivalentes :*

158. **N.B.** L'ensemble des parties L-accessibles de $\mathrm{Ob}\,\mathcal{M}$ est stable par petites intersections, et par réunions *finies*. L'image inverse d'une partie L-accessible par un foncteur ([159]) $f : \mathcal{M} \longrightarrow \mathcal{N}$ de catégories accessibles est L-accessible.

159. un L_0-*foncteur* : qui commute aux petites $\varinjlim$ filtrantes.

a) $\underline{S}$ *est* π*-accessible. (Il sera automatiquement stable par petites* $\varinjlim$ *filtrantes, donc L-accessible.)*

b) Pour tout $x \in \mathrm{Ob}\,\mathcal{M}$*, on a* $x \in \mathrm{Ob}\,\underline{S}$ *si et seulement si* $\underline{S}(\pi)/x$ *est cofinale dans* $\mathcal{M}_\pi/x$. p. 136

c) Pour tout $x \in \mathrm{Ob}\,\mathcal{M}$*, et toute représentation* $x \simeq \varinjlim_{i\in I} x_i$ *qui est L-*π*-adaptée (cf. page* [page 359] *343, c), on a ceci :* $x \in \mathrm{Ob}\,S$ *si et seulement si* $I_{\underline{S}}$ *est cofinal dans* I*.*

c′) Comme c), avec I *ordonnée.*

c″) (Si on a choisi, pour tout $x \in \mathrm{Ob}\,\mathcal{M}$*, une représentation* π*-adaptée* $x \simeq \varinjlim_{I} x_i$*) :* $x \in \mathrm{Ob}\,\underline{S} \iff$ *l'ensemble* $I_{\underline{S}}$ *est cofinal dans* I*.*

Démonstration. C'est essentiellement l'énoncé de 4.13.22 dans le cas particulier où $\Phi =$ ensemble des catégories *filtrantes* de cardinal $\leqslant \pi$, mais où, pour simplifier, on a supposé d'avance que $\underline{S}(\pi)$ satisfait à $\mathrm{L}(\Phi)$. L'équivalence de a) b) c) est contenue dans 4.13.22, ainsi que c $\Longrightarrow$ c′. Mais pour c′ $\Longrightarrow$ a, l'hypothèse accessoire $\pi^{\pi_0} = \pi$ et que les $J \in \Phi$ seront grandes devant π_0, n'est pas satisfaite ici, et il faut un démonstration indépendante, calquée sur celle des pages 333-336. Il suffit pour cela, à l'endroit `[de]` □, page 333, d'invoquer le

Lemme 4.13.37. *Soient* $\mathcal{M}$ *une catégorie accessible stable par* $\varinjlim$ *filtrantes,* π *un cardinal utile pour* $\mathcal{M}$*. Alors pour tout* $x \in \mathrm{Ob}\,\mathcal{M}$*, on a une représentation* [page 360]

$$x \;=\; \varinjlim_{i\in I} x_i$$

L-π*-adaptée (i.e. avec*

1) I *équivalente à une petite catégorie, et* I *grande devant* π*,*

2) I *stable par* $\varinjlim$ *filtrantes de cardinal* $\leqslant \pi$*,*

3) $I \longrightarrow \mathcal{M}$ *commute à ces* $\varinjlim$ *,*

d) $x_i \in \mathrm{Ob}\,\mathcal{M}_\pi \;\forall\, i \in I$*),*

avec de plus I ordonné.

En effet, on part de

$$x \;=\; \varinjlim_{j\in J} x_j \;, \qquad J \;\simeq\; \underbrace{(\mathcal{M}_\pi/x)_0}_{\substack{\text{sous-catégorie réduite}\\ \text{équivalente à } \mathcal{M}_\pi/x}} \;.$$

On définit I comme l'ensemble des sous-catégories *filtrantes* J' de J, de cardinal `["cardinal" biffé]` $\leqslant \pi$, I ordonné par inclusion, et on pose, pour $J' \in I$,

$$x_{J'} \;=\; \varinjlim_{j\in J'} x_j \;.$$

Il est immédiat qu'on obtient ainsi un système inductif dans $\mathcal{M}$, indexé par I.

D'autre part, il est clair que I est petite, je dis que I est stable par $\varinjlim$ filtrantes de [page 361] cardinal $\leqslant \pi$, et que le foncteur $J' \longmapsto x_{J'} : I \longrightarrow \mathcal{M}$ y commute, enfin que les $x_{J'}$ sont dans $\mathcal{M}_\pi$. Il reste à voir que I est grande devant π, i.e. que si on a $(J'_r)_{r\in A}$, avec $\mathrm{card}\,A \leqslant \pi$, les J'_r dans I, alors $\exists\, J' \in I$ qui majore les J'_r. Soit K la sous-catégorie de J engendrée par les J'_r, on voit facilement que $\mathrm{card}\,K \leqslant \pi$. Tout `["tout" biffé]` revient à prouver :

Lemme 4.13.38 ([160]). *Soient* J *une catégorie grande devant* π*,* K *une sous-catégorie* p. 137 *de* J *de cardinal* $\leqslant \pi$*. Alors il existe une sous-catégorie* K' filtrante *de* J*, contenant* K*, de cardinal* $\leqslant \pi$*. Si on suppose que l'on n'est pas, dans le cas où* J *contient un objet maximal, et que* K *contienne tous les objets maximaux de* J*, on peut même prendre* K' *telle que* [page 362]

160. **N.B.** Pour la démonstration de 4.13.37, il suffit de prouver 4.13.38 dans le cas où J est ordonnée, auquel cas les contorsions de la fin sont inutiles.

$\operatorname{Ob} K' = \operatorname{Ob} K \cup \{e\}$, *où* e *est un* objet final *de* K', *et* K *est une sous-catégorie pleine de* K'. *(Donc si* $K' \neq K$, K' *est isomorphe au cône à droite construit sur* K, *"déduit de* K *en lui ajoutant un objet final".)*

Commentary · Exposition [ms. 361]

Making the presentation continuous

The ordered presentation in Lemma 4.13.37 has a purpose beyond replacing a category by a poset. Grothendieck needs the index poset to contain the bounded filtered colimits used to improve an approximation, and he needs the presentation itself to preserve them. The ordinary statement that every object is a filtered colimit of compact objects supplies neither requirement by itself.

There is a short proof of the bounded enlargement used here. In any filtered category J, start with a subcategory K having at most the infinite cardinal π arrows. For every pair of its objects choose a common target and arrows to it. For every parallel pair of its arrows choose an equalizing arrow. Adjoin these choices and close under finite composition; the resulting subcategory still has at most π arrows. Repeat this construction countably many times. The union K_∞ has at most π arrows and is filtered: every finite configuration occurs in one stage, and its required witnesses occur at the next. Include one object at the start if K is empty. This proves the first assertion of 4.13.38 under the weaker assumption that J is ordinarily filtered. The stronger ambient filteredness is needed elsewhere, including the one-vertex variant, but not for this bounded enlargement.

Apply this to the small skeleton J of $\mathcal{M}_\pi/x$. Let P be the poset of its filtered subcategories of size at most π. Given at most π members, generate their union under composition and apply the enlargement above. This makes P π^+-filtered. A filtered union of at most π members is itself filtered and still of size at most π; it is their least upper bound in P. Thus the required bounded filtered colimits in the index poset are simply unions.

For $J' \in P$, put $x_{J'} = \varinjlim_{j \in J'} x_j$. Each x_j is π^+-presentable, and the diagram has at most π arrows, so $x_{J'}$ is again π^+-presentable. The colimit comparison for a filtered union of subcategories is an isomorphism: a cocone on the union is exactly a compatible collection of cocones on its pieces. Therefore $J' \mapsto x_{J'}$ preserves the required colimits. The same description of cocones, now over all of P, gives $x \simeq \varinjlim_P x_{J'}$. This supplies all four conditions of an L-π-adapted presentation, including the continuity which drives the cofinal-membership criterion.

That continuity must also be read into condition c″ of 4.13.36, where the printed text abbreviates the phrase to "π-adaptée". To see what fails if it is omitted, let $\mathcal{M}$ be sets and $\underline{S}$ the full subcategory of sets of cardinal at most one. It is accessible and closed under filtered colimits. Over the ordinal π^+ take the constant object $\{0,1\}$, with every strict transition the map sending both points to 0. This is a π^+-filtered presentation by compact objects and its colimit is a singleton, but no stage lies in $\underline{S}$. At a limit stage the displayed object is still a two-element set, whereas the colimit of the earlier constant-transition diagram is a singleton. Precisely the missing continuity detects the defect.

Démonstration. Si K admet un objet final, on prend $K' = K$. Sinon, comme J est grande devant $\operatorname{card} \operatorname{Ob} K$, il existe un $j \in \operatorname{Ob} J$ qui majore tous les objets de K. Choisissons, pour tout $k \in \operatorname{Ob} K$, une flèche

$$\alpha_k \ : \ k \longrightarrow j \ .$$

Pour toute flèche

$$u \ : \ k' \longrightarrow k$$

dans K, considérons la double-flèche

$$(\alpha_k \circ u, \alpha_{k'}) \ : \ k' \rightrightarrows j \ .$$

L'ensemble de ces double-flèches, de but j, est de cardinal $\leqslant \operatorname{card} \operatorname{Fl} K \leqslant \pi$, donc J étant grande devant π, il existe une flèche $\rho : j \longrightarrow e$ dans J qui égalise toutes ces double-flèches. Soit $K' \subset J$, ayant comme objets $\operatorname{Ob} K \cup \{e\}$, et ayant comme flèches, en plus de celles de K, les flèches $\rho\alpha_k : k \longrightarrow e$ (pour $k \in \operatorname{Ob} K$), et id_e. *Si* $e \notin \operatorname{Ob} K$, on voit que c'est bien une [page 363]
sous-catégorie, admettant e comme objet final et K comme sous-catégorie pleine. Si on avait $e \in \operatorname{Ob} K$, et s'il existe un objet e' de J qui majore e et qui n'est pas dans K, on se ramène aussitôt au cas précédent, en remplaçant e par e'.

([161]). Donc il reste le cas où il existe un objet e dans K qui est un plus grand élément dans K, et tel que tout objet de J majorant e soit dans K. Cela implique, J étant filtrante, que e est un plus grand objet de J. (Car si $x \in J$, $\exists\, x'$ majorant commun de x et e, donc x' est dans K, donc majoré par e, qui majore donc x.) On voit comme tantôt qu'il existe une flèche $p : e \longrightarrow j$ dans J, qui égalise toutes les double-flèches $k \rightrightarrows e$ de but e *dans* K. Quitte à composer avec $j \longrightarrow e$, on peut supposer $j = e$. On a donc un endomorphisme p de e dans J, tel que $pu = pv$ pour toute double-flèche $k \overset{u}{\underset{v}{\rightrightarrows}} e$ dans K, de but e.

Pour $k \in \mathrm{Ob}\, K$, soit [page 364]

$$f_k \ : \ k \longrightarrow e$$

la valeur commune des pu, pour $u \in \mathrm{Hom}_K(k, e)$. On voit tout de suite que si on a $k' \overset{v}{\to} k$ dans K, alors

$$f_{k'} \ = \ f_k \circ v \ .$$

En particulier, prenant $k' = e$, on trouve p. 138

$$f_k \circ v \ = \ f_e \,(= \ p\ ) \qquad \text{si } v : e \longrightarrow k \ .$$

Soit donc K' la sous-catégorie de J ayant mêmes objets que K, et comme flèches, en plus de celles de K, les flèches composées $k \overset{u}{\to} e \overset{p^r}{\longrightarrow} e \overset{v}{\to} k'$, avec u, v dans K, et $r \geqslant 1$, i.e. les flèches composées $k \overset{f_k}{\longrightarrow} e \overset{p^{r'}}{\longrightarrow} e \overset{v}{\to} k'$, avec $k, k' \in \mathrm{Ob}\, K$, $v \in \mathrm{Fl}\, K$, $r' \geqslant 0$. Il faut voir que c'est stable par composition (pour avoir bien une sous-catégorie). C'est clair pour vu si u ou v sont dans $\mathrm{Fl}\, K$. Si `[ni]` u ni v ne le sont, on doit prendre un composé

$$k \xrightarrow{u_1} e \underset{r\geqslant 1}{\xrightarrow{p^r}} e \xrightarrow{u_2} k' \xrightarrow{v_1} e \underset{s\geqslant 1}{\xrightarrow{p^s}} e \xrightarrow{v_2} k'' \ ,$$

avec u_1, u_2, v_1, v_2 dans $\mathrm{Fl}\, K$, $r, s \geqslant 1$. Or on a

$$p(v_1 u_2) \ = \ p \ , \qquad \text{d'où} \qquad p^s(v_1 u_2) \ = \ p^{s-1}(p v_1 u_2) \ = \ p^{s-1} p \ = \ p^s \ ,$$

donc le composé est

$$k \xrightarrow{u_1} e \xrightarrow{p^{r+s}} e \xrightarrow{v_2} k'' \ ,$$

qui est donc bien dans $\mathrm{Fl}\, K'$.

Ainsi, K' est une sous-catégorie de J, mais est-elle filtrante ? La condition PS 1′ est évidente, puisque e est un plus grand élément de J, reste la condition PS 2 de la double-flèche. On voit aisément que cette condition est satisfaite dans K', si et seulement si elle est satisfaite pour toute double-flèche [page 365]

$$e \overset{p^r}{\underset{p^s}{\rightrightarrows}} e \qquad \text{avec } r, s \geqslant 0 \ .$$

(En effet, on se ramène aussitôt aux double-flèches de but e, et on note que toute flèche de K' de but e s'écrit comme un composé $k \overset{u}{\to} e \overset{p^r}{\longrightarrow} e \overset{v}{\to} e$, avec $r \geqslant 0$ et u, v des flèches dans K'. En composant avec $e \overset{p}{\to} e$, on trouve alors, comme $pv = pu$, $k \overset{u}{\to} e \overset{p^{r+1}}{\longrightarrow} e$, soit $k \overset{f_k}{\longrightarrow} e \overset{p^r}{\longrightarrow} e$.) Mais on voit aussitôt que la possibilité d'égaliser (p^r, p^s) dans K' équivaut à l'existence de $t \geqslant 0$ tel que $p^{r+t} = p^{s+t}$. Donc K' est filtrante si et seulement si $r \longmapsto p^r$ est une suite stationnaire (faire $r = 0$, $s = 1$, d'où $p^r = p^{r+1}$ pour r grand). Ce n'est pas forcément le cas. [page 366]

Posons donc $K = K_0$, $K' = K_1$, et construisons par induction une suite croissante de sous-catégories K_i ($i \in \mathbf{N}$), avec $\mathrm{Ob}\, K_i = \mathrm{Ob}\, J$, et (pour $i \geqslant 1$) K_i étant déduites de K_{i-1} en lui rajoutant une flèche $p_i : e \longrightarrow e$, comme ci-dessus. Ainsi toute double-flèche dans un K_i

161. La construction qui suit est contenue dans l'énoncé plus général et plus précis 4.13.39.

peut s'égaliser dans K_{i+1}. Prenons $K_\infty = \varinjlim K_i$, K_∞ est une sous-catégorie *filtrante* de J, contenant K et de cardinal $\leqslant \pi$, q.e.d.)

On peut préciser cette construction ainsi :

Corollaire 4.13.39. *Sous les conditions de 4.13.38, supposons que K contienne un objet e maximal dans J. Soit Σ l'ensemble des endomorphismes p de e dans J, tels que pour toute double-flèche $k \overset{u}{\underset{v}{\rightrightarrows}} e$ dans K, on ait $pu = pv$. Alors Σ est stable par composition, et il existe une partie non vide Σ_∞ [$= \Sigma_0$] de Σ, telle que pour $p, p' \in \Sigma_0$, existe $q \in \Sigma_0$ tel que $qp = qp'$ (i.e. telle que la sous-catégorie J_0 de J dont l'ensemble des objets est $\{e\}$, et l'ensemble des flèches $\{\mathrm{id}_e\} \cup \Sigma_\infty$, soit filtrante). Si Σ_0 est choisie ainsi, soit $\mathcal{F}$ l'ensemble réunion de* $\mathrm{Fl}\, K$ *et de l'ensemble des flèches composées** p. 139 [page 367]

$$(*) \qquad k \xrightarrow{u} e \xrightarrow{p} e \xrightarrow{v} k' \ ,$$

avec $u, v \in \mathrm{Fl}\, J$, $p \in \Sigma_\infty$. Alors $\mathcal{F}$ est l'ensemble des flèches d'une sous-catégorie K' de J, ayant mêmes objets que J, et admettant e pour plus grand élément. De plus, K' contient K et est filtrante.

Démonstration. Que Σ soit stable par composition est clair. Pour construire Σ_∞ ayant les propriétés énoncées, on note que, J étant grande devant π, Σ est non vide ([162]). On construit par récurrence une suite d'éléments

$$p_0 \ , \ p_1 \ , \ \cdots \ , \ p_n \ , \ \cdots$$

de Σ, en prenant pour p_0 un élément quelconque de Σ, et pour $i \geqslant 1$, prenant $p_i \in \Sigma$ tel que pour toute double-flèche (p, p') du sous-monoïde M_{i-1} de $\mathrm{End}_J(e)$ engendré par $(p_j)_{0 \leqslant j \leqslant i-1}$, on ait $p_i p = p_i p'$. Un tel p_i existe, car prenant l'ensemble des double-flèches de la forme précédente (p, p'), avec $p, p' \in M_{i-1}$, et de celles de la forme $(u, v) : k \rightrightarrows e$, avec $u, v \in \mathrm{Fl}\, J$, l'ensemble de toutes ces double-flèches est de cardinal $\leqslant \pi$ (M_{i-1} étant dénombrable, donc de cardinal $\leqslant \pi$), donc il existe une flèche $e \longrightarrow j$ dans J qui les égalise toutes (J étant grande devant π). Quitte à composer avec $j \longrightarrow e$ (e étant objet maximal de J), on trouve le $p_i : e \longrightarrow e$ cherché. [page 368]

Soit alors Σ_0 le sous-ensemble multiplicatif de Σ engendré par les p_i ($i \in \mathbf{N}$), limite inductive des ensembles similaires Σ_i engendrés par les p_j pour $j \in [0, i]$. Si p, p' sont dans Σ_∞, il sont dans un même Σ_i, donc on aura $p_{i+1} p = p_{i+1} p'$, ce qui prouve que Σ_∞ a la propriété filtrante exigée.

Prouvons maintenant que $\mathcal{F}$ est l'ensemble de flèches d'une sous-catégorie K' de J, ayant $\mathrm{Ob}\, K$ comme ensemble d'objets. Il reste à établir la stabilité par composition vu. Mais si u et v sont dans $\mathrm{Fl}\, K$, ou si l'un des deux est dans $\mathrm{Fl}\, K$, l'autre non (donc de la forme $(*)$), cette stabilité est évidente. Reste à voir le cas où ni [u] ni v sont dans $\mathrm{Fl}\, K$, donc sont tous deux de la forme $(*)$:

$$k \xrightarrow{u} e \xrightarrow{p} e \xrightarrow{v} k' \xrightarrow{u'} e \xrightarrow{p'} e \xrightarrow{v'} k'' \ ,$$

avec $u, v, u', v' \in \mathrm{Fl}\, K$, $p, p' \in \Sigma_\infty$. Comme $(u'v, \mathrm{id}_e)$ est une double-flèche de K de but e, on a p. 140 [page 369]

$$p' u' v \ = \ p' \mathrm{id}_e \ = \ p' \ ,$$

donc le composé en question s'écrit aussi

$$k \xrightarrow{u} e \xrightarrow{p'p} e \xrightarrow{v'} k'' \ ,$$

où $p'p \in \Sigma_\infty$ puisque Σ_∞ est stable par composition, donc il est dans $\mathcal{F}$, q.e.d.

162. cf. argument plus bas pour construction de p_i.

Il est clair que K' contient K, et ayant mêmes objets que K qui admet e comme plus grand élément, que e est un plus grand élément de K'. Reste à prouver que K' est filtrante. Comme K' a un plus grand élément, il reste à voir que toute double-flèche $k \rightrightarrows l$ dans K' peut être égalisée dans K'. Quitte à composer avec $l \longrightarrow e$, on peut supposer $l = e$. Or on voit que toute flèche $k \longrightarrow e$ dans K' est de la forme

$$k \xrightarrow{u} e \xrightarrow{p} e \xrightarrow{v} e \ ,$$

avec $u, v \in \mathrm{Fl}\, K$ et $p \in \Sigma_\infty \cup \{\mathrm{id}_e\}$. Quitte à composer avec $p_0 \in \Sigma_\infty$ fixé, cette flèche devient (puisque $p_0 v = p_0 \mathrm{id}_e = p_0$)

$$k \xrightarrow{u} e \xrightarrow{p_0 p} e \ , \qquad \text{i.e. } p_0 p u \ .$$

Pour une flèche $v'p'u' : k \longrightarrow e$, on trouve $p_0 p' u'$. Soit alors $q \in \Sigma_0$ tel que $q(p_0 p) = q(p_0 p')$, soit r (q existe puisque $p_0 p, p_0 p' \in \Sigma_\infty$). Donc $(q(p_0 p u), q(p_0 p' u')) = (ru, ru')$, et on a $ru = ru'$ puisque $r \in \Sigma_\infty$. Au total, qp_0 égalise les deux flèches vpu et $v'p'u'$, q.e.d.

[page 370]

Commentary · Exposition [ms. 369]

The exceptional vertex and its endomorphisms

Grothendieck pursues the one-vertex construction because it describes how much enlargement an approximation really needs. If a cocone vertex lies outside K, adding it with its compatible incoming arrows produces a terminal object immediately. If every possible vertex is already present, the obstruction lies in endomorphisms, and a weakly terminal object need not become terminal after a single equalization.

The exceptional-case proof needs one preliminary adjustment. A vertex e which is maximal in the reachability preorder of J receives arrows in J from every object of K, but those arrows need not belong to K. Adjoin one such arrow from each object and close under composition. This preserves the object set and the bound π on arrows. After this adjustment e is weakly terminal in K, and the formula $f_k = pu$ is defined for every k. The later normal-form argument then applies exactly as written, with its local J/K slips read correctly.

Here is the point of the powers of p. If p equalizes all K-arrows with target e, then a new arrow can be written $vp^r u$ with u, v in K. Products reduce because $p(v_1 u_2) = p$ for every K-endomorphism $v_1 u_2$ of e. But the powers $1, p, p^2, \ldots$ need not equalize one another. Filteredness of the resulting one-object part forces, by equalizing 1 and p, an equality $p^t = p^{t+1}$ at some stage. Conversely that equality equalizes every pair of powers after further multiplication. Thus the additional iteration is mathematically necessary.

In 4.13.39 the countable sequence p_i arranges this for all words already constructed. At stage $i+1$ one equalizes pairs in the monoid generated by $p_0, \ldots, p_i$, including the identity, together with the original parallel arrows of K ending at e. There are at most π pairs. Their simultaneous equalizer in J can be returned to e by maximality. Any two words occur at a finite stage, so a later p_i equalizes them. The resulting semigroup gives the filtered enlargement claimed. The proof uses arrows of K in its normal forms and retains $\mathrm{Ob}\, K$; the printed substitutions of J at these places are recorded in the correction register.

4.14 Critères d'accessibilité pour grosses catégories

Théorème 4.14.1. *Soient $\mathcal{C}$ une catégorie équivalente à une petite catégorie, Φ, Ψ deux petits ensembles de catégories, équivalentes à des petites catégories. Pour toute catégorie I, on désigne par $I_\bullet$ (resp. ${}_\bullet I$) le cône droit (resp. gauche) sur I, déduit de I en ajoutant un objet final (resp. initial) $e = e_I$. Soit Λ_1 (resp. Λ_2) un ensemble de couples (I, φ) (resp. (I, ψ)), où $I \in \Phi$ (resp. $I \in \Psi$), et où*

(4.14.1.1) $\qquad \varphi \ : \ I \longrightarrow \mathcal{C} \qquad$ *(resp.* $\psi \ : \ I \longrightarrow \mathcal{C}$ *)*

est un foncteur. Pour toute catégorie $\mathcal{N}$ stable ([163]), par $\varinjlim$ de type Φ et par $\varprojlim$ de type Ψ on désigne par

$$\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C},\mathcal{N}) \subset \underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N}) \tag{4.14.1.2}$$

la sous-catégorie strictement pleine de $\underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N})$ formée des foncteurs $f : \mathcal{C} \longrightarrow \mathcal{N}$ ayant la propriété suivante :

a) $\forall\ (I,\varphi) \in \Lambda_1$, le foncteur composé

$$I_\bullet \xrightarrow{\varphi} \mathcal{C} \xrightarrow{f} \mathcal{N}$$

est I-exact à gauche, i.e. fait de $(f\varphi)(e_I)$ une $\varinjlim_I$ de $f\varphi|I$.

p. 141
[page 371]

b) Pour tout $(I,\psi) \in \Lambda_2$, le foncteur composé

$$_\bullet I \xrightarrow{\psi} \mathcal{C} \xrightarrow{f} \mathcal{N}$$

est I-exact à droite, i.e. fait de $(f\psi)(e_I)$ une limite projective de $(f\psi)|I$.

Avec ces notations : si $\mathcal{N}$ est une catégorie accessible, il en est de même de $\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C},\mathcal{N})$.

Commentary · Context [ms. 370]

Marked cones and categories of models

Grothendieck now turns the calculus of accessible parts into a way of constructing categories. A functor $\mathcal{C} \to \mathcal{N}$ carries raw diagram data; marking a cone or a cocone in $\mathcal{C}$ asks that some of those data satisfy a universal property. Section 4.14 treats the resulting categories of models uniformly. This is why the preceding theorem on inverse images matters: the condition that a canonical comparison be an isomorphism is an accessible condition on the functor.

The data in display (4.14.1.1) must include the whole marked cone. For a colimit condition one has $\varphi : I_\bullet \to \mathcal{C}$, not just $\varphi : I \to \mathcal{C}$; for a limit condition one has $\psi : {}_\bullet I \to \mathcal{C}$. The cone vertex is the object to which the universal property is attached. With the first of these data and an arbitrary $F : \mathcal{C} \to \mathcal{N}$, the comparison is

$$\varinjlim_{i \in I} F\varphi(i) \longrightarrow F\varphi(e_I).$$

The full subcategory of functors making this map invertible expresses exactly the desired colimit condition. The dual comparison expresses a limit condition. Taking the small intersection of these conditions gives the theorem, once accessibility of the comparison functors has been established. The hypothesis that $\mathcal{N}$ admits the indicated colimits and limits makes those comparison functors defined on the entire ambient functor category.

This is the language of sketches: a small category or graph together with specified diagrams, cones and cocones, whose models realize the specified universal constructions. The background is the study of categories presented by small data, including Gabriel and Ulmer (1971), and the theory of accessible categories developed by Makkai and Paré (1989). The latter appeared in 1989 and is contemporaneous with this manuscript; it should not be described simply as a later verification of Grothendieck's work. The comparison here concerns the mathematical formulations, without asserting a documented line of influence.

For a concrete example, take the one-sorted finite-product theory of groups. Its objects are the finite powers $1, x, x^2, \ldots$, and its maps are tuples of group terms modulo the group identities. Mark the finite-product cones. A product-preserving functor to sets chooses a set G, sends multiplication, inverse and unit terms to operations on G, and makes the term equalities precisely the group axioms. Conversely those operations determine the functor. A natural transformation is determined by its component at x, and naturality for the operation terms says exactly that this component is a group homomorphism. Thus the model category is the usual category of groups. Finite presentations supply

163. Cette propriété de stabilité n'est pas nécessaire pour la définition de $\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C},\mathcal{N})$, et il est presque sûr que le théorème est valable sans faire cette hypothèse sur $\mathcal{N}$. Cf. 4.14.16, où on voit que c'est en tous cas inutile pour Ψ.

its compact generators; an arbitrary group is the filtered colimit of the finite generators-and-relations approximations mapping to it. This familiar example exhibits the full programme: the source encodes operations and equations, and the marked cones enforce the intended relation between the different arities.

The same method is useful for large source categories after restriction to compact objects, but then the chosen bound must control both the diagram shapes and the operations being imposed. This is a mathematical requirement on the restriction argument, not merely a matter of replacing a large set of formulas by a smaller notation.

Commentaire. On utilisera ce théorème surtout quand on a $\Lambda_2 = \emptyset$ ou $\Lambda_1 = \emptyset$, auquel cas on note $\underline{\mathrm{Hom}}_{\Lambda_1}(\mathcal{C},\mathcal{N})$, resp. $\underline{\mathrm{Hom}}^{\Lambda_2}(\mathcal{C},\mathcal{N})$, la catégorie $\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C},\mathcal{N})$. On appliquera le théorème surtout quand $\mathcal{C}$ elle-même est stable par $\varinjlim$ de type Φ et par $\varprojlim$ de type Ψ, et quand Λ_1 (resp. Λ_2) est déjà formé de foncteurs φ (resp. ψ) qui sont I-exacts à gauche (resp. à droite). Donc $\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C},\mathcal{N})$ est alors formée des $f : \mathcal{C} \longrightarrow \mathcal{N}$ qui commutent à certaines $\varinjlim$ de type Φ, et à certaines $\varprojlim$ de type Ψ. En particulier, on trouve :

Corollaire 4.14.2. *Soient $\mathcal{C}$ une catégorie équivalente à une petite catégorie, $\mathcal{N}$ une $\mathfrak{U}$-catégorie, Φ et Ψ deux petits ensembles de catégories I, équivalentes à des petites catégories. On suppose $\mathcal{C}$ et $\mathcal{N}$ stables par $\varinjlim$ de type Φ, par $\varprojlim$ de type Ψ. Soit $\underline{\mathrm{Hom}}^{\Psi}_{\Phi}(\mathcal{C},\mathcal{N})$ la sous-catégorie strictement pleine de $\underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N})$ formée des $f : \mathcal{C} \longrightarrow \mathcal{N}$ qui commutent aux $\varinjlim$ de type Φ et aux $\varprojlim$ de type Ψ. Alors, si $\mathcal{N}$ est accessible, il en est de même de $\underline{\mathrm{Hom}}^{\Psi}_{\Phi}(\mathcal{C},\mathcal{N})$.* [page 372]

Voici des cas particuliers remarquables de ce corollaire :

Corollaire 4.14.3. *Soient $\mathcal{M}$, $\mathcal{N}$ deux catégories accessibles, et π_0 un cardinal infini, tel que $\mathcal{M}$ satisfasse à L_{π_0}. Soit $\underline{\mathrm{Hom}}_{\pi_0}(\mathcal{M},\mathcal{N})$ la sous-catégorie strictement pleine de $\underline{\mathrm{Hom}}(\mathcal{M},\mathcal{N})$ formée des foncteurs π_0-accessibles. Alors $\underline{\mathrm{Hom}}_{\pi_0}(\mathcal{M},\mathcal{N})$ est accessible.*

(Le cas où π_0 est utile pour $\mathcal{M}$ a déjà été traité.) [page 373]

Démonstration. Dans le cas général, soit $\pi > \pi_0$ un cardinal utile pour $\mathcal{M}$, de sorte qu'on a

$$\mathcal{M} \xleftarrow{\sim} \mathrm{Ind}_{\pi}(\mathcal{C}) \qquad \text{avec } \mathcal{C} = \mathcal{M}_{\pi} \ .$$

On peut supposer $\mathcal{M} = \mathrm{Ind}_{\pi}(\mathcal{C})$. Le fait que $\mathcal{M}$ satisfasse à L_{π_0} implique que $\mathcal{C}$ est stable par $\varinjlim$ grandes devant π_0, et de cardinal $\leqslant \pi$. Soit Φ l'ensemble des catégories de cette nature. Φ n'est pas petit, mais il existe $\Phi_0 \subset \Phi$ petit, tel que toute $I \in \Phi$ soit isomorphe à une $I_0 \in \Phi_0$, ce qui suffira pour la validité de 4.14.1 et 4.14.2 (où on fera ici $\Psi = \emptyset$). On peut considérer $\underline{\mathrm{Hom}}_{!\,\pi_0}(\mathcal{M},\mathcal{N})$ comme une sous-catégorie strictement pleine de $\underline{\mathrm{Hom}}_{!\,\pi}(\mathcal{M},\mathcal{N}) \xrightarrow{\sim} \underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N})$ (cf. 4.12.3, p. 275). Pour un foncteur $f : \mathcal{M} \longrightarrow \mathcal{N}$ qui est π-accessible, dire qu'il est même π_0-accessible revient à dire que sa restriction à $\mathcal{C}$, i.e. son image dans $\underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N})$, commute aux $\varinjlim$ de type Φ. (Cf. 4.13.20, page 341 ([164]), où on prend $\alpha = \alpha_{\pi}$, notant que $J_{\alpha_{\pi}}$ grande devant π_0 puisque $\pi > \pi_0$).

Donc on trouve [page 374]

$$\underline{\mathrm{Hom}}_{!\,\pi_0}(\mathcal{M},\mathcal{N}) \xrightarrow{\sim} \underline{\mathrm{Hom}}_{\Phi}(\mathcal{C},\mathcal{N}) \ ,$$

et le corollaire 4.14.2 donne la conclusion voulue. p. 142

Commentary · Present state [ms. 374]

The target colimits in the functor-category argument

Grothendieck wants fixed-threshold accessible functors to form an accessible category even when their source is large. Restricting to a sufficiently large small subcategory of presentable objects is the right approach. It reduces preservation of all the relevant filtered colimits to preservation of a bounded family, provided the target has the colimits needed in the reduction.

Corollary 4.14.3 is stated with L_{π_0} only on $\mathcal{M}$. Its proof then invokes Corollary 4.14.2 for shapes which are π_0^+-filtered and have size at most π. That corollary assumes these colimits exist in $\mathcal{N}$.

164. La référence n'est pas tout à fait adéquate. Il faudrait réunir dans un paragraphe à part tous les énoncés de ce type, dont certains utilisent le théorème de représentation indicielle.

Accessibility of $\mathcal{N}$ by itself gives colimits above some sufficiently large threshold, which need not be the specified π_0. Choosing π useful for both categories repairs the equivalence with functors on $\mathcal{M}_\pi$, but does not supply the missing smaller-threshold colimits. Thus the printed deduction proves the assertion with the additional hypothesis $\mathcal{N} \models L_{\pi_0}$. The unrestricted case is not established by that deduction; it is part of the issue about colimit conditions without ambient colimit completeness explicitly raised in 4.14.16. We do not infer a counterexample to the unrestricted statement from this proof gap.

There is a separate, elementary correction to the sentence about the ordinal α_π. Its index category is π_0^+-filtered when $\mathrm{cf}(\pi) > \pi_0$, not simply when $\pi > \pi_0$. A power-of-two rank as above ensures the needed cofinality. In Corollary 4.14.4 the target filtered-colimit hypothesis is included, but the restriction to $\mathcal{M}_\pi$ should also be made after simultaneous uniformization of the selected limit and colimit functors. Merely bounding the sizes of their shapes does not guarantee that their values on presentable diagrams remain presentable. These rank adjustments leave the intended method intact and state precisely which version its argument proves.

Corollaire 4.14.4. *Soient $\mathcal{M}$, $\mathcal{N}$ deux catégories accessibles, Φ et Ψ deux ensembles des catégories comme dans 4.14.2, on suppose que $\mathcal{M}$ et $\mathcal{N}$ satisfassent L_{π_0}, et* [soient] *stables par $\varinjlim$ de type Φ et par $\varprojlim$ de type Ψ. Soit $\underline{\mathrm{Hom}}^{\Psi}_{\Phi,\pi_0}(\mathcal{M},\mathcal{N})$ la sous-catégorie strictement pleine de $\underline{\mathrm{Hom}}(\mathcal{M},\mathcal{N})$ formée des foncteurs π_0-accessibles qui commutent aux $\varinjlim$ de type Φ, et aux $\varprojlim$ de type Ψ. Alors $\underline{\mathrm{Hom}}^{\Psi}_{\Phi,\pi_0}(\mathcal{M},\mathcal{N})$ est accessible.*

Démonstration. Cette fois, on choisit $\pi > \pi_0$ tel qu'on ait $\operatorname{card}\text{réd}\, I \leqslant \pi$ pour tout I dans Φ ou dans Ψ. La catégorie envisagée s'interprète alors (posant encore $\mathcal{C} = \mathcal{M}_\pi$) comme [page 375]

$$\underline{\mathrm{Hom}}^{\Psi}_{\Phi,\pi_0}(\mathcal{M},\mathcal{N}) \xrightarrow{\sim} \underline{\mathrm{Hom}}^{\Psi}_{\Phi'}(\mathcal{C},\mathcal{N}) \ ,$$

où Φ' est formée des catégories qui sont soit dans Φ, ou qui sont grandes devant π_0 et de cardinal $\leqslant \pi$. Il suffit donc d'appliquer encore 4.14.2.

Corollaire 4.14.5. *Considérons les trois ensembles suivants :*

a) Φ_1 est formée de toutes les catégories équivalentes à des petites catégories.

b) Φ_2 comme a), mais en restreignant aux catégories filtrantes.

c) Φ_3 formé des catégories discrètes, et de celles qui sont grandes devant π_0 (π_0 un cardinal infini donné).

Soit Φ l'un des ensembles de catégories Φ_1, Φ_2, Φ_3, $\Phi_2 \cup \Phi_3$ ou la réunion d'un de ceux-ci et d'un petit ensemble Φ_0 de catégories essentiellement petites ([165]). Soit Ψ un petit ensemble de catégories. Soient $\mathcal{M}$, $\mathcal{N}$ des catégories accessibles, stables par $\varinjlim$ de type Φ, et par $\varprojlim$ de type Ψ. Alors $\underline{\mathrm{Hom}}^{\Psi}_{\Phi}(\mathcal{M},\mathcal{N})$ est accessible.

Démonstration. Soit $\pi_0' \geqslant \pi_0$ un cardinal utile pour $\mathcal{M}$, π un cardinal ayant les propriétés [page 376] suivantes.

a) $\pi \geqslant \sup(\pi_0', \operatorname{card}\text{réd}\, \mathcal{M}_{\pi_0'})$, $\pi > \pi_0$.

b) $\pi^{\pi_0'} = \pi$.

c) $I \in \Phi_0 \cup \Psi \Longrightarrow \operatorname{card}\text{réd}\, I \leqslant \pi$.

Soit $\mathcal{C} = \mathcal{M}_\pi$, d'où $\mathcal{M} \simeq \mathrm{Ind}_\pi(\mathcal{C})$. Dans tous les cas envisagés, Φ contient l'ensemble des catégories essentiellement petites qui sont grandes devant π_0, a fortiori celles qui sont grandes devant π, donc la catégorie $\underline{\mathrm{Hom}}^{\Psi}_{\Phi}$ s'interprète comme une sous-catégorie strictement pleine de

$$\underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N}) \ .$$

Si d'autre part Φ_π désigne l'ensemble des $I \in \Phi$ telles que $\operatorname{card} I \leqslant \pi$, on trouve

$$\underline{\mathrm{Hom}}^{\Psi}_{\Phi}(\mathcal{M},\mathcal{N}) \ \simeq \ \underline{\mathrm{Hom}}^{\Psi}_{\Phi_\pi}(\mathcal{C},\mathcal{N}) \ ,$$

p. 143

et on applique 4.14.2. [page 377]

Commentary · Exposition [ms. 376]

A bounded sketch for a large functor category

Grothendieck is trying to make preservation of universal constructions into an accessible condition. The domain may have a proper class of objects and the demand may concern all small colimits. The preceding work with cardinals serves to replace that demand by a set of tests on one essentially small category. This is why these corollaries belong to the same argument as the long cofinality constructions: a good presentation rank makes the large category recoverable from its bounded part.

Choose π useful for $\mathcal{M}$ and write $\lambda = \pi^+$, so that the objects of $\mathcal{M}_\pi$ are λ-presentable in modern terminology. Choose a small skeleton $\mathcal{A}$ of that subcategory. A functor preserving λ-filtered colimits is determined, including its natural transformations, by its restriction to $\mathcal{A}$. Its extension is expressed by

$$F(X) \simeq \varinjlim_{(A \to X) \in \mathcal{A}/X} F(A).$$

The choice of a common rank must ensure that the target has these filtered colimits. Preservation of additional shapes is then tested by comparison arrows associated to a set of bounded cones. One asks that these arrows become invertible. The category of candidates is therefore obtained from an accessible diagram category by inverse images of an accessible isomorphism subcategory and a small intersection. These are precisely the operations established in the preceding section.

The colimit assertion in 4.14.6 illustrates both the strength and the exact range of this method. If $\mathcal{M}$ and $\mathcal{N}$ are locally presentable, the category of cocontinuous functors between them is accessible by the bounded-sketch argument. It is also cocomplete. Given a small diagram (F_j) of cocontinuous functors, define $F(X) = \varinjlim_j F_j(X)$. For a small diagram (X_i) one has

$$\begin{aligned} F(\varinjlim_i X_i) &\simeq \varinjlim_j \varinjlim_i F_j(X_i) \\ &\simeq \varinjlim_i \varinjlim_j F_j(X_i) \simeq \varinjlim_i F(X_i). \end{aligned}$$

The interchange is just the universal property of a colimit over the product indexing category; no exactness condition on $\mathcal{N}$ enters. Thus this functor category is locally presentable. The first assertion of 4.14.6, with only accessibility of $\mathcal{N}$, is not justified by the cited corollary: the latter assumes the target colimits that the former omits. We retain that distinction in the audit instead of silently adding a hypothesis.

The tensor product in 4.14.8 uses the other side of the construction. Its objects are functors $\mathcal{M}^{op} \to \mathcal{N}$ carrying colimits in $\mathcal{M}$ to limits in $\mathcal{N}$. The relevant constraints are limit-cone constraints, and the argument on manuscript page 389 shows that these can be recognized even when other limits in the target do not exist. Here $\mathcal{N}$ is complete, so limits of such functors are computed pointwise: two successive limits commute. Consequently the tensor category is accessible and complete, hence locally presentable. This argument does not require the erroneous covariant representability assertion that follows.

A small calculation makes the construction concrete. Every set X is the coproduct of X copies of the singleton. Therefore a functor $F : \mathbf{Set}^{op} \to \mathcal{N}$ taking colimits to limits must satisfy $F(X) \simeq F(1)^X$. For a map $a : X \to Y$, its image sends a family indexed by Y to the family indexed by X obtained by composition with a. Conversely, for any $N \in \mathcal{N}$, the functor $X \mapsto N^X$ takes colimits of sets to limits: applying $\mathrm{Hom}(T, -)$ identifies the claim with the familiar contravariant representable functor $\mathrm{Hom}_{\mathbf{Set}}(-, \mathrm{Hom}(T, N))$. A natural transformation between these functors is determined by its component at 1, since projections to the singleton coordinates detect it. Hence $\mathbf{Set} \boxtimes \mathcal{N} \simeq \mathcal{N}$. The unit of the tensor construction is already visible in this elementary case.

En particulier, on trouve :

Corollaire 4.14.6. *Soient $\mathcal{M}$, $\mathcal{N}$ deux catégories accessibles, supposons $\mathcal{M}$ stable par petites $\varinjlim$ (i.e. $\mathcal{M}$ est une catégorie paratopos). Alors la catégorie $\underline{\mathrm{Hom}}_!(\mathcal{M}, \mathcal{N})$ des foncteurs $f : \mathcal{M} \longrightarrow \mathcal{N}$ qui commutent aux petites $\varinjlim$ est accessible. Si $\mathcal{N}$ est elle aussi un paratopos,*

165. On pourrait faire ici un énoncé qui englobe 4.14.4 en rajoutant un

d) Φ_4 formé des catégories grandes devant π_0,

et prendre Φ de la forme de Φ_1, Φ_2, Φ_4, Φ_3, $\Phi_3 \cup \Phi_2$, $\Phi_3 \cup \Phi_4$, ou la réunion de ceux-ci et d'un Φ_0.

$\underline{\mathrm{Hom}}_!(\mathcal{M},\mathcal{N})$ *est un paratopos.*

Démonstration. La première assertion est le cas particulier de 4.14.5 relatif au cas où $\Phi = \Phi_0$, $\Psi = \emptyset$. La deuxième assertion en résulte, puisque $\underline{\mathrm{Hom}}_!(\mathcal{M},\mathcal{N})$ est visiblement stable par petites $\varinjlim$, donc c'est un paratopos étant accessible (4.8.9, page 207).

Corollaire 4.14.7. *Soient Φ, Ψ, $\mathcal{M}$ comme dans 4.14.5. Alors pour toute catégorie accessible $\mathcal{N}$, la catégorie* [page 378]

$$\underline{\mathrm{Hom}}^{\Phi}_{\Psi}(\mathcal{M}^\circ,\mathcal{N}) \;\simeq\; (\underline{\mathrm{Hom}}^{\Psi}_{\Phi}(\mathcal{M},\mathcal{N}^\circ))^\circ$$

est accessible.

Démonstration. On procède comme pour 4.14.5, pour expliciter

$$\underline{\mathrm{Hom}}^{\Psi}_{\Phi}(\mathcal{M},\mathcal{N}^\circ) \xrightarrow{\sim} \underline{\mathrm{Hom}}^{\Psi}_{\Phi_\pi}(\mathcal{C},\mathcal{N}^\circ)\ ,$$

d'où

$$\underline{\mathrm{Hom}}^{\Phi}_{\Psi}(\mathcal{M}^\circ,\mathcal{N}) \xrightarrow{\sim} \underline{\mathrm{Hom}}^{\Phi_\pi}_{\Psi}(\mathcal{C}^\circ,\mathcal{N})\ ,$$

et on applique 4.14.2 à $\mathcal{C}^\circ$, Ψ, Φ_π.

Corollaire 4.14.8. *Soient $\mathcal{M}$ et $\mathcal{N}$ deux catégories paratopos. Alors*

$$\mathcal{M}\boxtimes\mathcal{N} \;\simeq\; \underline{\mathrm{Hom}}^!(\mathcal{M}^\circ,\mathcal{N}) \qquad \textit{(cf. 4.2 et 4.3)}$$

est un paratopos.

En effet, en vertu de 4.14.7 (avec $\Phi = \Phi_\pi$ [?], $\Psi = \emptyset$), c'est une catégorie accessible.

D'autre part, il est immédiat qu'elle est stable par petites $\varprojlim$, $\mathcal{N}$ l'étant. Donc on conclut [page 379] encore par 4.8.9 (page 207) que c'est une catégorie paratopos.

Corollaire 4.14.9. *Soient $\mathcal{M}$, $\mathcal{N}$ deux catégories paratopos, et $\underline{\mathrm{Hom}}^!(\mathcal{M},\mathcal{N})$ la catégorie des foncteurs $\mathcal{M}\longrightarrow\mathcal{N}$ qui commutent aux petites $\varprojlim$. On a alors une équivalence de catégories*

$$\begin{aligned}\underline{\mathrm{Hom}}^!(\mathcal{M},\mathcal{N}) &\xrightarrow{\sim} \underline{\mathrm{Hom}}_!(\mathcal{N},\mathcal{M})^\circ\\ f &\longmapsto \textit{adjoint à gauche de } f\ ,\end{aligned}$$

!! *et par suite la catégorie* **opposée** *à $\underline{\mathrm{Hom}}^!(\mathcal{M},\mathcal{N})$ est accessible.*

Ceci résulte du

Lemme 4.14.10 (pour mémoire). *Soient $\mathcal{M}$* `[une]` *catégorie pseudo-topos, $f:\mathcal{M}\longrightarrow\mathcal{N}$ un foncteur. Pour que f admette un adjoint à gauche (resp. à droite), il faut et il suffit que f commute aux petites $\varprojlim$ (resp. aux petites $\varinjlim$).*

Ceci équivaut au cas particulier : p. 144

Corollaire 4.14.11. *Soit $\mathcal{M}$ un paratopos, et f un foncteur covariant (resp. contravariant)* [page 380] *de $\mathcal{M}$ dans* Ens. *Pour que f soit représentable, il faut et il suffit que f commute aux $\varprojlim$.*

Ça a été vu – le cas des contrafoncteurs étant le plus évident (cf. 4.1 – il suffit que $\mathcal{M}$ soit un paratopos, et même que $\mathcal{M}$ admette une petite sous-catégorie pleine génératrice, cf. SGA 4 I 8.12.7 (pour l'énoncé dual). Dans les cas d'un foncteur covariant, la difficulté provient du fait que $\mathcal{M}$ n'admet pas forcément de petite sous-catégorie cogénératrice. Il faut utiliser l'existence d'une filtration cardinale (généralisée), cf. loc. cit. 8.3.12.)

Après tous ces beaux corollaires, on est mûr pour s'attaquer à la démonstration de 4.14.1 !

Commentary · Examples [ms. 380]

Continuity does not supply a solution set

Grothendieck wants the familiar passage between left and right adjoints to turn the preceding accessibility theorem into its dual. The formal passage is sound, but its input in 4.14.9–4.14.11 is too broad. A functor preserving all small limits need not have a left adjoint, even when its source and target are locally presentable. This is a genuine mathematical error in the printed statement, not a defect introduced by the transcription. The source's marginal mark beside 4.14.9 is retained without assigning it a meaning beyond what can be read on the page.

The obstruction was already available in the literature being cited: Artin et al. (1972, Exposé I, Example 8.12.9) attributes a continuous nonrepresentable functor on groups to H. Bass. Grothendieck himself had recalled this example and the need for an extra cogeneration hypothesis at the beginning of the chapter (Grothendieck, 1990–1991n, ms. 50–52). We give an explicit version so that the missing hypothesis has a visible effect. For every infinite cardinal κ choose a simple group S_κ of cardinality κ; one may take the group of even permutations of a set of that size having finite support. Simplicity follows from the finite alternating groups: a nonidentity element of a normal subgroup lies in a finite alternating subgroup on at least five letters, and its normal closure there contains a 3-cycle; conjugation gives all 3-cycles, which generate the finitary alternating group.

Define a covariant functor on groups by

$$B(G) = \prod_{\kappa \text{ infinite}} \operatorname{Hom}(S_\kappa, G).$$

This notation denotes a set, despite its apparent indexing by all infinite cardinals. A nontrivial homomorphism from a simple group is injective, so the factor indexed by $\kappa > |G|$ is a singleton. One can therefore define $B(G)$ by the product over $\kappa \le |G|$, with trivial coordinates understood elsewhere. Postcomposition defines B on homomorphisms and respects these omitted coordinates.

To verify continuity, take any small diagram (G_i) with limit G. There is a cardinal bounding the sizes of G and of every G_i. Above that cardinal all coordinates are trivial. Below it, each functor $\operatorname{Hom}(S_\kappa, -)$ preserves limits, and a set-indexed product of such functors does so as well. Thus the canonical map

$$B(\varprojlim_i G_i) \longrightarrow \varprojlim_i B(G_i)$$

is bijective. This checks all small shapes, including products with arbitrarily large small indexing sets.

To see why representability fails, suppose that an isomorphism $\operatorname{Hom}(H, -) \simeq B$ existed. By Yoneda it would be determined by an element $b \in B(H)$. Choose $\kappa > |H|$. The κ-coordinate of b is trivial, and therefore every element obtained from b by postcomposition has trivial κ-coordinate. But $B(S_\kappa)$ contains the family whose κ-coordinate is id_{S_κ} and whose other coordinates are trivial. That family cannot lie in the image of $\operatorname{Hom}(H, S_\kappa)$, a contradiction. Nor can B have a left adjoint, since an adjunction would give $B(G) \simeq \operatorname{Hom}(L(1), G)$.

The correct version of 4.14.9 uses accessible continuous functors. Between locally presentable categories these are exactly the right adjoints, and taking left adjoints gives

$$\operatorname{Fun}^R(\mathcal{M}, \mathcal{N}) \simeq \operatorname{Fun}^L(\mathcal{N}, \mathcal{M})^{op}.$$

The reversal on natural transformations is the mate correspondence. Accessibility supplies the solution-set requirement in the adjoint functor theorem. For a precise modern statement, including a bound on the sizes of limits that need to be tested once accessibility has been fixed, see Tendas (2022, Theorems 2.9 and 2.11).

The other half of 4.14.10 remains valid, even with its stated pseudo-topos hypothesis: a cocontinuous functor from a cocomplete locally small category with a small family generating by strict epimorphisms to a locally small category has a right adjoint. This is the dual of SGA 4 I 8.12.7–8.12.8. Locally presentable categories are a special case. Correspondingly, a contravariant set-valued functor taking colimits to limits is representable. There is no license to reverse this theorem without also reversing its size hypotheses. The reference printed as SGA 4 I 8.3.12 points toward 8.13.2, whose prorepresentability criterion explicitly assumes accessibility of the functor.

Commentary · Exposition [ms. 380]

Testing universal arrows on small generators

The proof that now begins returns to the part of the argument that works without the representability detour. Grothendieck encodes a universal property by a comparison arrow and then tests whether that arrow is invertible. This makes the preservation condition a property of an object in an accessible arrow category, where the inverse-image theorem can be used.

For a prescribed cocone, its comparison arrow is

$$\varinjlim_{i \in I} F\varphi(i) \longrightarrow F\varphi(e_I).$$

Its accessibility follows directly from pointwise colimits and interchange of colimits. For a prescribed cone, the comparison has the opposite orientation,

$$F\varphi(e'_I) \longrightarrow \varprojlim_{i\in I} F\varphi(i),$$

and a cardinal bound enters. Fix a regular λ larger than the number of arrows of I, and a small strong generating family $\mathcal{A}$ of λ-presentable objects in $\mathcal{N}$. If (D_j) is a λ-filtered diagram of I-diagrams, then for $A \in \mathcal{A}$ the comparison between $\operatorname{colim}_j \lim_i D_j(i)$ and $\lim_i \operatorname{colim}_j D_j(i)$ becomes

$$\varinjlim_j \varprojlim_i \operatorname{Hom}(A, D_j(i)) \longrightarrow \varprojlim_i \varinjlim_j \operatorname{Hom}(A, D_j(i)).$$

It is a bijection because λ-filtered colimits of sets commute with limits having fewer than λ arrows. The strong generators detect the original isomorphism. This explains both the size hypothesis and the correction of the printed $\varinjlim_I$ to $\varprojlim_I$ on manuscript page 383.

The isomorphism subcategory is especially transparent. The functor $X \mapsto \mathrm{id}_X$ is fully faithful from $\mathcal{N}$ to $\mathcal{N}^{[1]}$, preserves the available filtered colimits, and has as its replete essential image the invertible arrows. Thus this subcategory is accessible. For monomorphisms one uses the same small family differently: u is monic precisely when every $\operatorname{Hom}(A, u)$ is injective. A generating family suffices here, whereas detection of isomorphisms requires strong generation.

The finite-set calculation left to the reader in 4.14.13 can be made without any representation theorem. Replace an injection by an actual inclusion $A \subset B$. Consider the poset of pairs of finite subsets $A_0 \subset A$ and $B_0 \subset B$ with $A_0 \subset B_0$. It is directed under union, and the colimit of its arrows $A_0 \hookrightarrow B_0$ is $A \hookrightarrow B$. Each finite arrow is finitely presentable in the arrow category: its morphisms to a filtered colimit factor at one stage, and the one commutative-square equation holds at a later stage. Filtered colimits of injections in sets remain injective. Hence these finite injections form a small family of finitely presentable generators of the injection category. For a bijection, take a finite subset of its source and its image in the target; the same argument gives the isomorphism assertion.

Finally, full faithfulness matters in 4.14.14. The formula

$$\operatorname{Hom}_{\mathrm{Ind}(\mathcal{C})}(\varinjlim_i C_i, \varinjlim_j D_j) \simeq \varprojlim_i \varinjlim_j \operatorname{Hom}_{\mathcal{C}}(C_i, D_j)$$

shows that a full inclusion $\mathcal{D} \subset \mathcal{C}$ induces a fully faithful functor on Ind-completions. Together with preservation of filtered colimits, this identifies its essential image with an accessible embedded full subcategory. Mere accessibility of an arbitrary functor would not imply the corresponding assertion about its full image.

[page 381]

Démonstration de 4.14.1. On sait que $\mathcal{M} = \underline{\mathrm{Hom}}(\mathcal{C}, \mathcal{N})$ est accessible (4.9.5, p. 220), et $\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C}, \mathcal{N})$ est une sous-catégorie strictement pleine de cette catégorie. Il suffit de prouver que c'est une sous-catégorie accessible dans $\mathcal{M}$ (4.13.1, p. 281). Pour tout $\xi = (I, \varphi) \in \Lambda_1$, on a un foncteur

$$L_\xi \ : \ \mathcal{M} \ = \ \underline{\mathrm{Hom}}(\mathcal{C}, \mathcal{N}) \longrightarrow \underline{\mathrm{Fl}}(\mathcal{N}) \ ,$$

donné par

$$L_\xi(f) \ = \ \text{flèche canonique } \varinjlim_{i\in I} f\varphi(i) \longrightarrow f\varphi(e_I) \ .$$

Je dis que le foncteur L_ξ est *accessible.* En effet, soit π_0 un cardinal tel que $\mathcal{N}$ satisfasse à L_{π_0}, il en est donc de même de $\mathcal{M} = \underline{\mathrm{Hom}}(\mathcal{C}, \mathcal{N})$ et de $\underline{\mathrm{Fl}}(\mathcal{N}) \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(\mathbf{\Delta}_1, \mathcal{N})$, les limites en question se calculent argument par argument. Je dis que L_ξ est π_0-accessible, i.e. commute aux $\varinjlim$ grandes devant π_0. Il suffit de voir qu'il en est ainsi des foncteurs composés avec les foncteurs

$$\underline{\mathrm{Fl}}(\mathcal{N}) \ \underset{\rho}{\overset{\sigma}{\rightrightarrows}} \ \mathcal{N}$$

"source" et "but", i.e. des foncteurs

$$f \longmapsto \varinjlim_{i\in I} f\varphi(i) \qquad \text{et} \qquad f \longmapsto f\varphi(e_I) \ .$$

[page 382]

Or le premier foncteur, $f \longmapsto \varinjlim_{i\in I} f\varphi(i)$, est le composé de

$$f \longmapsto f\circ\varphi_I \ : \ \underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N}) \longrightarrow \underline{\mathrm{Hom}}(I,\mathcal{N})$$

(lequel commute aux $\varinjlim$ qui sont représentables dans $\mathcal{N}$, et en particulier aux $\varinjlim$ grandes devant π_0) et du foncteur

$$\varinjlim_{I} \ : \ \underline{\mathrm{Hom}}(I,N) \longrightarrow \mathcal{N} \ ,$$

qui lui aussi commute aux limites inductives représentables dans $\mathcal{N}$, et en particulier à celles grandes devant π_0. Quant au foncteur $f \longmapsto (f\circ\varphi)(e_I) = f(\varphi(e_I))$, il est clair qu'il commute également aux $\varinjlim$ représentables dans $\mathcal{N}$, donc il est π_0-accessible.

Ceci posé, notons que p. 145

$$\underline{\mathrm{Hom}}_{\Lambda_1}(\mathcal{C},\mathcal{N}) \ = \ \bigcap_{\xi\in\Lambda_1} \underline{\mathrm{Hom}}_{\{\xi\}}(\mathcal{C},\mathcal{N}) \ ,$$

et que $\underline{\mathrm{Hom}}_{\xi}(\mathcal{C},\mathcal{N})$ est l'image inverse, par le foncteur accessible L_ξ précédent, de la sous-catégorie strictement pleine $\underline{\mathrm{Is}}(\mathcal{N})$ de $\underline{\mathrm{Fl}}(\mathcal{N})$ formée des *isomorphismes* dans $\mathcal{N}$. Si on prouve que cette dernière est accessible dans $\underline{\mathrm{Fl}}(\mathcal{N})$, il s'ensuit que $\underline{\mathrm{Hom}}_{\xi}(\mathcal{C},\mathcal{N})$ est accessible dans $\mathcal{M}$ (4.3.31, page 350). Donc, Φ étant petite, il s'ensuit que $\underline{\mathrm{Hom}}_{\Lambda_1}(\mathcal{C},\mathcal{N})$ est accessible dans $\mathcal{M}$ (4.13.7, page 291). [page 383]

On prouve de la même façon que $\underline{\mathrm{Hom}}^{\Lambda_2}(\mathcal{C},\mathcal{N})$ est accessible dans $\mathcal{M} = \mathrm{Hom}(\mathcal{C},\mathcal{N})$. Ici, on doit considérer les foncteurs

$$L'_\xi \ : \ \mathcal{M} = \underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N}) \longrightarrow \underline{\mathrm{Fl}}(\mathcal{N})$$

définis par

$$L'_\xi \ = \ \text{flèche canonique } f\varphi(e'_I) \longrightarrow \varprojlim_{i\in I} f\varphi(i) \ .$$

Pour prouver que ce foncteur est accessible, on procède comme tantôt, en prenant cependant π_0 assez grand pour qu'on ait

$$\begin{cases} I\in\Psi \implies \mathrm{card}\,\mathrm{réd}\, I \leqslant \pi_0. \\ \mathcal{N}_{\pi_0} \text{ est génératrice dans } \mathcal{N}. \end{cases}$$

Je dis qu'alors L'_ξ est π_0-accessible : en effet, en procédant comme tantôt pour L_ξ, on est ramené à voir que

$$\varinjlim_{I} \underline{\mathrm{Hom}}(I,\mathcal{N}) \longrightarrow \mathcal{N}$$

est π-accessible. Or cela est contenu dans SGA 4 I 9.8.

Ainsi, on a prouvé que les deux sous-catégories strictement pleines [page 384]

$$\underline{\mathrm{Hom}}_{\Lambda_1}(\mathcal{C},\mathcal{N}) \ , \qquad \underline{\mathrm{Hom}}^{\Lambda_2}(\mathcal{C},\mathcal{N})$$

de $\mathcal{M} \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(\mathcal{C},\mathcal{N})$ sont accessibles dans $\mathcal{M}$. Il en est donc de même de leur intersection (4.13.7)

$$\underline{\mathrm{Hom}}^{\Lambda_2}_{\Lambda_1}(\mathcal{C},\mathcal{N}) \ = \ \underline{\mathrm{Hom}}_{\Lambda_1}(\mathcal{C},\mathcal{N}) \cap \underline{\mathrm{Hom}}^{\Lambda_2}(\mathcal{C},\mathcal{N}) \ ,$$

q.e.d.

Il reste à prouver le

Lemme 4.14.12. *Soit $\mathcal{N}$ une catégorie accessible. Alors la catégorie $\underline{\mathrm{Fl}}(\mathcal{N}) \overset{déf}{=} \underline{\mathrm{Hom}}(\mathbf{\Delta}_1,\mathcal{N})$ est accessible (4.9.5), et la sous-catégorie strictement pleine $\underline{\mathrm{Is}}(\mathcal{N})$ formée des flèches inversibles dans $\mathcal{N}$ est accessible dans $\underline{\mathrm{Fl}}(\mathcal{N})$. (Il en est de même de la sous-catégorie strictement pleine $\underline{\mathrm{Mon}}(\mathcal{N})$ formée des monomorphismes dans $\mathcal{N}$.)*

Démonstration. Soit $\mathcal{C}$ une petite sous-catégorie strictement génératrice de $\mathcal{N}$, et considérons la petite famille des foncteurs

$$h_x \;=\; (y \longmapsto \mathrm{Hom}(x,y)) \;:\; \mathcal{N} \longrightarrow \mathrm{Ens}\ ,$$

d'où des foncteurs

$$\underline{\mathrm{Fl}}(h_\xi) \;:\; \underline{\mathrm{Fl}}(\mathcal{N}) \longrightarrow \underline{\mathrm{Fl}}(\mathrm{Ens})\ .$$

p. 146
[page 385]

Pour qu'une flèche $u : y \longrightarrow z$ dans $\mathcal{N}$ soit isomorphe (resp. monomorphe), il faut et il suffit que pour tout $x \in \mathrm{Ob}\,\mathcal{C}$, $h_x(u)$ le soit. Ainsi, $\underline{\mathrm{Is}}(\mathcal{N})$ (resp. $\underline{\mathrm{Mon}}(\mathcal{N})$) apparaît comme l'intersection des images inverses, par les foncteurs $\underline{\mathrm{Fl}}(h_\xi)$ ci-dessus, de la sous-catégorie $\underline{\mathrm{Is}}(\mathrm{Ens})$ (resp. $\underline{\mathrm{Mon}}(\mathrm{Ens})$) de $\underline{\mathrm{Fl}}(\mathrm{Ens})$. Cela nous ramène au cas où $\mathcal{N} = (\mathrm{Ens})$. Mais si $\mathcal{C}$ désigne la sous-catégorie strictement pleine de Ens formée des ensembles *finis*, ceux-ci forment une famille strictement génératrice formée d'objets de *présentation finie*, et comme Ens est stable par petites $\varinjlim$, donc par $\varinjlim$ filtrantes, il s'ensuit qu'on a

$$(*) \qquad \mathrm{Ind}(\mathcal{C}) \longrightarrow (\mathrm{Ens})\ ,$$

d'où aussitôt (SGA 4 I 8.8.5, p. 104)

[page 386]

$$(*) \qquad \mathrm{Ind}(\underline{\mathrm{Fl}}(\mathcal{C})) \xrightarrow{\sim} \underline{\mathrm{Fl}}(\mathrm{Ens})\ .$$

Donc le résultat d'accessibilité voulu résulte des deux lemmes suivants :

Lemme 4.14.13. *L'équivalence* $(*)$ *précédente induit des équivalences*

$$\begin{array}{rcl} \mathrm{Ind}(\underline{\mathrm{Is}}(\mathcal{C})) & \xrightarrow{\sim} & \underline{\mathrm{Is}}(\mathrm{Ens}) \\ \mathrm{Ind}(\underline{\mathrm{Mon}}(\mathcal{C})) & \xrightarrow{\sim} & \underline{\mathrm{Mon}}(\mathrm{Ens}) \end{array}$$

(où $\mathcal{C} = (\mathrm{Ensf})$ *est la sous-catégorie pleine de* (Ens) *formée des ensembles* finis*.)*

Lemme 4.14.14 ([166]). *Soit* $\mathcal{C}$ *une catégorie équivalente à une petite catégorie. Alors :*

a) $\mathcal{M} \overset{déf}{=} \mathrm{Ind}(\mathcal{C})$ *est une catégorie accessible.*

b) Pour toute sous-catégorie pleine $\mathcal{D}$ *dans* $\mathcal{C}$*, l'image essentielle de* $\mathrm{Ind}\,\mathcal{D}$ *dans* $\mathcal{M} = \mathrm{Ind}(\mathcal{C})$ *est une sous-catégorie L-accessible dans* $\mathcal{M}$*.*

Démonstration des deux lemmes immédiate et "laissée au lecteur". Le b) dans 4.14.14 provient du fait que le foncteur $\mathrm{Ind}(\mathcal{D}) \longrightarrow \mathrm{Ind}(\mathcal{C})$ provenant d'un foncteur $\mathcal{D} \longrightarrow \mathcal{C}$ (ici un foncteur d'inclusion) est un L-foncteur (i.e. commute aux petites $\varinjlim$ filtrantes), et a fortiori est accessible (et même $\aleph_0$-accessible). [page 387]

4.14.15. On ne peut s'empêcher de se demander si pour $\mathcal{N}$ accessible, la sous-catégorie strictement pleine $\underline{\mathrm{Ép}}(\mathcal{N})$ dans $\underline{\mathrm{Fl}}(\mathcal{N})$, formée des épimorphismes dans $\mathcal{N}$, est accessible dans $\mathcal{N}$. Il est immédiat que si $\mathcal{N}$ satisfait à L_{π_0}, alors $\underline{\mathrm{Ép}}(\mathcal{N})$ est stable dans $\underline{\mathrm{Fl}}(\mathcal{N})$ par les $\varinjlim$ de type L_{π_0}, a fortiori par facteurs directs. Elle aurait donc dû mal à ne pas être accessible dans $\underline{\mathrm{Fl}}(\mathcal{N})$. Notons quand même :

Corollaire 4.14.15.1 (de 4.14.13). *Soit* $\mathcal{N}$ *une catégorie accessible stable par sommes amalgamées* $y \amalg_x z$ ([167])*. Alors* $\underline{\mathrm{Ép}}(\mathcal{N})$ *est une sous-catégorie accessible dans* $\underline{\mathrm{Fl}}(\mathcal{N})$*.*

Considérons en effet le foncteur

p. 147
[page 388]

$$\begin{array}{rcl} \gamma \;:\; \underline{\mathrm{Fl}}(\mathcal{N}) & \longrightarrow & \underline{\mathrm{Fl}}(\mathcal{N}) \\ (x \longrightarrow y) & \longmapsto & (y \amalg_x y \xrightarrow{\text{codiag}} y)\ . \end{array}$$

166. **N.B.** À équivalence près, on trouve les catégories accessibles $\mathcal{M}$ stables par petites $\varinjlim$ filtrantes, et telles que $\mathcal{M}_{\mathrm{pf}}$ (sous-catégorie des objets de présentation *finie*) soit strictement génératrice.

167. Je suis presque sûr que cette hypothèse est superflue. Comparer page 390.

Ce foncteur commute aux types de $\varinjlim$ qui sont représentables dans $\mathcal{N}$, en particulier, il est accessible. D'autre part, $\underline{\text{Ép}}(\mathcal{N})$ est l'image inverse par γ de la sous-catégorie strictement pleine $\underline{\text{Is}}(\mathcal{N})$ de $\underline{\text{Fl}}(\mathcal{N})$. Donc le corollaire résulte du fait que par 4.14.13 cette dernière est accessible dans $\underline{\text{Fl}}(\mathcal{N})$.

Commentary · Examples [ms. 388]

Epimorphisms as degenerate pushout squares

Grothendieck turns to epimorphisms because they expose the asymmetry between testing arrows into an object and testing arrows out of it. A small generating family detects monomorphisms. There need not be a corresponding small cogenerating family to detect epimorphisms. The self-pushout replaces all those outgoing tests by one universal comparison.

Let $u : X \to Y$, and suppose its self-pushout $P = Y \amalg_X Y$ exists, with maps $i_1, i_2 : Y \to P$ and codiagonal $d : P \to Y$. If u is epic, the equality $i_1 u = i_2 u$ implies $i_1 = i_2$. Since $di_1 = di_2 = \mathrm{id}_Y$, one has $i_1 d = \mathrm{id}_P$ by the pushout universal property; hence d is invertible. Conversely, if d is invertible then $i_1 = i_2 = d^{-1}$. Given $a, b : Y \to Z$ with $au = bu$, the induced map $P \to Z$ shows that $a = b$. Thus u is epic exactly when d is invertible. This proves the inverse-image description in 4.14.15.1, and functoriality of pushouts makes its comparison functor accessible.

For sets, the self-pushout of u consists of two copies of Y, with corresponding points identified exactly where they belong to the image of u. The codiagonal is bijective precisely when no point remains doubled, that is, when u is surjective. A surjection $A \twoheadrightarrow B$ is a filtered colimit of finite surjections: index by finite subsets $A_0 \subset A$ and take $A_0 \twoheadrightarrow u(A_0)$. The finite subsets form a directed poset, their source union is A, and their image union is B. A square from a finite arrow factors through one stage, and its finitely many equations become valid at a later stage. Conversely, a finitely presentable surjection is a retract of one stage of this presentation, and therefore has finite source and target. Consequently the category of surjections of sets is finitely accessible with exactly the finite surjections as its finitely presentable objects.

The categorical formulation remains useful when epimorphism does not mean surjection of underlying sets. In commutative unital rings, $\mathbf{Z} \to \mathbf{Q}$ is epic: two ring maps out of $\mathbf{Q}$ agreeing on $\mathbf{Z}$ agree on every fraction, since the images of denominators have forced inverses. The corresponding codiagonal is the multiplication map

$$\mathbf{Q} \otimes_{\mathbf{Z}} \mathbf{Q} \longrightarrow \mathbf{Q}, \qquad r \otimes s \longmapsto rs.$$

Its inverse sends q to $q \otimes 1$. In the tensor product, $1 \otimes n = n \otimes 1$ for every nonzero integer n; inverting this equality gives $1 \otimes n^{-1} = n^{-1} \otimes 1$, and therefore $r \otimes s = rs \otimes 1$. This proves the claimed inverse directly, although $\mathbf{Z} \to \mathbf{Q}$ is far from surjective as a map of sets.

There are useful sharper results in algebraic settings. For a locally λ-presentable abelian category, Positselski (2024, Lemma 10.7) proves that its epimorphism category is locally λ-presentable, with precisely the epimorphisms between λ-presentable objects as its λ-presentables. This fixed-rank statement uses the abelian hypotheses and does not settle the unrestricted question on the preceding page.

4.14.16. Je présume que 4.14.1 reste valable sans supposer $\mathcal{N}$ stable par les $\varinjlim$ de type Φ et par les $\varprojlim$ de type Ψ. Si on a une essentiellement petite catégorie I, la question est de savoir si la sous-catégorie strictement pleine $\underline{\mathrm{Hom}}_{\square}(I_\bullet, \mathcal{N})$ de $\underline{\mathrm{Hom}}(I_\bullet, \mathcal{N})$, formée des foncteurs satisfaisant la condition a) de 4.14.1, est accessible dans $\underline{\mathrm{Hom}}(I_\bullet, \mathcal{N})$, et de même [page 389]
pour $\underline{\mathrm{Hom}}^{\square}({}_\bullet I, \mathcal{N})$. Pour ce deuxième cas, ça a l'air OK, car si $\mathcal{C}$ est une petite sous-catégorie strictement génératrice de $\mathcal{N}$, et si pour tout $x \in \mathrm{Ob}\ [\mathcal{C}]$ on considère encore le foncteur

$$h_x \ : \ \mathcal{N} \longrightarrow \mathrm{Ens}\ ,$$

d'où

$$\bar{h}_x \ : \ \underline{\mathrm{Hom}}({}_\bullet I, \mathcal{N}) \longrightarrow \underline{\mathrm{Hom}}({}_\bullet I, \mathrm{Ens})\ ,$$

on voit que $\underline{\mathrm{Hom}}^{\square}({}_\bullet I, \mathcal{N})$ est l'intersection des images inverses des sous-catégories $\underline{\mathrm{Hom}}^{\square}({}_\bullet I, \mathrm{Ens})$ de $\underline{\mathrm{Hom}}({}_\bullet I, \mathrm{Ens})$. Donc ces dernières étant accessibles dans $\underline{\mathrm{Hom}}({}_\bullet I, \mathrm{Ens})$,

par 4.14.1 ((Ens) étant stable par petites $\varprojlim$), il s'ensuit bien que $\underline{\mathrm{Hom}}^{\square}({}_{\bullet}I,\mathcal{N})$ l'est dans $\underline{\mathrm{Hom}}({}_{\bullet}I,\mathcal{N})$, q.e.d.

Le cas de $\underline{\mathrm{Hom}}_{\square}(I_{\bullet},\mathcal{N})$ dans $\underline{\mathrm{Hom}}(I_{\bullet},\mathcal{N})$ semble plus délicat, dans le cas où [page 390]

$$I = \quad \bullet \quad , \qquad \text{donc} \qquad I = \quad \bullet \quad ,$$

si l'énoncé envisagé est vrai, on en conclura que $\underline{\mathrm{Ép}}(\mathcal{N})$ est accessible dans $\underline{\mathrm{Fl}}(\mathcal{N})$, pour toute catégorie accessible, car c'est l'image inverse de $\underline{\mathrm{Hom}}_{\square}(I_{\bullet},\mathcal{N})$ par le foncteur canonique (accessible)

$$\begin{array}{ccc} \underline{\mathrm{Fl}}(\mathcal{N}) & \longrightarrow & \underline{\mathrm{Hom}}(I_{\bullet},\mathcal{N}) \\ (x \xrightarrow{u} y) & \longmapsto & \left(\begin{array}{ccccc} & & y & & \\ & \overset{u}{\nearrow} & & \overset{\mathrm{id}_y}{\searrow} & \\ x & & & & y \\ & \underset{u}{\searrow} & & \underset{\mathrm{id}_y}{\nearrow} & \\ & & y & & \end{array} \right) . \end{array}$$

C'est dire que la généralisation envisagée de 4.14.1 n'est pas oiseuse, mais est sans doute p. 148
utile.

[page 391]

Théorème 4.14.17 ([168]). *Soit $p : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur cofibrant ou fibrant, avec $\mathcal{C}$ essentiellement petite (i.e. équivalente à une petite catégorie), et tel que les catégories fibres soient accessibles, et les foncteurs cochangement de base (cas cofibrant) ou de changement de base (cas fibrant) associés aux flèches u de $\mathcal{C}$ soient accessibles. Alors la catégorie $\underline{\Gamma}(\mathcal{E}/\mathcal{C})$ des sections de $\mathcal{E}$ sur $\mathcal{C}$ est accessible, et pour tout $s \in \mathrm{Ob}\,\mathcal{C}$, le foncteur "évaluation en s" $\varepsilon_s : \underline{\Gamma}(\mathcal{E}/\mathcal{C}) \longrightarrow \mathcal{E}_s$ est accessible.*

Commentary · Development (commentators') [ms. 390]

Why the epimorphism question reaches set theory

Grothendieck's proposed generalization in 4.14.16 asks whether actual universal cones can be recognized accessibly without assuming that all cones of the same shape have universal objects. For limits, his representable test on page 389 proves the assertion. For colimits, the degenerate square on page 390 puts the epimorphism question inside the proposed generalization. The following consequence explains why closure under filtered colimits cannot by itself finish the proof.

Proposition (epimorphism accessibility forces co-wellpoweredness). [ours] Let $\mathcal{K}$ be accessible. If the full subcategory $\mathrm{Epi}(\mathcal{K}) \subset \mathcal{K}^{[1]}$ is accessible and accessibly embedded, then $\mathcal{K}$ is co-wellpowered: for each object X, its epimorphic quotients form a set up to isomorphism over X.

Proof. The domain functor $d : \mathrm{Epi}(\mathcal{K}) \to \mathcal{K}$ is accessible. Form its iso-comma category with the functor $\mathbf{1} \to \mathcal{K}$ selecting X. The latter functor is accessible, because a constant diagram indexed by a nonempty filtered category has its chosen value as colimit. By the iso-comma theorem 4.14.21, this category is accessible. Its objects are epimorphisms $e : A \to B$ equipped with an isomorphism $X \simeq A$, and it is equivalent to the full subcategory $\mathcal{Q}_X$ of $X/\mathcal{K}$ on the epimorphisms out of X.

Between any two objects of $\mathcal{Q}_X$ there is at most one morphism: if $he = ke$ and e is epic, then $h = k$. Thus $\mathcal{Q}_X$ is a preorder. We check directly that every accessible preorder is essentially small. Choose a set $\mathcal{G}$ of presentable generators. An object q determines the subset

$$D_q = \{g \in \mathcal{G} : g \longrightarrow q\}.$$

If $D_q \subset D_r$, express q as a filtered colimit of objects of $\mathcal{G}$. Every object in that presentation has a map to r, and these maps are automatically compatible because there is at most one. The colimit supplies $q \to r$. Equality of the two subsets therefore implies arrows both ways, hence an isomorphism. Isomorphism classes inject into the power set of $\mathcal{G}$, which is a set. Applying this to $\mathcal{Q}_X$ proves the proposition. □

168. Cf. généralisation dans [le] théorème page 422, th. 4.14.26.

The proof is supplied here as a direct consequence of the chapter's own machinery; the marker records our presentation and does not assert priority. We checked the literature on accessible epimorphism categories and on co-wellpoweredness. The argument is closely related to the use of the quotient preorder in Bagaria et al. (2015, Corollary 7.6); we did not locate this exact iso-comma formulation as a separate named result.

There is a definite foundational consequence. The discussion following that corollary, on published pages 574–575, records that co-wellpoweredness of every accessible category implies a proper class of measurable cardinals, and that a proper class of strongly compact cardinals suffices. Our proposition therefore gives the same necessary lower bound for the universal assertion that all accessible categories have accessible epimorphism categories. In particular, that universal assertion cannot be treated as an unconditional theorem of ZFC. This is an obstruction, not a determination of its precise consistency strength. The cited discussion also connects the strong-compact hypothesis to detectability of colimits through Makkai–Paré's Theorem 6.3.8(i).

The limit-cone argument has no such reversal of tests. For a small diagram $D : I \to \mathcal{K}$ with a proposed cone $x \to D$, choose a small dense subcategory $\mathcal{A}$ of presentables. The cone is limiting exactly when

$$\operatorname{Hom}(A, x) \longrightarrow \varprojlim_{i \in I} \operatorname{Hom}(A, D(i))$$

is bijective for every $A \in \mathcal{A}$. Density makes this criterion sufficient, and each test is accessible at a sufficiently large common rank. Hence the category of existing limit cones is an accessible intersection of inverse images of the corresponding set-valued cone category. The source thus resolves its limit question while leaving a substantially different colimit question.

Corollaire 4.14.18. *Soit π_0 un cardinal infini tel que les catégories fibres satisfassent la condition L_{π_0}, et que les foncteurs cochangement de base (resp. changement de base) entre icelles satisfassent également L_{π_0}. (Un tel π_0 existe.)*

ⓐ *Alors $\mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$ satisfait la condition $\underline{\mathrm{L}}_{\pi_0}$, et les foncteurs ε_s aussi, i.e. les $\varinjlim$ grandes devant π_0 dans $\underline{\Gamma}(\mathcal{E}/\mathcal{C})$ se calculent argument par argument.*

ⓑ *Soit un cardinal $\pi \geqslant \sup(\pi_0, \operatorname{card} \operatorname{réd} \mathcal{C})$. Pour qu'un objet f de $\mathcal{M}$ appartienne à $\mathcal{M}_\pi$, il* suffit *que $\forall\ s \in \operatorname{Ob} C$, $f(s) \overset{déf}{=} \varepsilon_s(x)$ [plutôt $\varepsilon_s(f)$] soit dans $\mathcal{E}_{s\,\pi}$. (Comparer 4.5.8, page 119.)*

ⓒ *Supposons pi_0 choisi de façon* [page 392]
à satisfaire les conditions supplémentaires suivantes : π_0 est utile pour $\mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$, et pour chacune des catégories fibres $\mathcal{E}_s$ ($s \in \operatorname{Ob} \mathcal{C}$) (un tel π_0 existe). Soit

$$\pi_1 \ = \ \sup(\pi_0, \operatorname{card} \operatorname{réd} \mathcal{C}, \operatorname{card} \operatorname{réd} \mathcal{M}_{\pi_0}) \ .$$

Alors pour tout cardinal $\pi \geqslant \pi_1$ et tel que $\pi^{\pi_0} = \pi$, on a

$$\mathcal{M}_\pi \ = \ \left\{ \begin{array}{l} \text{sous-catégorie strictement pleine de } \mathcal{M} \text{ formée des } f \in \\ \operatorname{Ob} \mathcal{M} \text{ telles que } f(s) \in \operatorname{Ob} \mathcal{E}_{s\,\pi} \ \forall\ s \in S \text{ [plutôt } s \in \\ \operatorname{Ob} C\text{]} . \end{array} \right.$$

Si de plus π est choisi tel qu'on ait

$$\pi \ \geqslant \ \sup_{s \in \operatorname{Ob} \mathcal{C}} \operatorname{card} \operatorname{réd} \mathcal{E}_{s\,\pi_0} \ ,$$

alors la sous-catégorie strictement pleine $\mathcal{E}(\pi)$ de $\mathcal{E}$ telle que $\operatorname{Ob} \mathcal{E}(\pi) = \bigcup_{s \in \operatorname{Ob} \mathcal{C}} \operatorname{Ob} \mathcal{E}_{s\,\pi}$ est une sous-catégorie $\mathcal{C}$-cofibrée (resp. $\mathcal{C}$-fibrée) de $\mathcal{E}$, et on a

$$\underline{\Gamma}(\mathcal{E}/\mathcal{C})_\pi \xleftarrow{\sim} \underline{\Gamma}(\mathcal{E}(\pi)/C),$$

donc (π étant utile pour $\mathcal{E}$) on a une équivalence de catégories

p. 149
$$\underline{\Gamma}(\mathcal{E}/\mathcal{C}) \xleftarrow{\sim} \operatorname{Ind}_\pi(\underline{\Gamma}(\mathcal{E}(\pi)/\mathcal{C})) \ .$$ [page 393]

Toutes ces assertions se prouvent facilement dans l'ordre où elles sont données, en utilisant 4.14.17 et les résultats généraux déjà prouvés. Bien sûr, on peut commencer par remplacer $\mathcal{C}$ par une sous-catégorie réduite $\mathcal{C}_0$ équivalente et $\mathcal{E}$ par $\mathcal{E}_0 = \mathcal{E}|\mathcal{C}$ `[plutôt` $\mathcal{E}|\mathcal{C}_0$`]`, de façon à se réduire (dans b) et c)) au cas où $\operatorname{card}\mathcal{C} \leqslant \pi$.

Commentary · Development (commentators') [ms. 392]

Sections and the two directions of transport

Grothendieck's section theorem assembles accessible categories over a small base. The objects are families in the fibres together with compatible transition arrows, so accessibility should follow by adjoining structure and imposing equations. The main theorem does hold. The presentability estimate in 4.14.18(b), however, needs a distinction between the two directions of transport that is absent from its printed statement.

First consider a fibration, and fix a cleavage. A section x consists of objects x_s and arrows $\alpha_a : x_s \to a^*x_t$ for $a : s \to t$, satisfying the unit and composition equations with the coherence isomorphisms of the cleavage. For sections x, y, their morphisms are the equalizer

$$\operatorname{Hom}_\Gamma(x,y) \longrightarrow \prod_{s\in \operatorname{Ob}\mathcal{C}} \operatorname{Hom}_{\mathcal{E}_s}(x_s, y_s) \rightrightarrows \prod_{a:s\to t} \operatorname{Hom}_{\mathcal{E}_s}(x_s, a^*y_t).$$

The two images of a family (h_s) at a are $a^*(h_t)\alpha_a$ and $\alpha_a^y h_s$. Take a regular λ exceeding the number of arrows of the base, suppose the transports preserve λ-filtered colimits, and suppose every x_s is λ-presentable. All terms on the right preserve those filtered colimits in the variable y, and the products and equalizer have fewer than λ entries. Interchange in sets proves that x is λ-presentable. This establishes the fibration half of 4.14.18(b).

For an opfibration, the second product instead has factors

$$\operatorname{Hom}_{\mathcal{E}_t}(a_*x_s, y_t).$$

Presentability of x_s does not guarantee presentability of a_*x_s merely because a_* is accessible. That missing implication cannot be repaired by the cardinality of the base.

Counterexample (pointwise presentability need not suffice). [ours] For every infinite regular λ, take the base [1], both fibres equal to **Set**, and the transition functor constant at a set B with $|B| = \lambda$. This functor preserves every filtered colimit: filtered categories are nonempty and connected. Its opfibration has section category

$$\mathbf{Set} \times (B/\mathbf{Set}),$$

where a section is $(X, B \to Y)$. The section $x = (\varnothing, B \to 1)$ has finite, hence λ-presentable, values in both fibres.

To test x itself, index by the poset of subsets $S \subset B$ of cardinality less than λ. This poset is λ-filtered, since the union of fewer than λ such subsets still has cardinality less than λ. Let B/S denote the quotient identifying all elements of S and leaving the other elements separate. The sections

$$x_S = (\varnothing, B \longrightarrow B/S)$$

form a λ-filtered diagram. Its colimit is x, because every pair of elements of B is identified at some stage. No map $x \to x_S$ exists over B: such a map would make $B \to B/S$ constant, although S has size less than $|B|$. Thus

$$\varinjlim_S \operatorname{Hom}(x, x_S) = \varnothing, \qquad \operatorname{Hom}(x, \varinjlim_S x_S) = \operatorname{Hom}(x,x) \neq \varnothing.$$

This disproves the opfibration half of 4.14.18(b) as written. For Grothendieck's indexing choose $\lambda = \pi^+$; the base is finite and the constant transition satisfies every condition L_{π_0} in the statement.

The corrected sufficient condition is explicit: require each transported object a_*x_s, as well as each x_s, to be λ-presentable. Choosing a common strong accessibility rank for the small family of transports ensures this condition for all pointwise presentable sections. After also enlarging the rank so that every evaluation preserves presentables, one obtains an eventual pointwise characterization. The printed numerical threshold in 4.14.18(c), however, does not itself ensure this enlargement.

Counterexample (the section skeleton does not bound evaluation). [ours] Let $\mathcal{P}(S)$ be the poset of subsets of a set S, ordered by inclusion. It is locally finitely presentable: unions compute colimits, finite subsets are finitely presentable, and every subset is the directed union of its finite subsets. Consider the [1]-opfibration given by the constant functor $\mathbf{1} \to \mathcal{P}(S)$ with value S. Its sections are pairs consisting of the unique object of $\mathbf{1}$ and an inclusion $S \subset Y \subset S$. There is therefore exactly one section, and its structure arrow is an isomorphism. Both the section category and its cocartesian subcategory are $\mathbf{1}$.

Choose $\pi_0 = \aleph_0$, $\pi = 2^{\aleph_0}$, and $|S| > \pi$. The fibres and section category admit presentations at π_0, and transport preserves every filtered colimit. The printed bound is $\pi_1 = \aleph_0$, since the section skeleton has one object and one arrow, and $\pi^{\pi_0} = \pi$. The unique section is presentable at every rank. Its value S is not π^+-presentable in $\mathcal{P}(S)$: the subsets of S of cardinality at most π form a π^+-filtered poset, their union is S, and no stage admits an inclusion from S. This refutes the first pointwise equality in 4.14.18(c), and also the pointwise equality in 4.14.20(c). The later additional bound involving the fibre skeletons excludes this particular example: the skeleton of $(\mathcal{P}(S))_{\pi_0}$ already contains all singletons.

These two examples were obtained by following the two missing size implications separately. We checked the fixed-rank results and hypotheses in Positselski (2024); we did not locate these exact counterexamples there or in the other sources consulted. The markers record the present constructions, without a claim of priority.

Cocartesian sections behave better even at a fixed rank. Their structure arrows identify $a_* x_s$ with x_t, so pointwise presentability already gives all the source objects needed by the equalizer. Thus the pointwise sufficient condition in 4.14.20(b) remains true for cocartesian sections, independently of the false unrestricted opfibration assertion. Cartesian sections likewise satisfy the fibration argument. Their filtered colimits are pointwise whenever transport preserves those colimits, because the induced structure comparisons remain isomorphisms. This accounts for the accessibility and reconstruction claims without conflating the two variance conventions.

Corollaire 4.14.19. *Sous les conditions de 4.14.17, la sous-catégorie* $\underline{\Gamma}_{\mathrm{cocart}}(\mathcal{E}/\mathcal{C})$ *de* $\mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$ *(cas p cofibrant), resp. la sous-catégorie* $\underline{\Gamma}_{\mathrm{cart}}(\mathcal{E}/\mathcal{C})$ *(cas p fibrant) est accessible dans* $\mathcal{M}$*, donc accessible et le foncteur d'inclusion* `[est]` *accessible.*

(**N.B.** Ces deux catégories sont strictement pleines dans $\underline{\Gamma}(\mathcal{E}/\mathcal{C})$, donc l'assertion qu'elles soient accessibles dans celle-ci *équivaut* à la dernière assertion.)

Démonstration de 4.14.19. On peut supposer $\mathcal{C}$ réduite, donc petite. Considérons le cas où p est cofibrant. Pour toute flèche $\lambda : s \longrightarrow t$ dans $\mathcal{C}$, considérons le foncteur

$$\varphi_\lambda \ : \ \mathcal{M} \longrightarrow \underline{\mathrm{Fl}}(\mathcal{E}_t)$$

défini par [page 394]

$$\varphi_\lambda(f) \ = \ (\lambda_*(f(s)) \xrightarrow{f(\lambda)^\natural} f(t)) \ .$$

C'est un foncteur accessible, car son composé avec les foncteurs source et but sont les foncteurs $\lambda_* \varepsilon_s$ et ε_t, donc accessibles, ε_s, ε_t et λ_* étant accessibles. Considérons la sous-catégorie strictement pleine

$$\underline{\mathrm{Is}}(\mathcal{E}_t) \ \subset \ \underline{\mathrm{Fl}}(\mathcal{E}_t) \ ,$$

on sait qu'elle est accessible dans $\underline{\mathrm{Fl}}(\mathcal{E}_t)$ (4.14.12). Donc son image inverse par φ_λ est accessible dans $\mathcal{M}$, et par suite aussi

$$\underline{\Gamma}_{\mathrm{cart}}(\mathcal{E}/\mathcal{C}) \ \overset{\text{déf}}{=} \ \bigcap_{\lambda \in \mathrm{Ob}\, \mathcal{C}} \varphi_\lambda^{-1}(\underline{\mathrm{Is}}(\mathcal{E}_t))$$

comme intersection d'une *petite* famille de sous-catégories accessibles dans $\mathcal{M}$, q.e.d. Le cas où p est fibrant se traite de façon similaire, en introduisant les foncteurs

$$\psi_\lambda \ : \ \mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C}) \longrightarrow \underline{\mathrm{Fl}}(\mathcal{E}_s)$$

[page 395]

donnés par

$$\psi_\lambda(f) \;=\; (f(s) \xrightarrow{f(\lambda)^\flat} \lambda^* f(t)) \;.$$

Corollaire 4.14.20. *Soit π_0 un cardinal infini choisi comme dans 4.14.18 a).*

ⓐ *Alors $\mathcal{M}_{\mathrm{c}} = \underline{\Gamma}_{\mathrm{cocart}}(\mathcal{E}/\mathcal{C})$ (resp. $\mathcal{M}_{\mathrm{c}} = \underline{\Gamma}_{\mathrm{cart}}$) est L_{π_0}-stable dans $\mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$, ou ce qui revient au même (comme elle est strictement pleine), elle satisfait L_{π_0}, et le foncteur d'inclusion satisfait à L_{π_0}. Les $\varinjlim$ grandes devant π_0 dans cette catégorie se calculent argument par argument.*

ⓑ *Pour tout cardinal $\pi \geqslant \pi_0$, tout objet de $\mathcal{M}_{\mathrm{c}}$ qui est π-accessible dans $\mathcal{M}$ l'est (tautologiquement) dans $\mathcal{M}_{\mathrm{c}}$. Si $\pi \geqslant \sup(\pi_0, \operatorname{card}\operatorname{réd}\mathcal{C})$, alors (par 4.14.18 b) tout objet f de $\mathcal{M}_{\mathrm{c}}$ tel que $f(s) \in \operatorname{Ob}\mathcal{E}_{s\,\pi}\ \forall\ s \in S$ [plutôt $s \in \operatorname{Ob} C$] est dans $\mathcal{M}_\pi$ et dans $\mathcal{M}_{\mathrm{c}\,\pi}$.*

ⓒ *Supposons π_0 choisi comme dans 4.14.18 c, et que de plus $\mathcal{M}_{\mathrm{c}}$ soit π_0-accessible dans $\mathcal{M}$. (Un tel π_0 existe.) On a donc, pour $\pi \geqslant \pi_1 = \sup(\pi_0, \operatorname{card}\operatorname{réd}\mathcal{C}, \operatorname{card}\operatorname{réd}\mathcal{M}_\pi)$ tel que $\pi^{\pi_0} = \pi$,* p. 150

$$(\mathcal{M}_{\mathrm{c}})_\pi \;=\; \mathcal{M}_\pi \cap \mathcal{M}_{\mathrm{c}} \;=\; \begin{array}{l}\text{Sous-catégorie strictement pleine de } \mathcal{M}_{\mathrm{c}} \text{ formée des } f \\ \text{telles que } f(s) \in \operatorname{Ob}\mathcal{E}_{s\,\pi}\ \forall\ s \in \operatorname{Ob}\mathcal{C}.\end{array}$$

Si de plus π est choisi tel qu'on ait $\pi \geqslant \sup_{s\in\operatorname{Ob}\mathcal{C}} \operatorname{card}\operatorname{réd}\mathcal{E}_{s\,\pi_0}$, alors [page 396]

$$\left\{\begin{array}{rcl} & \mathcal{M}_{\mathrm{c}\,\pi} & \xleftarrow{\sim} \quad \underline{\Gamma}_{\mathrm{cocart}}(\mathcal{E}(\pi)/\mathcal{C}) \\ \textit{resp.} & \mathcal{M}_{\mathrm{c}\,\pi} & \xleftarrow{\sim} \quad \underline{\Gamma}_{\mathrm{cart}}(\mathcal{E}(\pi)/\mathcal{C}) \;, \end{array}\right.$$

donc (π étant utile pour $\mathcal{M}_{\mathrm{c}}$) une équivalence de catégories

$$\begin{array}{rcl} \underline{\Gamma}_{\mathrm{cocart}}(\mathcal{E}/\mathcal{C}) & \xleftarrow{\sim} & \operatorname{Ind}_\pi(\underline{\Gamma}_{\mathrm{cocart}}(\mathcal{E}(\pi)/\mathcal{C})) \\ \textit{resp.} \quad \underline{\Gamma}_{\mathrm{cart}}(\mathcal{E}/\mathcal{C}) & \xleftarrow{\sim} & \operatorname{Ind}_\pi(\underline{\Gamma}_{\mathrm{cart}}(\mathcal{E}(\pi)/\mathcal{C})). \end{array}$$

Démonstration. Tout est clair dans l'ordre où c'est donné en utilisant les deux corollaires précédents.

Corollaire 4.14.21. *Considérons un diagramme de foncteurs*

$$(*) \qquad \begin{array}{ccccc} \mathcal{E}_1 & & & & \mathcal{E}_2 \\ & \searrow^{p_1} & & \swarrow_{p_2} & \\ & & \mathcal{E}_0 \;, & & \end{array}$$

les catégories et les foncteurs étant accessibles. [page 397]

a) Le produit 2-fibré

$$\mathcal{M}_0 \;=\; \mathcal{E}_1 \overset{2}{\times}_{\mathcal{E}_0} \mathcal{E}_2$$

est accessible, et les foncteurs canoniques $\mathcal{M} \longrightarrow \mathcal{E}_1$, $\mathcal{M} \longrightarrow \mathcal{E}_2$ sont accessibles.

b) ([169]). La catégorie $\mathcal{M}$ des triples (x_1, x_2, u) avec $x_1 \in \operatorname{Ob}\mathcal{E}_1$, $x_2 \in \operatorname{Ob}\mathcal{E}_2$, et

$$u \;:\; p_1(x_1) \;\longrightarrow\; p_2(x_2) \;,$$

est accessible, et les foncteurs canoniques $\mathcal{M} \longrightarrow \mathcal{E}_1$, $\mathcal{M} \longrightarrow \mathcal{E}_2$ sont accessibles.

c) La sous-catégorie strictement pleine $\mathcal{M}_0$ de $\mathcal{M}$ est accessible dans $\mathcal{M}$.

Démonstration. Soit $\mathcal{C}$ la catégorie

$$\begin{array}{ccccc} 1 & & & & 2 \\ & \searrow & & \swarrow & \\ & & 0 \;, & & \end{array}$$

p. 151
[page 398]

et $\mathcal{E}$ la catégorie cofibrée sur $\mathcal{C}$ définie par le diagramme $(*)$. On est sous les conditions de 4.14.17. La catégorie $\Gamma = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$ s'interprète comme la catégorie des quintuplets $(x_0, x_1, x_2, u_1, u_2)$, avec $x_i \in \mathrm{Ob}\,\mathcal{E}$ pour $i \in \{0,1,2\}$, et $u_1, u_2 \in \mathrm{Fl}\,\mathcal{E}_0$,

$(**)$
$$\begin{array}{ccc} p_1(x_1) & & p_2(x_2) \\ & {\scriptstyle u_1}\searrow \quad \swarrow{\scriptstyle u_2} & \\ & x_0\ . & \end{array}$$

En vertu de 4.14.18, cette catégorie $\underline{\Gamma}$ est accessible. La catégorie $\mathcal{M}$ est équivalente à la sous-catégorie strictement pleine Γ_0 de Γ, formée des quintuplets pour lesquels on a $u_2 \in \underline{\mathrm{Is}}\mathcal{E}_0$. On a en effet des foncteurs quasi-inverses l'un de l'autre

$$\mathcal{M} \underset{\beta}{\overset{\alpha}{\rightleftarrows}} \Gamma_1$$

donnés par

$$\begin{aligned} \alpha(x_1, x_2, u) &= (p_2(x_2), x_1, x_2, u, \mathrm{id}_{p_2(x_2)}) \\ \beta(x_0, x_1, x_2, u_1, u_2) &= (x_1, x_2, u_2^{-1}u_1)\ , \end{aligned}$$

on a alors

$$\begin{aligned} \beta\alpha &= \mathrm{id}_{\mathcal{M}} \\ \alpha\beta &\xrightarrow{\sim} \mathrm{id}_{\Gamma_1}\ . \end{aligned}$$

D'autre part, Γ_1 est évidemment accessible dans $\mathcal{M}$, comme image inverse de $\underline{\mathrm{Is}}(\mathcal{E}_0)$ (qui est accessible dans $\underline{\mathrm{Fl}}(\mathcal{E}_0)$ par le foncteur accessible [page 399]

$$\underline{\Gamma} \longrightarrow \underline{\mathrm{Fl}}(\mathcal{E}_0)$$

donné par $(x_1, x_1, x_2, u_1, u_2) \longmapsto u_2$. Cela prouve que $\mathcal{M}$, qui est équivalente à Γ_1, est également accessible, et l'accessibilité du foncteur canonique $\mathcal{M} \longrightarrow \mathcal{E}_i$ $(i \in \{1,2\})$ résulte de celle de $\Gamma \longrightarrow \mathcal{E}_i$, impliquant celle du composé $\Gamma_1 \hookrightarrow \Gamma \longrightarrow \mathcal{E}_i$. Cela prouve donc b). Pour prouver a), il suffit de voir que $\mathcal{M}_0$ est accessible dans $\mathcal{M}$, or c'est encore l'image inverse de $\underline{\mathrm{Is}}(\mathcal{E}_0) \subset \underline{\mathrm{Fl}}(\mathcal{E}_0)$ par le foncteur accessible canonique

$$\mathcal{M} \longrightarrow \underline{\mathrm{Fl}}(\mathcal{E}_0)\ ,$$

donc $\mathcal{M}$ est bien accessible dans $\mathcal{M}$, comme image inverse d'une sous-catégorie accessible dans $\underline{\mathrm{Fl}}(\mathcal{E})$. On peut d'ailleurs aussi interpréter $\mathcal{M}$, à équivalence de catégories près, comme [page 400]

$$\mathcal{M}_0 \simeq \underline{\Gamma}_{\mathrm{cocart}}(\mathcal{E}/\mathcal{C})\ ,$$

les foncteurs canoniques $\mathcal{M}_0 \longrightarrow \mathcal{E}_i$ $(i \in \{0,1\})$ s'interprétant comme des foncteurs évaluation, ce qui donne a) directement, comme cas particulier de 4.14.19.

Commentary · Exposition [ms. 400]

A two-fibre product remembers the comparison isomorphism

Grothendieck closes this sequence of corollaries by giving a useful model for gluing accessible categories. Given $p_1 : \mathcal{E}_1 \to \mathcal{E}_0$ and $p_2 : \mathcal{E}_2 \to \mathcal{E}_0$, the ordinary comma category remembers an arrow $p_1x_1 \to p_2x_2$; its iso-comma subcategory requires that arrow to be invertible. The superscript 2 is substantive: equality of two objects in the base is replaced by a specified isomorphism.

The cospan section category makes the proof concrete. Its objects consist of $x_i \in \mathcal{E}_i$ and arrows $u_i : p_ix_i \to x_0$. Require u_2 to be invertible. One can then discard x_0 and replace u_1 by $u_2^{-1}u_1$. The inverse operation sends (x_1, x_2, u) to the quintuple with $x_0 = p_2x_2$ and $u_2 = \mathrm{id}$. The natural

169. Ceci est contenu dans 4.14.22.1 ci-dessus (p. 406), appliqué à $\Pi = \mathcal{E}_1 \times \mathcal{E}_2$, $\Pi' = \mathcal{E}_0$, et $F, G : \Pi \rightrightarrows \Pi'$ donnés par $F = p_1 \circ \mathrm{pr}_1$ et $G = p_2 \circ \mathrm{pr}_2$. D'autre part, a) et c) résultent facilement de b).

isomorphism between the composite and the original quintuple has component u_2 at the vertex 0 and identity components at $1, 2$. This checks the equivalence, including its action on morphisms, rather than merely comparing its object descriptions.

The condition on u_2 is an accessible inverse image of the isomorphism category of $\mathcal{E}_0$. The comma category is consequently accessible. Requiring the remaining comparison u to be an isomorphism is another such inverse image, yielding the iso-comma theorem. This proof uses only the opfibration section theorem already established earlier, so its use in the subsequent proof for fibrations creates no circularity.

As an example, take two copies of **1** mapping into **Set** by selecting the same set A. Their strict pullback is **1**. Their iso-comma category is the discrete category of permutations of A: an object is a bijection $u : A \to A$, and a morphism between two such objects must have identity components in both copies of **1**, so it exists exactly when the two bijections are equal. The set of comparison isomorphisms is therefore part of the categorical answer. Discarding it would change the result even in this elementary diagram.

For the cospan opfibration, a cocartesian section requires both u_1 and u_2 to be invertible. Its section category is thus equivalent to the same iso-comma category, exactly as in the final display of the source. The missing subscripts and exchanged names in the surrounding paragraphs are edition slips; none affects this argument once the three categories, the comma category, its iso-comma subcategory, and the cospan section category, are kept distinct.

p. 152

4.14.22. Démonstration de 4.14.17. Le cas où p est cofibrant a déjà été démontré (th. 4.10.8, p. 263). Nous allons voir que le cas où p est fibrant se ramène au théorème précédent (dans un cas très particulier), en utilisant à fond les résultats généraux sur les parties accessibles d'une catégorie accessible. Notons que les assertions a) et b) du corollaire 4.14.18 se prouvent de façon AQT `[âne qui trotte]` sans avoir à faire appel à 4.14.17. Le a) implique déjà que les foncteurs évaluation $\varepsilon_s : \mathcal{M} \longrightarrow \mathcal{E}_s$ sont accessibles. Il reste donc à prouver que $\mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$ est accessible, dans le cas où p est *fibrant*. On supposera de plus [page 401] que $\mathcal{C}$ est petite (quitte à remplacer $\mathcal{C}$ par une petite sous-catégorie pleine équivalente).

Soient

$$\begin{aligned} \Pi &= \prod_{s\in \mathrm{Ob}\,\mathcal{C}} \mathcal{E}_s \\ \Pi' &= \prod_{\lambda\in \mathrm{Fl}\,\mathcal{C}} \mathcal{E}_{s(\lambda)} \ , \end{aligned}$$

où $s(\lambda)$ désigne la *source* s de la flèche $\lambda : s \longrightarrow t$ dans $\mathcal{C}$. Π, Π' sont des catégories accessibles, comme (petits) produits de catégories accessibles. (Cas particulier trivial de 4.10.8, pour une catégorie d'indices discrète.) On va définir deux foncteurs

$$\Pi \underset{G}{\overset{F}{\rightrightarrows}} \Pi'$$

en définissant pour tout $\lambda : s_0 \longrightarrow t_0$ dans $\mathrm{Fl}\,\mathcal{C}$ deux foncteurs [page 402]

$$\left\{ \begin{array}{lcll} \Pi & \underset{G_\lambda}{\overset{F_\lambda}{\rightrightarrows}} & \mathcal{E}_{s(\lambda)=s_0} & \\ F_\lambda & = & \mathrm{pr}_{s_0} & \text{projection de } \Pi = \prod_s \mathcal{E}_s \text{ sur le facteur } \mathcal{E}_{s_0} \\ G_\lambda & = & \lambda^* \mathrm{pr}_{s_1} & \text{composé } \Pi \xrightarrow{\mathrm{pr}_{s_1}} \mathcal{E}_{s_1} \xrightarrow{\lambda^*} \mathcal{E}_{s_0} \\ & & & \texttt{[plutôt } \lambda^*\mathrm{pr}_{t_0} \texttt{ resp. } \Pi \xrightarrow{\mathrm{pr}_{t_0}} \mathcal{E}_{t_0} \xrightarrow{\lambda^*} \mathcal{E}_{s_0}\texttt{]} \end{array} \right. \qquad \left([170], [171]\right) .$$

170. Il est immédiat que les F_λ, G_λ, donc F et G, sont des foncteurs *accessibles*.

171. **N.B.** On suppose choisi pour tout $\lambda \in \mathrm{Fl}\,\mathcal{C}$ un foncteur image inverse $\lambda^* : \mathcal{E}_t \longrightarrow \mathcal{E}_s$. On suppose que si λ est une flèche identique, id_s, `[on]` choisit $\lambda^* = \mathrm{id}_{\mathcal{E}_s}$.

Commentary · Exposition [ms. 401]

First choose the arrows, then impose the laws

Grothendieck is now extracting a reusable construction from the section theorem. A section contains objects in the fibres, arrows above the arrows of the base, and equations expressing functoriality. The first two sorts of data can be assembled before the equations are imposed. This separation explains why accessibility survives: the preliminary construction is an inserter, and the final constraints are a small family of equifiers.

Choose a normalized cleavage of the fibration. A prospective section is a family $X = (X_s)$ together with arrows

$$a_\lambda : X_s \longrightarrow \lambda^* X_t \qquad (\lambda : s \longrightarrow t).$$

For the moment these arrows need satisfy no laws. A morphism from (X, a) to (Y, b) is a family $h_s : X_s \to Y_s$ satisfying

$$\lambda^*(h_t) a_\lambda = b_\lambda h_s.$$

This is precisely the inserter of the two functors $F, G : \Pi \rightrightarrows \Pi'$ on the page. The word "diagram" here means the underlying directed graph: it does not already incorporate identities or composition. Consequently the preliminary category is larger than the section category even when the underlying objects have been fixed.

The cleavage need not be split. If $\lambda : s \to t$ and $\mu : t \to u$, cartesian factorisation supplies a canonical isomorphism

$$c_{\lambda,\mu} : \lambda^*\mu^* \xrightarrow{\sim} (\mu\lambda)^*.$$

The composition equation in fibre coordinates is

$$a_{\mu\lambda} = c_{\lambda,\mu,X_u}\, \lambda^*(a_\mu)\, a_\lambda.$$

The unit equation is $a_{\mathrm{id}_s} = \mathrm{id}_{X_s}$ with the chosen normalization. Associativity of these comparisons is inherited from composition in $\mathcal{E}$. There is therefore no extra assumption that all transition functors compose as literal equalities. Grothendieck's use of the actual arrow $f_1(\mu)f_1(\lambda)$ keeps this coherence implicit and correct.

To see what the cardinal estimates must control, choose a regular cardinal κ at which the fibres and the small family of transition functors admit and preserve filtered colimits. For a filtered diagram of prospective sections, put $X_s = \varinjlim_i X_{i,s}$. The structure arrow a_λ is induced by the compatible arrows $X_{i,s} \to \lambda^* X_{i,t}$ and the comparison $\varinjlim_i \lambda^* X_{i,t} \simeq \lambda^* X_t$. The equations for a genuine section pass to these colimits. This proves colimit preservation by the relevant comparison functors; accessibility of the equation loci additionally uses the preceding small-generation results. Stability under filtered colimits alone would not supply that conclusion.

There is also a useful formula for the morphisms between two sections. They form the equalizer

$$\mathrm{Hom}_\Gamma(X, Y) \longrightarrow \prod_s \mathrm{Hom}_{\mathcal{E}_s}(X_s, Y_s) \rightrightarrows \prod_{\lambda : s \to t} \mathrm{Hom}_{\mathcal{E}_s}(X_s, \lambda^* Y_t).$$

The two arrows send (h_s) respectively to $(\lambda^* h_t)a_\lambda$ and $b_\lambda h_s$. If κ exceeds the number of arrows of the base and every X_s is κ-presentable, the right-hand expression preserves κ-filtered colimits in Y, provided the transition functors do. This gives the pointwise sufficient condition for presentability directly. The converse requires a larger common bound; forgetting structure does not preserve presentability at every initial rank.

Soit $f \in \mathcal{M} = \underline{\Gamma}(\mathcal{E}/\mathcal{C})$, alors pour tout $\lambda \in \mathrm{Fl}\mathcal{C}$, f définit une flèche

$$\alpha_\lambda(f) \ : \quad \underbrace{f(s)}_{=F_\lambda(\varepsilon(f))} \quad \xrightarrow{f(\lambda)^\flat} \quad \underbrace{\lambda^*(f(t))}_{=G_\lambda(\varepsilon(f))} \ ,$$

fonctorielle en f. On a un foncteur

$$\varepsilon \ = \ (\varepsilon_s)_{s \in \mathrm{Ob}\,\mathcal{C}} \ : \ \mathcal{M} \ \longrightarrow \ \Pi \ ,$$

et pour tout $\lambda \in \mathrm{Fl}\mathcal{C}$ un homomorphisme fonctoriel

$$\alpha_\lambda \ : \ F_\lambda \circ \varepsilon \ \longrightarrow \ G_\lambda \circ \varepsilon \ ,$$

d'où un homomorphisme fonctoriel

$$\alpha \;=\; (\alpha_\lambda)_{\lambda\in \mathrm{Fl}\,\mathcal{C}} \;:\; F\circ\varepsilon \;\longrightarrow\; G\circ\varepsilon\;.$$

Soit alors $\mathcal{M}'$ la catégorie suivante : p. 153 [page 403]

$$\begin{array}{rcl}\mathcal{M}' & = & \text{catégorie des couples } (X,u), \text{ avec } X \text{ dans } \mathrm{Ob}\,\Pi,\\ & & \text{et } u : F(X)\longrightarrow G(X) \text{ une flèche dans } \Pi'.\end{array}$$

L'homomorphisme fonctoriel $\alpha : F\circ\varepsilon \longrightarrow G\circ\varepsilon$ définit un foncteur

$$\mathcal{M} \;\longrightarrow\; \mathcal{M}'\;,$$

et il est immédiat que ce foncteur est pleinement fidèle. En fait, la catégorie $\mathcal{M}'$ est isomorphe à la catégorie formée des couples (f_0, f_1) de deux applications

$$\begin{array}{rccccc} f_0 : & \mathrm{Ob}\,\mathcal{C} & \longrightarrow & \mathrm{Ob}\,\mathcal{E} & s & \longmapsto & f_0(s)\\ f_1 : & \mathrm{Fl}\,\mathcal{C} & \longrightarrow & \mathrm{Fl}\,\mathcal{E} & \lambda & \longmapsto & f_1(\lambda)\end{array}$$

de telle façon que f_1 et f_0 soient compatibles avec les applications source et but, i.e. qu'ils définissent un homomorphisme de *diagrammes* $f : \mathrm{diag}\,\mathcal{C} \longrightarrow \mathrm{diag}\,\mathcal{E}$, et que cet homomorphisme soit inverse à droite de $\mathrm{diag}(p) : \mathrm{diag}\,\mathcal{E} \longrightarrow \mathrm{diag}\,\mathcal{C}$.

Le foncteur précédent $\mathcal{M} \hookrightarrow \mathcal{M}'$ s'interprète comme le foncteur qui associe à toute sections f de $\mathcal{E}$ sur $\mathcal{C}$, le morphisme de diagrammes correspondant. C'est donc l'inclusion d'une sous-catégorie *strictement pleine* de $\mathcal{M}'$. Donc pour prouver que $\mathcal{M}$ est accessible, il suffit de prouver : [page 404]

a) $\mathcal{M}'$ est accessible.

b) $\mathcal{M}$ est accessible dans $\mathcal{M}'$.

Prouvons d'abord b) (en admettant a). La sous-catégorie $\mathcal{M}$ de $\mathcal{M}'$ est définie par deux types des conditions, sur un objet $f = (f_0, f_1)$ de $\mathcal{M}'$:

1°) $\forall\; s \in \mathrm{Ob}\,\mathcal{C},\; f_1(\mathrm{id}_s) = \mathrm{id}_{f_0(s)}$.

2°) Si $s \xrightarrow{\lambda} t \xrightarrow{\mu} u$ sont deux flèches composables dans $\mathcal{C}$, alors

$$f_1(\mu\lambda) \;=\; f_1(\mu)f_1(\lambda)\;.$$

Ces conditions s'explicitent l'une et `[l'autre par]` l'égalité d'une double-flèche dans $\mathcal{E}_s$, savoir [page 405]

$$f_0(s) \underset{\mathrm{id}_{f_0(s)}}{\overset{f_1(\mathrm{id}_s)}{\rightrightarrows}} f_0(s)$$

dans le cas 1°), et

$$f_0(s) \underset{(f_1(\mu)f_1(\lambda))^\flat}{\overset{f_1(\mu\lambda)^\flat}{\rightrightarrows}} (\mu\lambda)^*(f_0(u))$$

dans le cas 2°). Dans l'un et l'autre cas, on a un foncteur

$$\mathcal{M}' \xrightarrow{\gamma_s \text{ resp. } \gamma_{\lambda,\mu}} \underline{\mathrm{Hom}}(I, \mathcal{E}_s)$$

dans la catégorie des double-flèches de $\mathcal{E}_s$ (I désignant la catégorie double-flèche type $0 \rightrightarrows 1$), foncteur qui est (trivialement) accessible. Soit alors $I \xrightarrow{i} \mathbf{\Delta}_1$ le foncteur canonique, et p. 154

$$\underbrace{\underline{\mathrm{Hom}}(\mathbf{\Delta}_1, \mathcal{E}_s)}_{\simeq \underline{\mathrm{Fl}}(\mathcal{E}_s)} \;\hookrightarrow\; \underline{\mathrm{Hom}}(I, \mathcal{E}_s)$$

[page 406]

le foncteur $u \longmapsto u \circ i$, qui est un foncteur strictement pleine fidèle, ayant comme image la sous-catégorie des double-flèches (u, v) telles que $u = v$. Comme le foncteur d'inclusion est accessible et $\underline{\mathrm{Hom}}(\mathbf{\Delta}_1, \mathcal{E}_s)$ et $\underline{\mathrm{Hom}}(I, \mathcal{E}_s)$ accessibles (cas particulier de 4.14.1, ou aussi de 4.10.8!), on voit que la sous-catégorie strictement pleine de $\underline{\mathrm{Hom}}(I, \mathcal{E}_s)$ des double-flèches égalisées dans $\mathcal{E}_s$, est accessible dans $\underline{\mathrm{Hom}}(I, \mathcal{E}_s)$. Donc, son image inverse dans $\mathcal{M}'$ est accessible. Donc l'intersection de ces images inverses pour $s \in \mathrm{Ob}\,\mathcal{C}$ et $(\lambda, \mu) \in \mathrm{Fl}_2(\mathcal{C})$ variables, l'est également ($\mathcal{C}$ étant petite).

Donc tout revient à prouver que $\mathcal{M}'$ est accessible, ce qui est contenu dans le

Lemme 4.14.22.1. *Soient* Π, Π' *deux catégories accessibles,* $F, G : \Pi \rightrightarrows \Pi'$ *deux foncteurs accessibles, et* $\mathcal{M}'$ *la catégorie des couples* (X, u)*, avec* $X \in \mathrm{Ob}\,\Pi$ *et* $u : F(x) \longrightarrow G(x)$ *une flèche de* Π'*. Alors* $\mathcal{M}'$ *est accessible, et le foncteur canonique* $\mathcal{M}' \longrightarrow \Pi$ *est accessible.*

Démonstration du Lemme. La donnée de Π, Π', F, G définit une catégorie cofibrée $\mathcal{F}$ sur la catégorie $I = (0 \rightrightarrows 1)$ précédente. La catégorie $\underline{\Gamma}(\mathcal{F}/I)$ s'interprète, à isomorphisme près, comme la catégorie des triples (x, u, v) avec $x \in \mathrm{Ob}\,\Pi$, $x' \in \mathrm{Ob}\,\Pi'$, et u et v des flèches [page 407]

$$\begin{array}{ccc} F(x) & & G(x) \\ & {\scriptstyle u}\searrow \quad \swarrow{\scriptstyle v} & \\ & x' & \end{array}$$

dans Π'. La catégorie $\mathcal{M}'$ est équivalente à la sous-catégorie strictement pleine de $\underline{\Gamma}(\mathcal{F}/I)$, formée des triples (x, u, v) tels que v soit un isomorphisme, i.e. à la sous-catégorie de $\underline{\Gamma}(\mathcal{F}/I)$, image inverse de $\underline{\mathrm{Is}}(\Pi')$ par le foncteur $(x, u, v) \longmapsto v$,

$$\underline{\Gamma}(\mathcal{F}/I) \longrightarrow \underline{\mathrm{Fl}}(\Pi') .$$

Or par 4.10.8, $\underline{\Gamma}(\mathcal{F}/I)$ est accessible, et le foncteur précédent est bien sûr accessible. Enfin, par 4.14.12, $\underline{\mathrm{Is}}(\Pi')$ est accessible dans la catégorie accessible $\underline{\mathrm{Fl}}(\Pi')$. Donc son image inverse $\mathcal{M}'$ dans $\underline{\Gamma}(\mathcal{F}/I)$ est accessible dans $\underline{\Gamma}(\mathcal{F}/I)$, donc accessible. Donc il en est de même de la catégorie équivalente, q.e.d. [page 408]

Commentary · Later developments [ms. 407]

The inserter and the later limit theorems

The auxiliary lemma is the familiar inserter theorem. Its proof in the manuscript is especially useful because it avoids treating an inserter as an unexplained closure operation. A pair of arrows $FX \xrightarrow{u} Y \xleftarrow{v} GX$ becomes an inserter object when v is invertible, by replacing the pair with $v^{-1}u : FX \to GX$. Conversely, an inserter object gives such a pair with $Y = GX$ and $v = \mathrm{id}$. On morphisms the two constructions are compatible, and the resulting comparison is an equivalence. The conclusion therefore follows from the already established accessibility of opfibration sections and of the isomorphism locus.

The surrounding theory had already acquired a systematic form in Makkai and Paré (1989, §5.1). Positselski (2024, Theorems 3.1, 4.1, and 8.1–8.3) gives explicit rank control for equifiers, inserters, and lax limits under a smaller-chain-colimit hypothesis. These hypotheses explain why existence of some accessibility rank is easier than retaining a prescribed rank. This literature confirms the construction here; it does not turn an arbitrary strict equalizer of accessible functors into an accessible category.

A small example makes the distinction visible. Let both F and G be the identity of Set. Their inserter is the category of sets equipped with one endomorphism, equivalently sets with an action of the free monoid $\mathbb{N}$. The object $(\mathbb{N}, n \mapsto n + 1)$ is free on one generator. A morphism from it to (X, u) is uniquely specified by the image x of 0, because the image of n must be $u^n(x)$. Hence

$$\mathrm{Hom}\big((\mathbb{N}, +1), (X, u)\big) \simeq X.$$

Filtered colimits of these actions are computed on the underlying sets, so the free action is finitely presentable. Its underlying set is infinite and is not finitely presentable in Set. To verify the latter

assertion, express $\mathbb{N}$ as the directed union of its finite subsets: its identity map does not factor through a finite subset. Thus the inserter projection is accessible while failing to preserve finitely presentable objects. There is no conflict with the manuscript's eventual comparisons after enlarging the cardinal.

For higher categories the corresponding section statement is explicit in Lurie (2009, Proposition 5.4.7.11 and Remarks 5.4.7.13–14): accessible fibres and accessible transport over a small simplicial base give accessible categories of sections, with specified cartesian or cocartesian conditions allowed. The higher theorem includes coherence as part of the section space. The ordinary equations written here give its one-categorical counterpart.

Ainsi, grâce aux résultats généraux sur les parties accessibles des catégories accessibles, le théorème 4.14.17, dans le cas où p est fibrant, est ramené aux cas cofibrant, dans le cas très particulier où la catégorie d'indices est $I = (0 \rightrightarrows 1)$. On pourrait d'ailleurs faire une réduction similaire dans le cas où p est cofibrant, par une démonstration pratiquement identique. En d'autres termes, le théorème 4.10.8 se ramène au cas où la catégorie d'indices p. 155
est $I = (0 \rightrightarrows 1)$. Mais je suspecte que la démonstration du théorème dans ce cas particulier, n'est pas essentiellement plus simple que dans le cas général.

4.14.23. On peut se demander de trouver un énoncé assurant l'accessibilité d'une catégorie [page 409]
$\underline{\Gamma}(\mathcal{E}/\mathcal{C})$, qui coiffe les deux cas envisagés dans 4.14.17. Voici ce que je peux proposer. Je vais faire l'hypothèse suivante sur les foncteur $p : \mathcal{E} \longrightarrow \mathcal{C}$ (en plus de celle que $\mathcal{C}$ soit essentiellement petite) :

H) Pour tout $\lambda \in \mathrm{Fl}\,\mathcal{C}$, la catégorie $\mathcal{E}_\lambda = \mathcal{E} \times_{\mathcal{C}} (\mathbf{\Delta}_1, i_\lambda)$, où $i_\lambda : \mathbf{\Delta}_1 \longrightarrow \mathcal{C}$ est le foncteur défini par λ, est accessible, et le foncteur canonique $\mathcal{E}_\lambda \xrightarrow{p_\lambda} \mathbf{\Delta}_1$ est accessible.

Notons que si $\lambda : s \longrightarrow t$ dans $\mathcal{C}$ est tel que $\mathcal{E}_\lambda$ et p_λ soient accessibles, alors $\mathcal{E}_s$ et $\mathcal{E}_t$ sont accessible, car isomorphes aux catégories image inverse par $p_\lambda : \mathcal{E}_\lambda \longrightarrow \mathbf{\Delta}_1$ des sous-catégories $\{0\}$ resp. $\{1\}$ de Δ_1, lesquelles sont accessibles dans la catégorie accessible $\mathbf{\Delta}_1$, donc $\mathcal{E}_{\lambda_0}$ et [page 410]
$\mathcal{E}_{\lambda_1}$ sont accessibles dans $\mathcal{E}_\lambda$, donc sont accessibles, donc aussi $\mathcal{E}_s$ et $\mathcal{E}_t$. Ainsi, l'hypothèse H) implique que les catégories fibres sont accessibles. Notons de plus :

Lemme 4.14.23.1. *Supposons que $p : \mathcal{E} \longrightarrow \mathcal{C}$ soit cofibrant ou fibrant, et soit $(\lambda : s \longrightarrow t) \in \mathrm{Fl}(\mathcal{C})$. Pour que $\mathcal{E}_\lambda$ soit accessible et $\mathcal{E}_\lambda \xrightarrow{p_\lambda} \mathbf{\Delta}_1$ accessible, il faut et il suffit que $\mathcal{E}_s$, $\mathcal{E}_t$ soient accessibles et $\lambda_* : \mathcal{E}_s \longrightarrow \mathcal{E}_t$ resp. $\lambda^* : \mathcal{E}_t \longrightarrow \mathcal{E}_s$ soit un foncteur accessible.*

Démonstration. On peut supposer que $\mathcal{C} = \mathbf{\Delta}_1$, et que $\mathcal{E}$ est la catégorie cofibrée (resp. fibrée) sur $\mathbf{\Delta}_1$ définie par un foncteur $\varphi : \mathcal{E}_0 \longrightarrow \mathcal{E}_1$ (resp. $\psi : \mathcal{E}_1 \longrightarrow \mathcal{E}_0$), et à montrer que $\mathcal{E}$ et $p : \mathcal{E} \longrightarrow \mathbf{\Delta}_1$ sont accessibles si et seulement si $\mathcal{E}_0$ et $\mathcal{E}_1$ et φ (resp. ψ) le sont.

Prouvons le "il faut". On a déjà vu que si $\mathcal{E}$, p sont accessibles, $\mathcal{E}_0$ et $\mathcal{E}_1$ sont accessibles [page 411]
dans $\mathcal{E}_s$, donc accessibles, et les foncteurs d'inclusion

$$\mathcal{E}_0 \hookrightarrow \mathcal{E} \hookleftarrow \mathcal{E}_1$$

accessibles. Dire que p est cofibrant (resp. fibrant) signifie que le foncteur d'inclusion $\mathcal{E}_1 \hookrightarrow \mathcal{E}$ admet un adjoint à droite $\bar{\varphi}$ (resp. que le foncteur $\mathcal{E}_0 \hookrightarrow \mathcal{E}$ admet un adjoint à gauche $\tilde{\psi}$). Alors φ (resp. ψ) est le composé $\mathcal{E}_0 \longrightarrow \mathcal{E} \xrightarrow{\bar{\varphi}} \mathcal{E}_1$ (resp. le composé $\mathcal{E}_1 \hookrightarrow \mathcal{E} \xrightarrow{\tilde{\psi}} \mathcal{E}_1$). Donc pour prouver que φ (resp. ψ) est accessible, il suffit de prouver que $\bar{\varphi}$ (resp. $\tilde{\psi}$) l'est. Cela est un cas particulier du

Lemme 4.14.23.2. *Soient $\mathcal{E}$, $\mathcal{E}'$ deux catégories accessibles ([172]), et $\mathcal{E} \underset{G}{\overset{F}{\rightleftarrows}} \mathcal{E}'$ un couple de foncteurs adjoints entre $\mathcal{E}$ et $\mathcal{E}'$. Alors F et G sont accessibles.*

En effet, F est accessible, car il commute aux petites $\varinjlim$ quelconques, a fortiori il satisfait [page 412]
L_{π_0} (où π_0 est tel que $\mathcal{E}$, $\mathcal{E}'$ satisfassent L_{π_0}). Prouvons que G est accessible. Si S est un petit p. 156

172. **N.B.** Il suffit que $\mathcal{E}$ admette une petite sous-catégorie génératrice, et que les objets de $\mathcal{E}'$ soient accessibles.

ensemble d'éléments générateur dans $\mathcal{E}$, de sorte que la petite famille des foncteurs

$$h_\xi \;=\; (x \longmapsto \mathrm{Hom}_{\mathcal{E}}(\xi, x)) \;:\; \mathcal{E} \;\longrightarrow\; \mathrm{Ens}$$

est conservative, pour prouver que G est accessible, il suffit de prouver que les $h_\xi \circ G$ ($\xi \in S \subset \mathrm{Ob}\,\mathcal{E}$) le sont. Or

$$L_\xi \circ G(x') \;=\; \mathrm{Hom}(\xi, G(x')) \;\simeq\; \mathrm{Hom}_{\mathcal{E}'}(F(\xi), x')\ ,$$

et comme $F(\xi)$ est un objet accessible de $\mathcal{E}'$, le foncteur

$$x' \;\longmapsto\; (L_\xi \circ G)(x') \;\simeq\; \mathrm{Hom}_{\mathcal{E}'}(F(\xi), x')$$

est bien accessible, q.e.d.

Cela prouve le "il faut" dans 4.14.23.1. Prouvons le "il suffit", i.e. supposons $\mathcal{E}_s$, $\mathcal{E}_t$ accessibles, et φ (resp. ψ) accessible.

[page 413]

Commentary · Exposition [ms. 412]

Why both adjoints are accessible

Grothendieck needs the adjunction lemma to recover a transition functor from the total category over an interval. The lemma concerns the existence of a sufficiently large filtered-colimit rank. It does not assert that a right adjoint preserves all filtered colimits, or that the same rank works for every adjunction.

Write $F : \mathcal{A} \rightleftarrows \mathcal{B} : G$ with $F \dashv G$. Choose a small strong generating family S of presentable objects of $\mathcal{A}$. Since the family is small and all the objects $F(s)$ are presentable at some ranks, choose one regular κ such that both categories admit κ-filtered colimits and every s and $F(s)$ is κ-presentable. For a κ-filtered diagram (b_i), consider

$$q : \varinjlim_i G(b_i) \longrightarrow G(\varinjlim_i b_i).$$

For each $s \in S$, adjunction and the two presentability assertions give

$$\begin{aligned}
\mathrm{Hom}_{\mathcal{A}}(s, \varinjlim_i Gb_i) &\simeq \varinjlim_i \mathrm{Hom}_{\mathcal{A}}(s, Gb_i) \\
&\simeq \varinjlim_i \mathrm{Hom}_{\mathcal{B}}(Fs, b_i) \\
&\simeq \mathrm{Hom}_{\mathcal{B}}(Fs, \varinjlim_i b_i) \\
&\simeq \mathrm{Hom}_{\mathcal{A}}(s, G \varinjlim_i b_i).
\end{aligned}$$

This composite is $\mathrm{Hom}(s, q)$, so the strong generator implies that q is an isomorphism. The left adjoint preserves all colimits that exist, which proves its accessibility at once. The modern reference for the lemma is Adámek and Rosický (1994, Proposition 2.23); the argument just given makes the otherwise implicit common-cardinal choice explicit.

The word "generating" on page 412 must include the stated conservativity, and the calculation also uses presentability of the chosen generators. Both are available for an accessible category. Footnote 172 suggests a weaker hypothesis on $\mathcal{A}$; the printed argument does not explain how to dispense with preservation by these representables or with the relevant colimits. We use the lemma under its stated accessible-category hypotheses and do not certify that additional weakening.

Two orientation slips on page 411 should be read through this argument. For an opfibration classified by $\varphi : \mathcal{E}_0 \to \mathcal{E}_1$, extend φ to $\bar\varphi : \mathcal{E} \to \mathcal{E}_1$ by the identity on $\mathcal{E}_1$. Then

$$\mathrm{Hom}_{\mathcal{E}}(x, i_1 y) \simeq \mathrm{Hom}_{\mathcal{E}_1}(\bar\varphi x, y), \qquad \bar\varphi \dashv i_1.$$

For a fibration classified by $\psi : \mathcal{E}_1 \to \mathcal{E}_0$, the extension satisfies $i_0 \dashv \widetilde{\psi}$. The edition prints the opposite adjunction directions, as well as the wrong final fibre in the composite defining ψ. Correcting the types leaves the proof of Lemma 4.14.23.1 intact because the next lemma applies to either adjoint.

Dans les deux cas, $\mathcal{E}_0$ est un ouvert de $\mathcal{E}$, $\mathcal{E}_1$ est le fermé complémentaire, et $\mathcal{E}$ est la catégorie "recollée" à l'aide du bifoncteur

$$H \ : \ \mathcal{E}_0^\circ \times \mathcal{E}_1 \ \longrightarrow \ \mathrm{Ens}$$

donné par

$$\begin{cases} H(x_0, x_1) \ = \ \mathrm{Hom}(\varphi(x_0), x_1) \\ \qquad \text{resp.} \\ H(x_0, x_1) \ = \ \mathrm{Hom}(x_0, \psi(x_1)) \ , \end{cases}$$

suivant qu'on est dans le cas p cofibrant ou p fibrant. On va utiliser la

Proposition 4.14.24 ([173]). *Soit $\mathcal{E}$ une catégorie, $\mathcal{E}_0$ une sous-catégorie ouverte, $\mathcal{E}_1$ la sous-catégorie fermée complémentaire. Conditions équivalentes :*

a) $\mathcal{E}$ est accessible, et $\mathcal{E} \longrightarrow \mathbf{\Delta}_1$ (de fibres $\mathcal{E}_0$, $\mathcal{E}_1$) est accessible.

b) $\mathcal{E}$ est accessible, et $\mathcal{E}_0$, $\mathcal{E}_1$ sont accessibles dans $\mathcal{E}$.

c) $\mathcal{E}_0$, $\mathcal{E}_1$ sont accessibles, et pour tout $x_0 \in \mathrm{Ob}\,\mathcal{E}_0$, le foncteur

$$x_1 \ \longmapsto \ \underline{\mathrm{Hom}}_{\mathcal{E}}(x_0, x_1) \ : \ \mathcal{E}_1 \ \longrightarrow \ \mathrm{Ens}$$

est accessible, et il existe π tel que pour tout $x_1 \in \mathrm{Ob}\,\mathcal{E}_1$, le foncteur [page 414]

$$x_0 \ \longmapsto \ \underline{\mathrm{Hom}}_{\mathcal{E}}(x_0, x_1)^\circ \ : \ \mathcal{E}_0 \ \longrightarrow \ (\mathrm{Ens})^\circ$$

soit π-accessible.

Admettons ce lemme `[plutôt cette proposition]`, achevons la démonstration de 4.14.23.1. On suppose $\mathcal{E}_0$, $\mathcal{E}_1$ et φ (resp. ψ) accessibles, on veut prouver la condition a) de 4.14.23.3. Pour ceci, il suffit de prouver la condition c). Or on a, dans le cas p cofibrant, p. 157

$$\mathrm{Hom}_{\mathcal{E}}(x_0, x_1) \ \simeq \ \mathrm{Hom}_{\mathcal{E}_1}(\varphi(x_0), x_1) \ ,$$

c'est bien accessible en x_1, puisque $\mathcal{E}_1$ est accessible, et π-accessible en x_0 si φ l'est, comme composé de φ avec $\mathcal{E}_1 \longrightarrow \mathrm{Ens}$, $\mathrm{Hom}(-, x_1)$, qui l'est. Dans le cas p fibrant, on a

$$\mathrm{Hom}_{\mathcal{E}}(x_0, x_1) \ \simeq \ \mathrm{Hom}_{\mathcal{E}_0}(x_0, \psi(x_1)) \ ,$$

c'est accessible en x_1, comme le composé du foncteur accessible $\psi : \mathcal{E}_1 \longrightarrow \mathcal{E}_0$, et du foncteur également accessible $\mathrm{Hom}(x_0, -) : \mathcal{E}_0 \longrightarrow \mathrm{Ens}$, qui est π-accessible en x_0 tautologiquement.

Pour achever la démonstration de 4.14.23.1, il reste donc à prouver la proposition 4.14.24. On a déjà noté qu'on a a $\Longrightarrow$ b, et b $\Longrightarrow$ c clair, puisque le foncteur envisagé $\mathcal{E} \longrightarrow \mathrm{Ens}$ est le composé $\mathcal{E}_1 \overset{\text{incl.}}{\hookrightarrow} \mathcal{E} \xrightarrow{\mathrm{Hom}_{\mathcal{E}}(x_0, -)} \mathrm{Ens}$, est accessible comme composé de deux foncteurs accessibles. Reste donc à prouver c $\Longrightarrow$ a. Soit donc π_0 un cardinal utile pour $\mathcal{E}_0$, et tel que [page 415] les foncteurs

$$x_0 \ \longmapsto \ H(x_0, x_1) \ : \ \mathcal{E}_0 \longrightarrow \mathrm{Ens}^\circ$$

soient π_0-accessibles, soit π un cardinal $\geqslant \sup(\pi_0, \mathrm{card\,réd}\,\mathcal{E}_{0\,\pi_0})$ tel que $\pi^{\pi_0} = \pi$ (donc utile pour $\mathcal{E}_0$), utile pour $\mathcal{E}_1$, et tel que les foncteurs

$$x_1 \ \longmapsto \ H(x_0, x_1) \ : \ \mathcal{E}_1 \longrightarrow \mathrm{Ens}$$

soient π-accessibles, pour $x_0 \in \mathrm{Ob}\,\mathcal{E}_{0\,\pi_0}$. Soit $\mathcal{E}(\pi)$ la sous-catégorie strictement pleine de $\mathcal{E}$, telle que

$$\mathrm{Ob}\,\mathcal{E}(\pi) \ = \ \mathrm{Ob}\,\mathcal{E}_{0\,\pi} \cup \mathrm{Ob}\,\mathcal{E}_{1\,\pi} \ .$$

Je dis que

173. cf. énoncés plus généraux et démonstration sympathique, 4.15.1 et 4.15.4 (p. 425, 432).

1°) $\mathcal{E}$ satisfait à L_π, et $\mathcal{E}_0$ et $\mathcal{E}_1$ sont stables dans $\mathcal{E}$ sous L_π, les foncteurs $\mathcal{E}_0 \longrightarrow \mathcal{E}$, $\mathcal{E}_1 \longrightarrow \mathcal{E}$, $\mathcal{E} \longrightarrow \mathbf{\Delta}_1$ satisfont L_π ([174]).

2°) $\mathcal{E}(\pi) = \mathcal{E}_\pi$ (d'où un foncteur pleinement fidèle

$$\mathrm{Ind}_\pi(\mathcal{E}(\pi)) \longrightarrow \mathcal{E} \ ).$$

3°) Ledit foncteur est essentiellement surjectif, donc une équivalence de catégories. [page 416]

Notons que 2°) et 3°) impliquent que $\mathcal{E}$ est accessible, et 1°) que $\mathcal{E} \longrightarrow \mathbf{\Delta}_1$ est accessible, d'où la condition a) du lemme qu'il s'agit d'établir. Donc tout revient à prouver les 1°, 2°, 3° ci-dessus.

Commentary · Exposition [ms. 414]

A collage is controlled by its cross-Homs

The passage to a gluing bifunctor frees the argument from the existence of chosen lifts. An open subcategory here is a sieve, and its closed complement is a cosieve. Thus there are no arrows from $\mathcal{E}_1$ to $\mathcal{E}_0$. The remaining arrows between the two pieces are recorded by

$$H : \mathcal{E}_0^{\mathrm{op}} \times \mathcal{E}_1 \longrightarrow \mathrm{Set}.$$

The category reconstructed from this information is now called the collage of H. Its composition laws involving a cross-arrow are exactly the two functorial actions of H.

The two preservation conditions in Proposition 4.14.24 have different jobs. The contravariant condition says that a colimit formed in $\mathcal{E}_0$ remains universal when tested against objects of $\mathcal{E}_1$. The covariant condition says that an object of $\mathcal{E}_0$ eventually remains small when maps from it are tested on filtered diagrams in $\mathcal{E}_1$. The first condition needs a common rank for all target objects; the second can initially have a different rank for each source object. Accessibility permits us to bound that second family on a small generating subcategory.

Here is the colimit argument without the incidental notation slips. Fix a regular κ such that both fibres have κ-filtered colimits and each $H(-, y)$ converts those in $\mathcal{E}_0$ to limits. A diagram contained in $\mathcal{E}_0$ has its fibrewise colimit in the total category because it has the required universal maps to targets in either fibre. A diagram that has reached $\mathcal{E}_1$ stays there after passing to a cofinal tail. Its colimit in $\mathcal{E}_1$ is also a colimit in the total category: there are no maps from this nonempty diagram to an object of $\mathcal{E}_0$. These two cases exhaust a filtered diagram.

The smallness argument is equally concrete. An object $x \in \mathcal{E}_1$ is κ-presentable in the collage precisely when it is κ-presentable in its fibre. For $x \in \mathcal{E}_0$ one must additionally require that $H(x, -)$ preserve κ-filtered colimits. The calculation on page 419 obtains this latter requirement from a small presentation of x in $\mathcal{E}_0$. Contravariance gives

$$H(\varinjlim_j a_j, -) \simeq \varprojlim_j H(a_j, -),$$

and a sufficiently filtered colimit of sets commutes with this small limit. This is why the cardinal controlling the presentation, the variance condition, and the size of its indexing category must be chosen together.

Once these properties hold at a useful common cardinal, the union of the two small generating subcategories generates the collage. This proves accessibility itself, not merely closure under filtered colimits. The proof also explains the two familiar cases. For an opfibration, $H(x, y) = \mathrm{Hom}(\varphi x, y)$, and the relevant size of a lower-fibre object is the size of φx. For a fibration, $H(x, y) = \mathrm{Hom}(x, \psi y)$, and preservation by ψ supplies the corresponding comparison.

1°) Comme $\mathcal{E}_1$ est fermée dans $\mathcal{E}$, il est clair que $\mathcal{E}$ est stable par toutes $\varinjlim$ représentables dans $\mathcal{E}$, et plus précisément, que pour un foncteur $I \longrightarrow \mathcal{E}_1$, sa limite inductive dans $\mathcal{E}_1$ existe p. 158

174. il suffit que $\mathcal{E}_0$ et $\mathcal{E}_1$ satisfassent L_π, et que

$$x_0 \longmapsto H(x_0, x_1) \ : \ \mathcal{E}_0 \longrightarrow \mathrm{Ens}^\circ$$

satisfasse L_π $\forall\, x \in \mathrm{Ob}\,\mathcal{E}$.

si et seulement si elle existe dans $\mathcal{E}$, et les deux sont isomorphes. Supposons I grande devant π, et soit $\varphi : I \longrightarrow \mathcal{E}$, $i \longmapsto x_i$. Distinguons deux cas.

a) φ prend ses valeurs dans $\mathcal{E}_0$. Soit x_0 sa limite inductive *dans* $\mathcal{E}_0$. Je dis que c'est aussi une limite inductive dans $\mathcal{E}$. Il faut prouver que pour $x_1 \in \mathrm{Ob}\,\mathcal{E}_1$, la flèche

$$\mathrm{Hom}_{\mathcal{E}}(x_0, x_1) \longrightarrow \varprojlim_{i\in I} \mathrm{Hom}_{\mathcal{E}}(x_i, x_1)$$

est isomorphe. Or c'est le cas par hypothèse sur π, [page 417]

$$\xi \longmapsto H(\xi, x_1) \ : \ \mathcal{E}_0 \longrightarrow (\mathrm{Ens})^\circ$$

satisfait à L_π pour tout x_1 dans $\mathrm{Ob}\,\mathcal{E}_1$.

b) φ ne se factorise pas par $\mathcal{E}_0$, i.e. $\exists\, i_0 \in \mathrm{Ob}\, I$ avec $\varphi(i_0) \in \mathrm{Ob}\,\mathcal{E}_1$. Alors on a $\varphi(i) \in \mathrm{Ob}\,\mathcal{E}_1$ pour tout $i \in \mathrm{Ob}\, I[i_0]$, où $I[i_0]$ désigne la sous-catégorie strictement pleine de I formée des i tels que $i \geqslant i_0$. Cette catégorie est cofinale dans I, donc grande devant π comme I, et pour que $\varinjlim_{I} x_i$ existe, il faut et il suffit que $\varinjlim_{I[i_0]} x_i$ existe, ce qui est le cas d'après les cas a) déjà traité.

Cela prouve donc en même temps que $\mathcal{E}$ satisfait à L_π, et que $\mathcal{E}_0$ et $\mathcal{E}_1$ sont L_π-stables. La démonstration montre en même temps que le foncteur $p : \mathcal{E} \longrightarrow \mathbf{\Delta}_1$ satisfait à L_π.

2°) De ceci résulte aussitôt que $\mathcal{E}_\pi \subset \mathcal{E}(\pi)$. Prouvons qu'on a aussi

$$\mathcal{E}(\pi) \ \subset \ \mathcal{E}_\pi \ ,$$

et distinguons encore deux cas, pour $x \in \mathrm{Ob}\, E(\pi)$, suivant que x est dans $\mathcal{E}_{0\,\pi}$ ou $\mathcal{E}_{1\,\pi}$. S'il est [page 418] dans $\mathcal{E}_{1\,\pi}$, pour prouver que

$$(*) \qquad \mathrm{Hom}_{\mathcal{E}}(x, \underbrace{\varinjlim y_i}_{y}) \xleftarrow{\sim} \varinjlim_{i} \mathrm{Hom}_{\mathcal{E}}(x, y_i)$$

(pour un système inductif $(y_i)_{i\in I}$ dans $\mathcal{E}$ grand devant π), si les y_i sont dans $\mathcal{E}_0$, donc $y \in \mathcal{E}_0$, alors les deux membres sont vides, et c'est OK. Sinon, on peut supposer (quitte à remplacer I par un $I[i_0]$) que les x_i sont dans $\mathcal{E}_1$, et alors c'est OK aussi, puisque y est aussi la $\varinjlim$ dans $\mathcal{E}_1$, d'après 1°).

Si x est dans $\mathcal{E}_{0\,\pi}$, alors $(*)$ est clair si les y_i sont dans $\mathcal{E}_0$. Sinon, on peut supposer encore que les y_i sont dans $\mathcal{E}_0$, et $(*)$ s'écrit

$$H(x, \varinjlim y_i) \xleftarrow{\sim} \varinjlim H(x, y_i) \ ,$$

pour $x \in \mathrm{Ob}\,\mathcal{E}_{0\,\pi}$, les y_i dans $\mathcal{E}_1$, I grande devant π. En d'autres termes, il faut prouver que le foncteur

$$x_1 \longmapsto H(x_0, x_1) \ : \ \mathcal{E}_1 \longrightarrow \mathrm{Ens}$$

est π-accessible, quand x_0 est dans $\mathcal{E}_{0\,\pi}$. Or par hypothèse sur π, il est π-accessible si x_0 est dans $\mathcal{E}_{0\,\pi_0}$. Mais si x est dans $\mathcal{E}_{0\,\pi}$, on aura p. 159 [page 419]

$$x_0 \ = \ \varinjlim_{i\in I} x_{0\,i} \qquad \begin{cases} I \ \text{grande devant} \ \pi_0, \\ \text{les} \ x_{0\,i} \ \text{dans} \ \mathcal{E}_{0\,\pi_0}, \\ \mathrm{card}\, I \leqslant \pi \end{cases}$$

(car π_0 est utile pour $\mathcal{E}_0$ par hypothèse, et π satisfait $\pi^{\pi_0} = \pi \geqslant \mathrm{card\,réd}\,\mathcal{E}_{\pi_0}$). Comme $x_0 \longrightarrow H(x_0, x_1) : \mathcal{E}_0 \longrightarrow \mathrm{Ens}$ satisfait à L_{π_0}, pour tout x_1 dans $\mathcal{E}_1$, on aura donc

$$H(x_0) \ \simeq \ \varprojlim_{i\in I} H(x_{0\,i})$$

(où pour x_0 dans $\mathcal{E}_0$, $H(x)$ désigne le foncteur $x_1 \longmapsto H(x_0, x_1) : \mathcal{E}_1 \longrightarrow (\mathrm{Ens})$). Comme les foncteurs $H(x_{0\,i})$ sont π-accessibles, et $\operatorname{card} I \leqslant \pi$, il s'ensuit que leur $\varprojlim_I H(x_0)$ est π-accessible (SGA 4 I 9.6 (ii)). Cela achève de prouver donc 2°).

3°). Pour prouver que $\mathrm{Ind}_\pi(\mathcal{E}(\pi)) \longrightarrow \mathcal{E}$ est essentiellement surjectif, il suffit de voir que tout $x \in \mathrm{Ob}\,\mathcal{E}_0$ et tout $x \in \mathrm{Ob}\,\mathcal{E}_1$ est dans l'image essentielle. Or cela résulte de l'hypothèse [page 420] que π est utile pour $\mathcal{E}_0$ et $\mathcal{E}_1$, et de 1°) qui implique que $\mathcal{E}_0 \longrightarrow \mathcal{E}$ et $\mathcal{E}_1 \longrightarrow \mathcal{E}$ satisfont L_π.

Cela achève de prouver la proposition 4.14.24, et de même le résultat suivant, plus précis que l'implication c) $\Longrightarrow$ a).

Corollaire 4.14.25. *Soient $\mathcal{E}$ une catégorie, $\mathcal{E}_0$ une sous-catégorie ouverte, $\mathcal{E}_1$ la sous-catégorie fermée complémentaire,*

$$H \;=\; ((x_0, x_1) \longmapsto \mathrm{Hom}_{\mathcal{E}}(x_0, x_1)) \;:\; \mathcal{E}_0^\circ \times \mathcal{E}_1 \;\longrightarrow\; \mathrm{Ens}$$

le foncteur recollement.

1°) Soit π un cardinal infini. Pour ce que $\mathcal{E}$ et $\mathcal{E}_0$ satisfassent à L_π, et le foncteur d'inclusion $\mathcal{E}_0 \hookrightarrow \mathcal{E}$ itou, il faut et il suffit que $\mathcal{E}_0$ satisfasse à L_π, et que pour tout x_1 dans $\mathcal{E}_1$, le foncteur $x_0 \longmapsto H(x_0, x_1) : \mathcal{E}_0 \longrightarrow \mathrm{Ens}^\circ$ satisfasse à L_π. Alors $\mathcal{E}_1$ et $\mathcal{E}_1 \hookrightarrow \mathcal{E}$ satisfont aussi à L_π, et on a [page 421]

$$\mathcal{E}_\pi \;\subset\; \mathcal{E}(\pi) \overset{\text{déf}}{=} \begin{array}{l} \textit{sous-catégorie strictement pleine de } \mathcal{E} \textit{ telle que} \\ \mathrm{Ob}\,\mathcal{E}(\pi) = \mathrm{Ob}\,\mathcal{E}_{0\,\pi} \cup \mathrm{Ob}\,\mathcal{E}_{1\,\pi}. \end{array}$$

2°) Supposons que la condition c) de 4.14.24 soit satisfaite, et soit π_0 un cardinal infini tel que π_0 soit utile pour $\mathcal{E}_0$, et que les foncteurs $x_0 \longmapsto H(x_0, x_1) : \mathcal{E}_0 \longrightarrow \mathrm{Ens}^\circ$ définis par les $x_1 \in \mathrm{Ob}\,\mathcal{E}_1$ soient π_0-accessibles. Soit π un cardinal tel que $\pi^{\pi_0} = \pi \geqslant \sup(\pi_0, \operatorname{card} \text{réd}\,\mathcal{E}_{0\,\pi_0})$, et tel que pour tout $x_0 \in \mathrm{Ob}\,\mathcal{E}_{\pi_0}$, le foncteur $x_1 \longmapsto H(x_0, x_1) : \mathcal{E}_1 \longrightarrow \mathrm{Ens}$ soit π-accessible. Alors on a

$$\mathcal{E}_\pi \;=\; \mathcal{E}(\pi)\ .$$

Commentary · Present state [ms. 420]

The missing closed-fibre hypothesis

The first part of Corollary 4.14.25 is stronger than the preceding proof and is false as printed. The proof assumed that both fibres had the relevant filtered colimits. The right-hand side of the corollary mentions only $\mathcal{E}_0$ and the functors $H(-, y)$, then attempts to deduce colimit existence in $\mathcal{E}_1$. Nothing in those conditions controls a diagram entirely within the closed fibre.

For a nonempty counterexample, fix the manuscript cardinal π and put $\kappa = \pi^+$. Take $\mathcal{E}_0$ to be the terminal category, $\mathcal{E}_1$ the ordinal κ regarded as an ordered category, and H the constant singleton functor. The collage is the ordinal κ with an additional least object. The open fibre has all filtered colimits, and every $H(-, y)$ takes its filtered colimits to limits. Nevertheless the identity diagram $\kappa \to \mathcal{E}_1$ is κ-filtered and has no upper bound in the collage, hence no colimit. This also shows why nonemptiness of the open fibre does not rescue the statement.

The correction is to add that $\mathcal{E}_1$ satisfies L_π on the right-hand side. Sufficiency is precisely the two-case argument above. For necessity, assume the left-hand side. A nonempty filtered diagram in $\mathcal{E}_1$ cannot have a colimit in $\mathcal{E}_0$, because there is no cocone from it to such an object. Its colimit in $\mathcal{E}$ therefore lies in $\mathcal{E}_1$ and is universal there. The preservation condition on H follows by testing a colimit from $\mathcal{E}_0$ against an object of $\mathcal{E}_1$. The assertions about fibrewise small objects then follow by restricting the relevant representables.

This omission does not invalidate Proposition 4.14.24: there the cardinal was explicitly chosen useful for both fibres. It matters when the corollary is reused as a separate fixed-cardinal criterion, which is exactly what its formulation invites the reader to do.

3°) Si π_0 et π sont comme dans 2°), et si de plus π est utile pour $\mathcal{E}_1$, alors π est utile pour $\mathcal{E}$, donc (en vertu de 2°)

$$\mathcal{E} \xleftarrow{\sim} \mathrm{Ind}_\pi(\mathcal{E}(\pi)) \ .$$

Nous pouvons maintenant énoncer la généralisation cherchée de 4.14.17 :

[page 422]

Théorème 4.14.26 (généralisation de 4.14.13). *Soit $p : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur, avec $\mathcal{C}$ petite. On suppose que p satisfait à l'hypothèse H) de la page 409, qui équivaut (moyennant 4.14.24) à la suivante :*

H′) $\forall\ s \in \mathrm{Ob}\,\mathcal{C}$, la catégorie fibre $\mathcal{E}_s$ est accessible, et pour tout $\lambda : s \longrightarrow t$ dans $\mathrm{Fl}\,\mathcal{C}$, le foncteur

$$\begin{cases} H_\lambda : \mathcal{E}_s^\circ \times \mathcal{E}_t & \longrightarrow & \mathrm{Ens} \\ \qquad (x_0, x_1) & \longmapsto & \mathrm{Hom}_\lambda(x_0, x_1) \end{cases}$$

satisfait les deux conditions suivantes :

a) $\forall\ x_0 \in \mathrm{Ob}\,\mathcal{E}_s^\circ$, $x_1 \longmapsto H_\lambda(x_0, x_1) : \mathcal{E}_t \longrightarrow \mathrm{Ens}$ est accessible.

b) Il existe un cardinal infini π_λ, tel que pour tout $x_1 \in \mathrm{Ob}\,\mathcal{E}_t$, le foncteur $x_0 \longmapsto H_\lambda(x_0, x_1) : \mathcal{E}_s \longrightarrow (\mathrm{Ens})^\circ$ soit π_λ-accessible.

Ceci posé, la catégorie $\underline{\Gamma}(\mathcal{E}/\mathcal{C})$ des sections de $\mathcal{E}$ sur $\mathcal{C}$ est accessible, et les foncteurs $\varepsilon_s : \underline{\Gamma}(\mathcal{E}/\mathcal{C}) \longrightarrow \mathcal{E}_s$ sont accessibles. On peut préciser de façon similaire à 4.14.18 (énoncé en forme laissé au lecteur).

[page 423]

Démonstration de 4.14.26. Elle se fait exactement comme celle de 4.14.17 (p. 400 ff.), mais est conceptuellement plus simple. On suppose $\mathcal{C}$ petite, et on introduit les catégories

$$\Pi \ = \ \prod_{s \in \mathrm{Ob}\,\mathcal{C}} \mathcal{E}_s \ , \qquad \Pi' \ = \ \prod_{\lambda \in \mathrm{Fl}\,\mathcal{C}} \mathcal{E}_\lambda \ ,$$

où

$$\mathcal{E}_\lambda \ = \ \mathcal{E} \times_{\mathcal{C}} (\mathbf{\Delta}_1, i_\lambda) \ ,$$

et les deux foncteurs canoniques

$$\Pi \underset{G}{\overset{F}{\rightrightarrows}} \Pi'$$

de composantes

$$\begin{aligned} F_\lambda \ &= \ i_\lambda \circ \mathrm{pr}_{s(\lambda)} \\ G_\lambda \ &= \ j_\lambda \circ \mathrm{pr}_{b(\lambda)} \ , \end{aligned}$$

où pour $\lambda : s \longrightarrow t$, on pose

$$s(\lambda) \ = \ s \ , \qquad b(\lambda) \ = \ t \ ,$$

et i_λ, j_λ sont les inclusions canoniques

$$\begin{array}{ccccc} \mathcal{E}_s & \xrightarrow{i_\lambda} & \mathcal{E}_\lambda & \xleftarrow{j_\lambda} & \mathcal{E}_t \ . \\ \big\downarrow \wr & & \big\downarrow & & \big\downarrow \wr \\ (\mathcal{E}_\lambda)_0 & & {\scriptstyle p_\lambda}\big\downarrow & & (\mathcal{E}_\lambda)_1 \\ & & \mathbf{\Delta}_1 & & \end{array}$$

On désigne par $\mathcal{M}'$ la catégorie

p. 161

[page 424]

$$\mathcal{M}' \ = \ \begin{array}{l} \text{catégorie des couples } (X, u), \text{ avec} \\ X \in \mathrm{Ob}\,\Pi,\ u : F(x) \longrightarrow G(x), \end{array}$$

qui est constructible par 4.14.22.1 est accessible (car Π et π' et les foncteurs F et G le sont, par l'hypothèse H) faite sur p). On peut l'interpréter comme la catégorie des sections de $\mathrm{Diag}(\mathcal{E})$ sur $\mathrm{Diag}(\mathcal{C})$. On a un foncteur strictement pleinement fidèle

$$\mathcal{M} \overset{\text{déf}}{=} \underline{\Gamma}(\mathcal{E}/\mathcal{C}) \hookrightarrow \mathcal{M}' ,$$

qui permet d'interpréter $\mathcal{M}$ comme une sous-catégorie strictement pleine de $\mathcal{M}'$. On voit alors comme dans le cas de 4.14.17 que cette sous-catégorie est accessible dans $\mathcal{M}'$ – c'est essentiellement sorital. Il s'ensuit que $\mathcal{M}$ est accessible et que les foncteurs $\mathcal{M} \longrightarrow \mathcal{E}_s$ le sont aussi, comme composés de

$$\mathcal{M} \overset{\text{acc.}}{\hookrightarrow} \mathcal{M}' \overset{\text{acc.}}{\hookrightarrow} \Pi \xrightarrow{\mathrm{pr}_s \quad \text{acc.}} \mathcal{E}_s ,$$

Commentary · Exposition [ms. 423]

Sections without a fibration structure

Theorem 4.14.26 identifies how much of the section argument actually used cartesian or cocartesian transport. A single base arrow $\lambda : s \to t$ determines a collage $\mathcal{E}_\lambda$, whether or not a preferred lift exists. The hypotheses say that this collage and its endpoint inclusions are accessible. That is enough to choose the arrow data of a section by an inserter.

For a family $X = (X_s)$, an arrow

$$i_\lambda X_s \longrightarrow j_\lambda X_t \quad \text{in } \mathcal{E}_\lambda$$

is exactly an arrow $X_s \to X_t$ of $\mathcal{E}$ lying over λ. Thus the new inserter is again the category of graph sections. The remaining equations are literal identities and compositions in $\mathcal{E}$. No comparison isomorphisms from a cleavage occur.

One accessibility check is compressed into the word "sorital" on page 424. Choose a common regular cardinal at which the fibres, the interval categories, their endpoint inclusions, and the graph-section construction admit and preserve filtered colimits. Given a filtered diagram of graph sections, form all its object values in the fibres. The structural arrow over λ is the unique map induced by the corresponding colimit cocones in $\mathcal{E}_\lambda$. For composable λ and μ, composition of the induced arrows agrees with the arrow induced by the composites: precomposing with every object of the source colimit gives the same arrow, and the universal property gives uniqueness. Consequently the two functors recording $a_{\mu\lambda}$ and $a_\mu a_\lambda$ preserve these filtered colimits. The same argument handles identity arrows.

To impose their equality, regard the pair as a diagram of parallel arrows in $\mathcal{E}_{\mu\lambda}$, with fixed endpoint degrees. The category of equal pairs is accessible and accessibly embedded, just as on pages 405–406. There are only a set of objects and composable pairs in the small base. Pulling back these equation loci and intersecting them gives an accessible full subcategory of graph sections. Its evaluation functors are accessible by composition with the inserter projection and the product projections. The hooked arrow $\mathcal{M}' \hookrightarrow \Pi$ in the last display should therefore be an ordinary forgetful arrow; the argument only uses its accessibility.

This proof is local along arrows in a precise sense. It tests the categories of arrows over each edge, while functoriality supplies the relations among edges. It does not assert that the total category $\mathcal{E}$ is accessible for an arbitrary small base. The next section imposes an additional condition on idempotents in the base to address that separate conclusion.

q.e.d.

[page 425]

4.15 Catégorie accessible sur une autre

Proposition 4.15.1. *Soit $f : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur avec $\mathcal{C}$ petite. On suppose de plus satisfaite la condition H (p. 409), qu'on explicite ici sous la forme équivalente H′ :*

H 1) Pour tout $s \in \mathrm{Ob}\,\mathcal{C}$, $\mathcal{E}_s$ est accessible.

H 2) Pour toute $\lambda \in \mathrm{Fl}\,\mathcal{C}$, $\lambda : s \longrightarrow t$, existe un cardinal infini π_λ tel que pour tout $x_1 \in \mathrm{Ob}\,\mathcal{E}_t$, le foncteur

$$x_0 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1) \ : \ \mathcal{E}_s \longrightarrow (\mathrm{Ens})^\circ$$

est π_λ-accessible ($\mathcal{E}_s$ satisfaisant de plus à L_{π_λ}).

H 3) Pour toute $\lambda \in \mathrm{Fl}\,\mathcal{C}$, $\lambda : s \longrightarrow t$, et pour tout $x_0 \in \mathrm{Ob}\,\mathcal{E}_s$, le foncteur

$$x_1 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1) \ : \ \mathcal{E}_t \longrightarrow (\mathrm{Ens})$$

est accessible.

Alors les foncteurs d'inclusion $i_s : \mathcal{E}_s \longrightarrow \mathcal{E}$ sont accessibles. De plus, si $\mathcal{C}$ "est sans projecteurs" (i.e. si tout endomorphisme p d'un objet s de $\mathcal{C}$ tel que $p^2 = p$, est l'identité), alors $\mathcal{E}$ est accessible, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ est accessible.

Cela résulte du résultat plus précis :

Commentary · Development (commentators') [ms. 425]

A presentability test and a necessary rank repair

Grothendieck's next aim is to reconstruct accessibility of the total category from its fibres. The explicit bounds in Corollary 4.15.2 are meant to make this reconstruction reusable. They omit one condition needed by the subsequent calculation: the initial presentation rank π_0 must already control the contravariant functors in H2. Bounding those ranks only by π_1 does not justify applying them to a π_0-filtered presentation. We make the issue concrete before giving a repair.

Fibrewise presentability test over a finite poset. [ours]

Let $p : \mathcal{A} \to P$ have finite poset base. Fix a regular infinite κ. Suppose every fibre $\mathcal{A}_s$ has κ-filtered colimits and, for $s \le t$ and $y \in \mathcal{A}_t$, the functor

$$\mathrm{Hom}_{s\le t}(-, y) : \mathcal{A}_s^{\mathrm{op}} \to \mathrm{Set}$$

sends these colimits to limits. Then the total category has κ-filtered colimits, computed in a cofinal fibre, and each fibre inclusion preserves them. An object $x \in \mathcal{A}_s$ is κ-presentable in $\mathcal{A}$ if and only if every functor $\mathrm{Hom}_{s\le t}(x, -)$, for $t \ge s$, preserves κ-filtered colimits. The case $t = s$ includes presentability in the fibre.

Proof. The image of a filtered diagram in the finite poset is a finite directed subset and therefore has a greatest element t. Choose an index mapping to t. The overcategory of that index is cofinal, and all its images equal t; the diagram has consequently reduced to one fibre. To show that a fibrewise colimit is universal in the total category, test maps to an object in every fibre. If there is no base arrow the relevant sets are empty; otherwise the assumed contravariant comparison is the required bijection. This proves colimit existence and preservation. If x is presentable in the total category, restrict its representable to a diagram in $\mathcal{A}_t$, using the just-proved preservation. Conversely reduce any target diagram to its cofinal fibre $\mathcal{A}_t$; the asserted preservation of the corresponding cross-Hom gives precisely the presentability comparison for x. This proves the test.

If the fibres are κ-accessible and every fibrewise κ-presentable object passes this test, the union of their small generating subcategories consists of total κ-presentables and generates $\mathcal{A}$. Hence $\mathcal{A}$ is κ-accessible. This last statement follows directly from the definition and does not require additional colimits.

Counterexample to the printed bound in 4.15.2(c). [ours]

Use Grothendieck's convention: π-presentable sets have cardinal at most π, corresponding to modern π^+-presentability. Put

$$|K| = \aleph_1, \qquad \pi_0 = \aleph_0, \qquad \pi_1 = 2^{\aleph_1}, \qquad \pi = \beth_{\omega_1}.$$

Take the opfibration over [1] classified by

$$\varphi : \mathrm{Set} \to \mathrm{Set}, \qquad X \longmapsto X^K.$$

Its cross-Hom is $H(X, Y) = \mathrm{Set}(X^K, Y)$. The functor φ preserves $\aleph_2$-filtered colimits: a K-indexed family and all equalities among its representatives are witnessed at one stage because $|K| < \aleph_2$. Thus H2 holds with $\pi_\lambda = \aleph_1$. Both fibres are useful at π_0, and their reduced π_0-presentable subcategories

have size at most $2^{\aleph_0}$. For countable X, the set X^K has size at most $2^{\aleph_1} = \pi_1$, so $H(X,-)$ is π_1-accessible. All three printed bounds of part (c) are satisfied.

The cardinal π is strong limit of cofinality $\aleph_1$. Every countable sequence in π is bounded, whence $\pi^{\aleph_0} = \pi$: for each bound $\nu < \pi$, one has $\nu^{\aleph_0} \leq 2^{\nu \cdot \aleph_0} < \pi$, and there are π possible bounds. In contrast, König's inequality gives $\pi^{\aleph_1} > \pi$. Choose a lower-fibre set X of size π. It is π-presentable in its fibre, but X^K has size greater than π. The π^+-filtered diagram of all subsets of X^K of size at most π, placed in the upper fibre, has colimit X^K. The identity of X^K does not factor through any of those subsets. Thus $H(X,-)$ does not preserve this colimit, and the fibrewise test proves that X is not π-presentable in the total category. The asserted inclusion $\mathcal{E}(\pi) \subseteq \mathcal{E}_\pi$ fails at the printed bounds.

The qualitative proposition is repaired by choosing π_0 useful for all fibres *and* at least every π_λ, then making the subsequent choices of π_1 and π as before. Now a π_0-filtered presentation may legitimately be passed through each contravariant $H_\lambda(-,y)$; the small-limit calculation on page 419 applies. This is also the missing justification in the continuation of the proof on manuscript page 430. We found no discussion of this precise printed rank omission in the accessible-category references checked here. The test is a direct reorganization of the manuscript's proof, and the counterexample concerns its formulation; neither is asserted as a priority claim.

p. 162
[page 426]

Corollaire 4.15.2 ([175]). *Les hypothèses sur $f : \mathcal{E} \longrightarrow \mathcal{C}$ sont celles de 4.15.1 ($\mathcal{C}$ petite, et f satisfait $H' = H$ 1) 2) 3)).*

a) Soit $s \in \mathrm{Ob}\,\mathcal{C}$ et soit π_1 un cardinal infini tel que pour toute $\lambda : s \longrightarrow t$ (flèche de $\mathcal{C}$ de source t), on ait $\pi_1 \geqslant \pi_\lambda$ (où π_λ est défini dans l'énoncé de H 2). Alors le foncteur $i_s : \mathcal{E}_s \longrightarrow \mathcal{E}$ est π_1-accessible.

b) On suppose $\mathcal{C}$ sans projecteurs. Soit π_1 un cardinal $\geqslant \sup(\pi_\lambda, \mathrm{card}\,\mathcal{C})$. Alors $\mathcal{E}$ satisfait L_{π_1}, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ est π-accessible.

c) Supposons encore que $\mathcal{C}$ soit sans projecteurs (p.ex. une catégorie "rigide", p.ex. une catégorie préordonnée). Soient π_0, π_1 des cardinaux tels que :

① $\forall\, s \in \mathrm{Ob}\,\mathcal{C}$, π_0 est utile pour $\mathcal{E}_s$ (un tel π_0 existe grâce à H 1 et au fait que $\mathcal{C}$, donc $\mathrm{Ob}\,\mathcal{C}$ petits).

② $\pi_1 \geqslant \sup(\pi_0, \mathrm{card}\,\mathcal{C}, \sup_{\lambda \in \mathrm{Fl}\,\mathcal{C}} \pi_\lambda, \sup_{s \in \mathrm{Ob}\,\mathcal{C}} \mathrm{card\,réd}\,\mathcal{E}_{s\,\pi_0})$.

③ $\forall \lambda \in \mathrm{Fl}\,\mathcal{C}$, et $x_0 \in \mathrm{Ob}\,\mathcal{E}_{s,\pi_0}$, le foncteur $H_\lambda(x_0)$ de H 3, $x_1 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1) : \mathcal{E}_t \longrightarrow \mathrm{Ens}$ est π_1-accessible.

Soit π un cardinal tel que $\pi^{\pi_0} = \pi \geqslant \pi_1$. Alors par b), $\mathcal{E}$ satisfait L_{π_1}, donc L_π, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ est π_1-accessible. De plus,

$$i_s(\mathcal{E}_{s\,\pi}) \;\subset\; \mathcal{E}_\pi \;,$$

ou encore

$$(*) \qquad \mathcal{E}(\pi) \;\subset\; \mathcal{E}_\pi \;,$$

où $\mathcal{E}(\pi)$ est la sous-catégorie pleine de $\mathcal{E}$ telle que

$$\mathrm{Ob}\,\mathcal{E}(\pi) \;=\; \bigcup_{s \in \mathrm{Ob}\,\mathcal{C}} \mathrm{Ob}\,(\mathcal{E}_{s\,\pi}) \;.$$

Comme $\mathcal{E}_\pi$ satisfait L_{π_1} par b), donc a fortiori L_π, on a donc par $(*)$ un foncteur pleinement fidèle

$$\mathrm{Ind}_\pi(\mathcal{E}_{s\,\pi}) \;\xrightarrow{\sim}\; \mathcal{E} \;,$$

et ce foncteur est une équivalence de catégories (donc $\mathcal{E}$ est accessible).

d) En fait, sous les hypothèses de c) sur $\mathcal{C}$, π_0, π_1, π, on a $\mathcal{E}(\pi) = \mathcal{E}_\pi$ (non seulement $\mathcal{E}(\pi) \subset \mathcal{E}_\pi$).

[page 427]

Démonstration de 4.15.1 et 4.15.2. Il est clair que 4.15.1 est contenu dans 4.15.2 a) et c). Nous allons donc prouver 4.15.2.

a) Soit $(x_i)_{i\in I}$ un système inductif dans $\mathcal{E}_s$, avec I grand devant π_0, et x sa limite inductive dans $\mathcal{E}_s$ (qui existe, car $\mathcal{E}_s$ satisfait à L_{π_λ}, donc à L_{π_0}). Il faut prouver que c'est une limite dans $\mathcal{E}$, donc que pour tout $y \in \mathrm{Ob}\,\mathcal{E}$, la flèche canonique

$$(*) \qquad \mathrm{Hom}_{\mathcal{E}}(x,y) \longrightarrow \varprojlim_I \mathrm{Hom}_{\mathcal{E}}(x_i,y)$$

est un isomorphisme. Or $\mathrm{Hom}_{\mathcal{E}}(x,y)$ et les $\mathrm{Hom}_{\mathcal{E}}(x_i,y)$ sont des objets de $\mathrm{Ens}/\mathrm{Hom}_{\mathcal{C}}(s,t)$, où $s=f(x)$, $t=f(y)$, et les flèches de transition sont des flèches dans $\mathrm{Ens}/\mathrm{Hom}_{\mathcal{C}}(s,t)$. Cela montre que la bijectivité de $(*)$ revient à celle de p. 163

$$(*) \qquad \mathrm{Hom}_{\lambda}(x,y) \longrightarrow \varprojlim_I \mathrm{Hom}_{\lambda}(x_i,y)$$

pour tout $\lambda \in \mathrm{Hom}_{\mathcal{C}}(x,y)$ [plutôt $\mathrm{Hom}_{\mathcal{C}}(f(x),f(y))$]. Pour λ fixé, et y fixé dans $\mathrm{Ob}\,\mathcal{E}_t$, la bijectivité dans $(*)$, pour tout système inductif grand devant π_1 dans $\mathcal{E}_s$, de limite x, signifie que le foncteur

$$x \longmapsto \mathrm{Hom}_{\lambda}(x,y) \,:\, \mathcal{E}_s \longrightarrow (\mathrm{Ens})^\circ$$

est π_0-accessible. Or c'est bien le cas, par hypothèse sur π_1, quel que soit la flèche $\lambda : s \longrightarrow t$ de source s, et quel que soit $y \in \mathrm{Ob}\,\mathcal{E}_t$.

Soit $(x_i)_{i\in I}$ un système inductif grand devant π_1, et $(s_i)_{i\in I}$ l'image de ce système dans $\mathcal{C}$. [page 428] Nous prouverons plus bas le

Lemme 4.15.3 ([176], [177]). *Soit $\mathcal{C}$ une catégorie, π un cardinal, tels que* $\mathrm{card}\,\mathcal{C} \leqslant \pi$, *et que $\mathcal{C}$ soit sans projecteurs. Alors pour tout système inductif $(s_i)_{i\in I}$ grand devant π dans $\mathcal{C}$, existe une partie cofinale J dans I telle que le système induit $(s_i)_{i\in J}$ soit* constant, *i.e. tel que les s_i soient égaux à un $s \in \mathcal{C}$, et que les morphismes de transition soient tous égaux à* id_s.

Mais attention, on s'appuie pour prouver 4.15.3 sur le théorème 4.8.13 (page 212-216), que je n'ai toujours pas prouvé. Dans le cas où $\mathcal{C}$ est rigide (i.e. $\mathrm{End}_{\mathcal{C}}(s) = \{\mathrm{id}_s\}\ \forall\ s \in \mathrm{Ob}\,\mathcal{C}$), la démonstration est cependant immédiate, cf. plus bas.

Pour prouver que $x = \varinjlim_I x_i$ existe dans $\mathcal{E}$, et commute à f, on peut remplacer I par une [page 429] sous-catégorie cofinale. Cela nous ramène, grâce au lemme, au cas où $(s_i)_{i\in I}$ est constant, donc au cas où le système inductif provient d'un système inductif dans une catégorie fibre $\mathcal{E}_s$. Mais par a), on sait que sa limite x dans $\mathcal{E}_s$ est une limite dans $\mathcal{E}$, d'où l'existence de cette dernière, et la commutation à f, puisque $\varinjlim s_i = s$ ($\varinjlim$ d'un système inductif filtrant constant).

Commentary · Examples [ms. 428]

What an idempotent in the base can obstruct

The restriction on the base is meant to force a sufficiently filtered diagram to become constant after a cofinal change of indices. If the base permits a nonidentity idempotent, such a diagram can instead settle on repeated applications of that idempotent. The simplest example shows why the local hypotheses alone do not guarantee accessibility of the total category.

Let B have one object $*$ and endomorphism monoid $\{1,e\}$ with $e^2 = e \neq 1$. Take $p = \mathrm{id}_B$. Its strict fibre is terminal. For either base arrow 1 or e, the pullback $B \times_B [1]$ is $[1]$, with its identity projection, so hypothesis H holds. Nevertheless B is not accessible. For any infinite regular κ, take the diagram indexed by the ordinal κ, constant on $*$, with every strictly increasing transition equal to e. This is a well-defined κ-filtered diagram because $e^2 = e$.

175. Pour a) et b) on n'utilise que H 1 et H 2, à l'exclusion de H 3.

176. Cf. démonstration page 452.

177. sous réserve de la validité de 4.8.13 (Mais c'est à présent établi, sous une forme suffisante, dans 4.15.10).

A cocone to $*$ is a family (a_i) with $a_j e = a_i$ whenever $i < j$. Since both $1e$ and ee equal e, and every index has a larger index, every a_i must be e. There is exactly one cocone. Were it colimiting, the map from $\mathrm{Hom}_B(*,*)$ to this singleton cocone set would be bijective. It sends both 1 and e to the same cocone and is not injective. There is no other possible colimit object. Hence B has no such colimit at any regular rank.

This is the elementary splitting obstruction: a colimit of the repeated-idempotent system would supply the missing image of e. The example explains the hypothesis without claiming it is necessary in every situation. A base with split nonidentity idempotents may be accessible, and additional total-category hypotheses can also supply the missing splittings.

For the general constant-subdiagram lemma the manuscript itself records a deferred dependency. We checked the continuation in the editors' complete Chapter XVIII: page 452 still uses 4.8.13, and Corollaries 4.15.10–11 on pages 462–463 finally justify the argument with the strict bound $\pi > \operatorname{card}\mathcal{C}$. Thus the qualitative conclusion of 4.15.1 is secured by increasing the chosen cardinal. The boundary equality $\pi = \operatorname{card}\mathcal{C}$ is not established by that continuation, and we do not report it as proved here. Separately, the two displayed slips on page 426 must be read as colimit existence in $\mathcal{E}$, and the equivalence $\mathrm{Ind}_\pi(\mathcal{E}(\pi)) \simeq \mathcal{E}$ using all fibres. These pages end during the next presentability calculation.

c) Il faut prouver que si $x \in \mathrm{Ob}\,\mathcal{E}_s$ est π-accessible dans $\mathcal{E}_s$, il l'est dans $\mathcal{E}$, i.e. que pour tout système inductif $(y_i)_{i\in I}$ grande devant π, la flèche canonique

$$(**) \qquad \varinjlim_i \mathrm{Hom}(x, y_i) \longrightarrow \mathrm{Hom}(x, y)$$

est bijective. Or comme par 2°) $\pi \geqslant \pi_1 \geqslant \sup(\operatorname{card} S, \sup_\lambda \pi_\lambda)$, il résulte encore du lemme que, quitte à remplacer I par une sous-catégorie cofinale, on peut supposer que le système inductif $(y_i)_{i\in I}$ provient d'un système dans une catégorie fibre $\mathcal{E}_t$, et que y est sa $\varinjlim$ dans $\mathcal{E}_t$. Mais alors les ensembles $\mathrm{Hom}(x,y)$ et $\mathrm{Hom}(x,y_i)$, et les morphismes de transition entre celles-ci, sont encore dans $\mathrm{Ens}/\mathrm{Hom}(s,t)$, et on est ramené

Overview · XVIII-d

Accessible conditions, categories of structures, and gluing.

These pages turn accessibility into a working calculus. Their central question is how a condition on the objects of a large category can be recognized, transported, and imposed without losing a small description of the resulting category. The first part completes a criterion for accessible full subcategories. The second applies it to functors preserving specified cones and cocones, to categories of sections, and finally to categories lying over a small base. The progression is deliberate: once membership in a subcategory can be read on a suitable presentation, many apparently new constructions become instances of the same argument.

One convention must be fixed before comparing the manuscript with current accounts. Grothendieck calls an indexing category *grande devant* π when it admits cocones on diagrams having at most π arrows. Thus the associated regular cardinal in present terminology is $\lambda = \pi^+$, and his π-accessible objects are λ-presentable objects. A useful π provides an essentially small full subcategory $\mathcal{M}_\pi$ generating $\mathcal{M}$ under these filtered colimits. The stronger phrase accessible *in* an ambient category keeps track of the inclusion and of ambient presentability, not just an abstract equivalence class of accessible categories.

The opening argument is a transfinite alternation between two presentations. A final functor $\varphi : I \to J$ and a full replete final subcategory $J' \subset J$ do not in general have a final strict inverse image: the even and odd natural numbers in their common ordered set already show the problem. Grothendieck adds an ordinal-colimit hypothesis. Starting from a chosen object of I, he constructs alternating maps

$$\varphi(i_\beta) \longrightarrow j_\beta \longrightarrow \varphi(i_{\beta+1}), \qquad j_\beta \in J',$$

whose composites are transition maps. At the final limit, the two chains have isomorphic colimits. One colimit comes from I, and the other lies in J'; repleteness then gives an object of the inverse image beyond the prescribed starting object. Lemma 4.13.17 is therefore a genuine cofinality statement with an additional closure hypothesis. The commentary supplies its final comparison explicitly and shows that the successor-stage equalizations in the manuscript are redundant.

This lemma drives Theorem 4.13.22. Suppose $\underline{S}$ is an accessible full subcategory of $\mathcal{M}$ closed under the indicated colimit shapes. In an adapted presentation $x = \varinjlim_i x_i$, membership $x \in \underline{S}$ is equivalent to finality of the full subcategory of indices for which $x_i \in \underline{S}$. Adaptedness says that the indexing category contains the specified colimits and that the presenting diagram preserves them. It is what prevents a presentation from hiding the condition at every finite stage. The worked example of divisible abelian groups exhibits the criterion through countable divisible subgroups; the familiar presentation of $\mathbb{Q}$ by cyclic groups explains why an arbitrary filtered presentation is insufficient.

The subsequent calculus treats enlargement of the accessibility rank, small unions and intersections, and inverse images under accessible functors. It also exposes a boundary of the method. The essential full image of an accessible functor need not be accessibly embedded, even after closing under retracts. We work out the split-monomorphism example recorded in Rosický (2009); Brooke-Taylor and Rosický (2017): forgetting chosen retractions allows diagrams whose colimit no longer splits. This failure is distinct from the controlled envelope construction. Starting with a small family of objects and closing it under a fixed filteredness threshold and a small set of additional colimit shapes does yield an accessible, accessibly embedded subcategory. The commentary proves this by choosing a sufficiently closed cardinal, making bounded filtered envelopes of index categories, and identifying the result with a fully faithful Ind-image.

The historical framework is already visible in Artin et al. (1972, Exposé I, 8.7), where Ind-objects and their universal extension property are developed. The systematic accessible-category theory of Makkai and Paré (1989) was published in 1989, before these pages were

written. The relation is therefore a comparison of formulations, not a claim that this manuscript first announced a theory later discovered by those authors. The modern presentation separates products, inserters, equifiers, and pseudopullbacks; Grothendieck often constructs the same operations through accessible loci in categories of diagrams. Positselski (2024) makes especially clear how additional chain-colimit hypotheses permit control of a specified rank.

Section 4.14 begins with marked cones and cocones in a small category. A functor is required to take the marked data to genuine limits or colimits. When the target has the relevant universal constructions, each condition is the inverse image of an isomorphism locus under an accessible comparison functor. Their small intersection is again accessible. This is the language of sketches and categories of models. Restriction to presentable objects then allows certain large-source functor categories to be treated by the same method.

Here the hypotheses require particular care. The proof of the fixed-threshold functor-category assertion invokes target colimits not supplied by accessibility alone. We distinguish the theorem established with the additional target-colimit hypothesis from the more general assertion the manuscript leaves to its later question about colimit cones. We also distinguish the two adjoint theorems: cocontinuous functors from a locally presentable category have right adjoints, whereas a limit-preserving covariant functor need not have a left adjoint unless a solution-set or accessibility condition is added. The stronger claim at pages 379–380 fails already for the category of groups, a warning that Grothendieck himself recalled near the beginning of this chapter. The counterexample and the appropriate repair are explained with the primary references.

The question about epimorphisms has a different status. Grothendieck observes that epimorphisms are stable under the relevant filtered colimits and asks whether their full subcategory in the arrow category is always accessible. Closure alone does not answer that question. The commentary proves that accessibility and accessible embedding of this epimorphism locus would force the underlying accessible category to be co-wellpowered. Published results show that the universal co-wellpoweredness assertion already has a large-cardinal lower bound, while stronger large-cardinal assumptions give positive results (Bagaria et al., 2015). This identifies a real set-theoretic obstruction. It does not settle the exact strength of the epimorphism-locus assertion. The recent study of pure epimorphisms by Positselski (2026) concerns an additional purity condition; its publisher abstract was checked as a status lead, and no result about the unrestricted epimorphism class is inferred from it.

Categories of sections provide the main constructive application. For a fibration, a prospective section consists of a family of fibre objects and arrows $X_s \to \lambda^* X_t$. Those data form an inserter. Identity and composition impose a small family of equations, and cartesian or cocartesian requirements impose isomorphism conditions. The proof keeps track of a nonsplit cleavage through its canonical coherence isomorphisms. It is thereby a genuinely categorical construction, not a pointwise prescription with the functoriality omitted. The higher-category analogue is the accessible section theorem of Lurie (2009, Proposition 5.4.7.11).

The qualitative section theorem is robust; several printed rank assertions are not. For unrestricted sections of an opfibration, pointwise presentability need not imply presentability of the section unless transport has an appropriate presentability bound. Conversely, the category of sections can be very small while a forced component is large. The commentary gives explicit examples for both directions. Cocartesian sections admit a separate argument, because their structure isomorphisms identify the transported source with the target component. Keeping that distinction avoids discarding a correct corollary along with an incorrect proof reference.

The final pages replace fibrations by intervalwise accessible data. An arbitrary functor $p : \mathcal{E} \to \mathcal{C}$ determines, over each base arrow, a category obtained by gluing its two endpoint fibres. Its cross-Hom bifunctor

$$H : \mathcal{E}_0^{\mathrm{op}} \times \mathcal{E}_1 \to \mathrm{Set}$$

controls the gluing. Contravariant preservation makes fibrewise colimits universal in the total

category; covariant preservation makes source objects presentable at a suitable rank. This proves the accessible-section theorem without requiring chosen lifts. An additional hypothesis on idempotents in the base addresses accessibility of the total category itself.

Two corrections matter for reusing this last argument. Corollary 4.14.25 omits the colimit hypothesis on the closed fibre from one side of its equivalence; an ordinal example disproves the printed version. Corollary 4.15.2 also fails to put the contravariant preservation ranks below the initial presentation rank. The power-functor collage $X \mapsto X^{\aleph_1}$ gives a counterexample satisfying the printed cardinal bounds. Both qualitative constructions survive a common-rank choice with the missing requirements included. These pages end during the proof; the complete chapter later justifies the constant-subdiagram argument with the strict inequality $\pi > |\mathcal{C}|$. That later repair is reported at its exact manuscript locations.

The audit records these distinctions assertion by assertion: what the source proves, sketches, states, or asks; what is merely a slip in the edition; and what needs a mathematical repair. A few exact formulations remain uncertified, including the unrestricted fixed-rank third variant of 4.13.21 and the broad weakening suggested in footnote 172. These are identified as limits of the present verification rather than declared counterexamples or new open problems. Proofs marked *[ours]* are arguments supplied by the commentators, with the scope of the literature check stated and no claim of priority.

est π-accessible, quand x_0 est dans $\mathcal{E}_{0\,\pi}$. Or par hypothèse sur π, il est π-accessible si x_0 est dans $\mathcal{E}_{0\,\pi_0}$. Mais si x est dans $\mathcal{E}_{0\,\pi}$, on aura p. 159 [page 419]

$$x_0 \;=\; \varinjlim_{i\in I} x_{0\,i} \qquad \begin{cases} I \text{ grande devant } \pi_0, \\ \text{les } x_{0\,i} \text{ dans } \mathcal{E}_{0\,\pi_0}, \\ \operatorname{card} I \leqslant \pi \end{cases}$$

(car π_0 est utile pour $\mathcal{E}_0$ par hypothèse, et π satisfait $\pi^{\pi_0} = \pi \geqslant \operatorname{card} \text{réd}\mathcal{E}_{\pi_0}$). Comme $x_0 \longrightarrow H(x_0, x_1) : \mathcal{E}_0 \longrightarrow \text{Ens}$ satisfait à L_{π_0}, pour tout x_1 dans $\mathcal{E}_1$, on aura donc

$$H(x_0) \;\simeq\; \varprojlim_{i\in I} H(x_{0\,i})$$

(où pour x_0 dans $\mathcal{E}_0$, $H(x)$ désigne le foncteur $x_1 \longmapsto H(x_0, x_1) : \mathcal{E}_1 \longrightarrow (\text{Ens})$). Comme les foncteurs $H(x_{0\,i})$ sont π-accessibles, et $\operatorname{card} I \leqslant \pi$, il s'ensuit que leur $\varprojlim_I H(x_0)$ est π-accessible (SGA 4 I 9.6 (ii)). Cela achève de prouver donc 2°).

3°). Pour prouver que $\mathrm{Ind}_\pi(\mathcal{E}(\pi)) \longrightarrow \mathcal{E}$ est essentiellement surjectif, il suffit de voir que tout $x \in \operatorname{Ob}\mathcal{E}_0$ et tout $x \in \operatorname{Ob}\mathcal{E}_1$ est dans l'image essentielle. Or cela résulte de l'hypothèse que π est utile pour $\mathcal{E}_0$ et $\mathcal{E}_1$, et de 1°) qui implique que $\mathcal{E}_0 \longrightarrow \mathcal{E}$ et $\mathcal{E}_1 \longrightarrow \mathcal{E}$ satisfont L_π. [page 420]

Commentary · Exposition [ms. 419]

The two cardinal bounds in the gluing argument

Grothendieck is finishing a construction of an accessible category from an open piece, a closed piece, and the arrows crossing from the first to the second. The point of the cardinal calculation is to make presentability in a piece agree with presentability in the whole category. The latter has an additional test: an object of the open piece must commute with sufficiently filtered colimits whose values lie in the closed piece. That test is measured by the gluing functor H.

We use the modern convention that a regular cardinal κ controls diagrams with fewer than κ arrows. Thus, for an infinite π, a diagram "grand devant π" is π^+-filtered, and an object called π-accessible here is π^+-presentable. A useful π gives a small family of such objects generating by those colimits. The shift by one successor is essential when interpreting the inequalities $\operatorname{card} I \leq \pi$ in the argument.

There are two distinct bounds. First, π_0 controls the presentation of an open object and the continuity of H in its contravariant variable. Second, π controls the number of terms in a presentation and the continuity of the mixed hom functors in their covariant variable. For a presentation $x_0 = \operatorname{colim}_{j\in J} a_j$ with $|\operatorname{Mor} J| \leq \pi$, the calculation is

$$\begin{aligned} H(x_0, \operatorname*{colim}_{i\in I} y_i) &\cong \lim_{j\in J} H(a_j, \operatorname*{colim}_{i\in I} y_i) \\ &\cong \lim_{j\in J} \operatorname*{colim}_{i\in I} H(a_j, y_i) \\ &\cong \operatorname*{colim}_{i\in I} H(x_0, y_i). \end{aligned}$$

The first and last identifications use continuity in the first variable at the rank of the J-presentation. The middle interchange uses the π^+-filteredness of I. To see the latter directly in sets, choose representatives for the at most π components of a compatible family, then choose one upper bound for their indices and for the at most π equations expressing compatibility. The same common-bound argument proves injectivity. This is the mechanism of SGA 4, I.9.6(ii) and I.9.8 (Artin et al., 1972).

This distinction will matter again on manuscript page 430. Increasing the rank at which a functor is known to preserve filtered colimits does not give continuity at the smaller rank used to present an object. Here the required smaller-rank continuity is explicitly assumed in Corollary 4.14.25(2); later it is inadvertently lost from the numerical hypotheses.

Cela achève de prouver la proposition 4.14.24, et de même le résultat suivant, plus précis que l'implication c) $\Longrightarrow$ a).

Corollaire 4.14.25. *Soient $\mathcal{E}$ une catégorie, $\mathcal{E}_0$ une sous-catégorie ouverte, $\mathcal{E}_1$ la sous-catégorie fermée complémentaire,*

$$H \;=\; ((x_0,x_1)\longmapsto \mathrm{Hom}_{\mathcal{E}}(x_0,x_1)) \;:\; \mathcal{E}_0^{\circ}\times\mathcal{E}_1 \;\longrightarrow\; \mathrm{Ens}$$

le foncteur recollement.

1°) Soit π un cardinal infini. Pour ce que $\mathcal{E}$ et $\mathcal{E}_0$ satisfassent à L_π, et le foncteur d'inclusion $\mathcal{E}_0\hookrightarrow\mathcal{E}$ itou, il faut et il suffit que $\mathcal{E}_0$ satisfasse à L_π, et que pour tout x_1 dans $\mathcal{E}_1$, le foncteur $x_0\longmapsto H(x_0,x_1):\mathcal{E}_0\longrightarrow\mathrm{Ens}^{\circ}$ satisfasse à L_π. Alors $\mathcal{E}_1$ et $\mathcal{E}_1\hookrightarrow\mathcal{E}$ satisfont aussi à L_π, et on a [page 421]

$$\mathcal{E}_\pi \;\subset\; \mathcal{E}(\pi) \overset{\text{déf}}{=} \begin{array}{l}\text{sous-catégorie strictement pleine de } \mathcal{E} \text{ telle que}\\ \mathrm{Ob}\,\mathcal{E}(\pi)=\mathrm{Ob}\,\mathcal{E}_{0\,\pi}\cup\mathrm{Ob}\,\mathcal{E}_{1\,\pi}.\end{array}$$

2°) Supposons que la condition c) de 4.14.24 soit satisfaite, et soit π_0 un cardinal infini tel que π_0 soit utile pour $\mathcal{E}_0$, et que les foncteurs $x_0\longmapsto H(x_0,x_1):\mathcal{E}_0\longrightarrow\mathrm{Ens}^{\circ}$ définis par les $x_1\in\mathrm{Ob}\,\mathcal{E}_1$ soient π_0-accessibles. Soit π un cardinal tel que $\pi^{\pi_0}=\pi\geqslant\sup(\pi_0,\mathrm{card\ réd}\mathcal{E}_{0\,\pi_0})$, et tel que pour tout $x_0\in\mathrm{Ob}\,\mathcal{E}_{\pi_0}$, le foncteur $x_1\longmapsto H(x_0,x_1):\mathcal{E}_1\longrightarrow\mathrm{Ens}$ soit π-accessible. Alors on a

$$\mathcal{E}_\pi \;=\; \mathcal{E}(\pi)\;.$$

Commentary · Examples [ms. 420]

The closed piece must have its colimits

The purpose of the first part of Corollary 4.14.25 is to separate existence of colimits from the presentability calculation. As printed, however, its right-hand condition says nothing about the existence of colimits in $\mathcal{E}_1$. This is a genuine omission in the edition. It cannot follow from continuity of the mixed hom functor.

Here is a finite example detecting the omission at every infinite rank. Let B have one object b and endomorphism monoid $\{1,p\}$, where $p^2=p\neq 1$. Put

$$\mathcal{E}=\{a\}\amalg B,\qquad \mathcal{E}_0=\{a\},\quad \mathcal{E}_1=B.$$

The gluing functor is constantly empty. For any nonempty filtered diagram, the limit of the constant empty-set diagram is empty, so the printed condition on H is satisfied. The terminal category $\mathcal{E}_0$ has all the required colimits.

To exhibit the failure in the closed piece, index a diagram by the ordinal π^+, send every index to b, and send every strict transition to p. This is a functor because $p^2=p$. The index is π^+-filtered. A cocone to b must have every leg equal to p: for each index i, choose $j>i$ and use $c_i=c_jp=p$. Thus there is exactly one cocone to b, whereas $B(b,b)$ has two elements. No object represents the cocone functor, and the diagram has no colimit in B or in $\mathcal{E}$.

The corrected criterion requires both pieces to admit L_π-colimits, and requires $H(-,x_1)$ to carry those in the open piece to limits. Its proof also explains why no further compatibility is needed. For a filtered diagram $D:I\to\mathcal{E}$, let I_1 consist of the indices whose values lie in the closed piece. If I_1 is nonempty, choose one of its objects. Every finite set of indices has an upper bound receiving an arrow from that chosen object, so I_1 is cofinal; the same argument with at most π indices gives the required higher filteredness. Its colimit is computed in $\mathcal{E}_1$. There are no arrows from the closed piece to the open one, so this is also a colimit in $\mathcal{E}$. If I_1 is empty, compute the colimit in $\mathcal{E}_0$; its universal property against targets in $\mathcal{E}_1$ is precisely the asserted continuity of H. Conversely, an existing total colimit of a nonempty diagram in $\mathcal{E}_1$ must lie in $\mathcal{E}_1$, since its cocone cannot point into the open piece.

3°) Si π_0 et π sont comme dans 2°), et si de plus π est utile pour $\mathcal{E}_1$, alors π est utile pour $\mathcal{E}$, donc (en vertu de 2°) p. 160

$$\mathcal{E}\;\xleftarrow{\sim}\;\mathrm{Ind}_\pi(\mathcal{E}(\pi))\;.$$ [page 422]

Nous pouvons maintenant énoncer la généralisation cherchée de 4.14.17 :

Théorème 4.14.26 (généralisation de 4.14.13). *Soit $p : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur, avec $\mathcal{C}$ petite. On suppose que p satisfait à l'hypothèse H) de la page 409, qui équivaut (moyennant 4.14.24) à la suivante :*

H′) $\forall\ s \in \mathrm{Ob}\,\mathcal{C}$, *la catégorie fibre $\mathcal{E}_s$ est accessible, et pour tout $\lambda : s \longrightarrow t$ dans $\mathrm{Fl}\,\mathcal{C}$, le foncteur*

$$\begin{cases} H_\lambda : \mathcal{E}_s^\circ \times \mathcal{E}_t & \longrightarrow & \mathrm{Ens} \\ \qquad (x_0, x_1) & \longmapsto & \mathrm{Hom}_\lambda(x_0, x_1) \end{cases}$$

satisfait les deux conditions suivantes :

a) $\forall\ x_0 \in \mathrm{Ob}\,\mathcal{E}_s^\circ$, $x_1 \longmapsto H_\lambda(x_0, x_1) : \mathcal{E}_t \longrightarrow \mathrm{Ens}$ *est accessible.*

b) Il existe un cardinal infini π_λ, tel que pour tout $x_1 \in \mathrm{Ob}\,\mathcal{E}_t$, le foncteur $x_0 \longmapsto H_\lambda(x_0, x_1) : \mathcal{E}_s \longrightarrow (\mathrm{Ens})^\circ$ soit π_λ-accessible.

Ceci posé, la catégorie $\underline{\Gamma}(\mathcal{E}/\mathcal{C})$ des sections de $\mathcal{E}$ sur $\mathcal{C}$ est accessible, et les foncteurs $\varepsilon_s : \underline{\Gamma}(\mathcal{E}/\mathcal{C}) \longrightarrow \mathcal{E}_s$ sont accessibles. On peut préciser de façon similaire à 4.14.18 (énoncé en forme laissé au lecteur).

Démonstration de 4.14.26. Elle se fait exactement comme celle de 4.14.17 (p. 400 ff.), [page 423] mais est conceptuellement plus simple. On suppose $\mathcal{C}$ petite, et on introduit les catégories

$$\Pi \;=\; \prod_{s \in \mathrm{Ob}\,\mathcal{C}} \mathcal{E}_s\ , \qquad \Pi' \;=\; \prod_{\lambda \in \mathrm{Fl}\,\mathcal{C}} \mathcal{E}_\lambda\ ,$$

où

$$\mathcal{E}_\lambda \;=\; \mathcal{E} \times_{\mathcal{C}} (\mathbf{\Delta}_1, i_\lambda)\ ,$$

et les deux foncteurs canoniques

$$\Pi \underset{G}{\overset{F}{\rightrightarrows}} \Pi'$$

de composantes

$$\begin{aligned} F_\lambda \;&=\; i_\lambda \circ \mathrm{pr}_{s(\lambda)} \\ G_\lambda \;&=\; j_\lambda \circ \mathrm{pr}_{b(\lambda)}\ , \end{aligned}$$

où pour $\lambda : s \longrightarrow t$, on pose

$$s(\lambda) \;=\; s\ , \qquad b(\lambda) \;=\; t\ ,$$

et i_λ, j_λ sont les inclusions canoniques

$$\begin{array}{ccccc} \mathcal{E}_s & \xrightarrow{\ i_\lambda\ } & \mathcal{E}_\lambda & \xleftarrow{\ j_\lambda\ } & \mathcal{E}_t\ . \\ \big\downarrow\wr & & \big\downarrow & & \big\downarrow\wr \\ (\mathcal{E}_\lambda)_0 & & {\scriptstyle p_\lambda} & & (\mathcal{E}_\lambda)_1 \\ & & \big\downarrow & & \\ & & \mathbf{\Delta}_1 & & \end{array}$$

Commentary · Exposition [ms. 422]

Sections retain the equations between arrows

Theorem 4.14.26 changes the task from assembling objects to assembling a diagram. A section chooses $X_s \in \mathcal{E}_s$ for every base object and a lift $u_\lambda : X_s \to X_t$ for every $\lambda : s \to t$. These choices must satisfy the unit and composition equations. Grothendieck first constructs all the choices and only then imposes the equations; this order makes the accessibility argument possible.

For each λ, the pullback $\mathcal{E}_\lambda$ is the collage of its two fibres with crossing hom functor H_λ. An arrow from the zero copy of X_s to the one copy of X_t is therefore exactly a lift of λ. The product Π

records all objects X_s, while the inserter of $F, G : \Pi \rightrightarrows \Pi'$ records these objects together with all arrows u_λ. A morphism in the inserter is a family $a_s : X_s \to Y_s$ satisfying

$$a_t u_\lambda = v_\lambda a_s \quad \text{for every } \lambda : s \to t.$$

These are already the naturality equations for a map of sections. What is still missing is functoriality of the chosen arrows themselves.

The asymmetry in H′ has a structural reason. A single cardinal must control the contravariant variable for all possible targets, because it ensures that colimits in a fibre remain colimits when one tests them against every object elsewhere. In the covariant variable one first tests only a small family of generators; their individual accessibility bounds can then be dominated by one larger cardinal. Confusing these two quantifiers would replace a genuine uniformity assumption by a pointwise statement.

This construction continues the older SGA 4 treatment of accessible section categories, particularly I.9.22–9.26, while allowing crossing hom functors which need not come from chosen cartesian transport (Artin et al., 1972). In current terminology, the argument belongs to the closure of accessible categories under products, inserters, and equifiers. Makkai–Paré's monograph appeared in 1989: its formalism was contemporary with this manuscript, rather than a subsequent solution. The relevant result is Theorem 5.1.6; an explicit modern use of precisely this sequence of constructions appears in the appendix of Ching and Riehl (2014). The use of a two-categorical limit theorem is substantive: arbitrary strict equalizers of functors between accessible categories do not enjoy the same general closure property.

p. 161
[page 424]

On désigne par $\mathcal{M}'$ la catégorie

$$\mathcal{M}' \;=\; \begin{array}{l}\text{catégorie des couples } (X, u), \text{ avec} \\ X \in \operatorname{Ob}\Pi,\ u : F(x) \longrightarrow G(x),\end{array}$$

qui est constructible par 4.14.22.1 est accessible (car Π et π' et les foncteurs F et G le sont, par l'hypothèse H) faite sur p). On peut l'interpréter comme la catégorie des sections de $\mathrm{Diag}(\mathcal{E})$ sur $\mathrm{Diag}(\mathcal{C})$. On a un foncteur strictement pleinement fidèle

$$\mathcal{M} \overset{\text{déf}}{=} \underline{\Gamma}(\mathcal{E}/\mathcal{C}) \;\hookrightarrow\; \mathcal{M}' \ ,$$

qui permet d'interpréter $\mathcal{M}$ comme une sous-catégorie strictement pleine de $\mathcal{M}'$. On voit alors comme dans le cas de 4.14.17 que cette sous-catégorie est accessible dans $\mathcal{M}'$ – c'est essentiellement sorital. Il s'ensuit que $\mathcal{M}$ est accessible et que les foncteurs $\mathcal{M} \longrightarrow \mathcal{E}_s$ le sont aussi, comme composés de

$$\mathcal{M} \overset{\text{acc.}}{\hookrightarrow} \mathcal{M}' \overset{\text{acc.}}{\hookrightarrow} \Pi \xrightarrow{\ \mathrm{pr}_s \ \text{ acc.}\ } \mathcal{E}_s \ ,$$

q.e.d.

[page 425]

Commentary · Later developments [ms. 424]

Writing out the omitted equifiers

Grothendieck's description of the last step as "essentiellement sorital" can be made precise without adding an assumption to the theorem. For each object s, impose

$$u_{1_s} = 1_{X_s},$$

and, for each composable pair $s \xrightarrow{\lambda} t \xrightarrow{\mu} v$, impose

$$u_{\mu\lambda} = u_\mu u_\lambda.$$

Both sides are natural transformations between the same accessible functors on the inserter. For example, the two transformations in the second equation take values in the mixed-arrow collage $\mathcal{E}_{\mu\lambda}$, from its zero copy of X_s to its one copy of X_v. Naturality follows from the commutative squares

already built into morphisms of the inserter. The unit equations have the same description using $\mathcal{E}_{1_s}$.

An equifier is the full subcategory on the objects where two specified natural transformations agree. The smallness of $\mathcal{C}$ makes the collection of unit and composition equations small; a product gathers their target categories, and equifiers impose all the equations. Accessibility of these constructions and of their structural functors gives both assertions of the theorem. The notation $\mathcal{M}' \hookrightarrow \Pi$ in the last display should be read as a forgetful arrow: different arrow assignments may have the same underlying family of objects, and a family of object maps need not satisfy the naturality squares. The projection is accessible, which is all the proof uses.

For a concrete illustration, take $\mathcal{C} = B\mathbf{N}$, the one-object category freely generated by one endomorphism, and take $\mathcal{E} = \mathcal{C} \times \mathbf{Set}$. A section is a set X with an endomorphism T. Before imposing the equations, one has an unrelated family of self-maps u_n for $n \in \mathbf{N}$; afterward $u_0 = 1$ and $u_n = T^n$. The free section on one element is $(\mathbf{N}, n \mapsto n+1)$: an equivariant map from it is uniquely determined by the image of zero. Hence this section is finitely presentable, although its underlying set is infinite. Evaluation preserves filtered colimits, but it need not preserve finitely presentable objects at that same rank. The distinction between accessibility and strong accessibility therefore appears even in this elementary example.

The product–inserter–equifier method is part of the broader theory of flexible limits developed by Bird et al. (1989). Its relevance here is exact: the equations constrain specified arrows between already chosen objects, rather than requiring unrelated object-valued functors to become literally equal.

4.15 Catégorie accessible sur une autre

Proposition 4.15.1. *Soit $f : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur avec $\mathcal{C}$ petite. On suppose de plus satisfaite la condition H (p. 409), qu'on explicite ici sous la forme équivalente H′ :*

H 1) Pour tout $s \in \mathrm{Ob}\,\mathcal{C}$, $\mathcal{E}_s$ est accessible.

H 2) Pour toute $\lambda \in \mathrm{Fl}\,\mathcal{C}$, $\lambda : s \longrightarrow t$, existe un cardinal infini π_λ tel que pour tout $x_1 \in \mathrm{Ob}\,\mathcal{E}_t$, le foncteur

$$x_0 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1) \ : \ \mathcal{E}_s \longrightarrow (\mathrm{Ens})^\circ$$

est π_λ-accessible ($\mathcal{E}_s$ satisfaisant de plus à L_{π_λ}).

H 3) Pour toute $\lambda \in \mathrm{Fl}\,\mathcal{C}$, $\lambda : s \longrightarrow t$, et pour tout $x_0 \in \mathrm{Ob}\,\mathcal{E}_s$, le foncteur

$$x_1 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1) \ : \ \mathcal{E}_t \longrightarrow (\mathrm{Ens})$$

est accessible.

Alors les foncteurs d'inclusion $i_s : \mathcal{E}_s \longrightarrow \mathcal{E}$ sont accessibles. De plus, si $\mathcal{C}$ "est sans projecteurs" (i.e. si tout endomorphisme p d'un objet s de $\mathcal{C}$ tel que $p^2 = p$, est l'identité), alors $\mathcal{E}$ est accessible, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ est accessible.

Cela résulte du résultat plus précis :

Corollaire 4.15.2 ([175]). *Les hypothèses sur $f : \mathcal{E} \longrightarrow \mathcal{C}$ sont celles de 4.15.1 ($\mathcal{C}$ petite, et f satisfait $H' = H$ 1) 2) 3)).* p. 162 [page 426]

a) Soit $s \in \mathrm{Ob}\,\mathcal{C}$ et soit π_1 un cardinal infini tel que pour toute $\lambda : s \longrightarrow t$ (flèche de $\mathcal{C}$ de source t), on ait $\pi_1 \geqslant \pi_\lambda$ (où π_λ est défini dans l'énoncé de H 2). Alors le foncteur $i_s : \mathcal{E}_s \longrightarrow \mathcal{E}$ est π_1-accessible.

b) On suppose $\mathcal{C}$ sans projecteurs. Soit π_1 un cardinal $\geqslant \sup(\pi_\lambda, \mathrm{card}\,\mathcal{C})$. Alors $\mathcal{E}$ satisfait L_{π_1}, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ est π-accessible.

c) Supposons encore que $\mathcal{C}$ soit sans projecteurs (p.ex. une catégorie "rigide", p.ex. une catégorie préordonnée). Soient π_0, π_1 des cardinaux tels que :

175. Pour a) et b) on n'utilise que H 1 et H 2, à l'exclusion de H 3.

① $\forall\ s \in \mathrm{Ob}\,\mathcal{C}$, π_0 est utile pour $\mathcal{E}_s$ *(un tel π_0 existe grâce à H 1 et au fait que $\mathcal{C}$, donc $\mathrm{Ob}\,\mathcal{C}$ petits).*

② $\pi_1 \geqslant \sup(\pi_0, \mathrm{card}\,\mathcal{C}, \sup_{\lambda\in \mathrm{Fl}\,\mathcal{C}} \pi_\lambda, \sup_{s\in \mathrm{Ob}\,\mathcal{C}} \mathrm{card\ réd}\mathcal{E}_{s\,\pi_0})$.

③ $\forall \lambda \in \mathrm{Fl}\,\mathcal{C}$, *et* $x_0 \in \mathrm{Ob}\,\mathcal{E}_{s,\pi_0}$, *le foncteur* $H_\lambda(x_0)$ *de H 3,* $x_1 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1) : \mathcal{E}_t \longrightarrow \mathrm{Ens}$ *est π_1-accessible.*

Soit π un cardinal tel que $\pi^{\pi_0} = \pi \geqslant \pi_1$. Alors par b), $\mathcal{E}$ satisfait L_{π_1}, donc L_π, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ est π_1-accessible. De plus,

$$i_s(\mathcal{E}_{s\,\pi}) \ \subset\ \mathcal{E}_\pi\ ,$$

ou encore

$$(*) \qquad \mathcal{E}(\pi) \ \subset\ \mathcal{E}_\pi\ ,$$

où $\mathcal{E}(\pi)$ est la sous-catégorie pleine de $\mathcal{E}$ telle que

$$\mathrm{Ob}\,\mathcal{E}(\pi) \ =\ \bigcup_{s\in \mathrm{Ob}\,\mathcal{C}} \mathrm{Ob}\,(\mathcal{E}_{s\,\pi})\ .$$

Comme $\mathcal{E}_\pi$ satisfait L_{π_1} par b), donc a fortiori L_π, on a donc par $(*)$ un foncteur pleinement fidèle

$$\mathrm{Ind}_\pi(\mathcal{E}_{s\,\pi}) \ \xrightarrow{\sim}\ \mathcal{E}\ ,$$

et ce foncteur est une équivalence de catégories (donc $\mathcal{E}$ est accessible).

d) En fait, sous les hypothèses de c) sur $\mathcal{C}$, π_0, π_1, π, on a $\mathcal{E}(\pi) = \mathcal{E}_\pi$ (non seulement $\mathcal{E}(\pi) \subset \mathcal{E}_\pi$).

Démonstration de 4.15.1 et 4.15.2. Il est clair que 4.15.1 est contenu dans 4.15.2 a) et c). Nous allons donc prouver 4.15.2. [page 427]

a) Soit $(x_i)_{i\in I}$ un système inductif dans $\mathcal{E}_s$, avec I grand devant π_0, et x sa limite inductive dans $\mathcal{E}_s$ (qui existe, car $\mathcal{E}_s$ satisfait à L_{π_λ}, donc à L_{π_0}). Il faut prouver que c'est une limite dans $\mathcal{E}$, donc que pour tout $y \in \mathrm{Ob}\,\mathcal{E}$, la flèche canonique

$$(*) \qquad \mathrm{Hom}_{\mathcal{E}}(x, y) \ \longrightarrow\ \varprojlim_I \mathrm{Hom}_{\mathcal{E}}(x_i, y)$$

est un isomorphisme. Or $\mathrm{Hom}_{\mathcal{E}}(x, y)$ et les $\mathrm{Hom}_{\mathcal{E}}(x_i, y)$ sont des objets de $\mathrm{Ens}/\mathrm{Hom}_{\mathcal{C}}(s, t)$, où $s = f(x)$, $t = f(y)$, et les flèches de transition sont des flèches dans $\mathrm{Ens}/\mathrm{Hom}_{\mathcal{C}}(s, t)$. Cela montre que la bijectivité de $(*)$ revient à celle de p. 163

$$(*) \qquad \mathrm{Hom}_\lambda(x, y) \ \longrightarrow\ \varprojlim_I \mathrm{Hom}_\lambda(x_i, y)$$

pour tout $\lambda \in \mathrm{Hom}_{\mathcal{C}}(x, y)$ [plutôt $\mathrm{Hom}_{\mathcal{C}}(f(x), f(y))$]. Pour λ fixé, et y fixé dans $\mathrm{Ob}\,\mathcal{E}_t$, la bijectivité dans $(*)$, pour tout système inductif grand devant π_1 dans $\mathcal{E}_s$, de limite x, signifie que le foncteur

$$x \ \longmapsto\ \mathrm{Hom}_\lambda(x, y)\ :\ \mathcal{E}_s \ \longrightarrow\ (\mathrm{Ens})^\circ$$

est π_0-accessible. Or c'est bien le cas, par hypothèse sur π_1, quel que soit la flèche $\lambda : s \longrightarrow t$ de source s, et quel que soit $y \in \mathrm{Ob}\,\mathcal{E}_t$.

Soit $(x_i)_{i\in I}$ un système inductif grand devant π_1, et $(s_i)_{i\in I}$ l'image de ce système dans $\mathcal{C}$. Nous prouverons plus bas le [page 428]

Commentary · Exposition [ms. 427]

Colimits in a fibre and colimits in the total category

Grothendieck now asks whether the same local data control the total category itself. The first step, preservation of colimits by a fibre inclusion, is more elementary than the final theorem and does not need H3. Let $x = \operatorname{colim}_i x_i$ be a sufficiently filtered colimit in $\mathcal{E}_s$, and let $y \in \mathcal{E}_t$. The decomposition

$$\mathcal{E}(x,y) = \coprod_{\lambda \in \mathcal{C}(s,t)} \operatorname{Hom}_\lambda(x,y)$$

is respected by every transition map in the comparison with $\mathcal{E}(x_i, y)$. Since the index category is nonempty and connected, a compatible family in the limit has one fixed base arrow λ. Thus its universal property reduces to the separate universal properties of $H_\lambda(-,y)$, which H2 supplies. The occurrences of π_0 in this proof are to be read as π_1, the bound specified in part (a).

The second step explains the hypothesis on the base. If the image of a sufficiently filtered diagram can be reindexed to become constant with identity transitions, the diagram lies in one fibre, so the preceding calculation supplies its total colimit. A small base with no nonidentity idempotents has this stabilization property at a sufficiently large rank. The proof of the required small-category statement is deferred until manuscript pages 440–463. For the existential conclusion of Proposition 4.15.1 it is enough to use the strict cardinal bound proved there; no claim about an optimal boundary cardinal is needed.

The phrase "sans projecteurs" must be kept distinct from "karoubienne". A groupoid has no nonidentity idempotents, although it may have many automorphisms. A Karoubian category may have nonidentity idempotents, provided their images exist. A constant-object diagram whose strict transitions are one such idempotent need not become a diagram of identity maps inside its original fibre. The later difficulty with a Karoubian base is therefore a difficulty of transport to the image of an idempotent, rather than a failure of the fibrewise universal property just proved.

Lemme 4.15.3 ([176], [177]). *Soit $\mathcal{C}$ une catégorie, π un cardinal, tels que* $\operatorname{card}\mathcal{C} \leqslant \pi$, *et que $\mathcal{C}$ soit sans projecteurs. Alors pour tout système inductif $(s_i)_{i\in I}$ grand devant π dans $\mathcal{C}$, existe une partie cofinale J dans I telle que le système induit $(s_i)_{i\in J}$ soit* constant, *i.e. tel que les s_i soient égaux à un $s \in \mathcal{C}$, et que les morphismes de transition soient tous égaux à* id_s.

Mais attention, on s'appuie pour prouver 4.15.3 sur le théorème 4.8.13 (page 212-216), que je n'ai toujours pas prouvé. Dans le cas où $\mathcal{C}$ est rigide (i.e. $\operatorname{End}_{\mathcal{C}}(s) = \{\mathrm{id}_s\}\ \forall\ s \in \operatorname{Ob}\mathcal{C}$), la démonstration est cependant immédiate, cf. plus bas.

Pour prouver que $x = \varinjlim_I x_i$ existe dans $\mathcal{E}$, et commute à f, on peut remplacer I par une [page 429]
sous-catégorie cofinale. Cela nous ramène, grâce au lemme, au cas où $(s_i)_{i\in I}$ est constant, donc au cas où le système inductif provient d'un système inductif dans une catégorie fibre $\mathcal{E}_s$. Mais par a), on sait que sa limite x dans $\mathcal{E}_s$ est une limite dans $\mathcal{E}$, d'où l'existence de cette dernière, et la commutation à f, puisque $\varinjlim s_i = s$ ($\varinjlim$ d'un système inductif filtrant constant).

c) Il faut prouver que si $x \in \operatorname{Ob}\mathcal{E}_s$ est π-accessible dans $\mathcal{E}_s$, il l'est dans $\mathcal{E}$, i.e. que pour tout système inductif $(y_i)_{i\in I}$ grande devant π, la flèche canonique

$$(**) \qquad \varinjlim_i \operatorname{Hom}(x, y_i) \longrightarrow \operatorname{Hom}(x,y)$$

est bijective. Or comme par 2°) $\pi \geqslant \pi_1 \geqslant \sup(\operatorname{card} S, \sup_\lambda \pi_\lambda)$, il résulte encore du lemme que, quitte à remplacer I par une sous-catégorie cofinale, on peut supposer que le système inductif $(y_i)_{i\in I}$ provient d'un système dans une catégorie fibre $\mathcal{E}_t$, et que y est sa $\varinjlim$ dans $\mathcal{E}_t$. Mais alors les ensembles $\operatorname{Hom}(x,y)$ et $\operatorname{Hom}(x,y_i)$, et les morphismes de transition entre celles-ci, sont encore dans $\operatorname{Ens}/\operatorname{Hom}(s,t)$, et on est ramené

à prouver que pour tout $\lambda : s \longrightarrow t$, la flèche

$$\varinjlim_i \operatorname{Hom}_\lambda(x, y_i) \longrightarrow \operatorname{Hom}_\lambda(x,y) \qquad \text{p. 164 [page 430]}$$

176. Cf. démonstration page 452.

177. sous réserve de la validité de 4.8.13 (Mais c'est à présent établi, sous une forme suffisante, dans 4.15.10).

est bijective. Pour x et λ fixés, et des systèmes inductifs variables dans $\mathcal{E}_t$, grands devant π, cela signifie que le foncteur

$$H_\lambda(x) \;=\; (y \longmapsto \mathrm{Hom}_\lambda(x,y)) \;:\; \mathcal{E}_t \;\longrightarrow\; \mathrm{Ens}$$

est π-accessible, et ceci quel que soit

$$x \;\in\; \mathrm{Ob}\,\mathcal{E}_{s\,\pi}\ .$$

Or c'est le cas si $s \in \mathrm{Ob}\,\mathcal{E}_{s\,\pi_0}$, en vertu de l'hypothèse 3°) (alors $H_\lambda(x_0)$ est π_1-accessible, et a fortiori π-accessible). Il faut passer de là au cas où $x \in \mathrm{Ob}\,\mathcal{E}_{s\,\pi}$. Or comme π_0 est utile pour $\mathcal{E}_s$ par 1°, on a

$$x \;=\; \varinjlim_{j\in J} x_j\ , \qquad x_j \in \mathrm{Ob}\,\mathcal{E}_{s\,\pi_0},\ J \text{ grande devant } \pi_0\ ,$$

et comme par 2°, $\pi^{\pi_0} = \pi \geqslant \pi_1 \geqslant \sup(\pi_0, \mathrm{card\,réd}\,\mathcal{E}_{s\,\pi_0})$, on en conclut qu'on peut prendre J de sorte que

$$\mathrm{card}\,J \;\leqslant\; \pi\ .$$

D'autre part, en vertu de $\pi \geqslant \pi_1 \;\geqslant\; \pi_\lambda$, le foncteur

$$\begin{cases} x_0 & \longmapsto & H_\lambda(x_0) \\ \mathcal{E}_s & \longrightarrow & (\underline{\mathrm{Hom}}(\mathcal{E}_s, \mathrm{Ens}))^\circ \end{cases}$$

est π_0-accessible, donc on a

$$H_\lambda(x_0) \;\simeq\; \varprojlim_{j\in J} H_\lambda(x_j)\ .$$

Comme $x_j \;\in\; \mathrm{Ob}\,\mathcal{E}_{s\,\pi_0}$, $H(x_j)$ est un foncteur π_1-accessible, et comme $\mathrm{card}\,J \leqslant \pi$, la $\varprojlim_{j\in J} H_\lambda(x_j)$ est aussi π-accessible (cf. SGA 4 I 9.8). [page 431]

Commentary · Development (commentators') [ms. 430]

The numerical rank assertion needs another hypothesis

Grothendieck wants to pass from continuity on a small family of generators to continuity on every object of the chosen larger rank. This is a sound strategy, but the displayed implication on this page uses first-variable continuity at π_0 although H2 only provides it at π_λ. The inequality $\pi \geq \pi_1 \geq \pi_\lambda$ does not repair that mismatch. The following example shows that the numerical assertion of Corollary 4.15.2(c), as stated, is false.

A bounded-powerset counterexample. [ours] Put $\pi_0 = \aleph_0$ and $\pi_1 = \pi = 2^{\aleph_0}$. Let both fibres over Δ_1 be copies of **Set**. For a set A, write $P_{\leq\pi}(A)$ for the set of its subsets of cardinal at most π, with direct image as its action on maps. Define the total category by the usual hom sets within each fibre, no arrows from the second fibre to the first, and

$$\mathrm{Hom}_{0\to1}(A,B) = \mathbf{Set}(P_{\leq\pi}(A), B).$$

Functoriality of bounded powerset defines both compositions involving a crossing arrow, so this is a category over Δ_1.

We check every numerical assumption. Both fibres have useful cardinal $\aleph_0$ in Grothendieck's convention: every set is the $\aleph_1$-filtered union of its countable subsets. A skeleton of the category of countable sets has $2^{\aleph_0}$ morphisms, so the reduced-size bound holds. Cardinal arithmetic gives $\pi^{\pi_0} = \pi$.

The functor $P_{\leq\pi}$ preserves π^+-filtered colimits. Indeed, a subset of the colimit of size at most π can be lifted by choosing at most π representatives and one common stage. If two lifted subsets have the same image, choose matching elements and witnesses for their equalities; at most π witnesses suffice, and a common upper stage makes the two subsets equal. These two observations prove surjectivity and injectivity of the canonical comparison. Consequently H2 holds with $\pi_\lambda = \pi$ for

the crossing arrow. H3 holds for every A, since the mixed hom functor is representable by the set $P_{\leq\pi}(A)$. If A is countable, this representing set has cardinal at most $2^{\aleph_0} = \pi$, so the stronger H3 bound demanded in part (c) also holds. The identity-arrow conditions are automatic.

Now choose A of cardinal π in the first fibre. It is π-accessible there. But $P_{\leq\pi}(A) = P(A)$ has cardinal $2^\pi > \pi$. Index a diagram in the second fibre by all subsets $B \subseteq P(A)$ with $|B| \leq \pi$, ordered by inclusion. This poset is π^+-filtered, its union is $P(A)$, and this is also its total colimit. The identity map of $P(A)$ belongs to $\mathrm{Hom}_{0\to1}(A, P(A))$ and factors through no such B. Therefore A is not π-accessible in the total category. This disproves both the inclusion in part (c) and the equality in part (d).

The repair is simple and preserves Proposition 4.15.1. Choose π_0 to dominate all π_λ before making the subsequent choices of π_1 and π. Then the π_0-filtered generator presentation can be carried through $H_\lambda(-, y)$, and the limit–colimit calculation on manuscript page 419 applies. Such a common initial choice is available because the base is small. We checked the standard uniformization and two-categorical closure results in the sources cited here; we did not find this particular bounded-powerset diagnosis of the printed rank statement. The example is supplied to isolate the missing hypothesis, without a claim of priority.

Ainsi on a prouvé $\mathcal{E}_{s\,\pi} \subset \mathcal{E}(\pi)$ pour tout $s \in \mathrm{Ob}\,\mathcal{C}$, i.e. l'inclusion

$$\mathcal{E}(\pi) \ \subset \ \mathcal{E}_\pi \ ,$$

d'où le foncteur pleinement fidèle

$$(*) \qquad \mathrm{Ind}_\pi(\mathcal{E}(\pi)) \longrightarrow \mathcal{E} \ ,$$

comme $\mathcal{E}$ satisfait à L_π. Il reste à prouver que c'est essentiellement surjectif. Mais si $x \in \mathrm{Ob}\,\mathcal{E}$, $s = f(x)$, on a $x \in \mathrm{Ob}\,\mathcal{E}_s$, et comme π_0 est utile pour $\mathcal{E}_s$ par 1°), et $\pi^{\pi_0} = \pi > \pi_0$, π est également utile pour π, donc on a *dans* $\mathcal{E}_s$

$$x \ = \ \varinjlim_I x_i \ , \qquad \text{les } x_i \in \mathcal{E}_{s\,\pi} \subset \mathcal{E}(\pi),\ I \text{ grande devant } \pi \ ,$$

et d'après a) (comme $\pi \geqslant \pi_1 \geqslant \sup_{\lambda\in \mathrm{Fl}\,\mathcal{C}} \pi_\lambda$) x est aussi limite des x_i dans $\mathcal{E}$, donc il est dans l'image essentielle de $(*)$. p. 165

d) Reste à prouver que l'on a $\mathcal{E}_\pi \ \subset \ \mathcal{E}(\pi)$. Mais on sait (par 4.8. …), comme $\mathcal{E} \ \simeq \ \mathrm{Ind}_\pi(\mathcal{E}(\pi))$, que $\mathcal{E}_\pi \ = \ \mathcal{E}(\pi)^\natural$, i.e. que pour $x \ \in \ \mathrm{Ob}\,\mathcal{E}_\pi$, $\exists\ y \ \in \ \mathcal{E}(\pi)$ et un projecteur p dans x, tel que x soit isomorphe à l'image de p dans $\mathcal{E}$. Or $f(p)$ est un projecteur dans $f(y) = s$, donc par hypothèse sur $\mathcal{C}$, $f(p) = \mathrm{id}_s$, i.e. p est un projecteur dans $\mathcal{E}_s$. Comme donc x est dans $\mathcal{E}_s$, et

même dans $\mathcal{E}_{s\,\pi}$, puisque $\mathcal{E}_{s\,\pi}$ est stable dans $\mathcal{E}_s$ par facteurs directs. Cela prouve que $x \in \mathrm{Ob}\,\mathcal{E}(\pi)$, q.e.d. [page 432]

On peut présenter 4.15.1 sous une forme plus sympathique.

Corollaire 4.15.4. *Soit $f : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur de $\mathfrak{U}$-catégories. Les conditions suivantes sont équivalentes :*

a) Pour tout foncteur $\mathcal{C}' \longrightarrow \mathcal{C}$, avec $\mathcal{C}'$ petite et sans projecteurs, $\mathcal{E}' \overset{déf}{=} \mathcal{E} \times_{\mathcal{C}} \mathcal{C}'$ est accessible, et $f' : \mathcal{E}' \longrightarrow \mathcal{C}'$ est accessible.

b) Comme a), mais avec $\mathcal{C}' = \mathbf{\Delta}_1$, en d'autres termes, c'est la condition H p. 409 : pour toute $\lambda \in \mathrm{Fl}\,\mathcal{C}$, $\mathcal{E}_\lambda = \mathcal{E} \times_{\mathcal{C}} (\mathbf{\Delta}_1, i_\lambda)$ est accessible, et $\mathcal{E}_\lambda \longrightarrow \mathbf{\Delta}_1$ est accessible.

c) La condition $H' = H\ 1 + H\ 2 + H\ 3$, explicitée dans l'énoncé de 4.15.1.

Démonstration. Elle se fait circulaire,

$$\mathrm{a} \implies \mathrm{b} \implies \mathrm{c} \implies \mathrm{a} \ ,$$

l'implication a $\implies$ b étant tautologique, b $\implies$ c l'étant presque (cf. 4.14.24, a $\implies$ b $\implies$ c). En fait, les conditions b et c sont des conditions sur les catégories $\mathcal{E}_s \xrightarrow{f_\lambda} \mathbf{\Delta}_1$ pour $\lambda \in \mathrm{Fl}\,\mathcal{C}$, donc stables par changement de base. Pour prouver [page 433]

c $\Longrightarrow$ a, on peut donc supposer que $\mathcal{C}' = \mathcal{C}$, $\mathcal{C}' \longrightarrow \mathcal{C}$ le foncteur identique, et prouver que si c) est satisfaite et si $\mathcal{C}$ est petite et sans projecteurs, alors $\mathcal{E}$ est accessible et f accessible. Or c'est ce qu'affirme 4.15.1.

Commentary · Exposition [ms. 432]

Recovering the generators without choosing a splitting

The conclusion Grothendieck needs is that the small generators of the total category can be recognized in the fibres. After correcting the uniformity assumption, the difficult inclusion is $\mathcal{E}(\pi) \subseteq \mathcal{E}_\pi$. The reverse inclusion has a short proof which also avoids a strict-fibre ambiguity in the printed retract argument.

Suppose $x \in \mathcal{E}_s$ is π-accessible in the total category. Let $y = \operatorname{colim}_i y_i$ be an L_π-colimit inside $\mathcal{E}_s$. The inclusion preserves it by part (a), so

$$\operatorname*{colim}_i \mathcal{E}(x, y_i) \xrightarrow{\sim} \mathcal{E}(x, y).$$

Both sides map to the fixed set $\mathcal{C}(s, s)$, and the transition maps preserve that map. Taking the fibre over 1_s commutes with the colimit: a representative has base arrow 1_s precisely when its image does, because every transition lies over the identity. We obtain the required bijection for $\mathcal{E}_s(x, -)$. Thus x is already π-accessible in its own fibre.

In the printed proof the projector must be on the chosen object y, not on x. Moreover, a splitting of that vertical projector in the total category may have an image over an object merely isomorphic to s. One can replace it by the splitting in the accessible fibre, but the identity-component argument proves the assertion directly and works without selecting an isomorphic representative.

Corollary 4.15.4 then expresses the result in a useful local form. H′ is unchanged by base change, because each new crossing hom functor is one of the original ones. Testing the walking arrow detects exactly this data, and the corrected existential theorem assembles it over any small base without nonidentity idempotents. The restriction on the testing bases is part of the assertion; it does not license replacement of an arbitrary strict pullback by a pseudopullback.

Remarque 4.15.5. Si $f : \mathcal{E} \longrightarrow \mathcal{C}$ est un foncteur pleinement fidèle, il est immédiat que la condition H est satisfaite (car $\mathcal{E}_\lambda \longrightarrow \mathbf{\Delta}_1$ sera pleinement fidèle, donc $\mathcal{E}_\lambda$ est équivalente à e où à $\mathbf{\Delta}_1$, donc accessible, et tout foncteur de $\mathcal{E}_\lambda$ dans une catégorie quelconque est accessible …). Mais si on suppose $\mathcal{C}$ petite *sans* supposer $\mathcal{C}$ sans projecteurs, il ne s'ensuit pas que $\mathcal{E}$ soit accessible, ou ce qui revient au même (étant essentiellement petite), que $\mathcal{E}$ soit karoubienne. (L'exemple le plus trivial est celui où $\mathcal{E} = \mathcal{C}$, $f = \mathrm{id}_{\mathcal{C}}$, $\mathcal{E}$ n'est karoubienne que si $\mathcal{C}$ l'est !) Mais même en supposant $\mathcal{C}$ une petite catégorie karoubienne, il ne s'ensuit pas forcément que $\mathcal{E}$ l'est. En effet, *toute* petite catégorie $\mathcal{E}$ (karoubienne ou non) se plonge comme sous-catégorie pleine dans son enveloppe karoubienne $\mathcal{C}$ – il suffit donc de prendre $\mathcal{E}$ non karoubienne. L'exemple le plus économique est [page 434]

$$\mathrm{Ob}\,\mathcal{E} \;=\; \{0\}\;, \qquad \mathrm{Fl}(\mathcal{E}) \;=\; \{\mathrm{id}_0, p\}\;, \qquad \text{avec } p^2 = p \neq \mathrm{id}_0\;,$$

l'enveloppe de Karoubi de $\mathcal{E}$ est donnée par p. 166

$$P \;=\; \left\{ 1 \underset{\sigma}{\overset{\rho}{\leftrightarrows}} 0 \circlearrowright p \qquad \begin{array}{l} \rho\sigma \;=\; \mathrm{id}_1 \\ \sigma\rho \;=\; p \;\neq\; \mathrm{id}_0 \end{array} \qquad \Longrightarrow\; p^2 = p \right\}.$$

Cela soulève la question de trouver un énoncé similaire à 4.15.1, donnant des conditions serviables simples, plus fortes que H′ = H (1+2+3), sur $f : \mathcal{E} \longrightarrow \mathcal{C}$, pour que $\mathcal{E}$ soit accessible et f accessible, en supposant $\mathcal{C}$ *karoubienne*. Ou encore, des conditions nécessaires et suffisants serviables (plus fortes que 4.15.4) sur $f : \mathcal{E} \longrightarrow \mathcal{C}$, pour que toute *petite* catégorie *karoubienne* $\mathcal{C}'$, et tout foncteur $\mathcal{C}' \longrightarrow \mathcal{C}$, la catégorie $\mathcal{E}' = \mathcal{E} \times_{\mathcal{C}} \mathcal{C}'$ soit accessible, et le foncteur $\mathcal{E}' \longrightarrow \mathcal{C}'$ accessible. Une idée naturelle, c'est qu'il suffirait que cette conclusion soit vraie quand $\mathcal{C}'$

est une des deux catégories $\mathbf{\Delta}_1$, P (où P est la catégorie à deux objets, à trois flèches non identiques, définie plus haut). Mais je doute qu'il en soit ainsi ([178]).

On va quand même essayer un énoncé un peu très particulier dans ce sens : [page 435]

Proposition 4.15.6 ([180]). *Soit $f : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur de $\mathfrak{U}$-catégories. On suppose :*

a) f est fibrant ou cofibrant ([181]).

b) Les catégories fibres $\mathcal{E}_s$ ($s \in \mathrm{Ob}\,\mathcal{C}$) sont accessibles, et pour toute flèche $\lambda : s \longrightarrow t$ dans $\mathcal{C}$, le foncteur changement de base $\lambda^* : \mathcal{E}_t \longrightarrow \mathcal{E}_s$ (resp. cochangement de base $\lambda_* : \mathcal{E}_s \longrightarrow \mathcal{E}_t$) est accessible.

c) $\mathcal{C}$ est essentiellement petite et karoubienne.

Alors $\mathcal{E}$ est accessible, et f est accessible.

Commentary · Examples [ms. 434]

Why a retract has to be lifted

Grothendieck's smallest example makes visible what the walking arrow does not test. Let B be the one-object category with $p^2 = p \neq 1$. Its Karoubi envelope P has objects $0, 1$, arrows $\sigma : 1 \to 0$ and $\rho : 0 \to 1$, and relations

$$\rho\sigma = 1_1, \qquad \sigma\rho = p.$$

The inclusion $B \hookrightarrow P$ is fully faithful. Every pullback along a walking arrow has total category equivalent to an empty category, a point, or Δ_1, and therefore satisfies the local accessibility condition H. Nevertheless B is not accessible: the long constant-object diagram with transition p has no colimit, as computed above. The base P is Karoubian, but its retract object has not been lifted into B.

This is why the next proposed test categories attach an incoming or outgoing arrow to a retract. The retract alone tests existence of an image; an incoming arrow tests maps into that image, and an outgoing arrow tests maps from it. Concretely, once a splitting $x \xrightarrow{r} z \xrightarrow{i} x$ with $ri = 1$ and $ir = p$ is fixed, an arrow $y \to z$ corresponds to an arrow $u : y \to x$ satisfying $pu = u$, by $v \mapsto iv$ and $u \mapsto ru$. The two composites are identities because $ri = 1$ and $pu = u$. Dually, arrows $z \to y$ correspond to arrows $u : x \to y$ satisfying $up = u$. These are the two three-object diagrams in footnote 178. Their later reformulation in §4.16.6 separates the global accessibility problem from the stronger requirement concerning all strict base changes.

The counterexample also explains why a (co)fibration is a promising extra assumption. Cartesian or cocartesian transport along the two arrows of a retract gives a way to move the problem into the fibre over its image. The proof below makes that move explicit; it resolves the doubts attached to Proposition 4.15.6 without pretending that its written proof is complete.

Démonstration. On a déjà vu que les conditions a) et b) impliquent H′, i.e. H (1+2+3). D'ailleurs, si $\mathcal{C}'$ est une catégorie et $\mathcal{C}' \xrightarrow{\sim} \mathcal{C}$ une équivalence, donc alors $\mathcal{E}' \overset{\text{déf}}{=} \mathcal{E} \times_{\mathcal{C}} \mathcal{C}' \longrightarrow \mathcal{E}$ est une équivalence, donc la conclusion voulue pour $\mathcal{E}$, f équivaut à la même conclusion pour $\mathcal{E}'$, $f' : \mathcal{E}' \longrightarrow \mathcal{C}'$. Donc on peut supposer que $\mathcal{C}$ est petite (et même réduite, si on y tient). En vertu de 4.15.2 a), on voit donc que les foncteurs d'inclusion $\mathcal{E}_s \longrightarrow \mathcal{E}$ sont accessibles (et même π_1-accessibles) dès que $\pi_1 \geqslant \sup_{\lambda \in \mathrm{Fl}\,\mathcal{C}} \pi_\lambda$. On voit d'ailleurs

178. Ça devrait marcher par contre si on prend les catégories $0 \longrightarrow 1$, [page 436]

$$2 \longrightarrow \underbrace{1 \underset{\sigma}{\overset{\rho}{\leftrightarrows}} 0 \circlearrowright p}_{P} \quad \text{et} \quad 2 \longleftarrow \underbrace{1 \underset{\sigma}{\overset{\rho}{\leftrightarrows}} 0 \circlearrowright p}_{P} \qquad ([179]),$$

3 objets et 5 flèches non identiques

grâce à 4.15.7, page 440.

179. ces catégories représentent respectivement les foncteurs Cat $\longrightarrow$ Ens associant à une catégorie $\mathcal{C}$ les diagrammes dans $\mathcal{C}$ formés de (x, y, p, u), avec p projecteur dans p `[plutôt dans C]`, et $u : y \longrightarrow x^\natural$ (i.e. $u : y \longrightarrow x$ avec $u = pu$), resp. $u : x^\natural \longrightarrow y$ (i.e. $u : x \longrightarrow y$ avec $u = up$).

180. *Faux ?*

181. Le cas fibrant n'est pas prouvé, peut-être *faux* – et de même pour le cas cofibrant !

par AQT [âne qui trotte] qu'on peut trouver des cardinaux π_0, π_1 ayant les propriétés suivantes :

p. 167

(1°) π_0 est utile pour $\mathcal{E}_s$, $\forall\ s \in \mathrm{Ob}\,\mathcal{C}$.

2°) $\pi_1 \geqslant \sup(\pi_0, \mathrm{card}\,\mathcal{C}, \sup_{\lambda\in \mathrm{Fl}\,\mathcal{C}} \pi_\lambda, \sup_{s\in \mathrm{Ob}\,\mathcal{C}} \mathrm{card\,réd}\,\mathcal{E}_s)$.

(3°) $\forall\ (\lambda : s \longrightarrow t) \in \mathrm{Fl}\,\mathcal{C}$ et $x_0 \in \mathrm{Ob}\,\mathcal{E}_{s\,\pi_0}$, le foncteur

$$H_\lambda(x_0)\ :\ (x_1 \longmapsto \mathrm{Hom}_\lambda(x_0, x_1))\ :\ \mathcal{E}_t\ \longrightarrow\ (\mathrm{Ens})$$

est π_1-accessible. (**N.B.** Si f est cofibrant, cela signifie que $\forall\ \lambda \in \mathrm{Fl}\,\mathcal{C}$, $\lambda : s \longrightarrow t$, $\boxed{\lambda_*(\mathcal{E}_{s\,\pi_0})\ \subset\ \mathcal{E}_{s\,\pi_1}}$. Si f est fibrant, il suffit d'exiger que $\forall\ \lambda \in \mathrm{Fl}\,\mathcal{C}$, $\lambda^* : \mathcal{E}_t \longrightarrow \mathcal{E}_s$ soit π_1-accessible.) Mais dans ce cas, on veut aussi $\boxed{\lambda^*(\mathcal{E}_{s\,\pi_0})\ \subset\ \mathcal{E}_{s\,\pi_1}}$.

(4°) Les foncteurs λ^* (cas f fibrant) resp. λ_* (cas f cofibrant) sont π_1-accessibles.

Soit alors π un cardinal tel que

$$(*) \qquad \pi\ =\ \pi^{\pi_0}\ \geqslant\ \pi_1\ ,$$

et soit $\mathcal{E}(\pi)$ la sous-catégorie (strictement) pleine de $\mathcal{E}$ définie par

$$\mathrm{Ob}\,\mathcal{E}(\pi)\ =\ \bigcup_{s\,\in\,\mathrm{Ob}\,\mathcal{C}} \mathrm{Ob}\,\mathcal{E}_{s\,\pi}\ .$$

Grâce à $(*)$, et à 1°, 4° et à

$$\begin{cases} \pi_1\ \geqslant\ \sup_s(\mathrm{card\,réd}\,\mathcal{E}_{s\,\pi_0}) & \text{(contenu dans 2°)} \\ \lambda^*(\mathcal{E}_{t\,\pi_0})\ \subset\ \mathcal{E}_{s\,\pi_1} \qquad \text{resp.} \qquad \lambda_*(\mathcal{E}_{s\,\pi_0})\ \subset\ \mathcal{E}_{t\,\pi_1} & \text{(contenu dans 3°)}\ , \end{cases}$$

on voit que $\mathcal{E}(\pi)$ est une sous-catégorie

fibrée, resp. une sous-catégorie cofibrée, sur $\mathcal{C}$ (le foncteur $\mathcal{E}(\pi) \longrightarrow \mathcal{E}$ étant donc cartésien resp. cocartésien). À $\mathcal{C}$-équivalence près, $\mathcal{E}$ se reconstitue alors à partir de $\mathcal{E}(\pi)$, en passant au $\mathrm{Ind}_\pi(\mathcal{E}_{s\,\pi})$, qui forment un système fibré resp. cofibré sur $\mathcal{C}$ par les foncteurs $\mathrm{Ind}_\pi(\lambda_\pi^*)$ resp. $\mathrm{Ind}_\pi(\lambda_*^\pi)$ … [page 437]

Prouvons que $\mathcal{E}$ satisfait à L_π et que $f : \mathcal{E} \longrightarrow \mathcal{C}$ est π-accessible ([182]). Comme $\mathcal{C}$ est karoubienne, et $\pi \geqslant \pi_1 \geqslant \mathrm{card}\,\mathcal{C}$, $\mathcal{C}$ satisfait à L_π et les ind-objets grands devant π de $\mathcal{C}$ sont essentiellement constants (4.8.13). Soit alors I grande devant π, et $I \longrightarrow \mathcal{E}$, $i \longmapsto x_i$, un foncteur, il faut construire une $\varinjlim$ dans $\mathcal{E}$, en utilisant la $\varinjlim$ déjà connue s des $s_i = f(x_i)$. On va prendre un x dans $\mathcal{E}_s$. Prenons d'abord le cas où f est cofibrant. On voit que les $\beta_i(x_i)$ forment un système inductif dans $\mathcal{E}_s$, puisque pour $i = j$, on a

$$\beta_{i\,*}(x_j)\ =\ \beta_{j\,*}\underbrace{\beta_{ji\,*}(x_i)}_{\longrightarrow\,x_j}\ \longrightarrow\ \beta_{j\,*}(x_j)\ .$$

$$\begin{array}{ccc} x_i & \xrightarrow{\quad\alpha_i\quad} & x\,? \\ s_i & \xrightarrow{\quad\beta_i\quad} & s \\ & {\scriptstyle\beta_{ji}}\searrow \quad \nearrow{\scriptstyle\beta_j} & \\ & s_j & \end{array}$$

On pose

$$x\ =\ \varinjlim_I \beta_{i\,*}(x_i)\ , \qquad \varinjlim\ \textit{dans}\ \mathcal{E}_s\ .$$

p. 168
[page 438]

182. Ici on utilise seulement $\pi \geqslant \mathrm{card\,réd}\,\mathcal{C}$.

On sait que c'est une $\varinjlim$ dans $\mathcal{E}$, donc que pour tout y dans $\mathcal{E}$, on a

$$\mathrm{Hom}(x,y) \xrightarrow{\sim} \varprojlim_I \mathrm{Hom}(\beta_{i*}(x_i),y) \ ,$$

ou ce qui revient au même, pour toute flèche $\lambda : s \longrightarrow t$, et y dans $\mathrm{Ob}\,\mathcal{E}_t$, on a

$$\underbrace{\mathrm{Hom}_\lambda(x,y)}_{=\mathrm{Hom}_{\mathcal{E}_t}(\lambda_* x,y)} \simeq \varprojlim \mathrm{Hom}_{\mathcal{E}_t}(\underbrace{\lambda_*\beta_{i*}(x_i)}_{(\lambda_i\beta_i)_*(x_i)},y) \ .$$

Cela résulte aussi du fait que λ_* est π-accessible (étant π_1-accessible) … On vérifie facilement que c'est une $\varinjlim$ des x_i dans $\mathcal{E}$. Et bien sûr, cette limite commute avec f par construction.

Mais dans le cas où f est fibrant, je ne vois comment faire pour construire une limite dans $\mathcal{E}_s$. Il est vrai qu'on peut supposer que tous les s_i sont égaux à s, mais les transitions β_{ji} ne sont pas l'identité, ni même des isomorphismes. Il faudrait prendre $\mathcal{C} = P$ pour essayer de comprendre – je ne vais pas insister ([183]).

Commentary · Exposition [ms. 438]

Constructing the missing colimit in a fibration

Grothendieck has already constructed total colimits in the opfibration case. For a fibration the direction of transport initially seems wrong, but the splitting of the stabilized base idempotent supplies exactly the missing direction. We give a direct proof, using the constant-idempotent reindexing established later in §4.15.7 and the sufficient strict bound in Corollary 4.15.11. This makes the proof independent of an unresolved optimal cardinal estimate.

Replace the fibration by an equivalent split fibration and choose a sufficiently large regular successor κ so that every fibre is κ-accessible, every reindexing functor preserves κ-filtered colimits, and the small-base stabilization theorem applies. This simultaneous choice uses only a small family of accessible functors. Reindex a given κ-filtered diagram cofinally by a κ-directed poset so that every base object is s and every strict transition is one idempotent p. If this poset has a greatest element, its value is the total colimit and the base colimit, and every hom comparison is immediate. Otherwise every index has a strictly larger index, since the poset is directed. Work in this latter case and split

$$s \xrightarrow{r} t \xrightarrow{i} s, \qquad ri = 1_t, \quad ir = p.$$

Write $U = i^* : \mathcal{E}_s \to \mathcal{E}_t$ and $R = r^* : \mathcal{E}_t \to \mathcal{E}_s$, so $UR = 1$ and $RU = p^*$. A strict transition $X_j \to X_k$ is represented by

$$a_{kj} : X_j \longrightarrow RUX_k.$$

Composition says $a_{\ell j} = RU(a_{\ell k})a_{kj}$ for $j < k < \ell$. Therefore $Z_j = UX_j$, with transition $z_{kj} = U(a_{kj})$, is a genuine diagram in $\mathcal{E}_t$. Form $Z = \mathrm{colim}_j Z_j$ there and denote its structural maps by c_j.

For $k > j$, the composite $R(c_k)a_{kj} : X_j \to RZ$ is independent of k: two choices admit a common later index, where the composition identity and $c_\ell z_{\ell k} = c_k$ give equality. These composites define a cocone from the original diagram to the total object Z, lying over r.

To prove universality, take a cocone to $Y \in \mathcal{E}_v$. Its base maps $\lambda_j : s \to v$ satisfy $\lambda_j = \lambda_k p$ for $j < k$. Choosing one further index shows that they are all equal to a map λ with $\lambda p = \lambda$. Hence $\lambda = \mu r$ for the unique $\mu = \lambda i : t \to v$. Its legs are maps $b_j : X_j \to R\mu^* Y$. Applying U gives a compatible family $Ub_j : Z_j \to \mu^* Y$. Conversely that compatible family recovers b_j from any later index by

$$b_j = R(Ub_k)a_{kj} \qquad (k > j).$$

These operations are inverse, by the cocone equation and $UR = 1$. Fibre cocones on Z_j correspond to maps $Z \to \mu^* Y$, so the original cocones correspond precisely to total maps $Z \to Y$. This proves both existence of the total colimit and its preservation by the projection.

The same transport also proves the Karoubian assertion in footnote 183. An idempotent on X over p is represented by $a : X \to RUX$ with $RU(a)a = a$. Then $b = Ua$ is a vertical idempotent on UX. Split $b = jq$, $qj = 1_Y$ in the accessible fibre $\mathcal{E}_t$. The maps represented by $Rq\,a : X \to RY$ and $j : Y \to UX$ give a splitting in the total category: their composites are 1_Y and the original idempotent. Thus the source's observation is correct, and transport explains it. [page 439]

Dans le cas où f est fibrant, admettons (comme hypothèse supplémentaire au besoin) que $\mathcal{E}$ satisfasse L et que f soit accessible, et prenons π assez grand pour que $\mathcal{E}$, f satisfassent L_π. Nous pouvons alors terminer la démonstration de 4.15.6. Il faut prouver

$$\mathcal{E}(\pi) \ \subset \ \mathcal{E}_\pi \ ,$$

donc que si $x \in \mathrm{Ob}\,\mathcal{E}_{s\,\pi}$, et $(y_i)_{i\in I}$ est un système inductif dans $\mathcal{E}$ grand devant π, de limite y, on a

$$\varinjlim \mathrm{Hom}_{\mathcal{E}}(x, y_i) \xrightarrow{\sim} \mathrm{Hom}_{\mathcal{E}}(x, y) \ .$$

Donc il faut prouver que toute flèche $x \xrightarrow{u} y$ se factorise, de façon essentiellement unique u_i, par un y_i. Mais la flèche $s \xrightarrow{\lambda = f(u)} t$ dans $\mathcal{C}$ se factorise, de façon essentiellement unique, par des $\lambda_i : s \longrightarrow t_i$. Donc on est ramené à trouver un λ_i-*morphisme* $x \longrightarrow y_i$ pour i grand, qui factorise. Dans le cas fibrant, cela signifie qu'on cherche $x \longrightarrow \lambda_i^*(y_i)$ qui factorise $x \longrightarrow \lambda^*(y)$, or les $\lambda_i^*(y_i)$ forment un système inductif dans $\mathcal{E}_s$, et sa limite *dans* $\mathcal{E}_s$ est $\lambda^*(y)$ (*à vérifier*). Comme x est dans $\mathcal{E}_{s\,\pi}$, l'hom `[omorphisme]` donné $x \longrightarrow \lambda^*(y)$ se factorise de façon essentiellement unique par un $\lambda_i^*(y_i)$. [page 440]

Commentary · Exposition [ms. 439]

Presentability after splitting the base idempotent

The preceding construction identifies the colimit whose existence was assumed on this page. It also verifies the pullback comparison marked "à vérifier", and proves the presentability statement needed for accessibility.

Keep the notation $Z_j = UX_j$, $Z = \operatorname{colim} Z_j$ and the splitting $s \xrightarrow{r} t \xrightarrow{i} s$. Let $x \in \mathcal{E}_u$ be κ-presentable in its fibre. A total arrow $x \to Z$ over $\nu : u \to t$ is a fibre arrow

$$x \longrightarrow \nu^* Z \cong \operatorname*{colim}_j \nu^* Z_j.$$

The displayed isomorphism follows from the chosen accessibility rank of ν^*. Fibre presentability factors this map through $\nu^* Z_j = (i\nu)^* X_j$, giving a total arrow $x \to X_j$ over $i\nu$. The cocone leg $X_j \to Z$ over r has fibre representative $d_j = R(c_k)a_{kj}$ for any $k > j$, and

$$U(d_j) = c_k U(a_{kj}) = c_k z_{kj} = c_j.$$

Consequently composition with that leg applies $\nu^* c_j$ to the chosen factorization, giving exactly the prescribed arrow to Z; its base is $ri\nu = \nu$. This proves surjectivity of the total hom comparison.

For injectivity, take two representatives whose composites to Z agree. Passing to a common index makes their base arrows have the same composite with r. Passing once more through a transition over $p = ir$ makes both base arrows equal to $i\nu$ for that common ν. They can now be interpreted as maps into the one fibre diagram $\nu^* Z_j$. Their equality at the colimit is witnessed at a later stage by the injectivity of the fibre hom comparison. This is exactly equality of the original total representatives after that transition.

Every fibrewise κ-presentable object is therefore κ-presentable in $\mathcal{E}$. Fibre inclusions preserve the relevant colimits: for a diagram in $\mathcal{E}_u$, test its fibre colimit against $Y \in \mathcal{E}_v$ separately over every $\lambda : u \to v$ using $\mathcal{E}_u(-, \lambda^* Y)$. Since the base is small, the union of small generating families in the fibres is small, and it generates all total objects. The fibration case of Proposition 4.15.6 follows, including accessibility of its projection.

Makkai–Paré's general theory treats accessible indexed categories and their total categories in §5.3 (Makkai and Paré, 1989). The proof here records directly the special small Karoubian-base situation Grothendieck needs; we do not use an unverified identification of a strict pullback with a two-categorical limit. For a (co)fibration, however, pullback along an equivalence of bases is safe because isomorphisms lift. This explains the reduction to a small skeleton at the start of his argument.

183. J'ai vérifié que si f est fibrant, alors $\mathcal{E}$ est *karoubienne*. Il y a donc de l'espoir …

Cette fois par contre, c'est le cas f cofibrant qui pose problème. En fait, je n'arrive pas à m'en tirer.

Ainsi, on trouve bien un foncteur

$$\mathrm{Ind}_\pi(\mathcal{E}(\pi)) \longrightarrow \mathcal{E}\ ,$$

qui est essentiellement surjectif, mais faute de savoir que $\mathcal{E}(\pi) \subset \mathcal{E}_\pi$ dans le cas cofibrant, il n'est pas clair que ce foncteur soit une équivalence de catégories. p. 169

Commentary · Exposition [ms. 440]

Completing the opfibration argument

The opfibration proof needs an additional transition after a fibre factorization. Choose a common strong rank κ for the direct-image functors: they then preserve κ-filtered colimits and κ-presentable objects. This is the uniformization recalled by Paré and Rosický (2013, Introduction and proof of Theorem 2.1). Reindex and split the base idempotent as above, and put

$$R = r_* : \mathcal{E}_s \to \mathcal{E}_t, \qquad U = i_* : \mathcal{E}_t \to \mathcal{E}_s,$$
$$RU = 1, \qquad UR = p_*.$$

A transition is represented by $a_{kj} : URX_j \to X_k$, with $a_{\ell j} = a_{\ell k} UR(a_{kj})$ for $j < k < \ell$. The diagram $Z_j = RX_j$ has transitions $z_{kj} = R(a_{kj})$, and its fibre colimit Z is the total colimit. To check this last assertion, base cocones again have one form μr. Maps out of Z over μ are maps $\mu_* Z \to Y$; preservation of the fibre colimit by μ_* identifies them with exactly the cocones $\mu_* RX_j \to Y$ arising from the original diagram. This completes the universal-property verification sketched on page 438.

Let $x \in \mathcal{E}_u$ be fibrewise κ-presentable. A total map $x \to Z$ over $\nu : u \to t$ is a map $h : \nu_* x \to Z$. Since $\nu_* x$ is κ-presentable, it factors through some $Z_j = RX_j$, say by $h_j : \nu_* x \to RX_j$. Applying U gives a map into URX_j, rather than into X_j. One later transition supplies the missing arrow:

$$(i\nu)_* x = U\nu_* x \xrightarrow{Uh_j} URX_j \xrightarrow{a_{kj}} X_k \qquad (k > j).$$

Its composite to Z is the desired total map. This proves surjectivity.

For injectivity, normalize two representatives to the same index and the same base arrow $i\nu$ by passing to a further transition. Write their fibre representatives as $b, b' : U\nu_* x \to X_j$. Equality at Z means equality of the two maps $Rb, Rb' : \nu_* x \to RX_j$ in the colimit. Fibre presentability gives a stage k where their composites with z_{kj} agree. After one additional transition to $\ell > k$, the original representatives become

$$a_{\ell k}\, U(z_{kj} Rb) \quad \text{and} \quad a_{\ell k}\, U(z_{kj} Rb'),$$

which are equal. The composition law above shows these are exactly their images in X_ℓ. Thus the total hom comparison is bijective.

Fibre generation and preservation of its colimits by the inclusions now give accessibility of the total category, and the displayed Ind functor is an equivalence at the chosen rank. The doubts in footnotes 180–181 concern an unfinished proof, not a false conclusion. The abstract result is consistent with Makkai–Paré's Theorem 5.4.7, which computes lax colimits of strong diagrams of accessible categories by taking the idempotent completion of the categorical lax colimit; this formulation is explicitly recalled by Paré and Rosický (2013, Introduction). We checked that attribution there rather than claiming to have inspected the unavailable book proof. The calculations above establish both orientations needed in this manuscript directly.

4.15.7. Il me faut reporter la démonstration du lemme 4.15.3 (p. 428), en admettant 4.8.13. (Non encore démontré – je vais revenir plus bas sur la démonstration de 4.8.13.) On va utiliser le

Lemme 4.15.7.1. *Soient $\mathcal{C}$ une catégorie, $\underline{x} = (x_i)_{i\in I}$ un ind-objet de $\mathcal{C}$. Pour que $\underline{x}$ soit essentiellement constant, i.e. isomorphe, dans* $\mathrm{Ind}(\mathcal{C})$*, au ind-objet constant défini par un objet*

de $\mathcal{C}$, il faut et il suffit qu'il existe un foncteur cofinal $\varphi : J \longrightarrow I$, avec J filtrant, de telle façon que le système réindexé $(x_j)_{j\in J}$, avec $x_j = x_{\varphi(j)}$, ait la propriété suivante : pour tout [page 441]
$j \in J$, on peut trouver un projecteur p_j dans x_j, de telle façon que :

1°) Pour toute flèche $\lambda : j \longrightarrow j'$ dans J, on ait commutativité dans

$$\begin{array}{ccc} x_j & \xrightarrow{x_\lambda} & x_{j'} \\ \downarrow{\scriptstyle p_j} & & \downarrow{\scriptstyle p_{j'}} \\ x_j & \xrightarrow{x_\lambda} & x_{j'} \end{array}$$

(où les x_λ sont les flèches de transition), i.e. $p_{j'} x_\lambda = x_\lambda p_j$.

2°) Pour tout $j \in \mathrm{Ob}\, J$, il existe une flèche $\lambda : j \longrightarrow j'$ dans J telle que $p_{j'} x_\lambda = x_\lambda p_j = x_\lambda$.

3°) Pour tout $j \in \mathrm{Ob}\, J$, le projecteur p_j dans x_j admet un image $x_j^\natural$.

4°) Pour toute flèche $\lambda : j \longrightarrow j'$ dans J, la flèche $x_\lambda^\natural : x_j^\natural \longrightarrow x_{j'}^\natural$ induite par x_λ (grâce à 1°) est un isomorphisme.

De plus, si on peut supposer J de la forme $i_0\backslash I$, le foncteur cofinal $J \longrightarrow I$ étant le foncteur canonique $i_0\backslash I \longrightarrow I$ (i_0 étant un objet fixé convenable de I) `[phrase incomplète]`

Notons tout de suite deux corollaires. [page 442]

Commentary · Exposition [ms. 441]

The retract inside an essentially constant system

Grothendieck wants to recover an actual stage of a large diagram from the ind-object it represents. The obstruction is already visible in a finite calculation: the limiting object may be a retract of a stage without being the whole stage. The projectors in 4.15.7.1 identify precisely the part which survives. We write $h_x = \mathrm{Hom}_{\mathcal{C}}(-, x)$ and

$$X = \varinjlim_{i \in I} h_{x_i} \quad \text{in} \quad [\mathcal{C}^{\mathrm{op}}, \mathrm{Ens}].$$

Essentially constant means that X is representable. It does not mean that the displayed diagram was already constant, or that its colimit inside $\mathcal{C}$, if one exists, is represented by the same presheaf.

Here is the proof with the two inverse maps kept in their correct order. Suppose $X \simeq h_z$, and write

$$\alpha : h_z \longrightarrow X, \qquad \beta : X \longrightarrow h_z, \qquad \beta\alpha = 1_{h_z}, \quad \alpha\beta = 1_X.$$

Yoneda gives a representative $\alpha_{i_0} : z \to x_{i_0}$ of α, while β gives compatible maps $\beta_i : x_i \to z$. The compatibility equation is $\beta_j \tau_{ji} = \beta_i$, for $\tau_{ji} : x_i \to x_j$. Several equations on manuscript pp. 449–450 reverse these composites; the reversals are printed so in the edition.

The upper slice $J = i_0\backslash I$ makes the chosen representative coherent. An object of J is an arrow $u : i_0 \to i$, and we put $\alpha_u = x(u)\alpha_{i_0}$. Then

$$\beta_i \alpha_u = 1_z, \qquad p_u = \alpha_u \beta_i, \qquad p_u^2 = p_u.$$

Thus p_u splits with image z, and a morphism of the slice acts as the identity on that image. Its naturality follows from the compatibility of both families. Finally $\alpha\beta = 1_X$ says that the class of p_u equals the class of 1_{x_i} in the appropriate filtered colimit of Hom sets. Equality there has a witness: some arrow $u \to v$ satisfies $x(u \to v)p_u = x(u \to v)$. Naturality gives the other absorbed composite. These are exactly the four conditions of the lemma.

For completeness, the slice has the required size of filteredness. A small diagram in $i_0\backslash I$ becomes a diagram in I after adjoining i_0 and its specified arrows. A cocone in I therefore gives a cocone in the slice. The same construction shows that the projection is final. In particular, if I admits cocones for diagrams of cardinal at most π_0, so does J.

Conversely, choose splittings $x_j \xrightarrow{r_j} z_j \xrightarrow{s_j} x_j$ of the stated projectors. Condition 1 makes the z_j a diagram, and condition 4 makes its arrows isomorphisms. A filtered category has trivial groupoid completion: common upper objects compare two paths, and equalization of parallel arrows removes their ambiguity. Hence the z_j are coherently isomorphic to one object z. Transporting r_j and s_j through this isomorphism produces maps $\beta : X \to h_z$ and $\alpha : h_z \to X$. The splitting identities give $\beta\alpha = 1$, while condition 2 gives $\alpha\beta = 1$ in the colimit. This also repairs the incomplete final sentence of the statement: one *can* choose the upper slice described above.

Corollaire 4.15.7.2. *Supposons que $\mathcal{C}$ soit sans projecteurs. Alors $\underline{x} = (x_i)_{i\in I}$ est un ind-objet essentiellement constant si et seulement s'il existe un foncteur cofinal, $J \longrightarrow I$, avec J filtrant ([184]), de telle façon que le système inductif réindexé $(x_j)_{j\in J}$ soit isomorphe* (dans la catégorie $\underline{\mathrm{Hom}}(J, \mathcal{C})$) *à un système inductif* constant *(i.e. défini par un foncteur constant $J \longrightarrow \mathcal{C}$: tous les x_j égaux à un même x, et les morphismes de transition des identités).*

La suffisance est claire, pour la nécessité on applique 4.15.7.1, qui nous dit qu'on peut réindexer de façon à satisfaire aux conditions 1°) à 4°) (pour des projecteurs p_j convenables dans les x_j). Mais l'hypothèse sur $\mathcal{C}$ implique que $p_j = \mathrm{id}_{x_j}\ \forall\, j \in \mathrm{Ob}\, J$, et les conditions 1°, 2°, 3° sont satisfaites tautologiquement pour un tel choix, la condition 4° signifie que les morphismes de transition sont des isomorphismes. Mais il est immédiat que pour un système inductif $(x_j)_{j\in J}$ donné, avec J 1-*connexe* (p.ex. J filtrant), la condition que les x_j sont des isomorphismes est nécessaire et suffisante pour que ce système soit isomorphe à un système inductif constant, d'où la conclusion.

p. 170
[page 443]

Corollaire 4.15.7.3. *Supposons que I soit grande devant π_0, où π_0 est un cardinal infini tel que $\pi_0 \geqslant \mathrm{card}\, \mathcal{C}$. Alors $(x_i)_{i\in I}$ est essentiellement constant si et seulement si on peut trouver un foncteur cofinal $J \longrightarrow I$ avec J grande devant π_0 (et ordonnée si on veut) ([185]), de telle façon que le système réindexé $(x_j)_{j\in J}$ satisfasse les conditions suivantes :*

1°) L'application $j \longmapsto x_j$ de $\mathrm{Ob}\, J$ dans $\mathrm{Ob}\, \mathcal{C}$ est constante, i.e. il existe un $x_0 \in \mathrm{Ob}\, \mathcal{C}$ tel que $x_j = x_0\ \forall\, j \in \mathrm{Ob}\, J$.

2°) Il existe un projecteur p dans x_0 tel que pour $j < j'$ dans J, on ait $\tau_{j',j} = p$.

3°) Le projecteur p admet une image dans $\mathcal{C}$.

Démonstration. Ces conditions impliquent évidemment celles de 4.15.7.1, en prenant $p_j = p\ \forall\, j \in \mathrm{Ob}\, J$, du moins si J n'admet de plus grand élément (ce qui fait une difficulté pour 2°). Mais si J admet un objet final, il en est de même de I, et il est clair alors que tout système inductif indexé par I est essentiellement constant. Donc, dans ces cas, les conditions 1°) 2°) 3°) ci-dessus impliquent que $\underline{x}$ est essentiellement constant. Inversement, supposons que [page 444]
$\underline{x}$ soit essentiellement constant, et prouvons que l'on peut réindexer comme indiqué. Le cas où I admet un objet final est trivial, on prendra $J = e$, $p = \mathrm{id}$. Supposons donc que I n'ait pas d'objet final. Comme I grande devant π_0 et $\pi_0 > \mathrm{card}\, \mathrm{Ob}\, \mathcal{C}$, on voit qu'il existe un $x_0 \in \mathrm{Ob}\, \mathcal{C}$ tel que la sous-catégorie pleine $I' = I_{x_0}$ de I, formée des i tels que $x_i = x_0$, soit cofinale dans I. Comme $(x_i)_{i\in I}$ est essentiellement constant, il en est de même de $(x_{i'})_{i'\in I'}$, et on peut lui appliquer le critère 4.15.7.1, avec $J \longrightarrow I'$ cofinal. La démonstration montrera de plus que si I' ||
est grand devant π_0 (cardinal infini sans autres conditions), on peut supposer J grande devant π_0 ([186]). De plus, il est clair qu'on peut supposer J ordonnée. Comme $\pi_0 \geqslant \mathrm{card}\, \mathrm{Hom}(x_0, x_0)$, on voit encore qu'il existe un projecteur p dans x_0 tel que la partie $J_1 = J'$ de J, formée des j tels que $p_j = p$, soit cofinale. Étant cofinale, elle est également grande devant π_0. Donc on peut supposer que tous les p_j sont égaux à un même p. Les conditions 1°-4° deviennent :

1°) $p\tau_{j'j} = \tau_{j'j}p$ pour $j \leqslant j'$.

2°) Pour tout j, existe $j' \geqslant j$ avec

$$p\tau_{j'j} \;=\; \tau_{j'j}p \;=\; \tau_{jj'}\ .$$

3°) L'image $x_0^\natural$ du projecteur p dans x_0 existe.

4°) L'endomorphisme $\tau^\natural_{j'j}$ de $x_0^\natural$ est un isomorphisme, pour $j \leqslant j'$.

Or on a le [page 445]

184. et on peut supposer $J = i_0\backslash I \xrightarrow{\text{can.}} I$

185. La démonstration (légèrement réarrangée) montre qu'on peut prendre pour J une sous-catégorie (pas pleine) d'une catégorie $i_1\backslash I$, pour un objet convenable i_1 de I. On a donc $\mathrm{card}\, J \leqslant \pi$ si $\mathrm{card}\, I \leqslant \pi$, π étant un cardinal infini donné.

186. en tenir compte dans la démonstration de 4.15.7.1.

Commentary · Context [ms. 442]

Constancy in the ind-category and constancy of a diagram

The distinction Grothendieck is using belongs to the original ind-object formalism. In SGA 4, Exposé I, 8.5.3, the quotation marks around a formal inductive limit indicate its formation in the ind-category; they prevent its identification with a colimit calculated in the original category. The same exposé, 8.7.8, locates the Karoubi envelope among retracts of representables (Artin et al., 1972). These pages return to that distinction because a small base category is supposed to stop a sufficiently filtered diagram from wandering. A surviving projector is the precise residue of that wandering.

Corollary 4.15.7.2 has the stronger hypothesis that there are *no nonidentity idempotents*. This is not another expression for idempotent completeness. A category of vector spaces is idempotent complete but has many projections. A groupoid has only identity idempotents and is therefore automatically idempotent complete. With the stronger hypothesis, every p_j in the preceding lemma is 1_{x_j}, and the image diagram is the original diagram.

There remains a small distinction even then. An isomorphism-valued diagram is naturally isomorphic to a constant diagram; its arrows need not literally be identities. To see the trivialization directly, fix j_0. For j, choose a common upper object k and put

$$\theta_j = x(j \to k)^{-1} x(j_0 \to k) : x_{j_0} \longrightarrow x_j.$$

Filteredness makes this independent of the common upper object and of the chosen arrows, and gives $x(\lambda)\theta_j = \theta_{j'}$. The family θ is the required natural isomorphism. The later thinning argument obtains literal identity arrows by passing to a further subsystem. Keeping these two operations apart will matter in Theorem 4.15.9, where the printed condition b) incorrectly demands identity arrows on an entire tail.

Commentary · Examples [ms. 443]

A two-element monoid which creates one missing retract

The projectors in the criterion are necessary even when the category is as small as possible. Let $\mathcal{C}$ have one object c and endomorphism monoid

$$M = \{1, p\}, \qquad p^2 = p, \qquad p \neq 1.$$

Choose any infinite regular ordinal κ, regard it as a directed poset, and form the diagram which has value c at every stage and transition p at every strict inequality. Composition holds because $p^2 = p$; identity arrows still have value 1.

The representable h_c has value M at the unique object. Every strict transition in its presheaf diagram is left multiplication by p, sending both elements to p. Consequently

$$X(c) = \varinjlim_{\alpha<\kappa} M = \{*\}.$$

The two elements of each stage become equal after one transition, and the resulting class is nonempty. The presheaf X is therefore the one-element right M-set, with both elements of M acting identically. It is a retract of h_c: the unique map $M \to \{*\}$ has the equivariant section $* \mapsto p$. Their composite on M is precisely left multiplication by p.

Yet X is not representable in $\mathcal{C}$, since its value has one element whereas the only representable has two. The ind-object is not essentially constant. The projectors commute, eventually absorb every transition, and induce identity maps on their images in the presheaf category; condition 3 of 4.15.7.1 fails exactly because that image does not belong to $\mathcal{C}$.

The Karoubi envelope repairs the defect by adjoining an object $d = (c, p)$. Explicitly,

$$\mathrm{Hom}(c, d) = \{p\}, \quad \mathrm{Hom}(d, c) = \{p\}, \quad \mathrm{End}(d) = \{p\},$$

where the last p is the identity of d. The composite $d \to c \to d$ is 1_d, and the reverse composite is the original endomorphism p of c. In this enlarged category the same diagram represents d.

Taking $\kappa = \pi^+$ makes the indexing poset grand devant π for any chosen infinite π. Thus increasing the cardinal cannot remove the need to split idempotents. It is the conclusion *Karoubi envelope*, rather than the original category, which survives without a hypothesis on projectors.

Lemme 4.15.7.4. *Soient $\mathcal{C}$ une catégorie, x_0 un objet de $\mathcal{C}$, p un projecteur dans x_0, τ un endomorphisme de x_0 satisfaisant les relations*

$$(*) \qquad \tau p \;=\; p\tau \;=\; \tau \;,$$

et tel que l'automorphisme de $x_0^\natural \overset{\text{déf}}{=} \operatorname{Im} p$ (défini p.ex. comme objet de $\mathcal{C}^\wedge$, $x_0^\natural = \operatorname{Ker}(\mathrm{id}_{x_0}, p)$ p. 171 *soit l'identité. Alors on a $\tau = p$.*

DÉMONSTRATION DE 4.15.7.4. On est ramené aussitôt, par le procédé standard, au cas où $\mathcal{C} = \mathrm{Ens}$, où la vérification est immédiate : les automorphismes τ de l'ensemble E $(= x)$ qui satisfait $(*)$ correspondent biunivoquement aux endomorphismes u de $E^\natural = pE$, via

$$\begin{cases} u \;\longmapsto\; \sigma u \rho \\ \tau \;\longmapsto\; \tau | E^\natural \end{cases} \qquad (\text{où} \quad E^\natural \underset{\rho}{\overset{\sigma}{\rightleftarrows}} E \quad \text{sont les flèches canoniques}) \;,$$

donc $\tau | E^\natural = \mathrm{id} \Longrightarrow u = \sigma\rho = p$.

Choisissons un $j_0 \in J$, et considérons les homomorphismes

$$\tau^\natural_{j,j_0} \;:\; x_0^\natural \longrightarrow x_0^\natural$$

induits par les τ_{j,j_0} avec $j \geqslant j_0$. Ici encore, comme l'ensemble des isomorphismes possibles est de

cardinal $\leqslant \pi_1$, et J/j_0 est grande devant π_0, on voit qu'il existe $J' \subset j_0\backslash J$, cofinale dans [page 446] $j_0\backslash J$, donc dans J, telle que pour $j \in J'$, les $\tau^\natural_{j,j_0}$ soient égaux à un même $\tau : x_0^\natural \xrightarrow{\sim} x_0^\natural$. Donc si $j', j'' \in J'$, avec $j' \leqslant j''$, on a

$$\underbrace{\tau_{j''j_0}}_{\tau} \;=\; \tau_{j''j'} \; \underbrace{\tau_{j'j_0}}_{\tau} \;,$$

d'où

$$\tau_{j''j'} \;=\; \mathrm{id}_{x_0^\natural} \;,$$

puisque la flèche τ est un isomorphisme. Donc le système inductif réindexé par J', la condition 4° est remplacée par la condition plus stricte $\boxed{4°\text{ bis) } \tau^\natural_{j',j} = \mathrm{id}_{x_0^\natural}.}$ Mais la condition 2° devient alors, grâce à 4.15.7.4,

$$\boxed{2°\text{ bis) Pour tout } j, \text{ existe } j' \geqslant j \text{ avec } \tau_{j',j} = p} \;.$$

Donc, on peut supposer 1°, 2° bis, 3°, 4° bis (on désigne à nouveau par J, au lieu de J', l'ensemble ordonné grand devant π_0 indexant).

Soit K l'ensemble ordonné défini par

[page 447]

$$\begin{cases} \operatorname{Ob} K \;=\; \operatorname{Ob} J \\ \text{si } j, j' \in \operatorname{Ob} J, \text{ on a } j \overset{K}{\leqslant} j' \text{ si et seulement si } j \overset{\mathrm{J}}{=} j', \text{ ou } j \overset{J}{<} j' \text{ et } \tau_{j',j} = p \,. \end{cases}$$

Il est immédiat que c'est une *relation d'ordre* sur J (car $p^2 = p$), plus fin que la relation d'ordre initiale. Le système inductif induit sur K satisfait aux conditions 1°, 2°, 3° de 4.15.7.3. D'autre part, $K \longrightarrow J$ est cofinal, donc aussi le composé $K \longrightarrow J \longrightarrow I$. Il reste à prouver que K est grande devant π_0, donc que toute partie $K' \subset K$ telle que $\operatorname{card} K' \leqslant \pi_0$ admet un majorant dans K. Elle admet un majorant *dans* J, soit j. Par hypothèse 2 bis, il existe $j' \geqslant j$ tel que $\tau_{j'j} = p$, et on peut supposer $j' > j$. (En effet, si $\tau_{j'j} = p$, on voit que la forme p. 172 initiale 2°) de la condition 2° bis que l'on a $\tau_{j''j} = p$ pour tout $j'' \geqslant j'$, donc si j n'est par [page 448] objet final de J, on peut supposer $j' > j$. Mais J n'a pas d'objet final, car sinon I en aurait

un, cas que l'on avait éliminé. Donc il existe j' tel que $j' \overset{K}{>} j$.) Or on a ceci (qu'on applique au cas $i \in K'$) :

$$i \leqslant j \ \text{ et } \ j \overset{K}{<} j' \qquad \Longrightarrow \qquad i \overset{K}{<} j' \ .$$

$$\underbrace{x_i}_{=x_0} \xrightarrow{\tau_{j,i}} x_j \xrightarrow{\tau_{j',j}=p} x_{j'} \ ,$$

$$\tau_{j'i} \ = \ \tau_{j'j}\tau_{ji} = \underbrace{p\tau_{ji}}_{\overset{1^\circ}{=}\tau_{ji}p} \overset{?}{=} \ p \ ,$$

on a en effet

$$\left.\begin{aligned} \tau_{j',i} \ &= \ p\tau_{j',i} \\ \tau_{j',i} \ &- \ \tau_{j',i}p \end{aligned}\right\} \quad \overset{\text{par } 4.15.7.4}{\Longrightarrow} \quad \tau_{j',i} \ = \ p \ .$$

Cela achève la démonstration du corollaire 4.15.7.3.

Corollaire 4.15.7.5 (de 4.15.7.3). *Soit $(x_i)_{i\in I}$ un système inductif essentiellement constant grand devant $\pi_0 \geqslant \operatorname{card}\mathcal{C}$, dans $\mathcal{C}$* sans projecteurs. *Alors il existe $J \longrightarrow I$ cofinal, avec J ordonné grand devant π_0, et tel que le système inductif induit sur J soit* constant.

Démontrons le lemme 4.15.7.1. Il faut expliciter l'existence de deux flèches dans $\mathrm{Ind}(\mathcal{C})$,

$$z \underset{\beta}{\overset{\alpha}{\rightleftarrows}} \text{"}\varinjlim_{i\in I}\text{"} x_i \ = \ \underline{x} \ ,$$

avec $\beta\alpha = \mathrm{id}_z$, $\alpha\beta = \mathrm{id}_{\underline{x}}$. La donnée

de x équivaut à celle d'un élément de $\varinjlim_{i\in I} \mathrm{Hom}(z, x_i)$, et est donc donné par un [page 449]

$$\alpha_{i_0} \ : \ z \longrightarrow x_{i_0} \ ,$$

la donnée de β équivaut à celle d'un élément de $\varprojlim_{i\in I} \mathrm{Hom}(x_i, z)$, i.e. de flèches

$$\beta_i \ : \ x_i \longrightarrow z \ ,$$

avec la condition de compatibilité habituelle. Quitte à remplacer I par I', avec $I' \longrightarrow I$ cofinal, on peut supposer I ordonnée (et grande devant π_0, si I initiale l'était), et la condition de compatibilité sur les β_i s'écrit

$$\beta_i\tau_{ji} \ = \ \beta_j \qquad \text{si } i \leqslant j \text{ dans } I,$$

où $\tau_{ji} : x_i \longrightarrow x_j$ désigne la flèche de transition. Il faut expliciter, en termes de ces données, les conditions

$$\alpha\beta \ = \ \mathrm{id}_z \ , \qquad \beta\alpha \ = \ \mathrm{id}_{\underline{x}} \ .$$

Commentary · Exposition [ms. 448]

A cofinal subsystem with one projector

The purpose of 4.15.7.3 is stronger than representability. Grothendieck needs a presentation whose arrows in the small base are literally controlled, so that a diagram upstairs can be studied in one fibre. The argument combines a cardinal pigeonhole principle with a careful deletion of arrows. Both operations preserve the filteredness needed later.

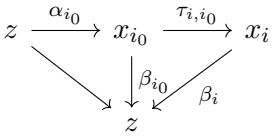
Throughout this argument, grand devant π_0 means that diagrams with at most π_0 morphisms admit a cocone. For a poset this says that every subset of cardinal at most π_0 has an upper bound; in modern terminology it is π_0^+-directed. Suppose such a poset I is coloured by a set A of at most π_0 colours. If no colour fibre were cofinal, we could choose, for every $a \in A$, an element i_a above which colour a never occurs. A common upper bound of all i_a would have no colour. Hence one fibre

is cofinal. A cofinal full subposet remains π_0^+-directed, since an upper bound in I can be moved into that subposet.

Replace the original index by a final π_0^+-directed poset, using the usual cofinal-poset theorem (also Lurie, 2009, Proposition 5.3.1.18 in its higher form). First apply this principle to the objects x_i, and then to the projectors supplied by 4.15.7.1. We obtain a fixed object x_0 and a fixed split idempotent p. Fixing a base index and applying the principle once more makes the isomorphisms from its image to the later images equal. Cancellation of these isomorphisms makes all induced transitions on $\operatorname{Im} p$ identities. There are at most π_0 possible image automorphisms: if $p = sr$ with $rs = 1$, the map $u \mapsto sur$ embeds their set into $\operatorname{End}_{\mathcal{C}}(x_0)$.

The elementary identity behind the remaining step is

$$\tau p = p\tau = \tau, \quad r\tau s = 1 \quad \Longrightarrow \quad \tau = sr\tau sr = s(r\tau s)r = p.$$



Thus the eventual absorption condition says that every index eventually maps by p. Define K on the same objects by retaining identities and only those strict arrows whose value is p. Transitivity follows from $p^2 = p$. To see that K remains π_0^+-directed, take at most π_0 objects and choose a common upper bound j in the old order. Choose $j' > j$ with $\tau_{j'j} = p$; the terminal-object case is treated separately by a singleton index. For each chosen i,

$$\tau_{j'i} = p\tau_{ji}.$$

This arrow is absorbed by p on both sides, and its action on the image is the identity. The displayed identity therefore gives $\tau_{j'i} = p$. Hence j' is an upper bound in K.

The inclusion $K \to J$ is final as a functor, not merely surjective on objects. For a fixed $j \in J$, the comma category j/K is nonempty; any two of its objects acquire a common upper object in K by the same construction. It is a directed poset and therefore connected. This is the missing explicit finality verification. The conclusion has exactly the form required: one object, one idempotent on every strict transition, and a sufficiently directed indexing category. The printed π_1 and lower slice J/j_0 on manuscript p. 446 should be read as π_0 and $j_0\backslash J$; they are retained in the source text and registered separately.

p. 173

La relation $\alpha\beta = \mathrm{id}_z$ équivaut à

$$(*_{i_0}) \qquad \beta_{i_0}\alpha_{i_0} \;=\; \mathrm{id}_z \;,$$

elle implique d'ailleurs, en posant pour $i \geqslant i_0$,

$$\alpha_i \;\overset{\text{déf}}{=}\; \tau_{i,i_0}\alpha_{i_0} \;:\; z \longrightarrow x_i \;,$$

que l'on a pour $i \geqslant i_0$

$$(*_i) \qquad \beta_i\alpha_i \;=\; \mathrm{id}_z \qquad \forall\, i \geqslant i_0 \;.$$

Posons alors

$$p_i \;=\; \alpha_i\beta_i \;:\; x_i \longrightarrow x_i \;, \qquad \text{[page 450]}$$

il est clair qu'on a

$$\begin{cases} p_i^2 \;=\; p_i \qquad (p_i \text{ un projecteur}) \\ \alpha_i \;:\; z \longrightarrow x_i \qquad \text{induit un isomorphisme} \\ \qquad z \xrightarrow{\sim} x_i^\natural \;\overset{\text{déf}}{=}\; \operatorname{Im} p_i \;=\; \operatorname{Ker}(\mathrm{id}_{x_i}, p_i) \;. \end{cases}$$

L'ensemble ordonné cofinal cherché J est $i_0\backslash I$, il est filtrant, et est grand devant π_0 si I l'est. À vrai dire, la réduction au cas I ordonné est inutile, on peut prendre directement $J = i_0\backslash I$,

il est immédiat que J est filtrante (I l'étant), et $i_0\backslash I \longrightarrow I$ cofinal, enfin que si I est grande devant un cardinal infini π_0, il en est de même de $i_0\backslash I$.

Exprimons que $\beta\alpha = \mathrm{id}_{\underline{x}}$; or on voit que $\beta\alpha$ est défini par l'endomorphisme $(p_j)_{j\in J}$ du système inductif $(x_j)_{j\in J}$ – le fait que ce soit bien un endomorphisme de ce système, i.e. qu'on ait la relation 1°) de 4.15.7.1,

$$p_{j'}x_\lambda \;=\; x_\lambda p_\lambda \qquad \text{si } \lambda : j \longrightarrow j' \text{ dans } J,$$

est immédiat, ça s'écrit

$$\alpha_{j'}\underbrace{\beta_{j'}x_\lambda}_{\beta_j} \;=\; \underbrace{x_\lambda\alpha_j}_{\alpha_{j'}}\beta_j\ , \qquad \text{or les deux membres sont égaux à } \alpha_{j'}\beta_j.$$

Dire que c'est l'identité, est exprimé par la condition 2°) sur $(x_j, p_j)_{j\in J}$. La condition 3° est clair par construction, p_j admettant une image isomorphe à z par α_j. D'autre part, on voit [tout] de suite que pour une flèche $\lambda : j \longrightarrow j'$ de J, on a commutativité dans p. 174 [page 451]

$$\begin{array}{ccc} x_j & \xrightarrow{x_\lambda} & x_{j'} \\ \uparrow & & \uparrow \\ x_j^\natural & \xrightarrow{x_\lambda} & x_{j'}^\natural \\ \wr\uparrow{\scriptstyle \overline{\alpha_j}} & & \wr\uparrow{\scriptstyle \overline{\alpha_{j'}}} \\ z & \xrightarrow[\sim]{\mathrm{id}_z} & z\ , \end{array}$$

où $\overline{\alpha_j}$, $\overline{\alpha_{j'}}$ sont les isomorphismes définis par α_j, $\alpha_{j'}$ respectivement. Cela prouve que $x_\lambda^\natural$ est un isomorphisme.

Cela prouve que si $(x_i)_{i\in I}$ est essentiellement constant, il existe $J \longrightarrow I$ comme indiqué. L'inverse est également vrai, car on peut supposer $J = I$, puisque $(x_i)_{i\in I}$ et $(x_j)_{j\in J}$ définissent des ind-objets isomorphes. Alors le système inductif des $x_j^\natural$ a des morphismes de transition des isomorphismes, et comme J est filtrante donc 1-connexe, on en déduit facilement qu'il est isomorphe à un système inductif constant, de valeur z. En choisissant un tel isomorphisme [page 452]

$$z \xrightarrow[\sim]{\overline{\alpha_i}} x_i^\natural\ ,$$

on trouve $z \xrightarrow{\alpha} \underline{x}$, et le système des p_i définit des

$$x_i \xrightarrow{\overline{p_i}} x_i^\natural \xrightarrow{\overline{\alpha_j}^{-1}} z\ , \qquad \beta_i \overset{\text{déf}}{=} \overline{\alpha_j}^{-1}\overline{p_i}$$

et on voit facilement que l'on aura

$$\beta\alpha \;=\; id_z\ , \qquad \alpha\beta \;=\; \mathrm{id}_{\underline{x}}\ ,$$

q.e.d.

Je peux maintenant prouver 4.15.3. C'est en effet essentiellement la conjonction des 4.15.7.5 (p. 448), et de 4.8.13, qui nous dit essentiellement que si $\mathcal{C}$ est *karoubienne* (condition vérifiée si $\mathcal{C}$ est sans projecteurs), alors tout système inductif dans $\mathcal{C}$, grand devant π_0, où $\pi_0 \geqslant \mathrm{card}\ \mathrm{réd}\,\mathcal{C}$, est essentiellement constant,

q.e.d.

4.15.8. Je veux revenir ici sur la démonstration inachevée de 4.8.13 (p. 212-216). Je reprends la démonstration où je l'avais laissée (p. 215). Il faut prouver que p. 175 [page 453]

$$F(\xi) \;=\; \varinjlim_{i\in I} M_i$$

est de cardinal $\leqslant \pi_0$. J'ai annoncé qu'on peut se ramener au cas où M est un monoïde de monomorphismes, i.e. que $uv = uv' \Longrightarrow v = v'$ (pour $u, v, v' \in M$). Je vais expliciter cet argument.

Pour tout $i \in I$, soit

$$N_i \;=\; \left\{ u \in M \;\middle|\; \begin{array}{l} \text{l'ensemble } I_{i,u} \text{ des } j \in I \text{ tels} \\ j \geqslant i,\ \alpha_{ji} = u \text{ est cofinal} \\ \text{dans } I, \text{ i.e. pour tout } j_0 \in I, \\ \text{existe } j \in I_{i,u}, \text{ avec } j \geqslant j_0 \end{array} \right\}. \tag{4.15.8.1}$$

Comme I, donc $i\backslash I$ est grande devant π_0, et $\operatorname{card} M \leqslant \pi_0$, on voit aussitôt que

$$N_i \;\neq\; \emptyset\ . \tag{4.15.8.2}$$

(Si d'autre part $i' \geqslant i$, on trouve

$$N_i \;=\; N_{i'}\alpha_{i'i}\ . \tag{4.15.8.3}$$

L'inclusion $N_{i'}\alpha_{i'i} \subset N_i$ est ± tautologique, prouvons $N_i \subset N_{i'}\alpha_{i'i}$. Soit $u \in N_i$, l'ensemble $J = I_{i,u} \cap (i'\backslash I)$ des $j \geqslant i'$ tels que $\alpha_{ji} = u$ est cofinal dans I, donc grand devant π_0.

$$i \xrightarrow[u=\alpha_{ji}]{} i' \xrightarrow{\alpha_{ji'}} j$$

Donc il existe un $v \in M$ tel que l'ensemble J' de $j \in J$ tels que $\alpha_{ji'} = v$ soit cofinal dans J, donc dans I. Comme cet ensemble J' est contenu dans $I_{i',v}$, cela implique que $I_{i',v}$ est cofinal dans I, i.e. $v \in N_{i'}$. On a d'autre part, pour $j \in J'$, [page 454]

$$\underbrace{\alpha_{ji'}}_{v}\alpha_{i'i} \;=\; \underbrace{\alpha_{ji}}_{u}\ ,$$

d'où $u = v\alpha_{i'i}$ avec $v \in N_{i'}$, d'où $u \in N_i\alpha_{i'i}$, q.e.d.)

Pour $i \in I$, soit

$$\alpha_i \;:\; \underbrace{\operatorname{Hom}(\xi, \underbrace{x_i}_{=\xi})}_{=M} \longrightarrow \underbrace{\operatorname{Hom}(\xi, F) \;=\; F(\xi)}_{\simeq \varinjlim_i \operatorname{Hom}(\xi, x_i)}$$

le morphisme canonique. On trouve ceci : p. 176

(4.15.8.4) Si $u \in N_i$, alors la relation d'équivalence R_i dans M définie par α_i ($v \overset{R_i}{\sim} v' \Longleftrightarrow \alpha_i(v) = \alpha_i(v')$) est égale à celle définie par l'application $v \longmapsto uv$ de M dans M, i.e.

$$\alpha_i(v) \;=\; \alpha_i(v') \qquad \Longleftrightarrow \qquad uv \;=\; uv'\ .$$

C'est immédiate, puisque $I_{i,u}$ étant cofinal dans I, on a $\alpha_i(v) = \alpha_i(v')$ si et seulement si $\exists\ j \in I_{i,u}$ avec $\alpha_{ji}v = \alpha_{ji}v'$, or $\alpha_{ji} = u$.

Pour $u \in M$, notons R_u la relation d'équivalence dans M définie par $v \longmapsto uv$. L'ensemble des relations d'équivalence dans $[M]$ obtenu ainsi est de cardinal $\leqslant \operatorname{card} M \leqslant \pi_0$, donc l'ensemble des relations d'équivalences R_i ($i \in I$) est lui aussi de cardinal $\leqslant \pi_0$. Cela montre, π_0 étant grand devant π_0, qu'il existe une relation d'équivalence de la forme R_u ($u \in M$), et un ensemble cofinal I' dans I, tel que $\forall\ i \in I'$ on ait $R_i = R_u$. Cela montre que, quitte à remplacer I par l'ensemble ordonné cofinal I', qu'on peut supposer que l'on a [page 455]

$$R_i \;=\; R_u \qquad \forall\, i \in I\ . \tag{4.15.8.5}$$

Soit alors

$$E \;=\; M/R_u \;=\; M/R_i \qquad (\forall\, i \in I)\ ,$$

on voit donc que les $\alpha_{ji} \in M$ (pour $i \leqslant j$) sont tels que l'application

$$\tau_{\alpha_{ji}} \;:\; v \;\longmapsto\; \alpha_{ji} v \;:\; M \;\longrightarrow\; M$$

est compatible avec la relation d'équivalence R_u, donc passe au quotient en une application

$$\overline{\alpha_{ji}} \;:\; E \;\longmapsto\; E\ ,$$

laquelle est d'ailleurs *injective.*

Soit M' le sous-monoïde de M formé des $u \in M$ qui ont la propriété de stabilité précédente, ainsi que la propriété d'injectivité qu'on vient de dire, et $\overline{M'}$ le monoïde image de M' dans le monoïde

$$\mathrm{Mon}(E) \;\subset\; \mathrm{End}_{\mathrm{Ens}}(E)$$

des applications injectives de E dans lui-même. On voit donc que le système inductif donné, défini par les α_{ji}, prend ses valeurs dans le sous-monoïde M' de M (i.e. de la sous-catégorie correspondante de la catégorie B_M), et que la limite inductive $F(\xi)$ qui nous intéresse (pour prouver $\mathrm{card}\, F(\xi) \leqslant \pi_0$) est isomorphe à la limite inductive du système inductif d'un système d'ensembles tous égaux à E, les morphismes de transition étant les $\overline{\alpha_{ji}} \in \overline{M'} \subset \mathrm{Mon}(E)$. De plus, on aura $\mathrm{card}\, \overline{M'} \leqslant \mathrm{card}\, M \leqslant \pi_0$. Le résultat $\mathrm{card}\, F(\xi) \leqslant \pi_0$ voulu résultera alors du [page 456]

Commentary · Exposition [ms. 455]

Removing identifications before counting new elements

The obstruction to a cardinal estimate is that a transition may both identify old elements and introduce new ones. Grothendieck separates these effects. The sets N_i record the transition maps which recur cofinally; each such map already detects every identification made after stage i.

For $u \in N_i$ and $v, v' \in M$, equality of the two classes in $\varinjlim M_j$ is witnessed at some later stage. Moving further into the cofinal fibre where the transition from i equals u gives

$$[v]_i = [v']_i \quad\Longleftrightarrow\quad uv = uv'.$$

The converse follows at any stage in that fibre. Thus the kernel relation R_i is one of the at most $|M|$ relations R_u. The cofinal-colour argument gives a subsystem with $R_i = R$ independent of i.

Passing from M to $E = M/R$ now removes exactly the identifications which the final colimit would make. The induced transition maps of E are injective: equality of the images of $[v]$ and $[v']$ implies equality of their final classes, hence vRv'. The total colimit is unchanged, because no additional equivalence has been imposed. What remains to be counted is actual growth by inclusions.

There is a useful bookkeeping point in this construction. The elements of M which preserve R and act injectively on E form a *submonoid* M_1. Its image

$$\overline{M_1} \subseteq \mathrm{Inj}(E, E)$$

is a quotient of M_1, has cardinal at most $|M|$, and is left cancellative. It need not be a quotient of the whole monoid M. Consequently the reduction on these pages proves a sufficient criterion involving such subquotients. The restricted quotient wording in 4.15.9 b) is not justified by this reduction alone.

The distinction does not affect the strict-cardinal conclusion. Its counting argument applies to *every* left-cancellative monoid below the chosen bound, including these subquotients. It does matter if one tries to read 4.15.9 as a sharp equivalence for one fixed category and one fixed cardinal. We retain the useful reduction while recording exactly what its proof supplies.

Lemme-clef 4.15.8.1. *Soit M un monoïde de monomorphismes (i.e. tel que $uv = uv' \Longrightarrow v = v'$, pour $u, v, v' \in M$), et soit $(\alpha_{ji})_{i \leqslant j}$ un système inductif dans B_M, indexé par un ensemble ordonné I grand devant π_0, où π_0 est un cardinal infini tel que* $\mathrm{card}\, M \leqslant \pi_0$. *Alors il existe un $i_0 \in I$ tel que pour tout $i \geqslant i_0$, $\alpha_{i_0,i}$ soit un isomorphisme.* p. 177 [page 457]

Commentary · Examples [ms. 456]

An ordinary filtered sequence which really grows

The increased filteredness assumption is doing real work. To measure it against a familiar sequence, take the one-object category with endomorphism monoid $(\mathbf{N}, +)$, whose identity is 0. At every integer stage put the unique object, and give the transition $i \to j$ the value $j - i$. Every strict transition is a nonunit.

Evaluating its ind-object at the unique object gives the sequence of regular right $\mathbf{N}$-sets

$$\mathbf{N} \xrightarrow{n \mapsto n+1} \mathbf{N} \xrightarrow{n \mapsto n+1} \mathbf{N} \longrightarrow \cdots .$$

Its colimit is $\mathbf{Z}$, with the usual action by addition of nonnegative integers. An explicit isomorphism sends the class of a at stage i to $a - i$. The transition relation preserves this difference. Every integer occurs by choosing i large enough, and two representatives with the same difference become equal at any stage above their two indices. This verifies both surjectivity and injectivity of the description.

The resulting right $\mathbf{N}$-set is not representable. The sole representable is $\mathbf{N}$, and an equivariant map $\mathbf{Z} \to \mathbf{N}$ cannot exist: if its value at 0 were b, equivariance would force the value at $-n$ to be $b - n$, which is negative for $n > b$. In particular $\mathbf{Z}$ is not a retract of the representable. Equivalently, the only idempotent of the additive monoid $\mathbf{N}$ is 0, so its Karoubi envelope adds nothing.

This sequence is filtered in the ordinary sense, but its index $\mathbf{N}$ is not grand devant $\aleph_0$: the whole countable set of indices has no upper bound. The next proposition shows that a diagram in the same monoid indexed by an $\aleph_1$-directed poset must have a constant tail. There is no contradiction with the explicit colimit above. The regular cardinal attached to the word filtered, and the source's successor convention, determine which of the two phenomena occurs.

Si on applique ce lemme au cas de $\overline{M'}$ et du $\overline{\alpha_{ji}}$, on trouve donc qu'il existe un $i_0 \in I$ tel que les $\overline{\alpha_{ji_0}}$ soient des isomorphismes. Cela implique que $F(\xi) \simeq \varinjlim_{i} \underbrace{E_i}_{E}$ est isomorphe à E_{i_0}, donc est de cardinal égal à $\operatorname{card} E_{i_0} = \operatorname{card} E \leqslant \pi_0$, ce qui achèvera la démonstration.

D'ailleurs, l'énoncé 4.8.13 implique 4.15.8.1, car dans le système inductif des $(M_i = M, \alpha_{ji})$, de $\varinjlim$ égale à $F(\xi)$, s'il n'existait *pas* de i_0 comme stipulé dans 4.15.8.1, alors on en conclurait aisément que l'on aurait $\operatorname{card} F(\xi) > \pi_0$, contrairement à 4.8.13. Nous allons dégager ceci dans un lemme :

Lemme 4.15.8.2. *Soit $(E_i)_{i \in I}$ un système inductif d'ensembles, indexé par un ensemble ordonné I grand devant π_0. On suppose qu'il existe $i_0 \in I$ tel que* [page 458]

a) $i \geqslant i_0$ *implique* $\operatorname{card} E_i = \pi_0$, *et*

b) $j \geqslant i \geqslant i_0$ *implique que* $u_{ji} : E_i \longrightarrow E_j$ *est un monomorphisme. Supposons de plus*

c) $\forall\, i \geqslant i_0\ \exists\, j > i$ *tel que* u_{ji} *ne soit* pas *un isomorphisme (i.e. ne soit pas surjectif). Soit* $E_\infty = \varinjlim_{i \in I} E_i$. *Alors* $\operatorname{card} E_\infty > \pi_0$.

Ce lemme implique donc l'*équivalence* de 4.8.13 et du "lemme-clef" 4.15.8.1. Pour prouver 4.15.8.2, nous allons prouver quelque chose d'un peu plus précis :

Commentary · Development (commentators') [ms. 457]

A boundary case controlled by right cancellation

Grothendieck has reduced his remaining difficulty to a monoid of injections. The source obtains a strict cardinal bound below. At the boundary, a recurring transition supplies an additional way to conclude if it can also be cancelled on the right. We record that limited extension, since it identifies the algebraic obstacle more precisely than the cardinal count alone.

Proposition: a cancellable recurring transition. [ours] Let π be infinite, let I be a π^+-directed poset, and let (a_{ji}) be a diagram in a left-cancellative monoid M of cardinal at most π. Suppose that, for some i_*, a cofinally recurring value u of a_{ji_*} is right cancellable: $vu = wu$ implies $v = w$. Then there is j_0 such that every a_{ij_0}, $i \geq j_0$, is a unit. On a cofinal full subposet all transitions are identities.

Proof. Let $J = \{j \geq i_* : a_{ji_*} = u\}$, which is cofinal by assumption. If $j \leq k$ belong to J, the cocycle identity gives

$$u = a_{ki_*} = a_{kj} a_{ji_*} = a_{kj} u.$$

Right cancellation gives $a_{kj} = 1$. Choose $j_0 \in J$. Given $i \geq j_0$, choose $k \in J$ with $k \geq i$. Then $a_{ki}a_{ij_0} = a_{kj_0} = 1$. In a left-cancellative monoid, $ab = 1$ also implies $ba = 1$, since $a(ba) = a = a1$. Thus a_{ij_0} is a unit. Moreover, for $j \geq i \geq j_0$,

$$a_{ji} = a_{jj_0}a_{ij_0}^{-1}$$

is a unit. The full subsystem on J already has identity transitions. This proves all assertions.

Corollary: two-sided cancellation. [ours] The key lemma 4.15.8.1 holds with $|M| \leq \pi$, including equality, if M is cancellative on both sides. More generally, if $|\operatorname{Mor}\mathcal{C}| \leq \pi$ and every endomorphism monoid of $\mathcal{C}$ is cancellative on both sides, every π^+-filtered diagram in $\mathcal{C}$ is essentially constant.

Proof. In the monoid case the cofinal-colour principle supplies a recurring u, and every u is right cancellable. For a general category, first replace the index by a final π^+-directed poset. Apply that principle to its at most π object values, obtaining a cofinal full subposet with one value x. The diagram now takes values in $\operatorname{End}(x)$, and the proposition supplies a further cofinal subsystem with identity transitions. Its presheaf colimit is h_x.

We checked the small-category and Cauchy-completion treatments cited below, together with searches for the left-cancellative stabilization formulation; we did not find this exact recurring-value statement in the literature consulted. The proof is an elementary continuation of Grothendieck's cofinal-fibre argument, with no claim of priority. It does not settle the general left-cancellative case: from $vu = u$ one cannot cancel u on the right without the extra hypothesis.

Corollaire 4.15.8.3. *Sous les conditions de 4.15.8.2, soit α_0 le premier ordinal tel que* $\operatorname{card}\alpha_0 > \pi_0$, *et soit I_{α_0} l'ensemble des ordinaux $\beta < \alpha$ (ensemble ordonné qui est grand devant π_0). Il existe alors une application strictement croissante*

$$I_{\alpha_0} \longrightarrow I\ , \qquad \alpha \longmapsto i_\alpha\ , \qquad \textit{appliquant } 0 \textit{ dans } i_0\ ,$$

tel que pour tout $\alpha \in I_{\alpha_0}$, on ait [page 459]

$$\underbrace{u_{i_{\alpha+1},i_\alpha}}_{\substack{\textit{c'est un } \text{monomorphisme,}\\ \textit{d'après b, vu que } i_{\alpha+1} > i_\alpha \geqslant i_0}} \qquad \textit{n'est pas un isomorphisme } ([187]).$$

On a alors

$$E'_\infty \overset{\text{déf}}{=} \underbrace{\varinjlim_{\alpha\in I_{\alpha_0}} E_{i_\alpha}}\ \hookrightarrow\ \varinjlim_{i\in I} E_i \overset{\text{déf}}{=} E_\infty$$

et

$$\operatorname{card} E'_\alpha \ \geqslant\ \underbrace{\operatorname{card} I_{\alpha_0}}_{=\ \textit{successeur de } \pi_0}\ >\ \pi_0\ ,$$

d'où $\operatorname{card} E_\infty \geqslant \operatorname{card} E'_\infty > \pi_0$.

Démonstration. La construction des i_α par récurrence transfinie est immédiate, en utilisant c) et le fait que I est grande devant π_0, et que pour tout $\alpha \in I_{\alpha_0}$, l'ensemble I_α des $\beta < \alpha$ est de cardinal $\leqslant \pi_0$. Le fait que $E'_\infty \longrightarrow E_\infty$ soit injectif résulte de b). Le fait que [p. 178]

$$\operatorname{card} E'_\infty \ \geqslant\ \operatorname{card} I_{\alpha_0}$$

résulte du fait que E'_∞ est réunion croissante de sous-ensembles identifiés à E_{i_α}, et pour tout α on peut trouver un [page 460]

$$\xi_\alpha \ \in\ E_{i_\alpha} \setminus \bigcup_{\beta<\alpha} E_{i_\beta}\ .$$

187. *mieux* : $\forall\ \alpha \in I_{\alpha_0}\ \varinjlim_{\beta\in I_\alpha} E_{i_\beta} \longrightarrow E_{i_\alpha}$ n'est pas surjectif.

L'application

$$\begin{aligned} \alpha &\longmapsto \xi_\alpha \\ I_{\alpha_0} &\longrightarrow E'_\infty \end{aligned}$$

est injective, donc $\operatorname{card} E'_\infty \geqslant \operatorname{card} I_{\alpha_0}$.

Corollaire 4.15.8.4. *Pour un M et un π_0 donnés, pour que le lemme-clef 4.15.8.1 soit valable, il faut et il suffit qu'il le soit dans le cas où $I = I_{\alpha_0}$, α_0 étant le premier ordinal tel que $\operatorname{card} \alpha_0 > \alpha_0$. Il revient au même qu'on ne puisse trouver de système inductif $(\alpha_{ji})_{j \geqslant i}$ indexé par I_{α_0}, à valeurs dans M, tel que pour $i < j$, on ait α_{ji} non inversible dans M.*

Je vais résumer ce qui a été obtenu dans un énoncé récapitulatif : [page 461]

Commentary · Exposition [ms. 460]

The transfinite growth argument, including limit stages

The point of 4.15.8.2 is to turn the failure of stabilization into too many distinct elements. Once transitions are injective, an element genuinely added at one stage can never disappear. The only care needed is at limit ordinals, where successive strict growth by itself does not guarantee that the next stage adds something beyond the whole preceding union.

Put $\kappa = \pi_0^+$. Starting at the prescribed i_0, choose a chain i_α for $\alpha < \kappa$. At a successor stage use hypothesis c) to choose a nonsurjective transition. At a nonzero limit α, the earlier indices form a set of cardinal at most π_0, so they have an upper bound b. Pass from b to a stage i_α by a nonsurjective transition. Its image contains the image of every earlier stage, and is a proper subset of E_{i_α}. This produces precisely the strengthened assertion in footnote 187:

$$\varinjlim_{\beta<\alpha} E_{i_\beta} \longrightarrow E_{i_\alpha} \quad \text{is not surjective.}$$

At $\alpha = 0$ the domain is empty and the source hypothesis $|E_{i_0}| = \pi_0$ makes the assertion valid.

Choose ξ_α outside the preceding union. Injectivity ensures that all these elements remain distinct in the chain colimit. That colimit injects into the original colimit: two representatives which become equal in the latter are equal at a common later stage, and injectivity then identifies them already at a stage of the chain above their two indices. Consequently the original colimit contains at least κ elements.

The cardinal equality $|E_i| = \pi_0$ is not used to prove this lower bound, apart from the harmless nonemptiness at the first stage. This makes the lemma applicable to a monoid of cardinal *at most* π_0, as required just above it. One can alternatively start counting at successor stages and omit the initial nonemptiness assumption altogether.

For a left-cancellative monoid, left multiplication by a is surjective exactly when a is a unit: a preimage of 1 is a right inverse, which is also a left inverse by cancellation. Thus nonunits give precisely the nonsurjective injections needed here. A product containing a nonunit cannot be a unit in such a monoid. The selected chain therefore has every strict transition noninvertible, proving the reduction in 4.15.8.4 to the ordinal π_0^+. Its printed condition $|\alpha_0| > \alpha_0$ is impossible; the intended condition is $|\alpha_0| > \pi_0$.

Théorème 4.15.9. *Soient $\mathcal{C}$ une petite catégorie, π un cardinal tel que $\pi \geqslant \operatorname{card} \mathcal{C}$. Les conditions suivantes sont équivalentes (et je conjecture qu'elles sont toujours satisfaites) :*

a) $\mathcal{M} \overset{déf}{=} \operatorname{Ind}_\pi \mathcal{C}$ est réduit à $\mathcal{M}_\pi$.

a′) (Si $\mathcal{C}$ est karoubienne.) Tout système inductif $\underline{x} = (x_i)_{i \in I}$ dans $\mathcal{C}$, grand devant π, est essentiellement constant.

a″) Pour tout système inductif $(x_i)_{i \in I}$ dans $\mathcal{C}$, grand devant π, il existe un foncteur cofinal $J \longrightarrow I$, avec J ensemble ordonné grand devant π, et tel que le système réindexé $(x_j)_{j \in J}$ satisfasse les conditions suivantes :

1) Tous les x_j sont égaux à un même élément x de $\mathcal{C}$.

2) Il existe un projecteur p dans x, tel que l'on ait $\alpha_{j'j} = p$ pour $j < j'$ $(j, j' \in J)$, où $\alpha_{j'j} : x_j \longrightarrow x_{j'}$ est la flèche de transition.

b) Pour tout $x \in \mathrm{Ob}\,\mathcal{C}$, et pour tout monoïde quotient M' de $M = \mathrm{End}_{\mathcal{C}}(x)$, tel que M' soit un monoïde de monomorphismes (i.e. $uv = uv' \Longrightarrow v = v'$ si $u, v, v' \in M'$), et pour tout système inductif grand devant π à valeurs dans $B_{M'}$ (définie par un système d'éléments $(\alpha_{ji})_{i \leqslant j,\ i,j \in I}$ d'un ensemble ordonné I grand devant π, avec $\alpha_{kj}\alpha_{ji} = \alpha_{ki}$ pour $i \leqslant j \leqslant k$), il existe $i_0 \in I$ tel que $\alpha_{ii_0} = 1$ pour $i \geqslant i_0$, i.e. $\alpha_{ji} = 1$ pour $j \geqslant i \geqslant i_0$. [page 462]

b′) M' étant un monoïde de monomorphismes comme dans b) (donc $\mathrm{card}\, M' \leqslant \mathrm{card}\, \mathcal{C} \leqslant \pi$*), soit de plus α_0 le plus petit ordinal tel que* $\mathrm{card}\, \alpha_0 > \pi$*, et soit $I = I_{\alpha_0}$ l'ensemble ordonné des ordinaux $\alpha < \alpha_0$ (lequel ensemble est grand devant π). Il n'existe* pas *de système inductif dans $B_{M'}$, tel que pour $i < j$ dans I, α_{ji} soit un élément non inversible dans M' (donc $u \longmapsto \alpha_{ji}u : M' \longrightarrow M'$ est injectif mais non surjectif).*

Signalons tout de suite le p. 179

Corollaire 4.15.10. *Les conditions équivalentes précédentes sont satisfaites, si* $\pi > \mathrm{card}\, \mathcal{C}$.

En effet, soit α_1 le plus petit ordinal tel que $\mathrm{card}\, \alpha_1 > \mathrm{card}\, \mathcal{C}$. Donc $\pi_1 \overset{\text{déf}}{=} \mathrm{card}\, \alpha_1$ est le successeur de $\pi_0 \overset{\text{déf}}{=} \mathrm{card}\, \mathcal{C}$, et on a $\pi \geqslant \pi_1$, donc (si α_0 est comme explicité dans b′ ci-dessus) $\mathrm{card}\, \alpha_0 > \pi_1$, donc $\alpha_1 < \alpha_0$. Soit (avec les notations de b′), pour $\alpha \in I$ [plutôt $\alpha \in I_{\alpha_0}$], i.e. $\alpha < \alpha_0$,

$$M_\alpha \;=\; \varinjlim_{i<\alpha} \underbrace{M_i}_{=M} \;,$$

on voit donc, comme les α_{ji} sont injectifs et non surjectifs, que

$$\mathrm{card}\, M_\alpha \;\geqslant\; \mathrm{card}\, \alpha \;,$$

et que pour $\alpha < \beta$, on a [463]

$$M_\alpha \;\hookrightarrow\; M_\beta \qquad \text{injectif} \;.$$

Appliquons ceci au cas où $\alpha = \alpha_1$, donc on trouve

$$\mathrm{card}\, M_{\alpha_1} \;\geqslant\; \mathrm{card}\, \alpha_1 \;=\; \pi_1 \;,$$

d'autre part, en prenant $\beta = \alpha_1 + 1$, d'où $M_\beta \simeq M$, on trouve une injection

$$M_{\alpha_1} \;\hookrightarrow\; M \;,$$

d'où

$$\pi_1 \;=\; \mathrm{card}\, M_{\alpha_1} \;\leqslant\; \mathrm{card}\, M \;=\; \pi_0 \;,$$

une contradiction, ce qui établit b′.

Commentary · Examples [ms. 462]

Invertibility is the invariant condition

Grothendieck wants a diagram to stop producing new ind-objects. This is invariant under an isomorphism of diagrams. Literal equality of its transition arrows with identities is not invariant in that way, and the distinction produces a small counterexample to condition b) as printed.

Let $G = \{1, g\}$ with $g^2 = 1$, let $\mathcal{C} = BG$, and let $I = \pi^+$ for any infinite cardinal π. Choose $h_\alpha \in G$ by taking $h_\alpha = g$ at successor ordinals and $h_\alpha = 1$ at zero and nonzero limit ordinals. Both values occur arbitrarily far out. Define

$$a_{\beta\alpha} = h_\beta h_\alpha^{-1} \qquad (\alpha \leq \beta).$$

Then $a_{\gamma\beta}a_{\beta\alpha} = a_{\gamma\alpha}$ and $a_{\alpha\alpha} = 1$, so this is a diagram in BG. The maps h_α give a natural isomorphism from the constant diagram to it. Its ind-object is therefore representable.

There is no α_0 such that every $a_{\beta\alpha_0}$ is 1 for $\beta \geq \alpha_0$: that would make $h_\beta = h_{\alpha_0}$ throughout a tail. Thus condition b) fails. Condition b′ holds automatically, because a group has no noninvertible elements. Conditions a), a′), and a″) hold as well: every filtered group-valued diagram trivializes, and the cofinal-colour argument makes it literally constant on a suitable subsystem. The equivalence asserted in 4.15.9 is therefore false in its printed form even for this two-arrow category.

The appropriate replacement for the tail condition is

$$\text{there exists } i_0 \text{ such that } a_{ii_0} \in (M')^\times \text{ for every } i \geq i_0.$$

The cocycle identity then makes all later transitions units. If literal identities are desired, one either changes the trivialization or restricts to a cofinal fibre of the finitely or cardinally many trivializing maps. This is exactly the distinction already handled correctly in 4.15.7.2–5.

The edition has $= 1$ in both places, so the transcription is retained. Corollary 4.15.10 inherits that literal defect when it says that *all* the preceding conditions hold. Its proof establishes the intended exclusion of nonunit chains, and its substantive conclusion, Corollary 4.15.11, remains valid. The separate subquotient issue noted above must also be respected when using the monoid reformulation.

Corollaire 4.15.11. *Soit $\mathcal{C}$ une catégorie essentiellement petite, π un cardinal tel que $\pi > \operatorname{card}\operatorname{réd}\mathcal{C}$. Soit $\mathcal{M} \overset{\text{déf}}{=} \operatorname{Ind}_\pi \mathcal{C}$, alors $\mathcal{M} = \mathcal{M}_\pi$, et c'est une enveloppe de Karoubi de $\mathcal{C}$.*

On peut supposer $\mathcal{C}$ réduite, donc $\operatorname{card}\mathcal{C} < \pi$, et on applique le corollaire précédent.

Ainsi, le résultat litigieux 4.8.13 (p. 212) est finalement prouvé sous une forme légèrement plus faible, avec $\pi > \operatorname{card}\operatorname{réd}\mathcal{C}$ au lieu de $\pi \geqslant \operatorname{card}\operatorname{réd}\mathcal{C}$. Du même coup, les applications de 4.8.13 qu'on a fait jusqu'à présent (notamment le lemme 4.15.3).

[464]

Commentary · Exposition [ms. 463]

Why a larger filteredness bound leaves only retracts

The counting proof reaches the result needed for accessibility: a sufficiently small category acquires no objects under sufficiently filtered colimits except its missing retracts. We first spell out the source's strict inequality. Write $\mu = |\operatorname{Mor}\mathcal{C}| < \pi$ and first suppose μ infinite. A chain of nonunits indexed by π^+, in any left-cancellative subquotient monoid M of cardinal at most μ, would give a partial colimit at μ^+ with at least μ^+ elements. That partial colimit injects into the next stage, a copy of M. The contradiction is

$$\mu^+ \leq \left| \varinjlim_{\alpha<\mu^+} M_\alpha \right| \leq |M| \leq \mu.$$

The equalities in the source's last display are unnecessary; these inequalities are the valid argument. If μ is finite, the assertion is immediate because an injective self-map of a finite set is surjective.

There is also a direct presheaf verification which explains the resulting retract. Let X be a π^+-filtered colimit of representables and let $\mathcal{E}_X$ be its category of elements, with objects (c, x) for $x \in X(c)$. A family of at most π such elements, including at most π relations between them, factors through one stage of the presentation: representables preserve the colimit on Hom, and π^+-filteredness makes the choices and relations simultaneous. Hence $\mathcal{E}_X$ is π^+-filtered.

If $\mathcal{E}_X$ had more than μ objects, select μ^+ of them. Their cocone would have distinct underlying arrows of $\mathcal{C}$: an arrow $f : c \to d$ and an element $y \in X(d)$ determine its source element uniquely as $X(f)(y)$. This contradicts $|\operatorname{Mor}\mathcal{C}| = \mu$. It follows that $\mathcal{E}_X$ has at most μ objects and at most μ^2 arrows. This bound is at most π, including the finite case, because π is infinite.

Apply its filteredness to its entire identity diagram, obtaining a cocone to (d, y). Write its component at (c, x) as $u_{c,x} : c \to d$. These components define a natural transformation

$$s : X \longrightarrow h_d, \qquad s_c(x) = u_{c,x}.$$

Naturality is the cocone equation. The element y defines $t : h_d \to X$, and the fact that every component lies in $\mathcal{E}_X$ says $t_c s_c(x) = X(u_{c,x})(y) = x$. Thus $ts = 1_X$: X is a retract of a representable. Conversely every split idempotent image occurs as a sufficiently filtered colimit by the constant-object construction in the worked example, using the desired regular ordinal as index. This proves

$$\operatorname{Ind}_\pi(\mathcal{C}) \simeq \operatorname{Kar}(\mathcal{C}) \qquad \text{when } \pi > |\operatorname{Mor}\mathcal{C}|.$$

The same proof sharpens the bound when each Hom set has cardinal less than π and $|\operatorname{Ob}\mathcal{C}| \leq \pi$. A family of π distinct elements of one $X(c)$ would force π distinct arrows in one $\operatorname{Hom}(c, d)$, which is impossible. Hence every $|X(c)| < \pi$, the category of elements has at most π arrows, and its identity diagram again has a cocone. This covers some equality cases, without assuming that it covers all of them.

Commentary · Later developments [ms. 463]

Small accessible categories and Cauchy completion

The conclusion belongs to a broader description of accessibility by completion. Makkai and Paré's 1989 monograph develops accessible categories through categorical model theory and mixed sketches (Makkai and Paré, 1989). The result here is especially close to the Cauchy-completion side of that theory: retracts of representables are the objects left after the filteredness bound is raised sufficiently.

A modern ordinary formulation is Tendas (2022, Lemmas 2.5–2.6 and Corollary 2.8): if the Hom sets have cardinal less than β, a γ-flat presheaf for $\gamma > \beta$ is small enough to be Cauchy, provided the object set also lies below γ. This makes the two cardinal bounds explicit. The paper's Theorem 3.7 extends the equivalence between small accessibility and Cauchy completeness to enriched categories.

For ∞-categories, Lurie (2009, Lemma 5.4.2.4 and Corollaries 5.4.3.5–5.4.3.6) identifies compact objects in an ind-completion with the idempotent completion, proves the sufficiently-large-bound collapse, and characterizes small accessible ∞-categories by idempotent completeness. Coherent idempotents replace the ordinary projectors. These statements preserve Grothendieck's conclusion while expressing the required redundancy through the sizes of mapping spaces.

Commentary · Present state [ms. 463]

The strict bound and the boundary question

Grothendieck finishes with the assertion he has actually proved: the bound may be chosen strictly larger than the reduced cardinal of the category. That is sufficient for the qualitative assertion that a small idempotent-complete category is accessible. It is also sufficient for earlier applications in which the chosen cardinal can be enlarged.

The stronger assertion at $\pi = |\operatorname{Mor}\mathcal{C}|$ must be kept separate. The checked modern references give a strict separation between the local Hom bound and the filteredness bound; their general statements do not automatically remove this boundary. The preceding proofs settle it when all Hom sets have cardinal less than π, and for categories with two-sided cancellative endomorphism monoids. We have not settled the unrestricted equality case, and did not find an exact resolution of that sharper formulation in the sources consulted. This records the limit of this commentary, rather than declaring a new open problem.

There is consequently no need to weaken the valid conclusion of 4.15.11, and no justification for silently strengthening its cardinal inequality. The audit also records the two logically separate defects in 4.15.9: the false literal identity condition, and the use of quotients where the preceding construction supplies subquotients.

4.16 Exemples et questions

4.16.0. J'avais cru que tout foncteur "raisonnable" (ou plus précisément, tout foncteur "logiquement accessible") entre catégories accessibles devrait être accessible. Ce n'est malheureusement pas vrai, puisqu'un composé de deux foncteurs Hom

$$\mathrm{Ens} \longrightarrow \mathrm{Ens}\ , \qquad E \longmapsto \underbrace{\mathrm{Hom}(\mathrm{Hom}(E,I),J)}_{J^{(I^E)}}$$

est non accessible, si I, J sont tous deux de cardinal $\geqslant 2$. Prenant p.ex. $I = J = \{0,1\}$, on trouve le foncteur p. 180

$$E \longmapsto \mathfrak{P}(\mathfrak{P}(E))\ ,$$

qui n'est pas accessible.

4.16.1. Deuxième désillusion : j'avais cru que pour toute catégories accessible $\mathcal{M}$, toute sous-catégorie $\mathcal{N}$ strictement pleine et stable par facteurs directs "raisonnable" (p.ex. "logiquement accessible") devrait être accessible dans $\mathcal{M}$. Il n'en est rien, même dans le cas particulier de l'image inverse de la sous-catégorie accessible dans Ens [465]

$$\underbrace{\mathrm{Ens}^*}_{=\{E\in\mathrm{Ens}\,|\,E\neq\emptyset\}} \subset \mathrm{Ens}$$

par un contrafoncteur accessible *représentable*

$$\begin{array}{ccc} \mathcal{M} & \longrightarrow & (\mathrm{Ens})^\circ \\ x & \longmapsto & \mathrm{Hom}_{\mathcal{M}}(x,z)\ , \end{array}$$

i.e. la sous-catégorie ouverte (donc strictement pleine) $\mathcal{M}_z$ de $\mathcal{M}$ formée des objets x tels que $\mathrm{Hom}_{\mathcal{M}}(x,z)\neq\emptyset$, n'est par toujours accessible dans $\mathcal{M}$. Ici, je ne suis pas parvenu à un exemple aussi élémentaire (cf. appendice) – j'ai pris $\mathcal{M}=(k\text{-alg. comm.})$, k un corps infini et z l'objet initial k de $\mathcal{M}$ – j'ai trouvé que $\mathcal{M}_z$ n'est pas L_π-stable dans $\mathcal{M}$, quelque soit le cardinal π – mais cet exemple utilisait que $\mathfrak{U}=\mathfrak{U}_1$, plus petit univers contenant $\mathbf{N}$. J'ignore si pour tout autre univers, on peut trouver un corps k de cardinal $\pi\in\mathfrak{U}$ assez grand, de façon que tout π-ultrafiltre sur un ensemble $E\in\mathfrak{U}$ soit trivial. Peut-être un tel exemple, où non la [466]
construction du couple $(\mathcal{M},\mathcal{N})$, mais la démonstration du fait que $\mathcal{N}$ n'est pas accessible dans $\mathcal{M}$, fait appel à des hypothèses particulières sur l'univers ambiant, ne doit pas être considéré comme (tout à fait !) "logiquement accessible". Pour être vraiment probant, il faudrait un exemple de nature plus élémentaire.

Commentary · Examples [ms. 464]

A double dual which defeats every rank

Grothendieck begins his examples by testing the hope that a familiar formula should automatically define an accessible functor. The double dual is a particularly useful test: each of its two steps is representable with the appropriate variance, but their composite can remember genuinely global information. The issue is visible without cardinal arithmetic beyond the definition of filteredness.

We use a regular cardinal κ in the modern convention: a category is κ-filtered when every diagram with fewer than κ arrows has a cocone. Thus a system grand devant π in the manuscript is π^+-filtered. Fix distinct $a,b\in I$ and distinct $c,d\in J$. The functor under discussion is

$$D(X)=\mathrm{Set}(\mathrm{Set}(X,I),J),\qquad D(u)(\varphi)(g)=\varphi(g\circ u).$$

This action on maps matters. When $I=J=2$, the notation $\mathfrak{PP}(X)$ describes its objects, but does not specify its action by itself.

For any infinite regular κ, choose a set X of cardinal κ. Its subsets of cardinal less than κ, ordered by inclusion, form a κ-directed system with union X. Define $\Phi: I^X\to J$ by setting $\Phi(g)=d$ when g is constantly a, and $\Phi(g)=c$ otherwise. If $S\subset X$ has cardinal less than κ, every member of the image of $D(S)\to D(X)$ depends only on $g|_S$. But the constant function a and the function which is a everywhere except at one point of $X\setminus S$, where it is b, have the same restriction to S and different values under Φ. Therefore Φ belongs to none of these images, and

$$\mathrm{colim}_{S\in[X]^{<\kappa}} D(S)\longrightarrow D(X)$$

is not surjective. This proves the assertion for every possible accessibility rank.

The calculation identifies the obstruction more precisely than growth of cardinalities would. An element of the double dual need not have a support of bounded size. Accessibility would supply one uniform bound, because every element would have to come from a stage in the displayed presentation. The failure concerns that uniformity, even though each individual value of the functor is an ordinary set.

Il reste la possibilité qu'il y ait un théorème métamathématique qui assure que tout couple $(\mathcal{M},\mathcal{N})$ logiquement accessible, avec $\mathcal{M}$ accessible, et $\mathcal{N}$ sous-catégorie strictement pleine L_π-stable dans $\mathcal{M}$ pour π assez grand, soit accessible dans $\mathcal{M}$ ([188]). Ceci s'appliquerait en particulier au cas d'une sous-catégorie *fermée* : toute sous-catégorie fermée (qui soit

188. C'est faux, même pour une sous-catégorie fermée, cf. 4.16.7.10 ci-dessous.

logiquement accessible) serait accessible dans $\mathcal{M}$. L'exemple-test le plus simple serait celui du complémentaire fermé $\mathcal{M}'_z$ de la sous-catégorie ouverte $\mathcal{M}_z$ ci-dessus ([189]), i.e. la catégorie des $x \in \mathrm{Ob}\,\mathcal{M}$ tels que $\mathrm{Hom}_{\mathcal{M}}(x,z) = \emptyset$, ou encore l'image inverse de la sous-catégorie fermée [467]
accessible

$$e \;=\; \{\emptyset\} \;\subset\; (\mathrm{Ens})$$

réduite à $\{\emptyset\}$, par le foncteur représentable $x \longmapsto \mathrm{Hom}(x,z) : \mathcal{M} \longrightarrow \mathrm{Ens}$. Il se pourrait donc qu'une telle catégorie soit toujours accessible dans $\mathcal{M}$. Mais j'ai été incapable de le prouver, p. 181
même dans le cas particulier ci-dessus, où $\mathcal{M} = (k\text{-alg. comm.})$, k étant un corps commutatif infini. La difficulté est (dans tous les cas) la suivante : trouver, pour z fixé, un cardinal $\pi > \pi_0$ tel que pour tout $x \in \mathrm{Ob}\,\mathcal{M}$, et tout système (ou *un* système) π_0-π-adapté $(x_i)_{i\in I}$ de limite inductive x_0 (π_0 un cardinal donné, utile pour $\mathcal{M}$), *si* $\mathrm{Hom}_{\mathcal{M}}(x,z)$ ($\simeq \varprojlim \mathrm{Hom}_{\mathcal{M}}(x_i,z)$) est vide, alors $\exists\, i_0 \in I$ tel que $\mathrm{Hom}_{\mathcal{M}}(x_{i_0},z)$ soit déjà vide. Dans l'exemple $\mathcal{M} = (k\text{-alg. comm.})$, il faut donc prouver que l'on peut trouver un cardinal π tel que pour tout k-algèbre A avec $\mathrm{Hom}_{\mathcal{M}}(A,k) = \emptyset$, il existe une sous-$k$-algèbre A_i de cardinal $\leqslant \pi$, telle que $\mathrm{Hom}_k(A_i,k) = \emptyset$ ([190]). J'ai tendance à croire que ça doit être vrai (et même sans supposer que k soit un corps, [468]
et aussi en prenant la condition $\mathrm{Hom}_{\mathcal{M}}(A,Z) = \emptyset$, où Z est un objet quelconque de $\mathcal{M}$). Ce genre de questions semble étonnement délicat …

Commentary · Exposition [ms. 466]

A point requires compatible choices

Grothendieck next moves the same difficulty into a category of algebraic objects. For a fixed $z \in \mathcal{M}$, the subcategory

$$\mathcal{T}_z = \{x : \mathrm{Hom}_{\mathcal{M}}(x,z) \neq \varnothing\}$$

is a sieve: an arrow $y \to x$ followed by a point $x \to z$ gives a point of y. Its complement $\mathcal{S}_z$ is a cosieve. Both are replete and closed under retracts. These are the meanings of open and closed throughout the closing pages; no topology on a space of objects is being introduced.

The representable contrafunctor sends every existing colimit to a limit of sets,

$$\mathrm{Hom}(\mathrm{colim}_i\, x_i, z) \cong \lim_i \mathrm{Hom}(x_i, z).$$

The existence of an element in every set on the right need not provide a compatible family. Consequently, preservation of these limits by the representable functor does not show that $\mathcal{T}_z$ is closed under the corresponding colimits. Describing $\mathrm{Hom}(-,z)$ as an accessible functor to Set^{op} means preservation of sufficiently filtered colimits into that target; it does not assert that Set^{op} is an accessible category.

The appendix supplies the concrete example with $\mathcal{M} = \mathsf{CAlg}_k$ and $z = k$. Its hypothesis on complete ultrafilters is part of the example. Under that hypothesis, for every infinite $\pi \geq |k|$ there is an algebra A with no map to k, although every subalgebra of cardinal at most π has such a map. The explicit reduced-product construction is proved in the appendix commentary. Since the poset of these subalgebras is π^+-directed, this proves that $\mathcal{T}_k$ is closed under no sufficiently large filtered-colimit class. Proposition 4.16.7.8 then transfers the failure of accessibility to its complementary cosieve $\mathcal{S}_k$.

The distinction explains the later marginal corrections. The no-point class is automatically closed under every nonempty colimit: one structure map from an object with no point would contradict a point on the colimit. Nevertheless, that closure does not furnish a small family of generators. The missing condition is eventually isolated in Corollary 4.16.7.3 as a small weakly initial family in the cosieve.

4.16.2. Il est possible, plus généralement, que la question suivante ait une réponse affirmative : Soit

$$f \;:\; \mathcal{M} \longrightarrow \mathcal{N}^\circ$$

un foncteur accessible, avec $\mathcal{M}$, $\mathcal{N}$ catégories accessibles, et soit $\underline{T}$ une sous-catégorie de $\mathcal{N}$ accessible dans $\mathcal{N}$, et telle qu'il existe un cardinal π ayant les propriétés suivantes : $\mathcal{N}^\circ$ satisfait

189. **N.B.** elles est accessible dans $\mathcal{M}$ si et seulement si $\mathcal{M}_z$ l'est !
190. C'est faux, cf. annotation marginale p. 466.

L_π (i.e. $\mathcal{N}$ stable par $\varprojlim$ grandes devant π_1). Alors $\underline{S} \overset{\text{déf}}{=} f^{-1}(\underline{T})$ est-elle accessible dans $\mathcal{M}$ ([191])? Ceci généralise le cas $\mathcal{N} = (\mathrm{Ens})$, $\underline{T} = \{\emptyset\}$, f foncteur représenté par $z \in \mathrm{Ob}\,\mathcal{M}$, envisagé tout à l'heure. Avec le même type d'exemple, mais en prenant $\mathcal{N} = (\mathrm{Ens})^*$ au lieu [469]
de $\mathcal{N} = \{\emptyset\}$, on voit que la condition supplémentaire de stabilité sur $\underline{T}$ n'est pas superflue. (**N.B.** Elle sont à assurer que $\underline{S}$ est L_π-stable dans $\mathcal{M}$ pour π grand.)

4.16.3. Questions apparentée : j'avais espéré que pour un foncteur accessible entre catégories accessibles

$$f : \mathcal{N} \longrightarrow \mathcal{M} ,$$

la $\natural$-image essentielle, formée des $y \in \mathrm{Ob}\,\mathcal{M}$ qui sont isomorphes à un facteur direct d'un objet de la forme $f(x)$, avec $x \in \mathrm{Ob}\,\mathcal{N}$, serait accessible dans $\mathcal{N}$. L'exemple ci-dessus (nullement élémentaire!) de la sous-catégorie $\mathcal{M}_z$ de $\mathcal{M}$ (formée des $x \in \mathrm{Ob}\,\mathcal{M}$ tels que $\mathrm{Hom}_{\mathcal{M}}(x, z) \neq \emptyset$) montre qu'il n'en est rien. En effet, $\mathcal{M}_z$ est l'image essentielle, et aussi l'image $\natural$-essentielle, du foncteur

$$\mathcal{M}/z \longrightarrow \mathcal{M} ,$$

or $\mathcal{M}/z$ est accessible, et le foncteur précédent accessible, si $\mathcal{M}$ est accessible (vérification par AQT `[âne qui trotte]`, cf. plus bas, énoncé plus général).

On a l'impression que la raison pour laquelle on a de tels contre-exemples, c'est que l'on a [470]
des $\natural$-images essentielles qui ne sont L_π-stables dans $\mathcal{M}$ pour aucun cardinal $\pi \in \mathfrak{U}$. Cela amène à modifier la conjecture ainsi : soit π un cardinal tel que $\mathcal{M}$ satisfasse à L_π, et soit $\underline{S}(\pi)$ la plus p. 182
petite sous-catégorie strictement pleine de $\mathcal{M}$, L_π-stable dans $\mathcal{M}$, et qui contienne l'image essentielle de f. (On pourrait appeler $\underline{S}(\pi)$ la L_π-image essentielle.) Alors $\underline{S}(\pi)$ est accessible dans $\mathcal{M}$. De plus, la famille (décroissante) des $\underline{S}(\pi)$, pour π variable, est stationnaire, i.e. il existe un cardinal π tel que $\pi' \geqslant \pi$ implique $\underline{S}(\pi') = \underline{S}(\pi)$. Il est clair alors que $\underline{S}(\pi)$ est la plus petite sous-catégorie de $\mathcal{M}$ qui soit accessible dans $\mathcal{M}$ et qui contienne l'image essentielle de f. La même question se pose pour un foncteur $g^\circ : \mathcal{N}^\circ \longrightarrow \mathcal{M}$, où $g : \mathcal{N} \longrightarrow \mathcal{M}^\circ$ est un foncteur accessible, $\mathcal{N}$ et $\mathcal{M}$ accessibles. Je conjecture que la réponse est encore affirmative.
[471]

Commentary · Development (commentators') [ms. 470]

Filtered closures need not settle at a final rank

Grothendieck tries to repair the failure of essential images by closing them under sufficiently filtered colimits. This does recover an accessible category at suitable ranks. The additional prediction that these closures eventually stop changing is stronger, and the appendix gives a way to disprove it.

The closure at a common strong rank. [ours] Let $F : \mathcal{A} \to \mathcal{B}$ be an accessible functor. Choose a regular κ such that both categories are κ-accessible and F preserves both κ-filtered colimits and κ-presentable objects. Let $\mathcal{C}$ be the small full subcategory of $\mathcal{B}_\kappa$ on one chosen representative of each isomorphism class in $F(\mathcal{A}_\kappa)$, with no additional objects. Then the smallest replete full κ-filtered-colimit-closed subcategory $\mathcal{S}_\kappa$ containing $F(\mathcal{A})$ is

$$\mathcal{S}_\kappa \simeq \mathrm{Ind}_\kappa(\mathcal{C}),$$

where this Ind notation uses the modern regular-cardinal convention. In particular, it is accessible and accessibly embedded in $\mathcal{B}$.

Indeed, extend $\mathcal{C} \hookrightarrow \mathcal{B}$ by κ-filtered colimits. For presentations $X = \mathrm{colim}_i\, c_i$ and $Y = \mathrm{colim}_j\, d_j$, compactness gives

$$\mathrm{Hom}_{\mathcal{B}}(X, Y) \cong \lim_i \mathrm{colim}_j\, \mathrm{Hom}_{\mathcal{C}}(c_i, d_j).$$

This is precisely the Ind hom formula, so the extension is fully faithful and its image is closed under κ-filtered colimits. Every $F(a)$ lies in that image, because a presentation of a by $\mathcal{A}_\kappa$ is preserved by F. Conversely, any closed full subcategory containing $F(\mathcal{A})$ contains $\mathcal{C}$ and all its κ-filtered colimits. This proves both the formula and minimality. The existence of arbitrarily large common strong ranks is the usual uniformization theorem; its formulation is recalled in the introduction of Paré and

191. Faux, avec $\mathcal{N} = \mathrm{Ens}$ et un foncteur représentable $\mathcal{M} \longrightarrow \mathrm{Ens}^\circ$, prenant $I = \{\emptyset\}$, cf. annotations marginales p. 466, 467.

Rosický (2013). The proof here applies that theorem rather than asserting the formula at every initially chosen rank.

Failure of eventual stabilization. [ours] Work under the universe hypothesis of the appendix: some infinite π_0 excludes all nonprincipal π_0^+-complete ultrafilters on small sets. Choose an infinite field k with $|k| \geq \pi_0$, put $\mathcal{B} = \mathsf{CAlg}_k$, and take $F : \mathcal{B}/k \to \mathcal{B}$. Its essential image is the sieve $\mathcal{T}$ of algebras admitting a k-point. For every regular rank κ, the appendix construction, with a cardinal bound at least κ, supplies a κ-filtered diagram in $\mathcal{T}$ whose colimit A has no k-point. Thus $A \in \mathcal{S}_\kappa \setminus \mathcal{T}$.

Choose a larger regular μ for which A is μ-presentable. The full subcategory

$$\mathcal{Z}_A = \{B : \mathrm{Hom}(A, B) = \varnothing\}$$

contains $\mathcal{T}$: an arrow $A \to B \to k$ would be a forbidden point. It is closed under μ-filtered colimits, because $\mathrm{Hom}(A, -)$ preserves them and a filtered colimit of empty sets is empty. By minimality, $\mathcal{S}_\mu \subseteq \mathcal{Z}_A$. But $A \notin \mathcal{Z}_A$, as its identity is a morphism. Consequently

$$A \in \mathcal{S}_\kappa \setminus \mathcal{S}_\mu.$$

There can be no final stationary rank. This also works when both ranks are chosen among common strong ranks, where the individual closures are accessible by the preceding argument.

The two assertions in the manuscript thus have different answers. We checked the accessible-colimit literature cited here and the large-cardinal image theorem discussed in the appendix; we did not find this particular application to the decreasing closures in those sources. The argument is presented as a development of these pages, without a claim of priority. The next development treats the contravariant stabilization assertion separately, using the same reduced products.

Commentary · Development (commentators') [ms. 470]

The contravariant closures also need not stabilize

The contravariant version of the conjecture can be tested with the very products used in the appendix. The following argument concerns stationarity; it does not assume, or establish, accessibility of each individual closure.

Conditional failure of contravariant stationarity. [ours] Under the universe hypothesis of Proposition 4 of the appendix, there are accessible categories $\mathcal{N}, \mathcal{M}$ and a functor $g : \mathcal{N} \to \mathcal{M}^{op}$ preserving all colimits for which the L_π-closures of the image of g^{op} never become stationary.

Choose an infinite field $k \in \mathfrak{U}$ with $|k| \geq \pi_0$, where π_0 is the cardinal in that universe hypothesis. Take $\mathcal{N} = \mathrm{Set}$, $\mathcal{M} = \mathsf{CAlg}_k$, and $g(E) = k^E$, with pullback of functions on arrows. The product universal property gives

$$\mathrm{Hom}_k(A, k^E) \cong \mathrm{Set}(E, \mathrm{Hom}_k(A, k)).$$

Consequently g takes every colimit of sets to the corresponding limit of algebras, and therefore preserves colimits as a functor to $\mathcal{M}^{op}$. This is the accessibility convention required in the manuscript; no accessibility of $\mathcal{M}^{op}$ is being asserted. Write $\mathcal{S}(\pi)$ for the smallest full replete subcategory containing all k^E and closed under π^+-filtered colimits in $\mathcal{M}$.

Fix an infinite π, choose $|E| > \pi$, and put

$$B_\pi = k^E / I_\pi, \qquad I_\pi = \{f : |\operatorname{supp} f| \leq \pi\}.$$

The ideal is proper, and restriction gives

$$B_\pi \cong \varinjlim_{F \in [E]^{\leq \pi}} k^{E \setminus F}.$$

The indexing poset is π^+-directed, so $B_\pi \in \mathcal{S}(\pi)$. It has no k-point. Indeed, the appendix's ultrafilter calculation says that every k-algebra map $k^E \to k$ is evaluation at a coordinate: the corresponding ultrafilter is $|k|^+$-complete, hence principal under the hypothesis. A point of B_π would therefore give evaluation at some $e \in E$. But the characteristic function of $\{e\}$ maps to zero in B_π and to one under that evaluation, a contradiction.

Choose $\pi' > \max\{\pi, |k|, |B_\pi|\}$. Then B_π is π'^{+}-presentable in CAlg_k: use one generator for each element and at most π' relations recording the algebra operations and constants. Let 0 denote the zero algebra, which is terminal, and consider the full replete class

$$\mathcal{Z} = \{0\} \ \cup \ \{A : \mathrm{Hom}_k(B_\pi, A) = \varnothing\}.$$

Every product k^J belongs to $\mathcal{Z}$. If $J \neq \varnothing$, a map $B_\pi \to k^J$ followed by a coordinate projection would be a forbidden k-point; if $J = \varnothing$, the product is 0.

The class $\mathcal{Z}$ is closed under π'^{+}-filtered colimits. For a diagram with no zero value, presentability of B_π makes the hom set into its colimit empty. If a zero value occurs, its zero-valued indices form a nonempty cofinal cosieve, since a unital map from 0 to an algebra forces that algebra to be zero. The colimit is then zero. By minimality, $\mathcal{S}(\pi') \subseteq \mathcal{Z}$. However, B_π is nonzero and has an identity map, so $B_\pi \notin \mathcal{Z}$. Thus

$$B_\pi \in \mathcal{S}(\pi) \setminus \mathcal{S}(\pi').$$

As π was arbitrary, there is no final stationary rank. The zero-algebra case is necessary because the contravariant image includes the empty product. This supplies a separate negative answer to the stabilization assertion for contravariant images, under the stated universe hypothesis. We did not find this application of the appendix's calculation in the literature checked; no claim of priority is intended.

Soit $\mathcal{M}$ une catégorie satisfaisant la condition L, et admettant une petite sous-catégorie pleine strictement génératrice $\mathcal{C}$, formée d'objets accessibles. On a donc un foncteur pleinement fidèle et accessible

$$\mathcal{M} \ \hookrightarrow \ \mathcal{C}^\wedge \ ,$$

$\mathcal{M}$ L_π-stable dans $\mathcal{C}^\wedge$ pour π convenable. Si $\overline{\mathcal{M}}$ est l'image essentielle, de sorte que $\mathcal{M} \simeq \overline{\mathcal{M}}$, c'est donc une sous-catégorie strictement pleine L_π-stable dans $\mathcal{C}^\wedge$. Donc on s'attend à ce qu'elle soit accessible dans $\mathcal{C}^\wedge$ (si la situation décrite est "logiquement accessible"), ou ce qui revient au même, que $\mathcal{M}$ soit accessible. (Comparer 4.8.1, p. 187.) Mais il ne doit pas être difficile ([192]), en procédant à un nombre $\pi_{\mathfrak{U}}$ de choix (où $\pi_{\mathfrak{U}} = \mathrm{card}\,\mathfrak{U}$), de faire quand même des exemples ("logiquement inaccessibles") d'une sous-catégorie strictement pleine $\mathcal{M}$ de $\mathcal{C}^\wedge$ qui soit L_π-stable, mais non accessible dans $\mathcal{C}^\wedge$. Cette $\mathcal{M}$ admet donc une petite sous-catégorie strictement génératrice formée d'objets accessibles ([193]) et satisfait à L_π, sans pourtant être accessible.

[472]

Commentary · Development (commentators') [ms. 471]

A dense family of presentables need not suffice

The restricted Yoneda argument at the start of this paragraph is correct. The difficulty in footnotes 192–193 is that an arbitrary full subcategory of a presheaf category need not contain its representables. We can repair the proposed counterexample by adjoining their retracts to a suitable nonaccessible cosieve. This gives an example satisfying the stronger hypothesis actually stated here, under the same universe assumption as the appendix.

Conditional counterexample. [ours] Assume that some infinite $\pi_0 \in \mathfrak{U}$ has the property that every π_0^{+}-complete ultrafilter on a $\mathfrak{U}$-small set is principal. There is a locally small category $\mathcal{M}$ with κ-filtered colimits and a small dense full subcategory consisting of κ-presentable objects, for one regular κ, although $\mathcal{M}$ is not accessible.

Choose an infinite field $k \in \mathfrak{U}$ with $|k| \geq \pi_0$. Put $\mathcal{A} = \mathsf{CAlg}_k$, and let $\mathcal{C}$ be the small full category of polynomial algebras $k[x_1, \ldots, x_n]$, for finite n. The restricted nerve

$$N : \mathcal{A} \longrightarrow \mathcal{P} = \mathrm{Set}^{\mathcal{C}^{op}}$$

is fully faithful and preserves filtered colimits. Indeed, its value on the algebra with n generators is the nth power of the underlying set. Naturality with respect to polynomial substitutions says exactly

192. OK en prenant un *fermé* $\underline{S}$ non accessible dans $\mathcal{M}$ d'une catégorie accessible $\mathcal{M}$, qu'on plonge dans un $\mathcal{C}^\wedge$. Mais ces $\underline{S}$ n'a *pas* une petite famille strictement génératrice !

193. Ce n'est pas clair, il faudrait pour cela que le foncteur d'inclusion soit un adjoint à gauche !

that a transformation between two such nerves preserves the algebra operations and constants. Finite powers commute with filtered colimits.

Set $Z = N(k)$ and

$$\mathcal{S} = \{X \in \mathcal{P} : \mathrm{Hom}_{\mathcal{P}}(X, Z) = \varnothing\}.$$

This is a full replete cosieve, closed under every nonempty colimit. It is not accessible in $\mathcal{P}$. Otherwise its inverse image under the accessible functor N would be accessible in $\mathcal{A}$, contrary to Proposition 4 of the appendix together with Corollary 4.16.7.9. Here the inverse-image theorem applies without a strict-pullback defect: the inclusion of a full replete subcategory is an isofibration, so its strict pullback is equivalent to the accessible pseudopullback. The latter is constructed by products, inserters and equifiers, using the closure theorem discussed in Ching and Riehl (2014, Appendix A). Full faithfulness identifies this inverse image with the algebras having no k-point.

Let $\mathcal{T}$ consist of the retracts of representable presheaves, including all isomorphic copies. It is essentially small, since retracts are classified by idempotents on representables, and is closed under retracts. Every member of $\mathcal{T}$ maps to Z: each representable has such a map by evaluating its polynomial generators at zero, and a retract inherits one. Consequently $\mathcal{S} \cap \mathcal{T} = \varnothing$.

We verify the required filtered closure of $\mathcal{T}$ explicitly. Choose an infinite $\mu \geq |\operatorname{Mor} \mathcal{C}|$ and put $\kappa = \mu^{++}$. Every object of $\mathcal{T}$ has at most μ elements in total across its components. If X is the presheaf colimit of a κ-filtered diagram in $\mathcal{T}$, then $|X(c)| \leq \mu$ for each c: otherwise μ^+ distinct elements would have representatives at one common stage, since $\mu^+ < \kappa$, contradicting that stage's bound. Thus X also has at most μ elements in total. Its category of elements has at most μ arrows, so its canonical expression as a colimit of representables makes X κ-presentable. Applying presentability to its original filtered presentation factors 1_X through a stage. Hence X is a retract of that stage and belongs to $\mathcal{T}$. Notice the strict inequality $\mu^+ < \kappa$ in this argument.

Now take the full replete subcategory

$$\mathcal{M} = \mathcal{S} \cup \mathcal{T} \subseteq \mathcal{P}.$$

It is closed under κ-filtered colimits. A diagram taking values only in $\mathcal{T}$ was just handled. If it has a value in $\mathcal{S}$, its $\mathcal{S}$-valued indices form a nonempty cosieve in the filtered indexing category, hence a cofinal filtered subcategory; its colimit belongs to $\mathcal{S}$. Thus these colimits in $\mathcal{M}$ are computed in $\mathcal{P}$.

The representables form a small dense full subcategory of $\mathcal{M}$. In fact, the restricted nerve is precisely the full inclusion $\mathcal{M} \hookrightarrow \mathcal{P}$, by Yoneda. This proves genuine density, rather than just the weaker generator property. Each representable is κ-presentable in $\mathcal{M}$, because its hom functor is evaluation and the relevant colimits are computed pointwise.

Finally, suppose $\mathcal{M}$ were accessible. Choose a regular $\lambda \geq \kappa$ at which it is accessible, with a small family $\mathcal{G}$ of λ-presentable generators. In a λ-filtered presentation of $X \in \mathcal{S}$ by $\mathcal{G}$, not all stages can belong to $\mathcal{T}$, since $\mathcal{T}$ is closed under such colimits. The $\mathcal{S}$-stages are therefore nonempty and cofinal. They present X using the small family $\mathcal{G} \cap \mathcal{S}$, whose members remain λ-presentable in $\mathcal{S}$. This makes $\mathcal{S}$ accessible; its inclusion into $\mathcal{P}$ preserves filtered colimits, contradicting the earlier conclusion. This is the mechanism of Corollary 4.16.7.9 in the present example.

The construction uses the appendix's explicit universe hypothesis, and does not establish failure in every universe. It repairs the dense-family issue without a universe-sized sequence of arbitrary choices. We did not find this particular adjoining-of-retracts construction in the literature checked for this commentary; it is supplied as a development of the manuscript, without a claim of priority.

4.16.4 ([194]). Soit $\mathcal{M}$ une catégorie telle que $\mathcal{M}$ et $\mathcal{M}^\circ$ soient accessibles. Je conjecture qu'alors $\mathcal{M}$ est essentiellement petite. Plus généralement, supposons $\mathcal{M}$ accessible, et que $\mathcal{M}$ admette une petite sous-catégorie qui soit *strictement co*génératrice. Alors $\mathcal{M}$ est-elle essentiellement petite ? Plus généralement, si $\mathcal{M}$ admet une petite sous-catégorie strictement génératrice, et aussi une petite sous-catégorie strictement cogénératrice, i.e. si $\mathcal{M}$ et $\mathcal{M}^\circ$ sont toutes deux équivalentes à des sous-catégories pleines d'une $\mathcal{C}^\wedge$, avec $\mathcal{C}$ petite, alors $\mathcal{M}$ est-elle essentiellement petite ?

4.16.5. Soit I une petite catégorie, $I_\bullet$ le cône droit sur I (obtenu en rajoutant un objet final e), $\mathcal{M}$ une catégorie accessible,

$$\underline{\mathrm{Hom}}_{\square}(I_\bullet, \mathcal{M}) \hookrightarrow \underline{\mathrm{Hom}}(I_\bullet, \mathcal{M})$$

194. descendre après 4.16.5.

la sous-catégorie strictement pleine de la catégorie (accessible) $\underline{\mathrm{Hom}}(I_\bullet, \mathcal{M})$, formée des foncteurs f qui font de $f(e)$ la limite inductive dans $\mathcal{M}$ des $f(i)$ ($i \in \mathrm{Ob}\, I$). Cette sous-catégorie est L_π-stable pour π grand, donc il y a lieu de conjecturer qu'elle est accessible [473] dans $\underline{\mathrm{Hom}}(I_\bullet, \mathcal{M})$. (Je rappelle qu'on a vu dans 4.14 que c'est OK si les $\varinjlim$ de type I sont représentables dans $\mathcal{M}$. Et qu'une réponse affirmative, dans le cas où p. 183

implique que la sous-catégorie $\underline{\mathrm{Ép}}(\mathcal{M})$ dans $\underline{\mathrm{Fl}}(\mathcal{M})$ est accessible dans $\underline{\mathrm{Fl}}(\mathcal{M})$.)

Commentary · Examples [ms. 472]

Isbell's large category seen from both sides

Grothendieck's three smallness questions ask whether having enough descriptions by small objects from both directions leaves room for a large category. Isbell had already constructed a decisive example. Let PInj have sets as objects and partial bijections as morphisms: a map $X \dashrightarrow Y$ is a bijection from a subset of X onto a subset of Y. Reversing that bijection defines an isomorphism $\mathsf{PInj}^{op} \cong \mathsf{PInj}$. Isbell's example is recorded by Avery and Leinster (2021, Example 8.7), who attribute the one-object dense and codense subcategory to Isbell (1968, Example 1). We verify the properties relevant here directly.

First, filtered colimits exist and finite sets are finitely presentable. To construct the colimit of a filtered diagram, adjoin a basepoint to every set and send an undefined value of a partial map to the basepoint. Take the colimit of this diagram of pointed sets. Each structure map is still injective away from the basepoint: if two elements from one stage become equal to the same nonbasepoint element, they become equal at a common later stage, where the transition is injective away from the basepoint. Removing the colimit basepoint therefore gives a partial bijection from each original stage.

For the universal property, a cocone of partial bijections gives a pointed-set map out of this colimit. If two distinct nonbasepoint classes had the same nonbasepoint image, represent them at a common stage; injectivity of that stage's cocone map would make them equal. Hence the induced map is a partial bijection, and its uniqueness follows from the pointed-set universal property. This proves the colimit assertion without assuming that all transitions are everywhere defined.

A partial bijection from a finite set K to this colimit has finitely many defined values. Represent those values at one common stage; their distinct nonbasepoint images ensure that the representatives are distinct and nonbasepoint. Leave the other elements of K undefined. This lifts the map to that stage. Two such lifts which agree in the colimit agree at a later stage, by applying the filtered equality criterion to their finitely many values, including the basepoint. Thus K is finitely presentable. Finally, every set is the filtered union of its finite subsets along total inclusions. There is a small skeleton of finite sets, so PInj is finitely accessible. Its self-duality proves the same for its opposite.

To see the stronger density assertion, let $D = \{1, 2\}$. Its partial-bijection endomorphism monoid has seven elements: the empty map, four singleton-domain maps, and two permutations. A natural transformation

$$\mathsf{PInj}(D, X) \longrightarrow \mathsf{PInj}(D, Y)$$

means a function equivariant for precomposition by these seven endomorphisms. Commutation with the empty map forces the empty map to be preserved. Commutation with the two partial identity maps shows that the image of a map defined only at 1 is again defined only at 1, or empty; this defines a partial function $h : X \dashrightarrow Y$. Commutation with the transposition gives the same h in the second coordinate. For distinct $x, x' \in X$, apply the transformation to the map $D \to X$ taking the two points to x, x'. Its image must still be a partial bijection. Hence, whenever both $h(x)$ and $h(x')$ are defined, they are distinct. Thus h is a partial bijection. The partial identities now show that the transformation is exactly postcomposition with h. Its uniqueness is detected by singleton-domain maps. The restricted nerve at D is therefore fully faithful, proving density of this one-object full subcategory. Self-duality proves codensity.

Sets of distinct cardinalities are not isomorphic in PInj. There are therefore universe-many isomorphism classes, while the dense and codense test category is finite. All three smallness assertions fail. No large-cardinal hypothesis is used in this example, and the conclusion is about accessibility, not about the much stronger assumption of having all small limits or colimits.

N.B. Si $\mathcal{M}$ admet une petite sous-catégorie *co*génératrice, alors la question est justiciable de la conjecture 4.16.2 relative à un foncteur accessible $\mathcal{M} \longrightarrow \mathcal{N}^\circ$, ici $\underline{\mathrm{Hom}}(I_\bullet, \mathcal{M}) \longrightarrow \underline{\mathrm{Hom}}(I^\circ \times \mathcal{C}, \mathrm{Ens})^\circ \ldots$

4.16.6. Il reste la question de l'accessibilité relative d'une catégorie $\mathcal{E}$ sur une petite catégorie $\mathcal{C}$. Je pense à présent, grâce à 4.15.9, et son corollaire 4.15.10, que l'énoncé suivant doit "tomber" par AQT `[âne qui trotte]` :

Proposition 4.16.6.1. *Soit $f : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur, avec $\mathcal{C}$ petite catégorie karoubienne. On suppose que f satisfait la condition $H' = H$ (1+2+3) de 4.15.1 (page 415), où il suffit H 2, H 3, pour toute flèche λ* non identique *de $\mathcal{C}$. On suppose de plus que pour une catégorie $\mathcal{C}'$ d'un des deux types qu'on va décrire, et un foncteur $\mathcal{C}' \longrightarrow \mathcal{C}$, $\mathcal{E}' = \mathcal{E} \times_{\mathcal{C}} \mathcal{C}'$ soit accessible, et $\mathcal{E}' \longrightarrow \mathcal{C}'$ accessible.*

[474]

Commentary · Development (commentators') [ms. 473]

Existing pushouts can form a nonaccessible class

Grothendieck wants the collection of universal cocones itself to have a manageable presentation. When all diagrams of a fixed shape have colimits, this is true: restriction identifies the category of colimit cocones with the accessible diagram category. The higher-categorical version has exactly this existence hypothesis in Lurie (2009, Example 5.4.7.9). The hypothesis becomes consequential when only some diagrams have colimits.

A counterexample from the appendix. [ours] Assume the appendix's universe hypothesis with cutoff π_0, and choose an infinite field k with $|k| \geq \pi_0$. There is a finitely accessible category $\mathcal{E}$ for which the full replete subcategory of pushout squares is not accessible and accessibly embedded in $\mathcal{E}^{\square}$.

To construct it, start with $\mathcal{A} = \mathsf{CAlg}_k$ and adjoin a new object $*$, with

$$\mathrm{Hom}_{\mathcal{E}}(A, *) = \mathrm{Hom}_k(A, k), \qquad \mathrm{Hom}_{\mathcal{E}}(*, A) = \varnothing, \qquad \mathrm{End}_{\mathcal{E}}(*) = \{1\}.$$

Composition of crossing maps is composition in $\mathcal{A}$. Thus $\mathcal{A}$ is the open piece of a collage and $\{*\}$ its closed piece. The new object and the old algebra k are distinct: in particular, there is no arrow from $*$ to k.

We first show that $\mathcal{E}$ is finitely accessible. A filtered diagram with a $*$-valued stage has a cofinal full subcategory of $*$-valued stages. Indeed, a common successor of such a stage and any other stage must again have value $*$, since no arrow leaves $*$ for the open piece. That subcategory is filtered, and its image diagram is constant with identity transitions. Its colimit is $*$. A filtered diagram entirely in $\mathcal{A}$ has its usual colimit there, which is also a colimit in $\mathcal{E}$: cocones to $*$ are precisely compatible maps to k, and representability identifies them with maps from the algebraic colimit to k. These two cases also show that each finitely presentable algebra remains finitely presentable in $\mathcal{E}$, and that $*$ is finitely presentable. A small skeleton of finitely presentable algebras together with $*$ generates $\mathcal{E}$ under filtered colimits. Hence $\mathcal{E}$ is finitely accessible.

For an algebra A, form the commutative square

$$\begin{array}{ccc} k & \longrightarrow & A \times k \\ \downarrow & & \downarrow{\scriptstyle \mathrm{pr}_2} \\ * & \xrightarrow[1]{} & *. \end{array}$$

Here the right vertical arrow means the crossing map specified by the algebra homomorphism $A \times k \to k$. Every cocone on the upper-left span has vertex $*$, because its leg from $*$ forces that vertex. Its remaining choice is a map $A \times k \to k$; compatibility with the leg from k is automatic for k-algebra maps. Since k is a field, the two complementary central idempotents of $A \times k$ show that

$$\mathrm{Hom}_k(A \times k, k) \cong \mathrm{Hom}_k(A, k) \amalg \{\mathrm{pr}_2\}.$$

The category of these cocones is discrete, because $*$ has only its identity endomorphism. The displayed canonical cocone is initial precisely when this set is a singleton, or equivalently when $\mathrm{Hom}_k(A,k)=\varnothing$.

The assignment $A\mapsto$ this square is an accessible functor $\mathcal{A}\to\mathcal{E}^{\square}$. Finite products in k-algebras commute with filtered colimits, the inclusion of the open piece preserves them by the preceding calculation, and the two constant $*$ components also preserve filtered colimits. If the full replete subcategory of pushout squares were accessible and accessibly embedded, its inverse image under this functor would be so as well. This last assertion is the accessible pseudopullback theorem, applied to a replete full inclusion, which is an isofibration; see Bourke and Lack (2024, Remark 4.9). The inverse image, however, is exactly the nonaccessible cosieve

$$\{A:\mathrm{Hom}_k(A,k)=\varnothing\}$$

proved nonaccessible in the appendix and Proposition 4.16.7.8. This contradiction establishes the claim.

The example also respects the source's observation that these cocones are closed under sufficiently filtered colimits: universal colimits commute with such pointwise colimits. It is the small generating family which fails. We did not find this collage realization in the checked accounts of accessible categories or in the all-colimits theorem cited above; the proof is given in full as a conditional development, without a priority claim.

The separate implication concerning epimorphisms is correct. For $u:A\to B$, the square with top and left edge u and bottom and right edge 1_B is a pushout exactly when u is epic: a pair of maps out of B agreeing after u must then agree. This gives the accessible inverse-image argument mentioned in the manuscript. It does not reverse the implication or remove the existence hypothesis from the preceding positive theorem.

(*On prend pour $\mathcal{C}'$ la catégorie*

$$\mathcal{Q}=\left\{\begin{array}{l}
\xi_0=\xi^{\natural}\ \underset{\rho}{\overset{\sigma}{\rightleftarrows}}\ \xi\circlearrowright p\qquad \rho\sigma = \mathrm{id}_{\xi_0}\\
\qquad\qquad\qquad\quad \downarrow{\scriptstyle u=u_0\rho}\qquad\quad \sigma\rho = p\ ,\quad d'où\ \left\{\begin{array}{rcl} p^2 &=& p\\ p\sigma &=& \sigma\\ \rho p &=& \rho\end{array}\right.\\
\qquad\quad {\scriptstyle u_0}\searrow\qquad\qquad\\
\qquad\qquad\ \eta\qquad\qquad\quad u = u_0\rho\ ,\quad d'où\ \left\{\begin{array}{rcl} up &=& u\\ u\sigma &=& u_0\end{array}\right.
\end{array}\right.$$

(trois objets ξ, ξ_0, η et cinq flèches non identiques σ, ρ, p, u_0, u, liés par les relations ci-dessus), ou la catégorie (isomorphe à Q°)

$$\mathcal{Q}'=\left\{\begin{array}{l}
\xi_0\ \underset{\rho}{\overset{\sigma}{\rightleftarrows}}\ \xi\circlearrowright p\qquad \left.\begin{array}{rcl}\rho\sigma &=& \mathrm{id}_{\xi_0}\\ \sigma\rho &=& p\end{array}\right\}\implies \left\{\begin{array}{rcl} p^2 &=& p\\ p\sigma &=& \sigma\\ \rho p &=& \rho\end{array}\right.\\
\quad {\scriptstyle u_0}\nwarrow\ \uparrow{\scriptstyle u}\\
\qquad\ \eta\qquad\qquad u = \sigma u_0\qquad\implies \left\{\begin{array}{rcl} pu &=& u\\ \rho u &=& u_0\end{array}\right.
\end{array}\right.$$

On se limite aux foncteurs $\mathcal{Q}\longrightarrow\mathcal{C}$, $\mathcal{Q}'\longrightarrow\mathcal{C}$ tels que p soit transformé en une flèche non identique *de $\mathcal{C}$ ([195]) (donc la condition relative à $\mathcal{Q}$, $\mathcal{Q}'$ devient vide, si $\mathcal{C}$ est sans projecteurs).*)

Sous ces conditions, $\mathcal{E}$ est accessible, et $f:\mathcal{E}\longrightarrow\mathcal{C}$ est accessible.

On trouve alors le

Commentary · Development (commentators') [ms. 474]

What the two split-idempotent tests supply

Grothendieck introduces $\mathcal{Q}$ and $\mathcal{Q}'$ to isolate the obstruction left after large filtered diagrams have been made constant in the base. One test attaches a target to a split idempotent; the other attaches a source. This is exactly the distinction between constructing a colimit and proving that a chosen object is presentable.

The finite-test assertion of Proposition 4.16.6.1. [ours] Let $f : \mathcal{E} \to \mathcal{C}$ satisfy the hypotheses stated there, with $\mathcal{C}$ small and Karoubian. Then $\mathcal{E}$ and f are accessible. In this assertion about the total category itself, it is enough to use the $\mathcal{Q}$ and $\mathcal{Q}'$ tests whose distinguished idempotent has nonidentity image in $\mathcal{C}$.

Here are the rank choices needed before the construction. The hypothesis H supplies accessible fibres, accessible pullbacks over arrows, and preservation of sufficiently filtered fibre colimits in those pullbacks. For a test category B equal to Δ_1, $\mathcal{Q}$, or $\mathcal{Q}'$, its fibre inclusions into $\mathcal{E}_B$ are accessible: maps from a fibre colimit to any other fibre are computed by the contravariant mixed hom functors of H2. This includes arrows of B whose images are identities, where the assertion is ordinary representability inside one fibre. There are only a small number of the indicated tests. Choose a common sufficiently large strong accessibility rank κ for their categories $\mathcal{E}_B$, their projections $\mathcal{E}_B \to B$, all fibres, and all fibre inclusions. Enlarge it to a suitable successor rank beyond the strict cardinal bound of Corollary 4.15.11. The uniformization used here is the same as in the preceding accessibility arguments; no claim at a prescribed smaller rank is needed.

Let $D : J \to \mathcal{E}$ be κ-filtered. The normal form proved near pp. 443–463 permits a cofinal, still κ-directed reindexing for which all base objects are one object s and every strict base transition is one idempotent $p : s \to s$. If the new index has a last object, its colimit is already a stage and there is nothing to construct. Otherwise every index has a strict successor. If $p = 1_s$, H2 shows directly that the colimit in $\mathcal{E}_s$ is a colimit in $\mathcal{E}$. Suppose then that $p \neq 1_s$, and split it in $\mathcal{C}$:

$$s \xrightarrow{r} t \xrightarrow{i} s, \qquad ri = 1_t, \quad ir = p.$$

Write K for the full split-idempotent subcategory of $\mathcal{Q}$ on ξ, ξ_0. The diagram lifts to $\mathcal{E}_K$ with all index objects labelled ξ. Extend $K \to \mathcal{C}$ to $\mathcal{Q} \to \mathcal{C}$ by sending η to t and u_0 to 1_t. In $\mathcal{Q}$ the colimit of this base diagram is ξ_0, with structure arrows ρ. Indeed, the strict successors force any cocone arrow a to satisfy $ap = a$, and these arrows factor uniquely through ρ. Accessibility of $\mathcal{E}_{\mathcal{Q}}$ supplies its colimit, and preservation by the projection puts its vertex over ξ_0: this finite category has no nontrivial isomorphisms. We obtain $z \in \mathcal{E}_t$ with cocone maps over r. Fullness of K restricts the universal property to $\mathcal{E}_K$, so this is also a colimit there.

To check all targets in $\mathcal{E}$, take $y \in \mathcal{E}_c$. The base arrows of any cocone $D \to y$ are constant, say $a : s \to c$, and satisfy $ap = a$. Hence $a = \mu r$ for the unique $\mu = ai : t \to c$. Use now the $\mathcal{Q}$ test with $\eta \mapsto c$ and $u_0 \mapsto \mu$. Its independently existing colimit again projects to ξ_0 and restricts to the same colimit in $\mathcal{E}_K$. The canonical isomorphism to z is vertical because $\mathrm{End}_K(\xi_0) = \{1\}$. Its universal property gives exactly one arrow $z \to y$ over μ producing the original cocone. This proves the total universal property and, at the same time, preservation of this colimit by f.

We next prove presentability, since existence of colimits alone does not prove accessibility. Let x be κ-presentable in a fibre $\mathcal{E}_c$, and let $x \to z$ lie over $\nu : c \to t$. In the $\mathcal{Q}'$ test put $\eta \mapsto c$, $\xi_0 \mapsto t$, $\xi \mapsto s$, $u_0 \mapsto \nu$, and $u \mapsto i\nu$. The object labelled (x, η) is κ-presentable in $\mathcal{E}_{\mathcal{Q}'}$ by the strong rank choice. Accessibility gives a colimit of the lifted diagram there, and its projection is again ξ_0. Restricting to the same full K identifies this colimit vertically with (z, ξ_0). Consequently $x \to z$ factors through some D_j, giving surjectivity of the hom-colimit comparison in $\mathcal{E}$.

For injectivity, consider two maps from x to stages with the same composite to z. Their base maps $a, b : c \to s$ have $ra = rb = \nu$. After advancing each stage once, their bases become $pa = pb = i\nu$. They are now maps in the same $\mathcal{Q}'$ test. Presentability there makes them equal at a common later stage. When $p = 1_s$, precisely this argument uses the corresponding Δ_1 test instead. The case with a final index is immediate. Thus every fibrewise κ-presentable object is κ-presentable in $\mathcal{E}$.

The union over the small base of small skeletons of these fibrewise objects is small. Every object of $\mathcal{E}$ is a κ-filtered colimit of them inside its own fibre, hence also in $\mathcal{E}$ by H2. This proves accessibility and completes the finite-test assertion. We did not locate this exact $\mathcal{Q}, \mathcal{Q}'$ formulation in the checked literature; the proof supplies the missing argument rather than attributing it to a later author. The restriction on p just justified is specific to this theorem. It cannot be carried unchanged through arbitrary strict base changes, as the next example shows.

Corollaire 4.16.6.2. *Soit $f : \mathcal{E} \longrightarrow \mathcal{C}$ un foncteur. Conditions équivalentes :*

a) Pour toute catégorie $\mathcal{C}'$ petite *et* karoubienne*, et tout foncteur $\mathcal{C}' \longrightarrow \mathcal{C}$, $\mathcal{E}' = \mathcal{E} \times_{\mathcal{C}} \mathcal{C}'$ est accessible, et le foncteur $\mathcal{E}' \longrightarrow \mathcal{C}'$ est accessible.*

b) Comme a), mais $\mathcal{C}'$ étant une des trois catégories Δ_1, $\mathcal{Q}$, $\mathcal{Q}'$ (où $\mathcal{Q}$, $\mathcal{Q}'$ sont définies dans 4.15.6.1 ci-dessus).

b′) ([196]). (Si $\mathcal{C}$ est sans projecteurs.) Comme b), mais en se limitant au cas $\mathcal{C}' = \mathbf{\Delta}_1$ (à l'exclusion de $\mathcal{Q}$, $\mathcal{Q}'$).

Corollaire 4.16.6.3. *Supposons $f : \mathcal{E} \longrightarrow \mathcal{C}$ fibrant ou cofibrant. Alors les conditions équivalentes précédentes impliquent que :*

1°) Les $\mathcal{E}_s$ sont accessibles ($s \in \mathrm{Ob}\,\mathcal{C}$).

2°) Pour toute flèche $\lambda : s \longrightarrow t$ dans $\mathcal{C}$, le foncteur $\lambda^* : \mathcal{E}_t \longrightarrow \mathcal{E}_s$ (resp. $\mathcal{E}_s \longrightarrow \mathcal{E}_t$) est accessible.

D'autre part, l'ensemble de ces conditions 1°, 2°) équivaut à la validité de b) ci-dessus, dans le cas $\mathcal{C}' = \mathbf{\Delta}_1$, ou encore à la validité de a) ci-dessus, quand $\mathcal{C}'$ est sans projecteurs. [page 476]

Commentary · Development (commentators') [ms. 475]

A strict pullback can expose a hidden projector

The uncertain clause b′ in Corollary 4.16.6.2 asks to discard both split-idempotent tests when the base has no nonidentity projectors. A strict pullback remembers more than the images of its arrows in that base. A projector upstairs may map to an identity downstairs, and this is exactly the case which the shortened criterion misses.

Counterexample to b′ ⇒a. [ours] Let $\mathcal{C}$ be the walking isomorphism, with objects $0, 1$ and exactly one arrow between each ordered pair. It has no nonidentity idempotents. Let $f : e \to \mathcal{C}$ select 0. For any functor $\Delta_1 \to \mathcal{C}$, the strict pullback is empty, a point, or Δ_1, according to which endpoints map to 0. Each is accessible and its projection to Δ_1 preserves sufficiently filtered colimits. Thus the printed condition b′ holds.

Let R be the walking split idempotent, with two objects a, b and arrows

$$a \xrightarrow{r} b \xrightarrow{i} a, \qquad ri = 1_b, \quad ir = p \neq 1_a.$$

Its only nonidentity endomorphism is p, and it is split, so R is a small Karoubian category. Send a to 0, b to 1, and r, i to the inverse isomorphisms of $\mathcal{C}$. Then p is sent to 1_0. The strict pullback $e \times_{\mathcal{C}} R$ has one object with endomorphism monoid $\{1, p\}$, where $p^2 = p \neq 1$.

This one-object category is not accessible. For any infinite regular κ, index a diagram by the ordinal κ, put the sole object at every stage, and put p on every strict transition. A cocone to the sole object must have every component equal to p. If it were a colimit cocone, the two endomorphisms 1 and p of its vertex would induce distinct cocones. They induce the same one, since $1p = pp = p$. Thus the required κ-filtered colimit does not exist, for any κ.

Condition a) therefore fails. The unrestricted equivalence a)⇔b) is repaired by retaining all $\mathcal{Q}$ and $\mathcal{Q}'$ tests, including those which send p to an identity. Indeed, applying Proposition 4.16.6.1 to a pullback over a small Karoubian $\mathcal{C}'$ may involve a nonidentity projector of $\mathcal{C}'$ whose image in $\mathcal{C}$ is an identity. The example was checked directly against the generators and compositions of these finite categories. We found no statement of this particular counterexample in the consulted sources; it is a correction of the queried implication, without a claim of priority.

Question 4.16.6.4. *Les conditions 1° et 2° précédentes impliquent-elles celles de 4.16.6.2 ? En d'autres termes, si la catégorie base $\mathcal{C}$ est égale à $\mathcal{Q}$ ou à $\mathcal{Q}'$, alors ces conditions impliquent-elles que $\mathcal{E}$ est accessible, et $f : \mathcal{E} \longrightarrow \mathcal{C}$ accessible ?*

Ça semble idiot de ne pas connaître la réponse !

4.16.6.5. J'ai envie d'appeler catégorie *accessible sur $\mathcal{C}$*, une catégorie $\mathcal{E}$ sur $\mathcal{C}$ satisfaisant les conditions équivalentes de 4.16.6.1 – du moins dans le cas où on suppose $\mathcal{C}$ petite. Pour

196. ?, à vérifier avec soin !

que cette terminologie soit vraiment satisfaisant, il faudrait que l'on sache prouver que ces conditions impliquent ceci : pour toute catégorie accessible $\mathcal{M}$ et tout foncteur accessible $\mathcal{M} \longrightarrow \mathcal{C}$, la catégorie $\mathcal{E} \times_{\mathcal{C}} \mathcal{M}$ est accessible, et le foncteur $\mathcal{E} \times_{\mathcal{C}} \mathcal{M} \longrightarrow \mathcal{M}$ est accessible.

L'idée, c'est qu'on appellerait (sous hypothèse de petitesse) *catégorie accessible* $\mathcal{E}$ sur une autre $\mathcal{C}$, une catégorie ayant la propriété qu'on vient de dire – mais en supposant maintenant de plus que $\mathcal{C}$ satisfasse à L_π, j'imagine, pour tout foncteur accessible $\mathcal{M} \longrightarrow \mathcal{C}$, avec $\mathcal{M}$ accessible, $\mathcal{E} \times_{\mathcal{C}} \mathcal{M}$ est accessible et le foncteur canonique $\mathcal{E} \times_{\mathcal{C}} \mathcal{M} \longrightarrow \mathcal{E}$ est accessible. [page 476bis]

Commentary · Development (commentators') [ms. 476bis]

Relative accessibility and lifting isomorphisms

Grothendieck wants relative accessibility to survive replacement of the base by an accessible category. The corrected finite tests do give this property. Their strict-pullback formulation also forces an additional feature which explains why a bare accessible functor is insufficient.

A criterion over a small Karoubian base. [ours] For $f : \mathcal{E} \to \mathcal{C}$ with $\mathcal{C}$ small and Karoubian, the following are equivalent: every strict pullback along a small Karoubian $\mathcal{C}' \to \mathcal{C}$ is accessible and has accessible projection to $\mathcal{C}'$; and $\mathcal{E}$ and f are accessible and f is an isofibration. Here isofibration means that for every $x \in \mathcal{E}$ and every isomorphism $u : f(x) \to t$ in $\mathcal{C}$, there is an isomorphism $\widetilde{u} : x \to y$ with $f(\widetilde{u}) = u$ and $f(y) = t$.

For necessity, use $\mathcal{C}' = \mathcal{C}$ to obtain accessibility of $\mathcal{E}$ and f. For the lifting assertion, use the walking split idempotent R from the preceding block, mapping its two objects to $f(x)$ and t, its arrows r, i to u, u^{-1}, and its projector p to $1_{f(x)}$. In the accessible strict pullback there is an idempotent $(1_x, p)$ on (x, a). An accessible category splits every idempotent: a sufficiently long regular-ordinal diagram with that idempotent on all strict transitions has a colimit, and its universal property gives the splitting. The only object of R at which p can split is b, since the monoid $\{1, p\}$ at a does not split it internally. The splitting object is therefore (y, b) for some $f(y) = t$. Its two splitting arrows project in $\mathcal{E}$ to inverse isomorphisms, because the first component of the original idempotent was 1_x. The arrow over r is the required lift of u.

For sufficiency, a small Karoubian category is accessible at a sufficiently large rank, and any functor between two such categories preserves sufficiently filtered colimits: those colimits reduce to splittings of idempotents, which every functor preserves. The iso-comma category of the accessible functors $\mathcal{E} \to \mathcal{C} \leftarrow \mathcal{C}'$ is accessible and its projections are accessible, by the pseudopullback theorem. Because f is an isofibration, its strict pullback is equivalent to this iso-comma category. Explicitly, an object $(x, c', \alpha : f(x) \cong g(c'))$ can be replaced, using a lift of α, by one with equal base objects and identity comparison. The inclusion of the strict pullback is fully faithful and this replacement proves essential surjectivity. This proves sufficiency.

The same argument now allows any accessible $\mathcal{M} \to \mathcal{C}$ in place of $\mathcal{C}'$. Its strict pullback is accessible, and both projections are accessible. This answers the intended base-change question of p. 476, and also reconciles the two different projections mentioned on p. 476 bis. The assertion here is over the stated small Karoubian base; the proposal for a general nonsmall base is a further definition.

The standard closure theorem used in this proof is discussed precisely in Bourke and Lack (2024, Examples 4.8 and Remark 4.9). The identification of Grothendieck's strict test property with isomorphism lifting is our deduction; we did not find this formulation in those references. For actual Grothendieck fibrations and opfibrations, isomorphisms already lift, and the total-category proof supplied near pp. 438–440 gives the remaining accessibility. Thus Question 4.16.6.4 has an affirmative answer in both orientations. The distinction between strict pullbacks and pseudopullbacks accounts for the failure of b′ without making that structured result problematic.

[page 477]

4.16.7. Retour sur les sous-catégories fermées d'une catégorie accessible (4.16.1).

Proposition 4.16.7.1. *Soient $\mathcal{M}$ une catégorie accessible, $(\underline{S}_i)_{i\in I}$ une famille de sous-catégories fermées accessibles dans $\mathcal{M}$. On ne suppose que* $\operatorname{card} I$ *soit petit. Soit $\underline{S}$ la sous-catégorie strictement pleine de $\mathcal{M}$ telle que* $\operatorname{Ob} \underline{S} = \bigcup_{i\in I} \operatorname{Ob} \underline{S}_i$. *Alors pour que $\underline{S}$ soit accessible dans $\mathcal{M}$, il faut et il suffit qu'il existe une* petite *partie $J \subset I$, telle que* $\operatorname{Ob} \underline{S} = \bigcup_{i\in J} \underline{S}_i$. *(En* p. 185

particulier, si I est ordonnée, et $i \longmapsto \underline{S}_i$ croissante et grande devant tout petit cardinal, il faut et il suffit qu'il existe un $i \in I$ tel que $\underline{S} = \underline{S}_i$, i.e. tel que $j \geqslant i$ implique $\underline{S}_j = \underline{S}_i$.)

C'est évidemment suffisant, en vertu de 4.13… Prouvons inversement que si $\underline{S}$ est accessible dans $\mathcal{M}$, alors la condition précédente est satisfaite. Soit π un cardinal $\geqslant \pi_0$ tel que $\underline{S}$ soit π-accessible dans $\mathcal{M}$, donc

$$\underline{S} \xleftarrow{\sim} \operatorname{Ind}_\pi \underline{S}(\pi) , \qquad \text{où } \underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi.$$

Soit $\underline{S}(\pi)_0$ une sous-catégorie réduite de $\underline{S}(\pi)$, telle que $\underline{S}(\pi)_0 \hookrightarrow \underline{S}(\pi)$ soit une équivalence, [page 478] de sorte que $\underline{S}(\pi)_0$ est petite. Pour tout $x \in \operatorname{Ob} \underline{S}(\pi)_0$, soit $i_x \in I$ tel que $x \in \operatorname{Ob} \underline{S}_{i_x}$. Soit J l'ensemble de tous les i_x, que est une petite partie de I, et soit $\underline{S}_J$ la sous-catégorie strictement pleine de $\mathcal{M}$ ayant pour ensemble d'objets $\bigcup_{j\in J} \operatorname{Ob} \underline{S}_j$. Donc $\underline{S}(\pi)_0$ est contenue dans $\underline{S}_J$, donc aussi $\underline{S}(\pi)$, puisque $\underline{S}_J$ est strictement pleine :

$$\underline{S}(\pi) \hookrightarrow \underline{S}_J .$$

D'ailleurs $\underline{S}_J$ est accessible dans $\mathcal{M}$ (loc. cit.), et est fermée dans $\mathcal{M}$ comme réunion de sous-catégories fermées, *a fortiori elle satisfait à L_π*. Donc, comme $\underline{S}(\pi) \subset \underline{S}_J$, le foncteur essentiellement surjectif $\operatorname{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \underline{S}$ se factorise par $\underline{S}_J$. Donc $\underline{S}_J \hookrightarrow \underline{S}$ est essentiellement surjectif, et comme $\underline{S}_J$ est strictement pleine, on en conclut $\underline{S}_J = \underline{S}$, q.e.d.

Proposition 4.16.7.2. [page 479] *Soient $\mathcal{M}$ une catégorie accessible, x un objet de $\mathcal{M}$, et ${}_x\mathcal{M}$ la sous-catégorie fermée de $\mathcal{M}$ engendrée par x, formée des $y \in \operatorname{Ob} \mathcal{M}$ tels que $\operatorname{Hom}(x, y) \neq \emptyset$, i.e. l'image essentielle de $x\backslash\mathcal{M} \longrightarrow \mathcal{M}$. Alors ${}_x\mathcal{M}$ est une sous-catégorie de $\mathcal{M}$ accessible dans $\mathcal{M}$.*

En effet, c'est l'image inverse de la sous-catégorie Ens^* accessible dans Ens par le foncteur représentable (donc accessible)

$$h_x \ : \ y \longmapsto \operatorname{Hom}(x, y) \ : \ \mathcal{M} \longrightarrow \mathrm{Ens} ,$$

donc est accessible dans $\mathcal{M}$ en vertu de 4.13…

Corollaire 4.16.7.3. *Soit $\mathcal{M}$ une catégorie accessible, $\underline{S}$ une sous-catégorie fermée. Pour que $\underline{S}$ soit accessible, il faut et il suffit qu'il existe une* petite *partie J de $\underline{S}$, telle que $\operatorname{Ob} \underline{S} = \bigcup_{x\in J} \operatorname{Ob}({}_x\mathcal{M})$.*

En effet, on a

$$\operatorname{Ob} \underline{S} = \bigcup_{x \in \operatorname{Ob} \underline{S}} \operatorname{Ob}({}_x\mathcal{M}) ,$$

i.e. $\underline{S}$ apparaît comme réunion de la famille (pas nécessairement petite) de sous-catégories [page 480] fermées ${}_x\mathcal{M}$ de $\mathcal{M}$ (indexées par $x \in \operatorname{Ob} \underline{S}$), accessibles dans $\mathcal{M}$ en vertu de 4.16.7.2. Donc notre assertion est un cas particulier de 4.16.7.1.

Commentary · Exposition [ms. 479]

Closed subcategories and small weakly initial families

Grothendieck's return to closed subcategories isolates the generation condition which the earlier examples lacked. A cosieve $\mathcal{S}$ is closed under any existing nonempty colimit of its objects: choosing one stage already gives an arrow from $\mathcal{S}$ into the colimit. Its accessibility therefore depends on how many different starting objects are required to reach every object of $\mathcal{S}$.

A family $A \subseteq \operatorname{Ob} \mathcal{S}$ generates the cosieve precisely when every $s \in \mathcal{S}$ receives a map from some $a \in A$. This is a weakly initial family; no uniqueness of the map is required. If it is small, choose a common useful rank at which all its objects are presentable. Let $\mathcal{T}$ be the complementary sieve. A sufficiently filtered diagram in $\mathcal{T}$ cannot have its colimit in $\mathcal{S}$: a map from one of the presentable generators to that colimit would factor through a stage, placing that stage in the cosieve. Thus $\mathcal{T}$ is closed under those colimits, and the canonical presentations used below prove accessibility of both parts.

Conversely, if $\mathcal{S}$ is accessible in $\mathcal{M}$, take a small skeleton of its presentable generators at a common useful rank. Every object of $\mathcal{S}$ is a nonempty filtered colimit of these generators, so receives a map from one of them. This proves Corollary 4.16.7.3 directly and explains why its small family is the right condition.

The union criterion follows with the same economy. If a union of accessible cosieves is accessible, choose one member of the family containing each object of a small generating skeleton of the union. These choices use only a small subfamily. Its union is itself a cosieve, hence contains every colimit generated by that skeleton and is the whole union. Conversely, the union of the small generating families of a small subfamily is again small. In particular, a union indexed by an order directed beyond every small cardinal is accessible exactly when a single stage already contains it. No finiteness or countability assertion is hidden in the word small: it is always relative to the fixed universe.

p. 186

On peut aussi, pour toute partie petite J de $\mathrm{Ob}\,\underline{S}$, considérer la sous-catégorie fermée $\underline{S}_J \subset \underline{S}$ de $\mathcal{M}$ engendrée par J. L'ensemble I des parties J en question, ordonné par inclusion, est grand devant tout cardinal $\pi \in \mathfrak{U}$, et $\underline{S}$ est réunion croissante des $\underline{S}_J$. D'autre part, la proposition nous dit que $\underline{S}$ est accessible dans $\mathcal{M}$ si et seulement s'il existe un $J \in I$, tel que $\underline{S}_J = \underline{S}$, i.e. tel que $\underline{S}_J = \underline{S}_{J'}$ pour $J \subset J'$.

Proposition 4.16.7.4. *Soit $\mathcal{M}$ une catégorie accessible. Les conditions suivantes sont équivalentes :*

a) Il existe une sous-catégorie $\underline{S}$ de $\mathcal{M}$ fermée dans $\mathcal{M}$, et non accessible dans $\mathcal{M}$.

b) Soit I l'ensemble des ordinaux α tels que $\mathrm{card}\,\alpha \in \mathfrak{U}$*, i.e. des ordinaux α qui sont dans $\mathfrak{U}$. Donc $I = I_{\alpha_0}$, où α_0 est le plus petit ordinal qui n'appartienne pas à $\mathfrak{U}$, et I est grand devant tout petit cardinal π, i.e. devant tout cardinal dans $\mathfrak{U}$ ([197]). La condition envisagée est la suivante :* [page 481]

Il existe une suite transfini

$$\underline{x} \;=\; (x_\alpha)_{\alpha\in I}$$

d'éléments de $\mathrm{Ob}\,\mathcal{M}$*, telle que l'on ait*

$$\mathrm{Hom}(x_\beta, x_\alpha) \;=\; \emptyset \qquad\qquad \textit{si } \beta < \alpha.$$

De façon précise, pour une telle suite transfinie, soit $\underline{S}$ ou ${}_{\underline{x}}\mathcal{M}$ la sous-catégorie fermée de $\mathcal{M}$ engendrée par la famille des x_α, i.e. telle que $\mathrm{Ob}\,\underline{S} = \bigcup_{\alpha\in I} \mathrm{Ob}\ {}_{x_\alpha}\mathcal{M} = \bigcup_{\alpha\in I} x_\alpha \setminus \mathrm{Ob}\,\mathcal{M}$. Alors ${}_{\underline{x}}\mathcal{M}$ est une sous-catégorie fermée non accessible dans $\mathcal{M}$, et toute sous-catégorie fermée non accessible dans $\mathcal{M}$ s'obtient de cette façon.

Démonstration. Considérons une suite $\underline{x} = (x_\alpha)_{\alpha\in I}$ comme dessus. Si J est une petite partie de I, il existe un $\alpha \in I$ qui majore les $\beta \in J$, donc $\mathrm{Hom}(x_\beta, x_\alpha) = \emptyset$, pour $\beta \in J$, ce qui signifie que x_α n'appartient à aucune des $\underline{S}_\beta = {}_{x_\beta}\mathcal{M}$, pour $\beta \in J$. Donc $\underline{S}$ n'est par réunion d'une petite sous-famille de la famille des ${}_{x_\alpha}\mathcal{M}$, donc en vertu de 4.16.7.1, $\underline{S}$ n'est par accessible dans $\mathcal{M}$. [page 482]

Inversement, soit $\underline{S}$ une telle sous-catégorie dans $\mathcal{M}$. Considérons un bon ordre sur $\mathrm{Ob}\,\underline{S}$ (objets s_α), et construisons la suite des x_α ($\geqslant s_\alpha$) par récurrence transfinie ([198]).

1) On choisit $x_0 =$ premier élément de $\mathrm{Ob}\,\underline{S}$ (existe, car $\mathrm{Ob}\,\underline{S} \neq \emptyset$, i.e. $\underline{S} \neq \emptyset$, car sinon, $\underline{S}$ serait accessible dans $\mathcal{M}$).

2) Si les x_β ($\beta < \alpha$) sont construits, on prend pour x_α le premier élément de $\underline{S}$ majorant les x_β et qui n'appartient pas à la sous-catégorie fermée de $\mathcal{M}$ engendrée par les x_β ($\beta < \alpha$). (Cette sous-catégorie fermée est $\subset \underline{S}$, et $\neq \underline{S}$, car $\underline{S}$ n'est pas accessible dans $\mathcal{M}$.) On a donc bien

$$\mathrm{Hom}(x_\beta, x_\alpha) \;=\; \emptyset \qquad\qquad \text{si } \beta < \alpha.$$

p. 187

197. introduire $I = I_{\mathfrak{U}}$ avant l'énoncé de la proposition. [page 483]

198. **N.B.** On a $\mathrm{card}\,\underline{S} \notin \mathfrak{U}$, sinon, $\underline{S}$ serait petite, donc accessible dans $\mathcal{M}$, contrairement à l'hypothèse.

Ainsi, la récurrence transfinie se poursuit sur I tout entier. On voit par récurrence transfinie qu'on a, pour tout $\alpha \in I$,

$$s_\alpha \leqslant x_\alpha$$

(card $x_\alpha > x_\beta \geqslant s_\beta$ pour $\beta < \alpha$, donc $x_\alpha > s_\beta$ pour tout $\beta < \alpha$, ce qui équivaut à $x_\alpha \geqslant s_\alpha$). De plus, on trouve aussi, par récurrence transfinie, que

$$(*) \qquad \beta < \alpha \quad \Longrightarrow \quad \begin{array}{l} s_\beta \text{ appartient à la sous-catégorie} \\ \text{fermée } \underline{S}_\alpha \text{ de } \mathcal{M} \text{ engendrée par} \\ \text{les } x_{\beta'} \text{ avec } \beta' < \alpha. \end{array} ,$$

puisque par construction s_α est le *premier* des éléments de $\underline{S}$ qui n'est *pas* dans ladite sous-catégorie $\underline{S}_\alpha$ de $\mathcal{M}$. Cela montre que tout s_β appartient à la sous-catégorie fermée ${}_{\underline{x}}\mathcal{M}$ de $\mathcal{M}$ engendrée par la famille de *tous* les x_α, donc on trouve que $\underline{S} \subset {}_{\underline{x}}\mathcal{M} \subset \underline{S}$, donc $\underline{S} = {}_{\underline{x}}\mathcal{M}$, q.e.d.

Proposition 4.16.7.5. *Pour un univers $\mathfrak{U}$ donné (contenant $\mathcal{N}$ comme élément), les conditions suivantes sont équivalentes :*

1) Il existe une catégorie $\mathfrak{U}$-accessible $\mathcal{M}$ ayant une sous-catégorie fermée non accessible dans $\mathcal{M}$. [page 484]

b) Il existe une catégorie $\mathcal{C} \in \mathfrak{U}$, et une suite transfinie d'éléments de

$$\mathcal{C}^\wedge \overset{\text{déf}}{=} \underline{\mathrm{Hom}}(\mathcal{C}, \mathrm{Ens}_\mathfrak{U}) ,$$

$\underline{x} = (x_\alpha)_{\alpha \in I}$, indexée par l'ensemble de tous les ordinaux $\alpha \in \mathfrak{U}$, et telle que

$$\mathrm{Hom}(x_\alpha, x_\beta) = \emptyset \qquad \textit{si } \alpha < \beta.$$

Commentary · Exposition [ms. 483]

The transfinite construction and its size bound

Grothendieck turns failure of a small weakly initial family into a sequence with no arrows pointing forward. The order used in the recursive construction is an external well order of representatives. It is not the preorder defined by existence of a morphism; confusing them would make the displayed condition contradict the instruction to choose a larger object.

Write $\mathfrak{U} = V_\theta$ for the fixed infinite Grothendieck universe. An accessible $\mathfrak{U}$-category has at most θ isomorphism classes. Indeed, a small dense subcategory embeds it fully faithfully in a presheaf category on a $\mathfrak{U}$-small category. For every cardinal bound below θ, only a $\mathfrak{U}$-small set of isomorphism classes of such presheaves has values within that bound; taking all bounds gives at most θ classes. We may therefore work with a skeleton of a cosieve $\mathcal{S}$, rather than a possibly much larger set of duplicate objects. If $\mathcal{S}$ is nonaccessible, this skeleton cannot have cardinal less than θ, by the small-family criterion. Enumerate it as $(s_\alpha)_{\alpha<\theta}$.

At stage α, let $\mathcal{S}_\alpha$ be the cosieve generated by the already chosen x_β, $\beta < \alpha$. This is generated by a small set, hence is not all of $\mathcal{S}$. Choose x_α to be the first element of the well order outside $\mathcal{S}_\alpha$. Then

$$\mathrm{Hom}(x_\beta, x_\alpha) = \varnothing \qquad (\beta < \alpha).$$

The indices of the chosen objects are strictly increasing, since every object preceding the least previously uncovered object was already covered. By induction, before stage α every s_β with $\beta < \alpha$ is covered: if one were still uncovered, the next least-uncovered index would be less than α, contrary to the strictly increasing sequence of prior choices. Thus the resulting family generates all of $\mathcal{S}$. In the printed explanation of this step, the least uncovered object is x_α, not s_α.

Conversely, let $(x_\alpha)_{\alpha<\theta}$ have no forward morphisms and let $\mathcal{S}$ be its generated cosieve. If it had a small weakly initial family (a_j), each a_j would receive a map from some x_{β_j}. The small set of ordinals β_j has a bound below θ. A later x_α would have to receive a map from one a_j, giving the forbidden composite $x_{\beta_j} \to a_j \to x_\alpha$. This proves nonaccessibility and both directions of Proposition 4.16.7.4.

The same full presheaf embedding proves Proposition 4.16.7.5, since it preserves the emptiness of hom sets. It does not prove the additional assertion about a sequence consisting entirely of fields: the algebras constructed in the appendix need not be fields. The following development at p. 485 answers that stronger question by a separate graph-to-field construction and identifies its exact dependence on the universe boundary.

Démonstration. On a b) $\Longrightarrow$ a) en prenant $\mathcal{M} = \mathcal{C}^\wedge$, en vertu de la proposition précédente. On voit de même a) $\Longrightarrow$ b), en plongeant $\mathcal{M}$ dans une catégorie $\mathcal{C}^\wedge$ ($\mathcal{C}$ étant une petite sous-catégorie strictement génératrice de $\mathcal{M}$).

Je n'ai pas été capable ([199]) de construire une suite $(x_\alpha)_{\alpha\in I}$ comme exigée dans cette proposition, ni de prouver qu'une telle suite n'existe pas, même dans un cas particulier tel que $\mathcal{M} = (k\text{-alg. comm.})$, k un anneau commutatif. Je n'ai pas même prouvé qu'on ne puisse [page 485] trouver une suite transfinie de *corps* k_α, ayant les propriétés dites.

A fortiori, je n'ai pu tirer au clair la question si une sous-catégorie $\underline{\mathrm{L}}$-stable d'une catégorie $\mathcal{M}$ accessible est toujours accessible dans $\mathcal{M}$ ([200]). Il se pourrait qu'il n'y ait pas de tel cas. Il se pourrait aussi qu'il y en ait, même avec une sous-catégorie fermée (laquelle est stable par tout type de $\varinjlim$ représentable dans $\mathcal{M}$, sauf la $\varinjlim$ sur une catégorie d'indices vide …).

Pour les sous-catégories *ouvertes*, je rappelle que j'ai construit (dans l'appendice) un p. 188 exemple d'une telle sous-catégorie, non accessible dans $\mathcal{M}$. Au sujet des sous-catégories ouvertes, je signale ici l'énoncé (quasi tautologique) :

Proposition 4.16.7.6 ([201]). *Soient $\mathcal{M}$ une catégorie accessible, $\underline{S}$ une sous-catégorie* [page 486] ouverte *de $\mathcal{M}$. Pour que $\underline{S}$ soit accessible dans $\mathcal{M}$, il faut et il suffit qu'elle soit $\underline{L}$-stable dans $\mathcal{M}$, i.e. qu'il existe un cardinal π_0 tel que $\mathcal{M}$ satisfasse à L_{π_0}, et que $\underline{S}$ soit stable dans $\mathcal{M}$ par $\varinjlim$ de type L_{π_0}. De façon plus précise, si cette condition est satisfaite, alors pour tout cardinal π tel que $\pi \geqslant \pi_0$ et que π soit utile pour $\mathcal{M}$, $\underline{S}$ est π-accessible dans $\mathcal{M}$. Ou encore : si π est un cardinal utile pour $\mathcal{M}$, alors $\underline{S}$ est π-accessible dans $\mathcal{M}$ si et seulement s'il est L_π-stable dans $\mathcal{M}$.*

Commentary · Development (commentators') [ms. 485]

The field question detects a Vopenka universe

The question about fields has an answer depending on the chosen universe. The later example with arbitrary k-algebras does not by itself answer this narrower question. A field functor from graph theory provides the missing passage.

Universe-relative field criterion. [ours] Let $\mathfrak{U} = V_\kappa$, with κ strongly inaccessible and $\omega \in \mathfrak{U}$. There exists a sequence $(k_\alpha)_{\alpha<\kappa}$ of fields in $\mathfrak{U}$ such that

$$\mathrm{Hom}(k_\alpha, k_\beta) = \varnothing \quad (\alpha < \beta)$$

if and only if κ is not a Vopěnka cardinal. If such a sequence exists, one can choose characteristic zero throughout and make the Hom sets empty for *all* distinct indices.

Here a Vopěnka cardinal means that every κ-element family of structures in V_κ in a fixed small language contains distinct members with an elementary embedding between them. All external subsets of V_κ are allowed as families. This is stronger than merely asking V_κ to satisfy an internally definable axiom scheme. A fixed language with one binary and one unary relation suffices (Brooke-Taylor, 2011, Definitions 1–3).

First suppose κ is Vopěnka. The proposed fields are pairwise nonisomorphic. For every infinite $\mu < \kappa$, at most $2^\mu < \kappa$ isomorphism types of fields have size at most μ: put their operations on subsets of μ and count the finite-arity tables. Regularity of κ therefore lets us thin the sequence to length κ with strictly increasing field cardinalities and indices. At each stage, the previous suprema are still below κ, whereas fewer than κ indices have bounded field size. Backwards homomorphisms

199. Mais si, finalement, cf. 4.16.7.10 plus bas.

200. C'est faux, cf. plus bas.

201. Cette proposition et son corollaire sont contenus dans 4.16.7.8 ci-dessous, il n'y a pas lieu d'en faire un énoncé séparé.

in this subsequence are impossible because field homomorphisms are injective. Forward ones are excluded by hypothesis. The Vopěnka property nevertheless supplies an elementary embedding between two distinct fields, hence a field homomorphism, a contradiction.

Conversely, suppose κ is not Vopěnka. Choose κ structures $M_\alpha \in V_\kappa$ in the fixed finite relational language with no elementary embedding between distinct members. For every formula $\varphi(\bar{x})$ add the relation R_φ of its true tuples, including negated formulas and sentences. This countable relational expansion has the property that any injection preserving all its relations is elementary: R_φ preserves truth and $R_{\neg\varphi}$ preserves falsity.

We give the graph encoding explicitly, to match the precise graph morphisms needed below. Make a core graph with an element vertex v_a for every $a \in M$, a tuple vertex $t_{\varphi,\bar{a}}$ for each true $R_\varphi(\bar{a})$, and a position vertex $s_{\varphi,\bar{a},j}$ for each coordinate. The core edges are exactly

$$t_{\varphi,\bar{a}} \;-\; s_{\varphi,\bar{a},j} \;-\; v_{a_j}.$$

This core is bipartite: elements and tuple vertices form one part, positions the other. Assign one type to elements, a distinct type to each formula's tuple vertices, and a distinct type to each formula-coordinate pair. There are countably many types; enumerate them by $n \in \omega$.

At every core vertex of type n, attach two cycles of lengths $4n+5$ and $4n+7$, identifying one vertex of each cycle with that core vertex and otherwise using fresh vertices. Every odd simple cycle in the resulting graph is one of these attached cycles. A simple cycle cannot enter and leave an attached block through its sole attachment vertex without repeating that vertex; a cycle confined to the core is even.

An induced-subgraph embedding must send each tag cycle to a tag cycle of the same length. The two cycles at a source core vertex meet exactly in that vertex; their images meet in its image. As the target tag cycles of these two lengths intersect only when they are attached at the same core vertex, that image is a core vertex of the same type. Thus every core type is preserved. The image of a tuple vertex has the same formula type, and its unique position neighbor of type (φ, j) forces the corresponding coordinate element to be the image of a_j. The induced injection on elements preserves every R_φ, and is elementary. The graphs $G(M_\alpha)$ consequently have no induced-subgraph embeddings between distinct members.

Their sizes are at most $\max(|M_\alpha|, \aleph_0)$: finite tuples, countably many relation symbols, and the finite tags do not exceed that bound. Now apply Miller et al. (2018, Theorem 1.1, Section 5.A and Remark 5.1). They construct a fully faithful functor from symmetric irreflexive graphs with induced-subgraph embeddings to fields with field homomorphisms. Its values have characteristic zero and size $\max(|G|, \aleph_0)$. One detail of their proof must be read with finite support in view: the real-specialization argument in Lemma 5.3(ii) is applied to the finite-vertex subfield containing the parameters of an alleged point and the indicated vertices i, j. An arbitrarily large whole field need not embed in $\mathbb{R}$, but that finite-parameter argument proves the stated exclusion at every cardinality. Therefore

$$k_\alpha = F(G(M_\alpha))$$

belongs to $\mathfrak{U}$ and has no homomorphism to k_β for $\alpha \neq \beta$. Standard presentations of cardinality below κ may be chosen inside V_κ. This completes the proof.

In particular, such a field sequence exists for the smallest universe containing ω. Its first inaccessible height cannot be Vopěnka. Indeed the characterization by extendibility below κ gives an elementary embedding $j : V_\eta \to V_\zeta$ of critical point $\delta < \kappa$, with $\eta > \delta + \omega$ (Brooke-Taylor, 2011, Proposition 7). The derived ultrafilter

$$\{X \subseteq \delta : \delta \in j(X)\}$$

is nonprincipal and δ-complete, so δ is measurable and hence inaccessible, contradicting first inaccessibility. At a Vopěnka universe the first half of the argument excludes the sequence.

This is a deduction from established theorems, with the reduction supplied in detail and no claim of priority. The field functor is a substantial algebraic construction: its cardinal preservation and full faithfulness, rather than merely the existence of fields with few automorphisms, are what the argument needs. The manuscript's question should accordingly be recorded as dependent on the universe, rather than left as an unqualified currently open field problem.

Cette dernière assertion résulte aussitôt du corollaire suivant, lui-même tautologique.

Corollaire 4.16.7.7. *Soit π un cardinal comme indiqué ci-dessus, soit $\underline{S}(\pi) = \underline{S} \cap \mathcal{M}_\pi$, et soit $x \in \mathrm{Ob}\,\mathcal{M}$ et*

$$x \simeq \varinjlim_{i \in I} x_i \qquad \begin{cases} x_i \in \mathrm{Ob}\,\mathcal{M}_\pi \\ I \text{ grande devant } \pi \end{cases}$$

une représentation de x comme image essentielle d'un objet de $\mathrm{Ind}_\pi \mathcal{M}_\pi$. Alors $x \in \mathrm{Ob}\,\underline{S} \iff x_i \in \mathrm{Ob}\,\underline{S}(\pi)\ \forall\, i \in I$.

J'ai finalement tiré au clair la question de l'accessibilité des sous-catégories ouvertes et des sous-catégories fermées d'une catégorie accessible : [page 487]

Proposition 4.16.7.8. *Soient $\mathcal{M}$ une catégorie accessible, $\underline{S}$ une sous-catégorie fermée de $\mathcal{M}$, $\underline{T}$ la sous-catégorie ouverte complémentaire de $\underline{S}$, π un cardinal infini utile pour $\mathcal{M}$. Les conditions suivantes sont équivalentes :*

a) $\underline{S}$ est π-accessible dans $\mathcal{M}$.

a′) $\underline{S}$ est le fermé engendré par $\underline{S}(\pi) \overset{\text{déf}}{=} \underline{S} \cap \mathcal{M}_\pi$, i.e. pour $x \in \mathrm{Ob}\,\mathcal{M}$, on a $x \in \mathrm{Ob}\,\underline{S}$ si et seulement si $\exists\, \xi \in \mathrm{Ob}\,\underline{S}(\pi)$ tel que $\mathrm{Hom}_{\mathcal{M}}(\xi, x) \neq \emptyset$.

b) $\underline{T}$ est π-accessible dans $\mathcal{M}$.

b′) $\underline{T}$ est $\underline{L}_\pi$-stable dans $\mathcal{M}$.

Notons tout de suite le

Corollaire 4.16.7.9. *Pour $\mathcal{M}$, $\underline{S}$, $\underline{T}$ comme dessus, conditions équivalentes :*

a) $\underline{S}$ est accessible dans $\mathcal{M}$.

a′) Il existe une petite *partie A de $\mathrm{Ob}\,\mathcal{M}$, telle que $\underline{S}$ soit la sous-catégorie fermée ${}_A\mathcal{M}$ engendrée par A, i.e. $\underline{S} = \bigcup_{\xi \in A} {}_\xi\mathcal{M}$, où ${}_\xi\mathcal{M}$ est la sous-catégorie fermée de $\mathcal{M}$ formée des $x \in \mathrm{Ob}\,\mathcal{M}$ tel que $\mathrm{Hom}(\xi, x) \neq \emptyset$.*

b) $\underline{T}$ est accessible dans $\mathcal{M}$. [page 488]

Commentary · Exposition [ms. 487]

One canonical slice proves the open–closed criterion

Grothendieck's final criterion makes the algebraic obstruction usable. It says that the inaccessible no-point cosieve and the failure of filtered-colimit closure of the point-admitting sieve are two manifestations of one phenomenon. The proof takes place in a single category of presentable objects over a fixed target; several omitted slice denominators in the printed proof obscure this otherwise exact argument.

Fix a useful π, write $\kappa = \pi^+$, and let $\mathcal{A}$ be a small skeleton of $\mathcal{M}_\pi$. For $x \in \mathcal{M}$, the canonical category $\mathcal{A}/x$ is κ-filtered, and its tautological diagram has colimit x. If $\mathcal{S}$ is a replete cosieve and $\mathcal{T}$ its complementary sieve, put

$$J_x = (\mathcal{S} \cap \mathcal{A})/x, \qquad K_x = (\mathcal{T} \cap \mathcal{A})/x.$$

These are a cosieve and its complementary sieve in $\mathcal{A}/x$, not in $\mathcal{S}(\pi)$. A nonempty full cosieve in a filtered category is cofinal. Given an object j in the cosieve and any object a of the ambient category, a common successor belongs to the cosieve; common successors and equalizations similarly verify connectedness of the relevant comma categories. For the stronger κ-filtered assertion, first cocone any fewer-than-κ diagram in the ambient category and then move its vertex into the cosieve. In contrast, a proper complementary sieve cannot be cofinal, since an object in the cosieve has no arrow into it. Hence

$$J_x \neq \varnothing \iff J_x \text{ cofinal}, \qquad K_x \text{ cofinal} \iff J_x = \varnothing.$$

For completeness, the Ind-image criterion used here has a direct proof. If x is a κ-filtered colimit of objects of a full $\mathcal{B} \subseteq \mathcal{A}$, every map $a \to x$ with $a \in \mathcal{A}$ factors through a stage by presentability. Equalities between two factorizations hold at a later stage. Therefore the presentation functor is

cofinal in $\mathcal{A}/x$, and so is the full subcategory $\mathcal{B}/x$ through which it factors. Conversely, if $\mathcal{B}/x$ is cofinal, restriction of the canonical presentation expresses x as its colimit. A full cofinal subcategory of this κ-filtered category is again κ-filtered: cocone a small diagram in the ambient category and use fullness after moving the vertex into the subcategory. This proves Lemma 4.16.7.11 with its slice variables restored.

Apply the criterion to $\mathcal{B} = \mathcal{S} \cap \mathcal{A}$. The condition that the Ind-image be exactly $\mathcal{S}$ becomes

$$x \in \mathcal{S} \quad \Longleftrightarrow \quad J_x \neq \varnothing,$$

which says precisely that $\mathcal{S}$ is generated by its π-presentable objects. Taking complements turns this into

$$x \in \mathcal{T} \quad \Longleftrightarrow \quad K_x \text{ is cofinal in } \mathcal{A}/x,$$

the identical Ind-image criterion for $\mathcal{T}$. Finally, if $\mathcal{T}$ is closed under the relevant filtered colimits, every presentation of an object in $\mathcal{T}$ has all its stages in $\mathcal{T}$, by the sieve condition, and conversely a presentation with all stages there has colimit there by closure. This proves its accessibility and gives the equivalence with b′.

Passing to a common larger useful rank yields Corollary 4.16.7.9. This proof explains both why the theorem is valid and why it settles the appendix's abandoned question about the complementary cosieve. The only changes required in the printed argument are the missing slice or presentability subscripts, the names of the Ind functor, and the final reference to Proposition 4.16.7.6.

p. 189

b′) $\underline{T}$ est $\underline{L}$-stable dans $\mathcal{M}$.

Corollaire 4.16.7.10. *Soit $\mathcal{M}$ une catégorie accessible. Les conditions suivantes sont équivalentes ([202]).*

a) Il existe une sous-catégorie fermée de $\mathcal{M}$, non accessible dans $\mathcal{M}$.

b) Il existe une sous-catégorie ouverte dans $\mathcal{M}$, non accessible dans $\mathcal{M}$.

c) Il existe une suite transfinie

$$\underline{x} \;=\; (x_\alpha)_{\alpha \in I}$$

d'objets de $\mathcal{M}$, indexée par l'ensemble I des ordinaux de l'univers de référence $\mathfrak{U}$, telle que l'on ait

$$\mathrm{Hom}(x_\alpha, x_\beta) \;=\; \emptyset \qquad \textit{pour } \alpha < \beta.$$

En effet, l'équivalence de a) et b) est claire par le corollaire précédent, et celle de a) et c) n'est autre que 4.16.7.4.

Démonstration de 4.16.7.8. Nous aurons à utiliser le

Lemme 4.16.7.11. *Soient $\mathcal{M}$ une catégorie accessible, π un cardinal utile pour $\mathcal{M}$, $\underline{S}$ une sous-catégorie pleine de $\mathcal{M}$, $\underline{S}(\pi) \overset{\text{déf}}{=} \underline{S} \cap \mathcal{M}_\pi$, d'où un foncteur pleinement fidèle*

$$\varphi \;:\; \mathrm{Ind}_\pi(\underline{S}(\pi)) \longrightarrow \mathcal{M}\ .$$

a) Soit $x \in \mathrm{Ob}\,\mathcal{M}$. Pour que x appartienne à l'image essentielle du foncteur ψ, il faut et il suffit que la sous-catégorie pleine $\underline{S}(\pi)/x$ de la catégorie $\mathcal{M}_\pi/x$ (qui est filtrante et même grande devant π) soit cofinale (donc aussi grande devant π). [page 489]

b) Pour que $\underline{S}$ soit π-accessible dans $\mathcal{M}$, il faut et il suffit que pour tout $x \in \mathrm{Ob}\,\mathcal{M}$, on ait

$$x \;\in\; \mathrm{Ob}\,\underline{S} \qquad \Longleftrightarrow \qquad \underline{S}(\pi)/x \textit{ est cofinale dans } \mathcal{M}_\pi/x$$

(ou encore, que $\underline{S}$ satisfasse à L_π, et que pour tout x dans $\mathcal{M}$, on ait

$$x \;\in \mathrm{Ob}\,\underline{S} \qquad \Longrightarrow \qquad \underline{S}(\pi)/x \textit{ cofinale dans } \mathcal{M}_\pi/x.)$$

202. Exemple où ces conditions sont satisfaites : $\mathcal{M} = (k\text{-alg. comm.})$, k un corps commutatif infini, $\mathfrak{U}$ étant le plus petit univers tel que $\mathbf{N} \in \mathfrak{U}$.

Commentary · Examples [ms. 488]

The criterion in sets and in a pointed category

The distinction between an arbitrary full subcategory and a sieve or cosieve is restrictive enough to make the final criterion concrete. In Set, a nonempty cosieve containing $\varnothing$ is all of Set, because $\varnothing$ maps to every set. If a cosieve contains a nonempty set X, the map $X \to 1$ puts 1 in the cosieve, and the maps $1 \to Y$ put every nonempty Y there. Thus the only replete cosieves are

$$\varnothing, \qquad \mathsf{Set}_{\neq\varnothing}, \qquad \mathsf{Set}.$$

The middle one is generated by 1 and its complementary sieve consists only of $\varnothing$. The former has the usual filtered presentations by nonempty finite subsets; the latter is the terminal category and is closed under filtered colimits. This computes both sides of the criterion at the smallest relevant ranks.

In a pointed category with zero morphisms, any two objects admit a map. Hence every nonempty cosieve, and every nonempty sieve, is the whole category. For example, the no-map construction cannot give a nontrivial open–closed decomposition of abelian groups: every group has its zero map to every fixed group. This is why commutative unital k-algebras are a useful test here. Their morphisms must preserve the unit and the specified copy of k, so the absence of a map to k is a genuine algebraic condition.

Démonstration. La partie b) est une conséquence tautologique de a), que je vais prouver. Dire que x est dans l'image essentielle de $\underline{S}$, signifie que

$$(*) \qquad x \simeq \varinjlim_{i\in I} x_i \ ,$$

avec I grande devant π et les x_i dans $\underline{S}(\pi)$. On sait que $(*)$ implique (I étant filtrante, et $\mathcal{M}$ étant équivalente à $\mathrm{Ind}_\pi(\mathcal{M})$ puisque π utile pour $\mathcal{M}$) que $I \longrightarrow \mathcal{M}_\pi/x$ est cofinale (4.4.2, page 79). Or ce foncteur se factorise par le foncteur d'inclusion pleinement fidèle $\underline{S}(\pi)/x \hookrightarrow \mathcal{M}_\pi/x$, lequel est cofinal si et seulement s'il satisfait la condition F 1. Il est immédiat que cette condition est satisfaite quand elle est satisfaite pour le foncteur composé en question, ce qui est bien le cas par hypothèse. p. 190

Inversement, supposons que $\underline{S}(\pi)/x$ soit cofinale dans $\mathcal{M}_\pi/x$. Comme on a [page 490]

$$x \xleftarrow{\sim} \varinjlim_{\mathcal{M}_\pi/x} x_i \ ,$$

π étant utile pour $\mathcal{M}$, on aura aussi par cofinalité

$$x \xleftarrow{\sim} \varinjlim_{\underline{S}(\pi)/\pi} x_i \ ,$$

or $\mathcal{M}_\pi$ étant grande devant π, il en est de même de la sous-catégorie pleine cofinale $\underline{S}(\pi)/x$. Donc x est dans l'image essentielle de $\mathrm{Ind}_\pi \underline{S}(\pi)$, q.e.d.

Lemme 4.16.7.12. *Soient I une catégorie filtrante, J une sous-catégorie fermée, K la sous-catégorie ouverte complémentaire. On a alors les équivalences*

$$J \neq \emptyset \iff J \text{ cofinale} \iff K \text{ non cofinale} \iff K \neq I \ .$$

Démonstration immédiate.

Je reviens à la démonstration de 4.16.7.8. On applique le lemme 4.16.7.11 à $\mathcal{M}$, π, et aux deux sous-catégories $\underline{S}$, $\underline{T}$ de $\mathcal{M}$, en notant que pour $x \in \mathrm{Ob}\,\mathcal{M}$, $\underline{S}(\pi)/x$ est une sous-catégorie [page 491] fermée de $\underline{S}(\pi)$, dont le complémentaire ouvert est $\underline{T}(\pi)/x$, de sorte qu'on peut appliquer le

lemme 4.16.7.12. On trouve :

$$\underline{S}\ \pi\text{-accessible} \overset{4.16.7.11}{\iff} \forall\, x \in \mathrm{Ob}\,\mathcal{M},\ \text{on a } (x \in \mathrm{Ob}\,\underline{S} \iff \underline{S}(\pi)/x \text{ cofinale dans } \mathcal{M}_\pi/x)$$
$$\iff \forall\, x \in \mathrm{Ob}\,\mathcal{M},\ \text{on a } \Big(\underbrace{x \notin \mathrm{Ob}\,\underline{S}}_{\text{(i.e. } x \in \mathrm{Ob}\,\underline{T}\text{, par 4.16.7.12)}} \iff \underbrace{\underline{S}(\pi)/x \text{ non cofinale dans } \mathcal{M}_\pi/x}_{\text{(i.e. } \underline{T}(\pi)/x \text{ cofinale dans } \mathcal{M}_\pi\text{, par 4.16.7.12)}} \Big)$$
$$\overset{4.16.7.11}{\iff} \underline{T} \text{ est } \pi\text{-accessible.}$$

On a donc l'équivalence de a) et b). D'autre part, $\underline{S}(\pi)/x$ cofinale dans $\mathcal{M}_\pi/x$ signifie simplement $\underline{S}(\pi)/x \neq \emptyset$ (4.16.7.12), donc $\underline{S}$ π-accessible signifie que $\underline{S}$ est formée des $x \in \mathrm{Ob}\,\mathcal{M}$ tels que $\underline{S}(\pi) \neq \emptyset$, ce qui signifie aussi que $\underline{S}$ est le fermé dans $\mathcal{M}$ engendré par $\underline{S}(\pi)$, d'où a $\iff$ a′. D'autre part, l'équivalence b $\iff$ b′ n'est autre que 4.6.7.6 (dernière formulation).

[page 1]

Appendice

Ultraproduits de corps, et catégories accessibles

Soit $(k_\xi)_{\xi \in E}$ une famille de corps, indexé par un ensemble E. (Soit Φ un filtre non trivial dans E, i.e. une partie $\Phi \subset \mathfrak{P}(E)$ telle que :

a) $\emptyset \notin \Phi$, i.e. $A \in \Phi \Longrightarrow A \neq \emptyset$.

b) $A, B \in \Phi \Longrightarrow A \cap B \in \Phi$.

c) Si $A \in \Phi$, $A \subset B$, alors $B \in \Phi$.

d) $\Phi \neq \emptyset$ ($\iff E \in \Phi$).

(Cela revient à dire que Φ est une partie fermée de l'ensemble ordonné $\mathfrak{P}(E)$, *filtrante à gauche*, et ne contient pas le plus petit élément de $\mathfrak{P}(E)$, i.e. non égale à $\mathfrak{P}(E)$ tout entier.))

Pour toute partie J de E, posons

$$k_J = \prod_{\xi \in J} k_\xi ,$$

on a donc un système projectif

$$(k_J)_{J \in \mathfrak{P}(E)} , \qquad \text{i.e. } J \subset J' \text{ donne } k_{J'} \longrightarrow k_J ,$$

et le système

$$(k_J)_{J \in \Phi}$$

est un système inductif d'annaux, indexé par l'ensemble ordonné filtrant Φ^o. Posons

$$k_\Phi = \varinjlim_{J \in \Phi} k_J .$$

Si Ψ est un filtre plus fin que Φ, i.e. tel que $\Psi \supset \Phi$, on trouve un homomorphisme canonique

[page 2]

$$k_\Phi \longrightarrow k_\Psi ,$$

donc si $\mathcal{F}(E) = \mathcal{F}$ est l'ensemble des filtres sur E, ordonnés par inclusion, on trouve un système inductif

$$\Phi \longmapsto k_\Phi \ : \ \mathcal{F} \longrightarrow \mathrm{Ann} \ .$$

On n'a pas utilisé encore que les k_ξ sont des corps, en fait il suffirait que ce soient des objets d'une catégorie $\mathcal{A}$ stable par petits produis et par petits $\varinjlim$ filtrantes. Prenons maintenant $\mathcal{A} = \mathrm{Ann}$ (catégorie des anneaux unitaires, non nécessairement commutatifs), et supposons que les k_ξ soient des corps.

Proposition 1. *Supposons que les k_ξ ($\xi \in E$) soient des* corps ([203]). *Pour que k_Φ soit un corps, il faut et il suffit que Φ soit un ultrafiltre, i.e. que pour toute décomposition $E = A \amalg B$, on ait $A \in \Phi$ ou $B \in \Phi$.* (NB Si $A \in \Phi$, on a $B \notin \Phi$, puisque sinon, on aurait $A \cap B \in \Phi$, donc $\emptyset \in \Phi$, absurde.) p. 192

Nécessité : Soit, pour toute partie A de E,

$$f_A \in k_E \qquad \text{défini par} \qquad f_A(\xi) \ = \ \begin{cases} 1_{k_\xi} & \text{si} \quad \xi \in A \\ 0_{k_\xi} & \text{si} \quad \xi \in E \backslash A \ . \end{cases}$$

Soit [page 3]

$$f_{A,\Phi} \ \in k_\Phi$$

l'image de f_A par l'homomorphisme canonique $k_E \longrightarrow k_\Phi$. Si $E = A \amalg B$, on aura

$$f_A \ + \ f_B \ = \ 1 \ , \qquad f_A \, f_B \ = \ 0 \ ,$$

d'où

$$f_{A,\Phi} \ + \ f_{B,\Phi} \ = \ 1 \ , \qquad f_{A,\Phi} \, f_{B,\Phi} \ = \ 0 \ .$$

Si k_Φ est un corps, cela implique qu'on a $f_{A,\Phi} = 0$ ou $f_{B,\Phi} = 0$. Mais si p.ex. $f_{A,\Phi} = 0$, on voit que cela signifie qu'il existe un $J \in \Phi$ tel que $f_A | J = 0$, ce qui signifie aussi que $J \subset B$. De même, si $f_{B,\Phi} = 0$, on aura $J \subset A$. Donc Φ est un ultrafiltre.

Commentary · Exposition [ms. 2]

Reduced products as germs on a filter

Grothendieck turns to fields because they offer a concrete way of separating the existence of many local solutions from the existence of one compatible solution. The categorical construction comes first: a filter specifies which parts of a product may be discarded, and a filtered colimit makes those restrictions into identifications. This is the reduced product; it is called an ultraproduct only when the filter is an ultrafilter.

Write $R = \prod_{\xi \in E} k_\xi$. Every element of k_Φ has a representative in R, since a section on $J \in \Phi$ extends by zero outside J. Two representatives f, g have the same image precisely when their equalizer belongs to Φ. Consequently

$$k_\Phi \cong R/I_\Phi, \qquad I_\Phi = \{f \in R : Z(f) \in \Phi\}, \qquad Z(f) = \{\xi : f(\xi) = 0\}.$$

This formula includes the order reversal in the indexing category: shrinking J moves forward in Φ^{op}. It also proves directly that I_Φ is a two-sided ideal. Intersect two sets on which two functions vanish to handle addition; multiplying a vanishing function by an arbitrary function preserves its zero set. Properness of the filter gives $1 \notin I_\Phi$.

The proof of Proposition 1 uses exactly the dichotomy supplied by an ultrafilter. If $[g] \neq 0$, its zero set is not in Φ. For an ultrafilter the complementary support A is therefore in Φ. Define $h(\xi) = g(\xi)^{-1}$ on A, and put $h(\xi) = 1$ elsewhere. Both gh and hg agree with 1 on A, so $[h]$ is a two-sided inverse. This proof applies to division rings. In the reverse direction, the images of the complementary characteristic functions $e_A, e_{E \backslash A}$ are orthogonal idempotents summing to 1. A division ring has no idempotents other than $0, 1$, so one of the two sets belongs to the filter.

203. NB Cette condition est nécessaire si on veut que k_Φ soit un corps pour tout ultrafiltre.

Several formulas in this short proof look like failures of transcription but are already printed in the edition. The conditions involving $f \neq \emptyset$ and $g(\xi) \neq \emptyset$ concern nonzero ring elements. The representative to invert is $g(\xi)$, and the concluding identity must mean $ff' = f'f = 1$. The later sentence saying that every k_Φ is a field needs $\Phi \in \mathcal{F}_0$. For example, $E = \{0, 1\}$ and $\Phi = \{E\}$ give $k_\Phi = k \times k$. These slips are retained in the source and interpreted by the argument above.

The field assertion is also an instance of Łoś's theorem: the axioms for division rings are first-order sentences, and ultraproducts preserve them. The modern construction and the theorem, including their proofs, can be read in Keisler (2010, Definitions 2.4–2.5 and Theorem 3.1). Grothendieck's elementary proof is especially useful here because it keeps visible the characteristic functions which will classify all maps to the ground field.

Inversement, supposons que Φ soit un ultrafiltre. Prouvons que k_Φ est un corps, i.e. que pour $f \in k_\Phi$, $f \neq \emptyset \Longrightarrow f$ inversible. Notons que f provient d'un élément d'un k_J ($J \in \Phi$), donc est l'image canonique d'un $g \in k_E$. Dire que $f = 0$ signifie que $\exists\ J \in \Phi$ tel que $g|J = 0$. L'inverse $f \neq 0$ signifie donc que pour tout $J \in \Phi$, on a $g|J \neq \emptyset$.
Soit alors A l'ensemble des $\xi \in E$ tel que $g(\xi) \neq \emptyset$, $B = E\backslash A$ l'ensemble des $\xi \in E$ tels que [page 4]
$g(\xi) \neq \emptyset$. On a donc $B \notin \Phi$ puisque $f \neq 0$, et comme Φ est un ultrafiltre, on a donc $A \in \Phi$. Mais soit $g' \in k_E$ défini par $g'(\xi) = f(\xi)^{-1}$ si $\xi \in A$, $g'(\xi) = 1$ si $\xi \in B$, et soit f' l'image de g' dans k_Φ. On voit alors qu'on a

$$f\ f' \ =\ f' \ =\ f \ =\ 1\ ,$$

ce qui montre bien que k_Φ est un corps.
Supposons maintenant que tous les k_ξ ($\xi \in E$) soient égaux à un même corps k. Alors les k_J forment un système projectif de k-algèbres, les k_Φ un système inductif de k-algèbres. Si k est commutatif, il en est de même des k_J, k_Φ, et en particulier pour Φ un ultrafiltre, k_Φ est une *extension* du corps k.
Revenons au cas général, mais les k_ξ commutatifs. Soit $\mathcal{F}_0 \subset \mathcal{F}$ l'ensemble des ultrafiltres sur E. Notons que pour tout $\Phi \in \mathcal{F}$, $k_E \longrightarrow k_\Phi$ est surjectif. Donc si $\Phi \in \mathcal{F}$, k_Φ s'identifie à un corps quotient de l'anneau k_E.
Pour tout anneau $\mathcal{A}$, soit $\mathrm{Max}(\mathcal{A})$ le spectre maximal, i.e. l'ensemble des idéaux maximaux p. 193
de $\mathcal{A}$. On trouve donc une application canonique [page 5]

$$(*) \qquad \begin{cases} \mathcal{F}_0 & \longrightarrow & \mathrm{Max}(k_E) \\ \Phi & \longmapsto & \mathrm{Ker}(k_E \longrightarrow k_\Phi) \ \overset{\text{déf}}{=}\ \mathfrak{m}_\Phi\ . \end{cases}$$

Proposition 2. *L'application précédente est* bijective.
Prouvons d'abord qu'elle est injective, cela résulte aussitôt du
Corollaire 1 ([204]). *Soit, pour $\Phi \in \mathcal{F}_0$,*

$$\chi_\Phi\ :\ k_E \longrightarrow k_\Phi$$

l'application canonique. Alors pour $A \in \mathfrak{P}(E)$, on a

$$A\ \notin\ \Phi \qquad \Longleftrightarrow \qquad \chi_\Phi(f_A)\ =\ 0\ , \quad \textit{i.e. } f_A \in \mathfrak{m}_\Phi$$

(i.e. $A \in \Phi \iff \chi_\Phi(f_A) \neq 0$, i.e. $f_A \notin \mathfrak{m}_\Phi$) ([205]).
En effet, $\chi_\Phi(f_A) = 0$ signifie qu'il existe $B \in \Phi$ tel que $f_A|B = 0$, i.e. tel que $B \subset E\backslash A$; mais cela équivaut à $E\backslash A \in \Phi$, donc à $A \notin \Phi$ puisque Φ est un ultrafiltre, q.e.d.

204. **NB** Pour $\Phi \in \mathcal{F}$ quelconque, $\mathfrak{m}_\Phi \overset{\text{déf}}{=} \mathrm{Ker}(\chi_\Phi : k_E \longrightarrow k_\Phi)$ détermine Φ, puisque

$$A\ \in\ \Phi \qquad \Longleftrightarrow \qquad \chi_\Phi(f_A)\ =\ 1 \qquad \text{[page 6]}$$

(mais il faut supposer les $K_\xi \neq 0$, i.e. $0_\xi \neq 1_\xi$ ...).

205. **NB** On a donc

$$(\chi_\Phi(f_A)\ \neq\ 0) \qquad \Longleftrightarrow \qquad (\chi_\Phi(f_A)\ =\ 1)\ .$$

Reste à prouver que l'application $(*)$ est surjective. Soit donc $\mathfrak{m}$ un idéal maximal de k_E, et soit

$$\Phi \overset{\text{déf}}{=} \{A \in \mathfrak{P}(E) \mid \chi(f_A) = 1\} ,$$

où $\chi : k_E \longrightarrow k_E/\mathfrak{m} = \kappa(\mathfrak{m})$ est l'application canonique. Je dis que Φ est un ultrafiltre. En effet :

a) $\emptyset \notin \Phi$ car $f_\emptyset = 0$, d'où $\chi(f_\emptyset) = 0 \neq 1$ dans k_Φ.

b) Si $A, B \in \Phi$, on a $A \cap B \in \Phi$, car $f_{A\cap B} = f_A \cdot f_B$, d'où $\chi(f_{A\cap B}) = \chi(f_A)\chi(f_B) = 1$.

c) Si $A \subset B$ et $A \in \Phi$, alors $B \in \Phi$. En effet, on a $f_A = f_A f_B$, d'où $\chi(f_A) = \chi(f_A)\chi(f_B)$, et comme $\chi(f_A) = 1$, on trouve $\chi(f_B) = 1$.

d) On a $E \in \Phi$, i.e. $\chi(f_E) = 1$, or $f_E = 1$, donc $\chi(f_E) = 1$.

Ainsi, Φ est un filtre – on n'a utilisé que le fait que $A/\mathfrak{m}$ est un anneau $\neq 0$ (pour conclure que $\emptyset \notin \Phi$). Prouvons que si $A/\mathfrak{m}$ est intègre, Φ est un *ultrafiltre*, i.e. :

e) Si $A \notin \Phi$, alors $B \overset{\text{déf}}{=} E\backslash A \in \Phi$.

En effet, on a $f_A + f_B = 1$, $f_A f_B = 0$, d'où

ⓐ $\chi(f_A) + \chi(f_B) = 1$, et

ⓑ $\chi(f_A)\chi(f_B) = 0$. p. 194

$\chi(f_A) \neq 1$, on conclut de ⓐ $\chi(f_B) \neq 0$, d'où par ⓑ $\chi(f_A) = 0$, d'où de ⓐ $\chi(f_B) = 1$, d'où $B \in \Phi$.

Prouvons enfin que $\mathfrak{m} = \mathfrak{m}_\Phi$. Comme $\mathfrak{m}_\Phi$ est un idéal maximal, il suffit de prouver [page 7]

$$\mathfrak{m}_\Phi \subset \mathfrak{m} .$$

Or si $A \in \mathfrak{P}(E)$ est telle que $A \notin \Phi$, ou $f_A \in \mathfrak{m}_\Phi$ (cor. 1), on a aussi $f_A \in \mathfrak{m}$. Donc il suffit de prouver le

Lemme. *Soit $\Phi \in \mathcal{F}_0$. Alors $\mathfrak{m}_\Phi$ est l'idéal engendré par les f_A pour $A \in \mathfrak{P}(E)\backslash\Phi$. Plus précisément, les f_A sont dans $\mathfrak{m}_\Phi$, et tout $f \in \mathfrak{m}_\Phi$ est de la forme ff_A, avec A comme dessus.*

En effet, $f \in \mathfrak{m}_\Phi$ signifie qu'il existe $B \in \Phi$ tel que $f|B = 0$. Mais cela signifie aussi que $f = ff_A$, où $A = E\backslash A$ [plutôt $A = E\backslash B$], d'où $A \notin \Phi$.

Cela prouve la proposition 2, et en même temps :

Corollaire 2. *Tout anneau quotient intègre de $k_E = \prod_{\xi\in E} k_\xi$ est un corps.*

Notons maintenant que si $\Phi \in \mathcal{F}$ est un filtre quelconque sur E, alors k_Φ est un anneau quotient de k_E, donc

$$(*) \qquad \mathrm{Max}(k_\Phi) \hookrightarrow \underbrace{\mathrm{Max}(k_E)}_{\simeq \mathcal{F}_0} .$$

Ceci posé, on trouve :

Corollaire 3 ([206]). *L'inclusion précédente identifie* $\mathrm{Max}(k_\Phi)$ *à l'ensemble des ultrafiltres Ψ sur E qui sont* plus fins *que Φ.*

En effet, si Ψ est un tel ultrafiltre, on a le diagramme commutatif

$$(**) \qquad k_E \xrightarrow{\chi_\Phi} k_\Phi \twoheadrightarrow k_\Psi \quad , \qquad \text{(via } \chi_\Psi\text{)} \qquad [\text{page 8}]$$

ce qui montre que Ψ [plutôt $\mathfrak{m}_\Psi$] est dans l'image de $(*)$. Inversement, supposons que $\Psi \in \mathcal{F}_0$ provienne de $\mathrm{Max}(k_\Phi)$, i.e. que l'on ait $\mathfrak{m}_\Phi \subset \mathfrak{m}_\Psi$ (où $\mathfrak{m}_\Phi$ est le noyau de χ_Φ), ou encore qu'on ait une factorisation $(**)$ de χ_Ψ. Prouvons que Ψ est plus fin que Φ, i.e. que $\Psi \supset \Phi$. Soit donc $A \in \Phi$, prouvons que l'on a $A \in \Psi$. Mais $A \in \Phi$ implique [le] fait que $\chi_\Phi(f_A) = 1$, donc son image dans k_Ψ est égale à 1, donc on a $A \in \Psi$ par le corollaire 1.

206. Marche pour tout système d'anneaux $(k_\xi)_{\xi\in E}$ *non nuls*, et $\Phi, \Psi \in \mathcal{F}$, Ψ plus fin que Φ, i.e. $\Phi \subset \Psi$ si et seulement si $\mathfrak{m}_\Phi \subset \mathfrak{m}_\Psi$ (pas la peine que Ψ soit un ultrafiltre).

Commentary · Context [ms. 7]

Idempotents recover the spectrum of a product

Grothendieck needs more than the existence of some residue fields: he needs to know exactly which quotients can return the original field. The characteristic idempotents make this classification possible. They form a Boolean algebra inside the product ring, and each prime quotient must decide every Boolean alternative.

Let $R = \prod_E k_\xi$ with commutative field factors. For $f \in R$, put $f^*(\xi) = f(\xi)^{-1}$ when $f(\xi) \neq 0$, and $f^*(\xi) = 0$ otherwise. Then

$$ff^* = e_{\mathrm{supp}(f)}, \qquad f = f^2 f^*.$$

In particular R is a commutative von Neumann regular, or absolutely flat, ring. If $R \to D$ is a nonzero domain quotient, a nonzero image $\bar{f}$ satisfies $\bar{f} = \bar{f}^2 \bar{f}^*$; cancellation gives $\bar{f}\bar{f}^* = 1$. Thus every domain quotient is a field. This is a second proof of Corollary 2 which isolates the ring-theoretic reason that all prime ideals are maximal.

For an ultrafilter U, the ideal I_U is maximal by Proposition 1. Conversely, if $\mathfrak{p}$ is prime, put

$$U_\mathfrak{p} = \{A \subseteq E : e_A \notin \mathfrak{p}\}.$$

In the domain $R/\mathfrak{p}$, each idempotent is 0 or 1. The identities $e_{A\cap B} = e_A e_B$ and $e_{E\setminus A} = 1 - e_A$ show that $U_\mathfrak{p}$ is an ultrafilter. If $Z(f) \in U_\mathfrak{p}$, then $e_{\mathrm{supp}(f)} \in \mathfrak{p}$ and $f = f e_{\mathrm{supp}(f)} \in \mathfrak{p}$. Hence $I_{U_\mathfrak{p}} \subseteq \mathfrak{p}$; maximality of the former gives equality. This proves the asserted bijection without assuming what it is meant to establish about the residue field.

There is a useful topological interpretation. Under this bijection the principal open subset $D(f) \subseteq \operatorname{Spec} R$ is

$$\{U : \mathrm{supp}(f) \in U\}.$$

It is both open and closed, with complement determined by the zero set of f. Thus $\operatorname{Spec} R$ is the Stone space of the Boolean algebra $\mathcal{P}(E)$; its points are ultrafilters and its principal points are the coordinates of E. This is the Boolean representation viewpoint originating with Stone (1936). The proof just given supplies the particular identification used here; the reference is historical, not a substitute for the proof.

For a proper filter Φ, passing from R to R/I_Φ restricts this space to

$$\{U : U \supseteq \Phi\} = \bigcap_{A\in\Phi} \{U : A \in U\}.$$

Indeed $I_\Phi \subseteq I_U$ if and only if $\Phi \subseteq U$, as one sees by applying ideal inclusion to $1 - e_A$. This also explains the scope of footnote 206. The order-recovery argument works for arbitrary nonzero coefficient rings. The assertion that all prime quotients are fields uses the field hypothesis and is not part of that generalization.

Supposons à présent que tous les k_ξ sont égaux [à] un même anneau $\boxed{k \neq 0}$. Donc k_J, k_Φ sont des 'anneaux sous k' $k \longrightarrow k_J \longrightarrow k_\Phi$, d'ailleurs $k \longrightarrow k_J$ (si $J \neq \emptyset$) et $k \longrightarrow k_\Phi$ sont injectifs. On se pose la question quand $k \longrightarrow k_\Phi$ est *bijectif*, i.e. surjectif. Comme $k_\Phi \simeq k_E/\mathfrak{m}_\Phi$, cela signifie donc que $k_E = k + \mathfrak{m}_\Phi$, i.e. que tout $f \in k_E$ s'écrit p. 195 [page 9]

$$f \;=\; c \;+\; g \qquad \begin{cases} c \;\in\; k\ , & \text{i.e. } c(\xi) = \underbrace{c_0}_{\in k}\ \forall\, \xi \in E\ , \\ g \;\in\; \mathfrak{m}_\Phi & \text{i.e. } \exists\, A \in \Phi \text{ avec } g|A = 0\ . \end{cases}$$

Mais pour $f \in k_E$, $c \in k$ et $A \in \Phi$ fixés, l'existence de $g \in k_E$ telle que $g|A = 0$ et $f = c + g$ équivaut à $f|A = c_A$ (fonction constante dans A, de valeur c), i.e. $A \subset f^{-1}(\{c\})$. Pour f, c fixés, l'existence de $A \in \Phi$ satisfaisant la relation équivaut à $f^{-1}(\{c\}) \in \Phi$. Et pour f fixé, l'existence de c équivaut à celle d'une fibre E_c de $f : E \longrightarrow k$, qui soit dans Φ. Ainsi :

Proposition 3. *Soit $\Phi \in \mathcal{F}$. Pour que $k \longrightarrow k_\Phi$ soit surjectif, il faut et il suffit que pour toute famille de parties* essentiellement disjointes *$(E_\xi)_{\xi\in k}$ de E indexée par k, de réunion E, il*

existe un $\xi \in k$ tel que $E_\xi \in \Phi$. A fortiori, il faut *que Φ soit un ultrafiltre (puisque* $\operatorname{card} k \geqslant 2$ *par hypothèse).*

En effet, la donnée d'une telle famille $(E_\xi)_{\xi\in k}$ équivaut à la donnée d'une application [page 10]
$E \longrightarrow k$, i.e. d'un élément de f_E.

Scholie. La propriété qu'on vient d'expliciter pour un filtre Φ sur E, ne dépend de k que par l'intermédiaire de $\pi = \operatorname{card} k$. On peut aussi l'énoncer en disant que pour toute *partition* $(E_i)_{i\in I}$ de E en un ensemble I des parties tel que $\operatorname{card} I \leqslant \pi$, il existe un (et un seul) des E_i qui soit dans Φ. On dit alors que Φ est un *π-ultrafiltre.*

Si $\pi \geqslant 2$ est fini, cette propriété équivaut à dire que Φ est un ultrafiltre. Par ailleurs, quel que soit π, les ultrafiltres Φ *triviaux* (i.e. tels qu'il existe $\xi \in E$ avec $\{\xi\} \in \Phi$, ou encore tel que $\Phi = \{A \in \mathfrak{P}(E) \mid \xi \in A\}$) sont des π-ultrafiltres. Si π est infini, il n'est pas clair qu'il existe des π-ultrafiltres non triviaux. On sait qu'il n'en existe sur E *que* si $\operatorname{card} E \notin \mathfrak{U}_1$, où $\mathfrak{U}_1$ est le plus petit univers tel que $\mathbf{N} \in \mathfrak{U}_1$, i.e. tel que $\mathfrak{U}$ contienne comme élément un ensemble [page 11]
infini.

Commentary · Exposition [ms. 10]

The successor hidden in a pi-ultrafilter

The ultrapower becomes trivial precisely when every function to the coefficient ring is almost constant. Grothendieck packages this condition as a property of the ultrafilter alone, so that the size of the field can later be chosen to exclude it. A small shift in cardinal convention is essential in comparing his terminology with modern set theory.

For an infinite cardinal π, his π-ultrafilter is an ultrafilter closed under intersections of *at most* π sets. With the usual convention that κ-complete means closed under intersections of fewer than κ sets, it is therefore a π^+-complete ultrafilter. To verify this equivalence, suppose first that the intersection of a family $(A_i)_{i<\delta}$ in U, with $\delta \leq \pi$, is not in U. Partition E into the first failures

$$(E \setminus A_i) \cap \bigcap_{j<i} A_j \quad (i < \delta), \qquad \text{and} \qquad \bigcap_{i<\delta} A_i.$$

Every cell lies outside U, contradicting the partition condition. Conversely, if a partition has at most π cells and none belongs to U, all their complements belong to U; completeness would put the empty intersection of the complements in U. This proves both implications, including the case of singular π.

Let $\theta = |k|$. Proposition 3 says exactly that

$$k \longrightarrow k^E/U \text{ is onto} \quad \Longleftrightarrow \quad U \text{ selects a fibre of every map } E \longrightarrow k.$$

For infinite k this is θ^+-completeness. For finite nonzero k every ultrafilter has the property, because a finite partition always has one selected cell. Consequently every ultrapower of a finite field is canonically the field itself, while a nonprincipal ultrapower of an infinite field can be a proper extension. The elementary embedding supplied by Łoś's theorem does not decide surjectivity; compare Keisler (2010, Corollary 3.3).

A concrete infinite example keeps the two questions apart. Take $k = \mathbb{Q}$, $E = \mathbb{N}$, and a nonprincipal ultrafilter U. The class $t = [n \mapsto n]$ differs from every constant, because each fibre of the function $n \mapsto n$ is finite. More strongly, for every nonzero polynomial $P \in \mathbb{Q}[X]$, the zero set of $P(n)$ is finite, so $P(t) \neq 0$. Thus $\mathbb{Q}^{\mathbb{N}}/U$ contains a transcendental element. It is an elementary extension of $\mathbb{Q}$, but it admits no $\mathbb{Q}$-algebra map back to $\mathbb{Q}$: any field homomorphism would be injective and would have to send the transcendental t to an element of $\mathbb{Q}$.

The later filter-extension terminology used by Brooke-Taylor and Rosický (2017, Definition 2.3) follows the fewer-than convention. We will keep θ^+ visible when moving from Grothendieck's partition condition to those compactness principles.

Si $\mathfrak{U} = \mathfrak{U}_1$, et si k est un corps infini, p.ex. $k = \mathbf{Q}$, alors pour tout ensemble $E \in \mathfrak{U}$ et pour tout ultrafiltre *non trivial* Φ sur E, k_E est une extension *non triviale* de k. Mais si $\mathfrak{U} = \mathfrak{U}_\alpha$ est un univers quelconque, et π le premier cardinal dans $\mathfrak{U}$ qui n'appartienne pas à un univers

$\mathfrak{U}' \subset \mathfrak{U}$ strictement plus petit, je présume que pour tout $E \in \mathfrak{U}$, tout π-ultrafiltre sur E est trivial.

p. 196

Application à un exemple d'une sous-catégorie non accessible.

Soit $\mathcal{M}$ une catégorie $\mathfrak{U}$-accessible, et $a \in \mathrm{Ob}\,\mathcal{M}$, d'où un foncteur

$$\begin{aligned} f^o \ : \ \mathcal{M}^o \ &\longrightarrow \ \mathrm{Ens} \\ x \ &\longmapsto \ \mathrm{Hom}_{\mathcal{M}}(x,a) \overset{\text{déf}}{=} a(x) \ , \end{aligned}$$

foncteur commutant aux $\varprojlim$ quelconques, donc tel que $f : \mathcal{M} \longrightarrow (\mathrm{Ens})^o$ commute aux $\varinjlim$ quelconques, et en particulier f est accessible. Considérons la sous-catégorie strictement pleine

[page 12]

$$\underbrace{\mathrm{Ens}^*}_{=\mathrm{Ens}\setminus\{\emptyset\}} \ \subset \ \mathrm{Ens}$$

des ensembles non vides, on sait qu'elle est accessible, mais elle n'est par stable par $\varprojlim$ de type L_π, quelque grand qu'on prenne π.

Commentary · Present state [ms. 11]

The universe hypothesis and its precise boundary

Grothendieck's first universe is chosen to exclude complete nonprincipal ultrafilters. This is a mathematical restriction on the available cardinals, not a harmless change in the notation for smallness. The link with measurable cardinals can be established directly, and it also clarifies the conjecture at the end of the page.

Suppose that U is a nonprincipal π^+-complete ultrafilter on E, with π infinite. Let μ be the least cardinal for which E has a partition into μ sets, none belonging to U. Such a partition exists, by singletons, and $\mu > \pi$. Pushing U forward along this partition gives an ultrafilter V on μ. It contains no singleton. Minimality of μ shows that U, and hence V, is closed under intersections of fewer than μ members: a failed intersection would yield a partition into fewer than μ null pieces by the first-failure construction. Thus V is a nonprincipal μ-complete ultrafilter, and μ is measurable.

For completeness, the inaccessibility needed here follows from the same argument. Every subset of μ of size less than μ is V-null. If μ were singular, a partition into $\mathrm{cf}(\mu)$ bounded pieces would contradict completeness. If $\mu \le 2^\lambda$ for some $\lambda < \mu$, assign distinct subsets of λ to the elements of μ. For each coordinate of λ, V chooses one of the two membership alternatives. The intersection of these fewer than μ chosen sets belongs to V, but contains at most one element, another contradiction. Hence μ is regular and a strong limit. This is the classical measure obstruction associated with Ulam (1930); compare the complete-ultrafilter discussion in Keisler (2010, Section 5). The argument is included because the universe boundary is decisive for the example.

If $\mathfrak{U} = V_\Omega$ is the least Grothendieck universe containing an infinite set as an element, Ω is the first inaccessible cardinal. A set $E \in \mathfrak{U}$ has cardinality less than Ω, whereas the construction above would produce an inaccessible $\mu \le |E|$. Therefore every such complete ultrafilter is principal. More generally, the hypothesis of Proposition 4 holds in V_Ω exactly when the measurable cardinals below Ω are bounded. In one direction an unbounded measurable cardinal supplies a sufficiently complete nonprincipal measure. In the other, a nonprincipal π_0^+-complete ultrafilter would produce a measurable cardinal above the chosen bound π_0.

The final conjecture on this page has a positive answer *when its proposed cardinal exists.* Suppose π belongs to no strictly smaller infinite universe inside $\mathfrak{U}$. A nonprincipal π-ultrafilter would produce a measurable $\mu > \pi$ in $\mathfrak{U}$. Then V_μ is a smaller universe containing π, which is impossible. There need not, however, be a first cardinal with the stated property: when the smaller inaccessible cardinals are cofinal in Ω, every cardinal below Ω belongs to a smaller universe. This separates the valid conditional assertion from an unstated existence assumption.

No conclusion about all universes follows from the first-universe example. A universe containing a sufficiently large strongly compact cardinal permits the opposite compactness behavior, as the final commentary block will show. The elementary algebraic construction remains the same; the supply of ultrafilters changes.

Considérons

$$\underbrace{\underline{S} \;=\; \underline{S}_a}_{\overset{\text{déf}}{=} f^{-1}(\mathrm{Ens}^*)} \;\subset\; \mathcal{M}\,,$$

sous-catégorie strictement pleine de $\mathcal{M}$ formée des $x \in \mathrm{Ob}\,\mathcal{M}$ tels que

$$a(x) \;\neq\; \emptyset\,, \qquad \text{i.e. } x \leqslant a \text{ pour le préordre canonique de } \mathcal{M}\,.$$

C'est donc une sous-catégorie *ouverte* de $\mathcal{M}$. Son complémentaire fermé $\underline{S}' = \underline{S}'_a$ est la sous-catégorie fermée image inverse, par f, de la sous-catégorie strictement pleine de Ens réduite au seul objet $\{\emptyset\}$. Cette sous-catégorie de Ens est la catégorie finale type. Elle est stable dans Ens par $\varinjlim$ quelconques, et par $\varprojlim$ filtrantes quelconques. Ainsi, $\underline{S}'$ est stable dans $\mathcal{M}$ par $\varinjlim$ filtrantes quelconques. Ainsi, $\underline{S}'$ est stable dans $\mathcal{M}$ par $\varinjlim$ filtrantes quelconques, en particulier, elle est L_π-stable pour π assez grand. Explicitons : [page 13]

$$\begin{array}{rl} \underbrace{\underline{S}' \;=\; \underline{S}'_a}\;\subset\;\mathcal{M} & \\ \Big\| \text{ déf} & \text{sous-catégorie fermée de } \mathcal{M} \\ f^{-1}(\{\emptyset\}) \;= & \text{formée des } x \in \mathrm{Ob}\,\mathcal{M} \text{ tels} \\ & \text{que } a(x) = \emptyset. \end{array}$$

Commentary · Exposition [ms. 12]

Existence of points is the missing compatibility condition

Grothendieck is testing a tempting inference: a representable functor behaves perfectly with respect to limits, so perhaps the property that its values are nonempty should also behave well. The obstruction is that an inverse limit asks for compatible elements. Separate nonemptiness supplies no such compatibility.

For any diagram with colimit A, the universal property gives

$$\mathrm{Hom}_{\mathcal{M}}(A, a) \cong \varprojlim_i \mathrm{Hom}_{\mathcal{M}}(A_i, a).$$

The full subcategory of objects admitting a map to a is therefore a sieve: if $B \to A$ and $A \to a$ exist, so does $B \to a$. Its complement is a cosieve. A nonempty colimit of objects of the complement cannot admit a map to a, since composing with even one structure map would contradict membership of that stage. Dually, a nonempty limit of objects in the sieve lies in the sieve, by composing any projection with a map to a. These observations prove the closure and retract assertions without choosing a compatible family of points.

Even highly directed inverse systems of nonempty sets can have empty limit. Given an infinite π, choose $|E| > \pi$ and let $I = [E]^{\leq \pi}$, ordered by inclusion. It is π^+-directed. The inverse system $X_F = E \setminus F$, with inclusion maps for $F \subseteq G$, has nonempty terms, while

$$\varprojlim_{F \in I} X_F = \bigcap_{F \in I} (E \setminus F) = \varnothing.$$

For the categorical counterexample, Grothendieck realizes the same disappearance of coordinates inside products of fields. Complete nonprincipal ultrafilters would create additional points not given by coordinates; the universe hypothesis removes precisely those additional points.

The statement that the contravariant representable is accessible needs its original convention. It sends existing colimits in $\mathcal{M}$ to limits of sets, or equivalently preserves them as a functor to $\mathrm{Set}^{\mathrm{op}}$. This does not assert that $\mathrm{Set}^{\mathrm{op}}$ is an accessible category in the modern sense. The example concerns the sieve of existence of a point, not a failure of representability to preserve its appropriate limits.

Comme $\underline{S}'$, étant fermée dans $\mathcal{M}$, est stable par $\varinjlim$ non vides et en particulier L_π-stable pour π grand, il y a plus de raison de s'attendre à ce que $\underline{S}'$ soit accessible dans $\mathcal{M}$ que

pour son complémentaire $\underline{S}$, dont il n'est pas clair qu'il ait cette propriété de stabilité, mais seulement stabilité par $\varprojlim$ non vides, et en particulier par facteurs directs.

En fait, nous allons voir qu'il peut arriver que $\underline{S}$ et $\underline{S}'$ soient tous deux non accessibles dans $\mathcal{M}$:

Proposition 4. *Soient $\mathfrak{U}$ un univers, contenant un cardinal infini π_0 tel que pour tout $E \in \mathfrak{U}$, tout π_0-ultrafiltre sur E soit trivial. Soit alors $k \in \mathfrak{U}$ un corps de cardinal $\pi_0' \geqslant \pi_0$, et soit $\mathcal{M}$ la catégorie des k-algèbres commutatives. Donc $\mathcal{M}$ est un $\mathfrak{U}$-paratopos, admettant k* p. 197
comme objet initial. Soit $\underline{S}'$ la sous-catégorie strictement pleine, stable par petites $\varinjlim$ non [page 14]
vides, formée des objets A de $\mathcal{M}$ tels que $\mathrm{Hom}_{\mathcal{M}}(A,k) = \emptyset$, et $\underline{S}$ la sous-catégorie strictement pleine complémentaire, formée des objets A tels que $\mathrm{Hom}_{\mathcal{M}}(A,k) = \emptyset$. Alors $\underline{S}'$ est une sous-catégorie fermée *dans $\mathcal{M}$, et $\underline{S}$ la sous-catégorie ouverte complémentaire, donc $\underline{S}$ (tout comme $\underline{S}'$) est stable par facteurs directs. Ceci posé :*

a) Il n'existe pas de cardinal π tel que $\underline{S}$ soit L_π-stable dans $\mathcal{M}$, a fortiori $\underline{S}$ n'est pas accessible dans $\mathcal{M}$.

b) ([207]). Bien que $\underline{S}'$ soit L_0-stable dans $\mathcal{M}$ (i.e. stable par $\varinjlim$ filtrantes, et même, on l'a dit, par toute $\varinjlim$ non vide), $\underline{S}'$ n'est pourtant pas accessible dans $\mathcal{M}$.

Démonstration. L'assertion a) va résulter du

Corollaire 1. *Sous les conditions de la proposition 4, soient $E \in \mathfrak{U}$ un ensemble infini, Φ_0 le filtre des complémentaires des parties finies de E. Alors $\mathrm{Hom}_{\mathcal{M}}(k_{\Phi_0}, k) = \emptyset$, a fortiori, pour tout filtre Φ sur E plus fin que Φ_0, on a $\mathrm{Hom}_{\mathcal{M}}(k_\Phi, k) = \emptyset$.*

On a posé ici, bien sûr, pour tout filtre Φ sur E, [page 15]

$$k_\Phi \;=\; \varinjlim_{J \in \Phi} k_J \ .$$

On sait que pour toute k-algèbre commutative $\mathcal{A}$, $\mathrm{Hom}(\mathcal{A}, k)$ est en correspondance 1-1 avec la partie de $\mathrm{Max}(\mathcal{A})$ formée des idéaux maximaux $\mathfrak{m}$ de $\mathcal{A}$ tels que $k \longrightarrow \mathcal{A}/\mathfrak{m}$ soit un isomorphisme. Si $\mathcal{A}$ est de la forme k_Φ, Φ un filtre sur E, cet ensemble est en correspondance biunivoque avec l'ensemble des π_0'-ultrafiltres Ψ sur E plus fins que Φ, où $\pi_0' = \mathrm{card}(k)$ (proposition 3, et cor. 3 de prop. 2, page 7). Comme $\pi_0' \geqslant \pi_0$, un tel ultrafiltre est trivial par hypothèse. Donc on trouve

$$(*) \qquad \mathrm{Hom}_{\mathcal{M}}(k_\Phi, k) \;\simeq\; \text{ensemble des } \xi \in E \text{ tels que } \{\xi\} = \textstyle\bigcap_{A \in \Phi} A \ .$$

Mais dire que Φ est plus fin que Φ_0 signifie aussi que pour tout $\xi \in E$, on a $E \backslash \{\xi\} \in \Phi$, i.e. $\exists\, A \in \Phi$ avec $A \subset E \backslash \{\xi\}$, i.e. $\{\xi\} \notin \bigcap_{A \in \Phi} A$. Donc on a alors $\mathrm{Hom}_{\mathcal{M}}(k_\Phi, k) = \emptyset$.

La conclusion du corollaire 1 s'exprime par la relation

$$k_\Phi \;\notin\; \mathrm{Ob}\,\underline{S} \ , \qquad \text{i.e. } k_\Phi \in \mathrm{Ob}\,\underline{S}' \ ,$$

d'autre part, on a par définition

$$k_\Phi \;=\; \varinjlim_{J \in \Phi} k_J \ ,$$

et il est clair (comme ces $J \in \Phi$ sont $\neq \emptyset$), que les k_J en question sont dans $\underline{S}$. Ainsi, pour un filtre Φ comme dans le corollaire 1, on trouve un système inductif d'objets de $\underline{S}$, indexé [page 16]
par Φ^o, dont la limite inductive n'est pas dans $\underline{S}$. Donc le a) de la proposition 4 se déduit en notant que pour tout cardinal $\pi \in \mathfrak{U}$, on peut trouver un ensemble $E \in \mathfrak{U}$, et un filtre Φ sur E plus fin que Φ_0, tel que l'ensemble ordonné Φ^o soit grand devant π. Pour trouver un tel Φ, il suffit de prendre E de cardinal $\pi' > \pi$, et pour Φ l'ensemble des complémentaires des parties de E de cardinal $\leqslant \pi$, de sorte que Φ^o est isomorphe à l'ensemble ordonné des parties de E de cardinal $\leqslant \pi$, lequel est bien grand devant π. Cela prouve le a) de la proposition 4. p. 198

207. ?, pas prouvé.

Prouvons maintenant le b). Notons le

Lemme. *Soit $\mathcal{M}$ une catégorie accessible stable par $\varinjlim$ de type I_α, α un ordinal limite donné, $\underline{S}'$ une sous-catégorie fermée, π un cardinal utile pour $\mathcal{M}$, tel que* $\operatorname{card}\alpha \leqslant \pi$. *Pour* [page 17] *tout $x \in \operatorname{Ob}\underline{S}'$, choisissons une représentation ω-π-adaptée (ω étant le premier ordinal infini)*

$$x \simeq \varinjlim_{i\in I_x} x_i$$

(donc I_x grande devant π, stable par $\varinjlim$ de type I_α, $i \longmapsto x_i : I \longrightarrow \mathcal{M}$ commute auxdites limites, enfin les $x_i \in \operatorname{Ob}\mathcal{M}_\pi$). Pour que $\underline{S}'$ soit π-accessible dans $\mathcal{M}$, il faut et il suffit que pour tout $x \in \operatorname{Ob}\underline{S}'$, il existe un $i \in I_x$ tel que $x_i \in \operatorname{Ob}\underline{S}'$.

Commentary · Examples [ms. 16]

A directed family of products loses every rational point

The proof of Proposition 4(a) becomes quite explicit once the filter is written in terms of the coordinates it allows us to discard. Fix an infinite π, choose E of cardinality greater than π, and set

$$\Phi_\pi = \{E \setminus F : F \subseteq E,\ |F| \leq \pi\}, \qquad A_\pi = k^E/I_\pi, \quad I_\pi = \{f : |\operatorname{supp}(f)| \leq \pi\}.$$

The set Φ_π is a proper filter, and its opposite order is π^+-directed: the union of at most π exceptional subsets still has size at most π. Its reduced product is exactly A_π. Restriction of functions gives

$$A_\pi \cong \varinjlim_{F\in[E]^{\leq\pi}} k^{E\setminus F}.$$

Every stage has a k-point, evaluation at any surviving coordinate.

Now let $\theta = |k|$, and assume the hypothesis of Proposition 4. A k-algebra map $A_\pi \to k$ is necessarily surjective, since it fixes all constants. Its kernel therefore gives a maximal ideal, hence an ultrafilter U extending Φ_π. The residue field is the ultrapower k^E/U, and the structural map from k to this field must be onto. Proposition 3 says that U is θ^+-complete. Since $\theta \geq \pi_0$, the universe hypothesis makes U principal. But Φ_π contains $E \setminus \{\xi\}$ for every ξ, so no principal ultrafilter extends it. This contradiction proves that A_π has no k-point.

The argument proves failure of closure for every allowed π; it does not merely show a failure of ordinary filtered-colimit closure. This is why it rules out accessibility of the inclusion at every eventual rank. It also identifies the exact role of the field hypothesis: a map to k has a field quotient, whose maximal ideal can be classified by an ultrafilter.

The formula $(*)$ on manuscript page 15 should be interpreted as

$$\operatorname{Hom}_{k\text{-alg}}(k_\Phi, k) \cong \bigcap_{A\in\Phi} A$$

under the principal-ultrafilter hypothesis. Each member of the intersection gives an evaluation map. The printed condition $\{\xi\} = \bigcap\Phi$ would fail already for $\Phi = \{E\}$ with two coordinates. The corrected membership condition, rather than singleton equality, is exactly what the proof uses.

En effet, notons que $\underline{S}'$ étant fermée, est stable dans $\mathcal{M}$ par toute $\varinjlim$ non vide représentable dans $\mathcal{M}$, et en particulier par $\varinjlim$ de type I_α. Donc on peut appliquer 4.13.22 (p. 342) à $\mathcal{M}$, $\underline{S}'$, π et à $\Phi = \{I_\omega\}$. Alors a) $\Longrightarrow$ c) implique que si $\underline{S}'$ est π-accessible dans $\mathcal{M}$, alors pour tout $x \in \operatorname{Ob}\underline{S}'$, l'ensemble $I_{x,S'}$ des $i \in I_x$ tels que $x_i \in \operatorname{Ob}\underline{S}$ est cofinal dans I_x. Cela implique qu'il est non vide. (Et réciproquement d'ailleurs, $\underline{S}'$ étant un fermé dans $\mathcal{M}$, puisque si $x_i \in \underline{S}'$, alors pour $j \in \operatorname{Ob} I_x$ avec $i \leqslant j$, on a $x_j \in \underline{S}'$, i.e. $I_{x,\underline{S}'}$ contient l'image essentielle de $i\backslash I_x$, laquelle est cofinale dans I …) Cela prouve le 'il faut'. Prouvons le 'il suffit'. Donc prouvons que $\underline{S}'$ est égale à l'image essentielle de $\operatorname{Ind}_\pi(\underline{S}'(\pi))$. Elle la contient, puisque $\underline{S}'$ est stable par $\varinjlim$ de type L_π.

Donc il reste à prouver que tout $x \in \operatorname{Ob}\underline{S}'$ est dans l'image essentielle. Or l'hypothèse [page 18] nous assure que $x \simeq \varinjlim_{i\in I_x} x_i$ est isomorphe à $\varinjlim_{i\in I_{x,\underline{S}'}} x_i$ (car $I_{x,\underline{S}'}$ est cofinale dans I_x), où cette

fois les x_i sont dans $\underline{S}'$. Comme I_x grande devant π, de même la sous-catégorie pleine cofinale $I_{x,\underline{S}'}$, donc on gagne.

Corollaire. *Sous les conditions précédentes, si $\underline{S}'$ est π-accessible, il en est de même de l'ouvert complémentaire $\underline{S}$,* pourvu *que $\underline{S}$ soit stable dans $\mathcal{M}$ par $\varinjlim$ de type L_π.*

Il faut prouver que $\underline{S}$ est égale à l'image essentielle de $\mathrm{Ind}_\pi \underline{S}(\pi)$. L'hypothèse 'pourvu' assure que cette image essentielle est $\subset \underline{S}$. Inversement, tout [?] $x \in \mathrm{Ob}\,\underline{S}$ est dans cette image essentielle. On aura

$$x \simeq \varinjlim_{i\in I} x_i\ , \qquad x_i \in \mathrm{Ob}\,\mathcal{M}_\pi,\ I = \mathcal{M}_\pi/x,\ \text{grande devant } \pi\ ,$$

et comme $x \in \mathrm{Ob}\,\underline{S}$ et $\underline{S}$ ouverte, les x_i sont dans $\underline{S}$, donc dans $\underline{S}(\pi)$, OK.

Dans le cas qui nous occupe, où $\mathcal{M} = (k\text{-alg.})$, comme $\underline{S}$ n'est justement *pas* stable dans $\mathcal{M}$ par L_π (quel que soit π) (c'est cela qui nous faisait conclure que $\underline{S}$ n'est pas accessible dans $\mathcal{M}$), on ne peut donc conclure de cette inaccessibilité de $\underline{S}$, celle de $\underline{S}'$. Notons le [page 19]

Commentary · Present state [ms. 18]

The main text completes the abandoned argument

Grothendieck distinguishes the two possible failures with care. The open class of algebras with points fails a closure condition. The closed class of algebras without points already has every nonempty colimit, so its possible failure of accessibility must concern the absence of a small family of generators. The appendix reaches this distinction but does not finish the second argument; footnote 207 records that fact.

The main text has already supplied the missing implication. Proposition 4.16.7.8 and Corollary 4.16.7.9 identify accessibility of a cosieve with accessibility of its complementary sieve. Hence Proposition 4(a), under its stated universe hypothesis, proves Proposition 4(b) as well. The final question in the appendix must be read with this later result in view; it is not an unresolved assertion under those hypotheses.

Here is the mechanism, in the notation needed for the last page. Let $\pi \geq |k|$ be infinite. A k-algebra of cardinality at most π has a presentation with at most π generators and relations: take one generator for each element and record its addition, multiplication and scalar relations. It is consequently π^+-presentable. Every algebra is the π^+-directed union of its subalgebras of cardinality at most π.

If the closed class S' were generated by its ambient π^+-presentable objects, an object $A \in S'$ would receive a map from one such object $B \in S'$. That map factors through a sufficiently large stage of any π^+-filtered presentation of A. Since S' is a cosieve, that stage lies in S'. Conversely, one stage in S' makes the full subcategory of S'-stages a nonempty cosieve in the filtered indexing category, hence cofinal; these stages then present A inside S'. This proves the appendix's criterion without its additional ordinal-continuity apparatus.

The corollary on manuscript page 18 does not perform this argument: its explicit proviso assumes closure of S, and that closure is known to fail. Grothendieck correctly refuses the inference based on that corollary alone. The stronger equivalence in the main text is what repairs the proof. The next block will exhibit the missing small-generator obstruction directly in the very reduced products he proposes.

Corollaire. *Soit π un cardinal infini. Pour que la sous-catégorie fermée $\underline{S}'$ de $\mathcal{M}$ (formée de k-algèbres commutatives A telles que $\mathrm{Hom}_{\mathcal{M}}(A,k) = \emptyset$) soit π-accessible, il faut et il suffit que pour tout k-algèbre A (de cardinal $> \pi$), telle que $\mathrm{Hom}_{\mathcal{M}}(A,k) = \emptyset$, existe une sous-algèbre A_i* de cardinal $\leqslant \pi$, *telle que $\mathrm{Hom}_{\mathcal{M}}(A_i,k) = \emptyset$.* p. 199

(On applique le lemme, en prenant pour α le premier ordinal infini.)

Question. *Cela est-il vérifié, en prenant simplement $\pi \geqslant \mathrm{card}\,k$?* La question de l'existence d'un cardinal π, ayant la propriété indiquée plus haut, me paraît délicate, et j'ignore la réponse. Si on veut construire un contre-exemple pour tout π, les développements précédents suggèrent de prendre pour A un produit infini d'extensions non triviales de k, ou un anneau k_Φ comme dans la démonstration de la proposition 4 a).

Commentary · Development (commentators') [ms. 19]

The proposed reduced products answer every bound

Grothendieck's final suggestion is especially effective because the reduced product can have many local evaluations even when it has no global point. The following calculation realizes that suggestion under the exact hypothesis of Proposition 4. We did not find this explicit small-subalgebra calculation in the sources checked here; its conclusion about nonaccessibility already follows from his own Corollary 4.16.7.9.

Small subalgebras of a co-small reduced power. [ours] Let k be an infinite field with $|k| \geq \pi_0$ in the universe of Proposition 4, and let $\pi \geq |k|$ be an infinite cardinal in that universe. Take $E = \pi^+$ and

$$A = k^E/I_\pi, \qquad I_\pi = \{f \in k^E : |\operatorname{supp}(f)| \leq \pi\}.$$

Then A has no k-point, but every k-subalgebra $B \subseteq A$ of cardinality at most π has a k-point.

Proof. The preceding product construction proves that A has no point. The ideal is proper because $|E| > \pi$, and it is an ideal because finite unions of supports of size at most π again have that size.

To construct a point on B, choose a representative $g_b \in k^E$ of each $b \in B$. For the embedded constants $c \in k$, choose the constant representative $g_c(\xi) = c$; constants are distinct in A, so these choices are consistent. Since addition and multiplication hold in the quotient, each of

$$g_{b+b'} - g_b - g_{b'}, \qquad g_{bb'} - g_b g_{b'} \quad (b, b' \in B)$$

has support of cardinality at most π. There are at most $|B|^2 \leq \pi$ such exceptional supports. Their union F has cardinality at most π. Choose $\xi \in E \setminus F$. Then

$$h : B \longrightarrow k, \qquad h(b) = g_b(\xi)$$

preserves addition and multiplication, and it fixes every constant. In particular $h(1) = 1$, and h is a k-algebra homomorphism. No compatibility between the initially chosen representatives was required; discarding the common exceptional set makes them compatible at one coordinate. This proves the assertion. □

The poset of these subalgebras is π^+-directed: the algebra generated by the union of at most π of them still has cardinality at most π. Their union is A. Thus the same algebra is both a directed colimit of products with points and a directed union of small subalgebras with points. The first presentation defeats closure of S; the second defeats the small-obstruction criterion for S'.

In particular, under Proposition 4's hypothesis the answer to the final question is negative for *every* cardinal bound, not only for $\pi = |k|$. This establishes the statement marked "pas prouvé" in footnote 207 by a direct argument. The conditional nature of the conclusion is retained: the proof that A has no point uses the absence of sufficiently complete nonprincipal ultrafilters. The local evaluation argument itself needs no such hypothesis.

Commentary · Development (commentators') [ms. 19]

The proposed first threshold fails without a universe hypothesis

The previous example depends on the universe only when excluding a global point. There is a different obstruction at the proposed smallest threshold which works for every infinite field and in any ambient universe containing the construction. It simply asks a field to accommodate more distinct elements than it has.

Pairwise distinct variables. [ours] Let k be an infinite field, $\theta = |k|$, and let J have cardinality θ^+. Put

$$B_J = k[x_j \mid j \in J][(x_i - x_j)^{-1} \mid i \neq j].$$

Then B_J has no k-point, while every k-subalgebra of B_J of cardinality at most θ has one.

Proof. A homomorphism $B_J \to k$ would assign values $a_j \in k$ with $a_i - a_j$ invertible for every distinct pair. Thus $j \mapsto a_j$ would inject J into k, which is impossible. The localization is nevertheless nonzero: it localizes the polynomial domain at nonzero elements.

Let $C \subseteq B_J$ have cardinality at most θ. Each element of C is represented by a polynomial fraction involving finitely many variables and finitely many inverted differences. Taking the union of these finite supports gives $J_0 \subseteq J$ with $|J_0| \leq \theta$ and $C \subseteq B_{J_0}$. Choose an injection $J_0 \hookrightarrow k$. Evaluation

at these distinct values makes every inverted difference nonzero, hence extends to $B_{J_0} \to k$. Its restriction is the required point of C. □

We checked this formulation against the reduced-product and accessible-image sources cited in the appendix; we did not locate this particular presentation there. The construction is an elementary cardinality obstruction, with no claim of priority. It disproves the suggestion that the bound $\pi = |k|$ should suffice. It does not exclude a larger bound: when $\pi \geq \theta^+$, the displayed algebra itself is a small obstruction of cardinality θ^+.

Commentary · Later developments [ms. 19]

A compact cardinal restores a uniform obstruction bound

Grothendieck's example anticipates a central feature of later accessibility theory: the existence of small witnesses can depend on compactness principles stronger than the existence of Grothendieck universes. Here the positive direction can be proved directly, so that the point of contact with the general theory remains explicit.

Let $\kappa > |k|$ be a regular uncountable cardinal such that every κ-complete filter extends to a $|k|^+$-complete ultrafilter. A strongly compact $\kappa > |k|$ satisfies this condition. In the terminology of Brooke-Taylor and Rosický (2017, Definition 2.3), the weaker assumption is $L_{|k|^+,\omega}$-compactness. Assume the cardinal and the sets used below belong to the chosen universe.

We claim that if every k-subalgebra of an algebra A of cardinality less than κ has a k-point, then A has a point. Let I be the set of those subalgebras. Regularity of κ and $|k| < \kappa$ imply that I is κ-directed: the subalgebra generated by fewer than κ of its members again has cardinality less than κ. The filter generated by the upper cones in I is κ-complete and proper. Extend it to a $|k|^+$-complete ultrafilter U. For each $B \in I$, choose a homomorphism $h_B : B \to k$.

For $a \in A$, define a function on I by $B \mapsto h_B(a)$ when $a \in B$, and give it the arbitrary value 0 otherwise. The upper cone of subalgebras containing a belongs to U. Since the function has at most $|k|$ values, completeness gives a unique value $h(a) \in k$ attained on a member of U. For $a, b \in A$, intersect the upper cone containing both with the three sets selecting $h(a), h(b), h(a+b)$. This intersection belongs to U and is nonempty. At any B in it,

$$h(a+b) = h_B(a+b) = h_B(a) + h_B(b) = h(a) + h(b).$$

The same argument proves multiplicativity. For a constant $c \in k$, all h_B take the value c, so $h(c) = c$. Hence $h : A \to k$ is a k-point. Taking the contrapositive yields a subalgebra of size less than κ witnessing the absence of a point.

For a finite field the same proof needs only the ordinary ultrafilter lemma. Use the directed poset of finitely generated subalgebras and an ultrafilter extending its upper-cone filter. Every function to the finite set k is constant on a member of this ultrafilter, without any additional completeness assumption. Therefore every algebra without a k-point has a finitely generated subalgebra without a k-point. Such a subalgebra has cardinality at most $\aleph_0$, so the final question has a positive answer with $\pi = \aleph_0$ for finite k, in every universe under consideration.

This is the usual complete-ultrafilter compactness argument specialized to Grothendieck's question, not a new compactness principle. It makes the relation to accessible images precise. The class S of algebras with a k-point is the full image of the domain functor

$$(\mathrm{CAlg}_k)/k \longrightarrow \mathrm{CAlg}_k.$$

It is closed under subobjects, so it is also that functor's powerful image. Theorem 3.4 of Brooke-Taylor and Rosický (2017), extending the work of Makkai and Paré, gives accessibility and accessible embedding of powerful images under appropriately large compactness assumptions. The elementary argument above proves the needed witness property in this particular case; Corollary 4.16.7.9 then also gives accessibility of the complementary cosieve.

The alternatives established here have definite hypotheses. In a universe with the cutoff assumed by Proposition 4, no uniform obstruction bound exists. In a universe containing a sufficiently large compact cardinal, such a bound exists. The exact weakest set-theoretic assumption for this one fixed field is not identified by these arguments, and the general powerful-image theorem should not be cited as an exact converse for this particular example.

Overview · XVIII-e

These final pages of Chapter XVIII examine how far accessibility survives constructions which are elementary at the level of categories but delicate at the level of cardinal bounds (Grothendieck, 1990–1991n). The passage begins inside the proof of a gluing theorem, moves through categories of sections and categories over a small base, and ends by testing the limits of the theory against subcategories defined by the existence of a morphism. The appended calculation with products of fields supplies the decisive examples. The announced section 4.17 on paratoposes contains no mathematical text in the edition; the reader should not look to that heading for an additional theorem.

One convention governs almost every argument. An indexing category grand devant an infinite cardinal π admits cocones for diagrams with at most π arrows. Thus the source's L_π means existence or preservation of π^+-filtered colimits in the modern regular-cardinal convention. The same successor occurs in a π-ultrafilter: its intersections may have at most π factors. A useful cardinal also controls a small family of presentable objects. These are separate requirements. An accessible category has arbitrarily large suitable ranks, but a proof using a rank chosen in advance must verify the additional uniformity it needs.

The gluing construction explains why these distinctions matter. A category over the walking arrow has an open fibre $\mathcal{E}_0$, a closed fibre $\mathcal{E}_1$, and a bifunctor $H(x_0, x_1)$ describing arrows between them. Presentability in a fibre need not be presentability in the glued category: the crossing Hom sets have to preserve the same filtered colimits. The calculations in SGA 4, Exposé I, 9.6 and 9.8, provide the small-limit interchange used in the proof (Artin et al., 1972). The audit identifies two necessary repairs. Corollary 4.14.25(1) needs existence of the relevant colimits in the closed fibre. Corollary 4.15.2 needs a common initial rank controlling the stated functors before its subsequent cardinal enlargement. Explicit counterexamples show that these are hypotheses with mathematical content. The existential accessibility theorem survives the repaired choice of ranks.

The categories of sections express the same problem in a more organized form. Products collect the objects, inserters collect the transition maps, and equifiers impose their equations. This relates the source directly to the accessible-category closure results of Makkai and Paré, whose book appeared in 1989, and to the contemporary theory of flexible limits. The detailed modern construction in Ching and Riehl (2014, Appendix A) also explains why this machinery became useful in homotopical algebra. For the total category of a fibration or an opfibration, the commentary gives separate proofs of colimit existence and presentability. The two orientations require different uses of cartesian or cocartesian factorization; merely reversing a statement about filtered colimits would not supply either proof.

The small-base argument is the technical centre of the passage. A sufficiently filtered diagram in a small category can be reduced to one object and one recurrent idempotent. Its formal ind-object is the image of that idempotent, so it becomes representable exactly when the surviving projector splits. The walking unsplit projector, with monoid $\{1, p\}$ and $p^2 = p$, is the simplest example. The source eventually proves the strict-bound conclusion

$$\mathrm{Ind}_\pi(\mathcal{C}) \simeq \mathrm{Kar}(\mathcal{C}) \qquad (\pi > |\operatorname{Mor}\mathcal{C}|).$$

Here the notation on the left retains the source's successor convention. The commentary supplies both its growth argument and a presheaf proof. The literal identity condition in 4.15.9 is false, even for a two-element group; eventual invertibility and an appropriate trivialization are the invariant conclusions. A separate monoid reduction produces a quotient of a submonoid, not necessarily a quotient of the whole monoid. Neither defect invalidates the strict-bound theorem. The general equality case remains unsettled here, although two-sided cancellation and a stricter local Hom bound give affirmative special cases. Modern comparisons with Cauchy completion and coherent idempotents are provided by Tendas (2022) and Lurie (2009, Sections 5.4.2–5.4.3).

The later questions expose several different ways in which accessibility can fail. The double-dual functor on sets fails to preserve filtered colimits at every rank. Isbell's category of partial bijections is self-dual and finitely accessible, yet has a one-object finite dense and codense subcategory and is not essentially small; this answers all three questions in 4.16.4 negatively (Avery and Leinster, 2021, Example 8.7). Other failures depend on the universe. Under the appendix's hypothesis, the commentary proves that the decreasing filtered-colimit closures of an accessible functor's image need not stabilize. A separate argument treats contravariant images. Adjoining retracts of representables to a nonaccessible cosieve also produces a category with a small dense family of presentable objects and sufficiently filtered colimits which is nevertheless not accessible. This repairs the precise defect which Grothendieck notices in his own proposed construction.

The question about existing colimits needs equal care. If all diagrams of a fixed shape have colimits, their colimit cocones form an accessible category, as in Lurie (2009, Example 5.4.7.9). The commentary constructs, under the appendix's hypothesis, a finitely accessible category whose existing pushout squares form a nonaccessible full subcategory. It is a collage obtained by adjoining one object to the category of k-algebras. Its pushout condition detects exactly the absence of a k-point. Thus closure under filtered colimits alone does not produce a small generating family.

The finite tests in 4.16.6 provide a positive result of a different kind. We prove the two split-idempotent tests by first constructing a colimit over the split image and then checking maps out of fibrewise presentable objects. A strict pullback can nevertheless retain an unsplit projector whose image in the base is an identity; the walking isomorphism gives a counterexample to the proposed shortcut b′. With all the tests retained, the intended relative property has a concise description. Over a small Karoubian base $\mathcal{C}$, it is equivalent to accessibility of $\mathcal{E}$ and $f : \mathcal{E} \to \mathcal{C}$, together with the lifting of every prescribed base isomorphism. Such an f is an isofibration. Its strict pullbacks are equivalent to accessible pseudopullbacks, so the proposed change from small test bases to accessible test bases is valid. The standard closure theorem and its applications are discussed in Bourke and Lack (2024, Examples 4.8 and Remark 4.9, published version).

The closing open–closed calculus supplies the conceptual explanation of the counterexamples. Open means a full sieve, closed means a full cosieve. A cosieve is accessible precisely when it has a small weakly initial family, and precisely when its complementary sieve is closed under sufficiently filtered colimits. The canonical slice of presentable objects over x proves these equivalences: a nonempty cosieve in that filtered slice is cofinal, whereas a proper complementary sieve cannot be. This argument repairs the omitted slice denominators in the edition and completes the implication left unfinished in the appendix. The transfinite no-forward-morphism construction is also justified with an explicit universe bound. For the additional question restricted to fields, the answer is exact: in V_κ such a κ-long sequence exists if and only if κ is not a Vopěnka cardinal, with external families allowed. The commentary proves the reduction using a typed graph construction and the fully faithful functor of Miller et al. (2018).

The appendix identifies every maximal ideal of a product of fields with an ultrafilter. A map from the product back to an infinite ground field k requires $|k|^+$-completeness. Its universe hypothesis says that sufficiently complete nonprincipal ultrafilters do not exist on small sets, equivalently that measurable cardinals below the universe boundary are bounded. Under that hypothesis, for every infinite $\pi \geq |k|$ the algebra

$$k^{\pi^+}/\{f : |\operatorname{supp}(f)| \leq \pi\}$$

has no k-point, while every subalgebra of size at most π has one. A complete proof evaluates representatives outside their common exceptional set. A second construction disproves the proposed bound $\pi = |k|$ for every infinite field without the universe hypothesis. Conversely,

a sufficiently large compact cardinal restores a uniform obstruction bound; for finite fields the ordinary ultrafilter lemma already gives a finitely generated obstruction. The comparison with powerful images uses Brooke-Taylor and Rosický (2017), without asserting an exact large-cardinal converse for this one fixed-field problem.

1 Rappels sur les couples de Quillen (couples de Quillen spéciaux)

p. 1 [page 1]

Je vais reprendre les notations et la terminologie pour les relations de LLP `[left lifting property]` et RLP `[right lifting property]` de Quillen. J'écris (pour une catégorie $\mathcal{M}$, et $\Phi, \Psi \subset \mathrm{Fl}(\mathcal{M})$)

$$\Phi \;\text{⌐⟶}\; \Psi \qquad \Longleftrightarrow \qquad (\Phi \subset \Psi^*) \qquad \Longleftrightarrow \qquad (\Psi \subset \Phi_*)\ , \tag{1.1}$$

i.e. Φ a la LLP par rapport à Ψ, ou encore Ψ la RLP par rapport à Φ. Je dis aussi que (Φ, Ψ) est un *couple* Q-*orthogonal.* Cette notion n'est pas symétrique, mais je me permets parfois (exceptionnellement) d'écrire

$$\Psi \;\text{⟵⌙}\; \Phi \qquad \text{comme synonyme de} \qquad \Phi \;\text{⌐⟶}\; \Psi\ . \tag{1.2}$$

Φ est Q-*orthogonal à gauche* de Ψ, Ψ est Q-*orthogonal à droite* à Φ, et la Q-orthogonalité à gauche (resp. à droite) est notée par le demi-sommet de flèche pointant vers le bas (resp. vers le haut). J'écris

$$\begin{cases} \Phi \;\text{⟵⌙}\; \Psi & \Longleftrightarrow \quad (\Phi = \Psi^*) \\ \Phi \;\text{⌐⟶}\; \Psi & \Longleftrightarrow \quad (\Psi = \Phi_*) \\ \Phi \;\text{⟵⌙}\; \Psi & \Longleftrightarrow \quad (\Phi = \Psi^* \ \text{ et } \ \Psi = \Phi_*)\ . \end{cases} \tag{1.3}$$

Ces trois cas de Q-orthogonalité renforcée sont donc ceux où on a de plus $\Phi = \tilde{\Phi}$ resp. $\Psi = \bar{\Psi}$ resp. $\Phi = \tilde{\Phi}$ et $\Psi = \bar{\Psi}$. On dit que Φ est Q-*clos à gauche* si $\Phi = \tilde{\Phi}$, que Ψ est Q-*clos à droite* si $\Psi = \bar{\Psi}$, que le couple Q-orthogonal (Φ, Ψ) est Q-*clos à gauche* (resp. *à droite*) si Φ (resp. Ψ) est Q-clos à gauche (resp. à droite). On dit qu'il est Q-*clos* si les deux conditions

sont satisfaites simultanément. Quand aucune confusion n'est à craindre, il m'arrivera de [page 2] dire simplement que Φ est Q-clos, ou que Ψ est Q-clos, sans spécifier si c'est à gauche où à droite. Mais pour un couple Q-orthogonal (Φ, Ψ) (ou je préfère l'écrire $\Phi \;\text{⌐⟶}\; \Psi$), Q-clos signifie toujours Q-clos à gauche et à droite.

Commentary · Exposition [ms. 2]

Orthogonality, closure, and factorization

Grothendieck begins by separating the ingredients that will later have to survive passage to a category of diagrams. A lifting property is easy to transport along an adjunction. A factorization requires a construction. The purpose of the elaborate arrows is to prevent the existence of that construction from being smuggled into the lifting notation.

For classes of arrows L, R in a locally small category, write $L \perp R$ when every commutative square with left side in L and right side in R has a diagonal filler. The filler need not be unique. In modern notation,

$$^{\square}R = \{i : i \perp R\}, \qquad L^{\square} = \{p : L \perp p\}.$$

These are the source's R^* and L_*. They form an antitone Galois connection: $L \subseteq {}^{\square}R$ if and only if $R \subseteq L^{\square}$. Consequently

$$\overline{L} = {}^{\square}(L^{\square}), \qquad \overline{R} = ({}^{\square}R)^{\square}$$

are extensive, monotone, idempotent operations. Grothendieck writes a small tilde for the first closure and an overbar for the second. An arrow with two complete heads means the stronger pair of identities $L = {}^{\square}R$ and $R = L^{\square}$. A transverse stroke adds the assertion that every f factors as pi with $i \in L$ and $p \in R$. Together these are precisely the data of a weak factorization system, without a chosen functorial factorization.

There is a genuine logical slip in the sentence following (1.3). For an arbitrary orthogonal pair, separate closedness of L and R does not imply that they are one another's orthogonals. Indeed, in

Set take both classes to be the isomorphisms. Each is closed under its appropriate double-orthogonal operation, because

$$\,^{\square}\mathrm{Fl} = \mathrm{Is}, \quad \mathrm{Is}^{\square} = \mathrm{Fl}, \quad \,^{\square}\mathrm{Is} = \mathrm{Fl}, \quad \mathrm{Fl}^{\square} = \mathrm{Is}.$$

For example, an arrow having the left lifting property against itself has a two-sided inverse, by using the square with identity horizontal sides; this proves the first identity. The other three follow in the same way or directly from invertibility. Thus $(\mathrm{Is}, \mathrm{Is})$ is separately closed and orthogonal, but is not a mutually maximal orthogonal pair unless the category is a groupoid.

The repair is to retain the explicit equalities of (1.3) as the meaning of a closed *pair*. There is no difficulty with the later terminology for a Quillen pair: once factorization is available, Proposition 1.3 shows that separate retract-closedness forces these equalities. The distinction matters precisely before factorization, where this chapter's questions lie. We therefore retain the printed sentence, record the defect in the audit, and use the mutually orthogonal meaning whenever a two-headed arrow occurs below.

Quand un couple Q-orthogonal $\Phi \longmapsto \Psi$ a la propriété de factorisation de Quillen, je l'indique par la barre verticale croisant l'horizontale, ainsi

$$\Phi \;\rightarrowtail\!\!\!\!\!\mid\; \Psi\ , \tag{1.4}$$

et on définit de même le sens des graphismes

$$\begin{cases} \Phi & \rightarrowtail\!\!\!\!\!\mid & \Psi \\ \Phi & \mid\!\!\!\!\!\leftarrowtail & \Psi \\ \Phi & \rightarrowtail\!\!\!\!\!\mid\!\!\!\!\!\rightarrow & \Psi \\ \Phi & \leftarrow\!\!\!\!\!\mid\!\!\!\!\!\rightarrow & \Psi\ . \end{cases} \tag{1.3}$$

Un couple Q-*orthogonal* Q-*factorisant* $\Phi \rightarrowtail\!\!\!\!\!\!\rightarrow \Psi$ est appelé un *précouple de Quillen.* S'il est de plus Q-clos, i.e. si on a $\Phi \longleftrightarrow \Psi$, on dit que c'est un *couple de Quillen.* p. 2

Φ est dit Q-*saturé à gauche* s'il contient les isomorphismes et est stable par cochangement de base, par (petite) composition transfinie, et par facteurs directs. Dualement Ψ est dit Q-*saturé à droite* s'il

contient les isomorphismes, est stable par changement de base, par composition transfinie, et par facteurs directs. Si Φ est Q-saturé à gauche, il est stable par (petites) sommes directes, i.e. si les $f_i : A_i \longrightarrow B_i$ ($i \in I$, I petit) sont dans Φ, $f = \coprod f_i : \coprod A_i \longrightarrow \coprod B_i$ aussi, et de même pour (petites) sommes amalgamées finies ou infinies (quand on se place dans un $A\backslash\mathcal{M}$ au lieu de $\mathcal{M}$). On a l'énoncé dual pour Ψ, quand Ψ est Q-saturé à droite. [page 3]

En fait, il y a des notions plus faibles de Q-saturation que celle que je viens de dire : Q-*saturation simple* (à gauche : Φ contient les isomorphismes, stable par composition binaire, par cochangement de base), Q-*saturation transfinie* (on exige de plus stabilité par composition transfinie), enfin Q-*saturation totale,* ou Q-saturation tout court (quand on exige de plus la stabilité par facteurs directs). On a les implications

$$\text{(1.6)} \qquad \begin{cases} \text{Q-clos à gauche} \\ \Downarrow \\ \text{Q-saturé (total)} \\ \Downarrow \\ \text{Q-saturé transfini} \\ \Downarrow \\ \text{Q-saturé simple.} \end{cases}$$

Pour $\Phi \subset \mathrm{Fl}(\mathcal{M})$, on a sa Q-clôture (à gauche) $\tilde{\Phi}$ (qui est la plus petite partie Q-close à gauche de $\mathrm{Fl}(\mathcal{M})$ contenant Φ) et de même son Q-saturé (total) à gauche, son Q-saturé transfini, son Q-saturé simple

avec les inclusions tautologiques [page 4]

$$\text{(1.7)} \qquad \Phi \subset \underbrace{\Phi'}_{\substack{\text{Q-saturé} \\ \text{à gauche simple}}} \subset \underbrace{\Phi''}_{\substack{\text{Q-saturé} \\ \text{à gauche transfini}}} \subset \underbrace{\Phi'''}_{\substack{\text{Q-saturé} \\ \text{à gauche total}}} \subset \underbrace{\tilde{\Phi}}_{\substack{\text{Q-clôture} \\ \text{à gauche}}},$$

et dualement pour Ψ. Entre Φ et Φ' il y a encore un Φ'_0,

$$\text{(1.8)} \qquad \Phi \subset \Phi'_0 \subset \Phi',$$

qui est le Q-*saturé pour cochangement de base* (contenant aussi, par définition, tous les isomorphismes). Pour construire tous ces saturés, on procède ainsi :

Commentary · Exposition [ms. 4]

What cellular closure does and does not supply

The four closures organize a constructive question: how much of a left lifting class can be built by attaching specified arrows? The elementary operations are chosen because every left lifting class survives them. For a pushout of i, a lifting square is equivalent, by the pushout property, to a lifting square against i. For a composite $i_2 i_1$, solve the lifting problem first against i_1 and then against i_2. For a continuous ordinal sequence $(X_\alpha)_{\alpha \leq \lambda}$, compatible fillers are constructed at successor stages and are assembled at a limit stage by the colimit property. The resulting map $X_\lambda \to E$ is the required filler for the transfinite composite. Finally, a lifting problem against a retract of an arrow is a retract of a lifting problem against that arrow, so a filler restricts along the retraction.

These arguments prove the implications in (1.6), including the dual assertions, whenever the indicated colimits or limits exist. They also explain why small coproducts need not be added as an independent closure operation. Well-order the indexing set S of a family $(A_s \to B_s)$. Starting with

$\coprod_s A_s$, replace the summand A_s by B_s at stage s, using a pushout. At a limit stage take the colimit. The final map is $\coprod_s A_s \to \coprod_s B_s$. The same construction in an undercategory treats amalgamated coproducts. This use of a well-order belongs to the usual set-theoretic choice convention.

The formula for Φ'' on the next page rests on a useful flattening argument. A pushout of a transfinite composite is the transfinite composite of the successive pushouts. A transfinite composite of transfinite composites can be indexed by the ordinal sum of the component ordinals. Thus the transfinite composites of pushouts of the original generators already form a class closed under pushout and transfinite composition. Identity maps allow stages at which nothing is attached. This proves the asserted description of Φ'' without first adding an unspecified hierarchy of repeated cellular operations.

What remains at this point is the relation with retracts. Closure under retracts alone gives no factorization, and the notation Φ''' initially means the smallest class stable under *all* the listed operations. Grothendieck will identify it with the retracts of Φ'' under small-generation hypotheses, and simultaneously identify both with the entire lifting class. The first of these equalities in fact has a general proof, given in the next block; the second is what the small object argument adds. This distinction prevents a positive answer to the elementary closure question from being mistaken for a factorization theorem. A modern reference for the latter is Hovey (1999a, Theorem 2.1.14 and Corollary 2.1.15).

1) Φ'_0 = ensemble des flèches $i : A \longrightarrow B$ s'insérant dans un carré cocartésien p. 3

$$\begin{array}{ccc} A_0 & \xrightarrow{i_0} & B_0 \\ \downarrow & & \downarrow \\ A & \xrightarrow{i} & B\ , \end{array}$$

avec $i_0 \in \Phi$ ou i_0 une identité (auquel cas on trouve pour i les isomorphismes).

2) Φ' = ensemble des flèches composées multiples

$$i_n\, i_{n-1}\ \cdots\ i_1\ ,$$

avec $i_\alpha \in \Phi'_0$.

3) Φ'' = ensemble des composés transfinis de flèches $\in \Phi'_0$.

On a envie de poser

$$\Phi''' \ = \ \Phi''^{\natural} \ \overset{\text{déf}}{=}\ \text{ensemble des facteurs directs d'éléments de } \Phi'',$$

et c'est un fait que $\Phi''^{\natural} \subset \Phi'''$ trivialement, mais il n'est par clair en général qu'on ait égalité, faute de pouvoir montrer que $\Phi''^{\natural}$ est stable, non seulement par facteurs directs, mais aussi par cochangement de base et par composition transfinie. Cependant, rappelons : [page 5]

Commentary · Later developments [ms. 5]

Retracts of cellular arrows are closed under transfinite composition

The uncertainty expressed here has a positive answer without a small generating set. If $\mathcal{M}$ is cocomplete and $\mathcal{C}$ contains the isomorphisms and is stable under pushout and transfinite composition, then $\mathrm{Retr}(\mathcal{C})$ has the same properties. This is Makkai and Rosický (2014b, Lemma 2.2). We give the explicit compatible-retraction construction, since it isolates exactly the issue Grothendieck raises.

First every retract of a map in $\mathcal{C}$ can be presented as a retract with its domain fixed. Suppose $f : A \to B$ is a retract of $g : X \to Y$, with maps $a : A \to X$, $b : X \to A$, $c : B \to Y$, $d : Y \to B$ satisfying

$$ba = 1_A, \quad dc = 1_B, \quad ga = cf, \quad fb = dg.$$

Push g out along b, obtaining $k : A \to P = A \amalg_X Y$ in $\mathcal{C}$. If $q : Y \to P$ is the other pushout map, put $s = qc : B \to P$. The maps $f : A \to B$ and $d : Y \to B$ induce $r : P \to B$. Then $sf = k$, $rk = f$, and $rs = 1_B$. Thus f is a retract of k in $A\backslash\mathcal{M}$.

Now let $(X_\alpha)_{\alpha \le \lambda}$ be a continuous chain with each $f_\alpha : X_\alpha \to X_{\alpha+1}$ in $\mathrm{Retr}(\mathcal{C})$. Choose fixed-domain presentations

$$X_\alpha \xrightarrow{h_\alpha} Z_\alpha, \quad s'_\alpha : X_{\alpha+1} \to Z_\alpha, \quad r'_\alpha : Z_\alpha \to X_{\alpha+1},$$

with $h_\alpha \in \mathcal{C}$, $s'_\alpha f_\alpha = h_\alpha$, $r'_\alpha h_\alpha = f_\alpha$, and $r'_\alpha s'_\alpha = 1$. Construct a second continuous chain Y_α and compatible retractions $X_\alpha \xrightarrow{s_\alpha} Y_\alpha \xrightarrow{r_\alpha} X_\alpha$, starting with $Y_0 = X_0$. At a successor stage set

$$Y_{\alpha+1} = Y_\alpha \amalg_{X_\alpha} Z_\alpha,$$

using s_α and h_α for the pushout. Its structure map $g_\alpha : Y_\alpha \to Y_{\alpha+1}$ lies in $\mathcal{C}$. Define $s_{\alpha+1}$ by the inclusion of Z_α composed with s'_α. Define $r_{\alpha+1}$ by $f_\alpha r_\alpha$ on Y_α and r'_α on Z_α; these agree on X_α. The equations

$$r_{\alpha+1}s_{\alpha+1} = 1, \quad g_\alpha s_\alpha = s_{\alpha+1}f_\alpha, \quad r_{\alpha+1}g_\alpha = f_\alpha r_\alpha$$

follow directly. At a limit stage take colimits of both the chains and these equations. The composite $X_0 \to X_\lambda$ is consequently a retract, with domain fixed, of $Y_0 \to Y_\lambda \in \mathcal{C}$.

Pushout stability follows by pushing out a fixed-domain retraction. Stability under retracts follows by composing retraction diagrams. Taking $\mathcal{C} = \Phi''$ therefore proves $\Phi''' = \mathrm{Retr}(\Phi'')$ in every cocomplete category, even for a proper class of generators. It does not prove $\Phi''' = {}^{\square}(\Phi^{\square})$: that last equality still needs a mechanism, such as Theorem 1.1, for constructing the appropriate factorizations.

Théorème 1.1. *Supposons $\mathcal{M}$ stable par petites $\varinjlim$, et que ses éléments soient accessibles. Supposons de plus que Φ soit petit, plus généralement, qu'il existe une partie $\Phi_0 \subset \Phi$ petite telle que $\Phi \subset \tilde{\Phi_0}$, donc*

$$\Psi \overset{\text{déf}}{=} \Phi_* = (\Phi_0)_* \qquad [1]. \tag{1.1.1}$$

Sous ces conditions, si Φ_0'' désigne le Q*-saturé à gauche transfini de Φ_0, alors on a $\Phi_0'' \rightarrowtail \Psi$, i.e. toute flèche f de $\mathcal{M}$ se factorise en $f = pi$, avec $i \in \Phi_0''$, $p \in \Psi$ [2]. A fortiori, si Φ'' désigne le* Q*-saturé à gauche transfini de Φ, on a*

$$\Phi'' \rightarrowtail \Psi .$$

Commentary · Exposition [ms. 5]

The small object argument and the retract that finishes it

Theorem 1.1 is the engine of the chapter. It recalls the transfinite construction developed in Grothendieck (1990–1991k, Chapter XV, §1, Theorem 1). Its force is not merely that sufficiently many cells exist, but that a *set* of generators admits one common bound on the stages needed to see all its lifting problems. Read "accessible object" here as an object whose maps into sufficiently filtered colimits are detected at a stage; for this argument the weaker condition of smallness relative to the relevant cellular sequences suffices. Local smallness is understood in the chosen universe. These hypotheses do not assert that the entire category is locally presentable.

Put $S = \Phi_0$ and let $f : X \to Y$. Choose an infinite regular cardinal κ such that every domain of an arrow of S is κ-small for the sequences being used. Such a common bound exists because S is a set. Starting from $X_0 = X$, form at stage $\alpha + 1$ the pushout

$$\begin{array}{ccc} \coprod_{\sigma} A_\sigma & \longrightarrow & X_\alpha \\ \downarrow & & \downarrow \\ \coprod_{\sigma} B_\sigma & \longrightarrow & X_{\alpha+1}, \end{array}$$

where σ runs over all commutative squares $s : A_\sigma \to B_\sigma$ against $X_\alpha \to Y$, with $s \in S$. There is a set of such squares, by local smallness and the smallness of S. Their lower maps induce $X_{\alpha+1} \to Y$. At a limit stage take the colimit. Choose the length λ so that the sequence is sufficiently filtered for every domain in S, for example a regular cardinal larger than a common smallness bound.

The composite $i : X \to X_\lambda$ lies in S'': attaching a coproduct of cells can be serialized as on the preceding page. The induced $p : X_\lambda \to Y$ has the right lifting property against S. Indeed, in a square from $s : A \to B$ to p, the map $A \to X_\lambda$ factors through some X_α. Together with the fixed map $B \to Y$, it is one of the squares attached at the next stage. The corresponding copy of B in $X_{\alpha+1}$ gives the filler after composition with $X_{\alpha+1} \to X_\lambda$. The equation with Y already holds at stage α, since all maps are over Y. This proves $f = pi$. Attaching *all* squares makes the construction functorial once colimit choices are fixed; a morphism of arrows sends each indexed square to an indexed square at the next stage.

The retract argument is independent of this construction and deserves to be explicit. Suppose $f : A \to B$ has the left lifting property against $p : E \to B$ and $f = pi$ for $i : A \to E$. A filler in

$$\begin{array}{ccc} A & \xrightarrow{i} & E \\ {\scriptstyle f}\downarrow & \overset{s}{\nearrow} & \downarrow{\scriptstyle p} \\ B & \xrightarrow[1_B]{} & B \end{array}$$

satisfies $sf = i$ and $ps = 1_B$. Hence $(1_A, s) : f \to i$ and $(1_A, p) : i \to f$ exhibit f as a retract of i in the arrow category. In particular, for any factorizing orthogonal pair (L, R),

$$^{\square}R = \mathrm{Retr}(L), \qquad L^{\square} = \mathrm{Retr}(R).$$

1. **N.B.** On a donc $\Phi \rightarrowtail \Psi$, a fortiori $\Phi_0 \rightarrowtail \Psi$.
2. Il y a même factorisation *fonctorielle* en f, propriété qui mérite une notation, p.ex. $\Phi_0'' \rightarrowtail\!\!\!\!\!\rightarrow \Psi$.

The reverse inclusions follow from stability of lifting under retracts. The double-orthogonal closures equal these classes because orthogonality is unchanged by taking retracts. This proves Proposition 1.3 and, applied to $(S'', S^{\square})$, Corollary 1.2. It also proves Corollary 1.4: factor an arrow of L as a map in W followed by a map in R, then use the same square. If W is retract-closed and (L, R) itself factorizes, the converse follows from $L \subseteq W$.

Corollaire 1.2. *Sous les conditions du théorème, on a*

$$\Phi''' \text{ (Q-saturé total à gauche de } \Phi) \;=\; \underbrace{\Phi''^{\natural}}_{\substack{\text{ensemble des}\\ \text{facteurs directs d'éléments}\\ \text{de } \Phi''}} \;=\; \tilde{\Phi}\,. \tag{1.2.1}$$

Plus généralement (en apparence seulement!), si Φ_1 *est une partie de* $\mathrm{Fl}(\mathcal{M})$ *qui est* Q*-saturée à gauche transfinie, et telle que*

$$\Phi_0 \;\subset\; \Phi_1 \;\subset\; \tilde{\Phi} \;=\; \tilde{\Phi_0}\,,$$

p. 4

alors [page 6]

a) *on a* $\Phi_1 \rightarrowtail \Psi$ *et*

b) $\Phi_1^{\sim} = \Phi^{\sim} = \Phi_1^{\natural}$.

Ce corollaire résulte du théorème en vertu de XV prop. 4.2, dont je rappelle ici l'essentiel :

Proposition 1.3. *Soit* $\Phi \rightarrowtail \Psi$. *Alors* $\Phi^{\sim} = \Phi^{\natural} = \Psi^{*}$, *et dualement on a* $\Psi^{-} = \Psi^{\natural} = \Phi_{*}$.

Notons aussi, dans cet ordre d'idées :

Corollaire 1.4. *Soit* $\Phi \longrightarrow \Psi$, *et soit* W *une partie quelconque de* $\mathrm{Fl}(\mathcal{M})$. *Pour qu'on ait* $\Phi \subset W^{\natural}$, *il suffit que toute flèche de* $\mathcal{M}$ *se factorise en* $f = pi$, *avec* $i \in W$, $p \in \Psi$. *(Et cette condition est évidemment aussi nécessaire si* $\Phi \rightarrowtail \Psi$, *et* W *stable par facteurs directs.)*

On dit qu'une partie Φ_0 de Φ est Q-*génératrice à gauche* de Φ si elle satisfait la condition

$$\Phi \;\subset \Phi_0^{\sim}\,, \tag{1.9}$$

et on dit que Φ est une partie *spéciale* si Φ admet une *petite* partie Q-génératrice à gauche. Si $\Phi_0 \subset \Phi$ est petit, et si $\mathcal{M}$ satisfait les conditions du théorème 1.1, alors Φ_0 est une partie Q-génératrice (à gauche) si et seulement si son Q-saturé total (à gauche) Φ_0''' contient Φ (condition en apparence plus forte que $\Phi \subset \Phi_0^{\sim}$, puisque en général on a $\Phi_0''' \subset \Phi_0^{\sim}$). Cela signifie donc aussi, via 1.2, que tout élément de Φ est facteur direct d'un composé transfini de [page 7]
flèches déduites de

$$\Phi_0 \cup (\text{Identités de } \mathcal{M})$$

par cochangement de base.

Je rappelle encore le sorite ± tautologique des foncteurs adjoints :

Proposition 1.5. *Soit*

$$\mathcal{M}' \underset{v^{*}}{\overset{v_{!}}{\leftarrow\!\!\!\rightarrow}} \mathcal{M} \tag{1.5.1}$$

un couple de foncteurs adjoints, soient

$$\Phi \;\subset\; \mathrm{Fl}(\mathcal{M})\,, \qquad \Psi' \;\subset\; \mathrm{Fl}(\mathcal{M}')\,,$$

alors on a

$$(v_{!}(\Phi) \longrightarrow \Psi') \qquad \Longleftrightarrow \qquad (\Phi \longrightarrow v^{*}(\Psi'))\,. \tag{1.5.2}$$

p. 5

Corollaire 1.6. *Pour toute partie* Φ *de* $\mathrm{Fl}(\mathcal{M})$,

$$(v_!(\Phi))_* \;=\; (v^*)^{-1}(\Phi_*)\ . \tag{1.6.1}$$

En effet, appliquant 1.5 à Φ et à $\{f'\}$, où $f' \in \mathrm{Fl}(\mathcal{M}')$, on trouve

$$f' \in (v_!(\Phi))_* \qquad \Longleftrightarrow \qquad v^*(f') \in \Phi_*\ ,$$

ce qui équivaut à (1.6.1). Dualement :

Corollaire 1.7. *Pour toute partie* Ψ' *de* $\mathcal{M}'$*, on a*

$$(v^*(\Psi'))^* \;=\; (v_!)^{-1}(\Psi'^*). \tag{1.7.1}$$

En effet, si $f \in \mathrm{Fl}(\mathcal{M})$, on a par (1.5.2)

$$f \in (v^*(\Psi'))^* \qquad \Longleftrightarrow \qquad v_!(f) \in \Psi^*\ .$$

(3).

Un couple Q-orthogonal $\Phi \rightarrowtail \Psi$ est dit *spécial* s'il satisfait les conditions suivantes. [page 8]

(1.10)
- a) $\mathcal{M}$ est stable par petites $\varinjlim$, les objets de $\mathcal{M}$ sont accessibles. (On dit alors que $\mathcal{M}$ est "spéciale".)
- b) Le couple est clos : $\Phi \longleftrightarrow \Psi$.
- c) Φ est *spéciale.*

Cela implique donc, par 1.1, que $\Phi \longleftrightarrow \Psi$ est un couple de Quillen. Si $\mathcal{M}$ satisfait a), les couples Q-orthogonaux spéciaux dans $\mathcal{M}$, ou encore les couples de Quillen spéciaux, correspondent donc biunivoquement aux parties Φ de $\mathrm{Fl}(\mathcal{M})$ qui sont *spéciales* et closes à gauche (ou ce qui revient au même, Q-saturées à gauche), en associant à une telle Φ le couple $\Phi \longleftrightarrow \Phi_*$.

Commentary · Exposition [ms. 7]

An adjunction transports the whole lifting problem

The next passage prepares the construction of diagrams by proving a statement more economical than a transfer theorem. If $L = v_!$ is left adjoint to $R = v^*$, a commutative square from Li to p' corresponds to a commutative square from i to Rp'. This correspondence includes the diagonal fillers: a map from the codomain of Li to the domain of p' corresponds to a map from the codomain of i to the domain of Rp', and the two triangle equations correspond by naturality of the adjunction. Thus

$$Li \perp p' \quad \Longleftrightarrow \quad i \perp Rp'.$$

There is no need for unique fillers, and no factorization hypothesis enters this equivalence.

Applying it one arrow at a time gives

$$(L\Phi)^{\square} = R^{-1}(\Phi^{\square}), \qquad {}^{\square}(R\Psi') = L^{-1}({}^{\square}\Psi').$$

Here the inverse image means inverse image of a class of arrows, rather than an inverse functor. The unprimed Ψ^* in the proof of Corollary 1.7 is a printed slip: its ambient category forces Ψ'^*.

The same calculation explains why a left adjoint preserves generation by a set even when it does not literally preserve a chosen list of cellular presentations. If $\Phi \subseteq {}^{\square}(\Phi_0^{\square})$, then $\Phi_0^{\square} \subseteq \Phi^{\square}$; inverse image under R gives

$$(L\Phi_0)^{\square} \subseteq (L\Phi)^{\square},$$

and taking left orthogonals gives $L\Phi \subseteq {}^{\square}((L\Phi_0)^{\square})$. This is Corollary 1.9. It needs neither accessibility nor cocompleteness. The extra hypotheses of Corollary 1.8 are used only after this calculation: the

3. donner ici 1.9 page 9.

small object argument in the target produces the factorizations and identifies the left class with the retracts of the relative $L\Phi_0$-cell complexes.

This order of reasoning is helpful throughout the chapter. First identify the desired right class as an inverse image. Then identify a small family that defines it. Only then apply a factorization theorem in the target. In particular, the source category's "specialness" in Corollary 1.8 is stronger than is required for the transport of generators itself; Grothendieck explicitly observes this when extracting Corollary 1.9. The later transfer of a *model structure* will require an additional condition on weak equivalences. That condition is absent here because a single weak factorization system has no class of weak equivalences to preserve.

Ceci posé :

Corollaire 1.8. *Supposons que $\mathcal{M}$, $\mathcal{M}'$ satisfassent la condition* a) *de* (1.10), *et soit* (Φ, Ψ) || *un couple de Quillen spécial dans $\mathcal{M}$. Alors* $\Big(\Phi' = v_!(\Phi)^\sim, \Psi' = (v^*)^{-1}(\Psi)\Big)$ *est un couple de Quillen spécial dans $\mathcal{M}'$.*

En effet, par le corollaire 1.6 on a

$$\Phi'_* \;=\; (v_!(\Phi))_* \;=\; (v^*)^{-1}(\Psi) \;=\; \Psi' \;,$$

donc $\Phi' \longleftrightarrow \Psi'$. Il reste à prouver que Φ' est spécial. Soit Φ_0 une partie petite de Φ telle que $\Phi \subset \Phi_0^\sim$, posons $\Phi'_0 \;=\; v_!(\Phi_0) \subset \Phi'$, il suffit de voir qu'on a

[page 9]

$$(*) \qquad v_!(\Phi) \;\subset\; v_!(\Phi_0)^\sim \;,$$

d'où résultera qu'on a $\Phi' \overset{\text{déf}}{=} (v_!(\Phi))^\sim \subset v_!(\Phi_0)^\sim$. Mais on a

$$v_!(\Phi_0)^\sim \;=\; (v_!(\Phi_0)_*)^* \;,$$

et

$$v_!(\Phi_0)_* \;=\; (v^*)^{-1}(\underbrace{\Phi_{0*}}_{\Psi}) \;=\; (v^*)^{-1}(\Psi) \;\overset{\text{déf}}{=}\; \Psi' \;,$$

p. 6

donc

$$v_!(\Phi_0)^\sim \;=\; \Psi'^* \;=\; \Phi' \;=\; v_!(\Phi)^\sim \;,$$

d'où $(*)$. Cet argument ne fait pas appel à l'hypothèse "spéciale" sur $\mathcal{M}$, et peut s'expliciter en le

Corollaire 1.9. [4] *Sous les conditions générales de* 1.5 *($v_! : \mathcal{M} \longrightarrow \mathcal{M}'$ étant un foncteur admettant un adjoint à droite), soient Φ_0, Φ deux parties de* $\mathrm{Fl}(\mathcal{M})$ *telles que $\Phi \subset \Phi_0^\sim$ (ou ce qui revient au même, $\Phi^\sim \subset \Phi_0^\sim$). Alors $v_!(\Phi) \subset v_!(\Phi_0)^\sim$, i.e. $v_!(\Phi)^\sim \subset v_!(\Phi_0)^\sim$.*

En effet, cette relation équivaut aussi à $v_!(\Phi_0)_* \;\subset\; v_!(\Phi)_*$, c'est-à-dire (par 1.6) $(v^*)^{-1}(\Phi_{0*}) \;\subset\; (v^*)^{-1}(\Phi_*)$, et est impliqué par $\Phi_{0*} \;\subset\; \Phi_*$. Cette dernière d'autre part équivaut à l'hypothèse $\Phi^\sim \subset \Phi_0^\sim$, q.e.d.

Si Ψ est une partie de $\mathrm{Fl}(\mathcal{M})$, on en déduit pour toute I dans Cat une partie

[page 10]

$$(1.11) \qquad \begin{cases} \Psi(I) \subset \mathrm{Fl}(\mathcal{M}(I)), \quad \text{avec } \; \mathcal{M}(I) = \underline{\mathrm{Hom}}(I^\circ, \mathcal{M}) \;, \\ f \in \Psi(I) \iff f(i) \in \Psi \;\; \forall\, i \in \mathrm{Ob}\, I \;. \end{cases}$$

Si on introduit la catégorie discrète I_0 sous-jacente à $\mathrm{Ob}\, I$, et le foncteur canonique

$$(1.12) \qquad v_I = v \;:\; I_0 \longrightarrow I \;,$$

on trouve un couple de foncteurs adjoints

$$(1.13) \qquad \mathcal{M}(I) \underset{v^*}{\overset{v_!}{\leftrightarrows}} \mathcal{M}(I_0) \;\simeq\; \mathcal{M}^{I_0} \;,$$

$$\Big(\underset{v_*}{\overset{\cdots\cdots}{\leftarrow}} \Big)$$

$$\left\{\begin{array}{rcl} u_!(\Phi\langle I\rangle) & \subset & \Phi\langle I'\rangle \\ u^*(\Psi(I')) & \subset & \Psi(I)\ . \end{array}\right. \tag{1.19}$$

Le corollaire 1.8 donne :

Commentary · Exposition [ms. 11]

Free diagrams and the projective construction

The reason for passing through the discrete category I_0 is that independent lifting problems can then be solved component by component. The left Kan extension freely inserts the naturality required by the arrows of I. Throughout this chapter $\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})$. For an object i of I, the left adjoint to evaluation at i is

$$i_!A(j) = \coprod_{I(j,i)} A.$$

Thus the free diagram on a family (A_i) has value $\coprod_i \coprod_{I(j,i)} A_i$ at j. This formula fixes the variance: it is the representable presheaf $I(-,i)$, not $I(i,-)$, that occurs.

Suppose (Φ, Ψ) is a mutually orthogonal pair and $S \subseteq \Phi$ generates it. The set

$$S_I = \{i_!s \mid i \in \mathrm{Ob}\, I,\ s \in S\}$$

generates the projective pair. Indeed, p has the right lifting property against $i_!s$ precisely when $p(i)$ has the right lifting property against s. Hence

$$S_I^{\square} = \Psi(I), \qquad {}^{\square}(S_I^{\square}) = \Phi\langle I\rangle.$$

This makes the smallness in Proposition 1.10 concrete. One need not use the much larger class of all objectwise Φ-arrows on the discrete category. If the domain A of s is small, then $i_!A$ is small for pointwise colimits because

$$\mathrm{Hom}(i_!A, X) = \mathrm{Hom}(A, X(i)).$$

The same common cardinal as in the original small object argument therefore suffices for these generators.

There is a small scope error in the preliminary equation (1.14). Its equality $\Psi(I_0) = \Phi(I_0)^{\square}$ is valid for the closed left classes used in Proposition 1.10: identities in Φ allow one to isolate a chosen coordinate, using identity arrows on the domains of the right-hand maps at all other coordinates. It is not valid for an arbitrary Φ merely satisfying $\Psi = \Phi^{\square}$. For instance, let $\Phi = \{\varnothing \to 1\}$ in Set and let I_0 have two objects. The arrow $(\varnothing \to \varnothing, \varnothing \to 1)$ has the right lifting property against the sole member $(\varnothing \to 1, \varnothing \to 1)$ of $\Phi(I_0)$, because no square can be formed in the first coordinate. Its second component is not surjective. Adding identities to Φ repairs this preliminary assertion; it is automatic in all the subsequent applications to a closed pair.

The source also asserts that the diagram category itself is special. Cocompleteness is pointwise. To check its object-smallness condition, fix $X : I^{\mathrm{op}} \to \mathcal{M}$ and choose one regular cardinal dominating the ranks of its set of values and the cardinality of the set of arrows of I. A natural transformation out of X is a family of component maps subject to one equation for each arrow of I. In a sufficiently filtered colimit, all these component maps occur at one stage, and all their naturality equations hold together at a later stage. Equality of two transformations is detected similarly. This proves smallness of X. If one uses the stronger filtered-presentability convention for accessible objects, the same argument is expressed by the equalizer of the two products computing the set of natural transformations.

Restriction plainly preserves the objectwise class $\Psi(I')$. Its left adjoint consequently preserves $\Phi\langle I\rangle$, by the preceding lifting correspondence. The dual construction uses objectwise left arrows $\Phi(I)$ and defines $\Psi[I] = \Phi(I)^{\square}$. This is the injective pair; its factorization is a different question. Any displayed right Kan extension is understood where its required limits exist. Cocompleteness and smallness of individual objects alone do not imply completeness: the ordered class of ordinals, with arrows $\alpha \to \beta$ for $\alpha \leq \beta$, has all small suprema and small individual objects, but no terminal object. This observation keeps the existence of the right adjoints separate from the lifting calculations that use them.

Proposition 1.10. *Supposons que $\Phi \longleftarrow\!\!\!\!\!\!+\!\!\!\!\!\!\longrightarrow \Psi$ soit un couple de Quillen* spécial *dans $\mathcal{M}$, i.e. de la forme (Φ, Φ_*), avec Φ partie Q-close à gauche spéciale dans $\mathcal{M}$ ($\mathcal{M}$ satisfaisant la condition* (1.10. a)*). Alors pour toute I dans* Cat, *$(\Phi\langle I\rangle, \Psi(I))$ est un couple spécial dans $\mathcal{M}(I)$, en particulier il satisfait au théorème de factorisation.*

Considérons la construction duale, qui nous fait introduire, à partir d'un couple $\Phi \longleftrightarrow \Psi$ dans $\mathcal{M}$, le couple

$$\Phi(I) \longleftrightarrow \Psi[I] \ , \tag{1.20}$$

où $\Phi(I)$ est défini par la formule générale (1.11) (où Ψ est remplacé par Φ), et où $\Psi[I]$ est défini soit comme $\Phi(I)_*$, soit comme

$$\Psi[I] \ = \ v_*(\Psi(I_0))^- \ = \ \Phi(I)_* \ . \tag{1.21}$$

On a alors, pour $u : I \longrightarrow I'$ [page 12]

$$\begin{cases} u^*(\Phi(I')) & \subset \quad \Phi(I) \\ u_*(\Psi[I]) & \subset \quad \Psi[I'] \ . \end{cases} \tag{1.22}$$

Il se pose encore la question si le couple $(\Phi(I), \Psi[I])$ satisfait au théorème de factorisation, sous des hypothèses convenables sur (Φ, Ψ). Je peux seulement hasarder la

Question-conjecture 1.11. *Supposons que (Φ, Ψ) soit un couple de Quillen* spécial, *en est-il de même de $(\Phi(I), \Psi[I])$ pour toute I dans* (Cat) *? En d'autres termes, si $\mathcal{M}$ est spéciale, condition* (1.10. a)*, et si Φ est une partie Q-close à gauche* spéciale *de $\mathcal{M}$, i.e. admettant une petite partie Q-génératrice, est-il vrai que pour toute I dans* Cat, *$\Phi(I)$ est également spéciale ? Je conjecture que oui, en faisant au besoin des hypothèses supplémentaires sur $\mathcal{M}$ (existence d'une filtration cardinale ?). P.ex. si Φ_0 est Q-génératrice dans Φ, et petite, alors $\Phi_0(I)$ est-elle Q-génératrice dans $\Phi(I)$?*

Commentary · Later developments [ms. 12]

The injective question under local presentability

Grothendieck's first question in 1.11 has a precise affirmative answer after the additional hypothesis of local presentability. In a locally presentable category, a weakly saturated class generated by a set remains generated by a set when imposed objectwise on a small diagram category. This is exactly Lurie (2009, Lemma A.2.8.3); its proof is supplied in the more general Lemma A.3.3.3. The corresponding statement for combinatorial categories, without introducing weak equivalences, is Makkai and Rosický (2014b, Corollary 3.4), using the numbering of the 2013 arXiv version. These statements apply directly to a cofibrantly generated weak factorization system and prove that $(\Phi(I), \Psi[I])$ is again cofibrantly generated.

The additional hypothesis is substantive. A category being cocomplete with individually accessible objects does not, by itself, specify a set of presentable objects generating the whole category under filtered colimits. The cited theorems therefore settle the locally presentable form of the question, not its entire literal generality. Our literature check did not establish a theorem with exactly that weaker generality. The final sentence of 1.11 asks for more than existence of *some* generating set: it proposes the particular set $\Phi_0(I)$. That proposal fails, as the following calculation shows.

Commentary · Examples [ms. 12]

Fixed points detect the missing generators

The difficulty with the proposed generators can be seen without homotopy theory. Work in Set with its usual choice convention. The single map $\varnothing \to 1$ generates the weak factorization system of injections and surjections: its right lifting property is surjectivity, injections lift against surjections by choosing preimages on their complements, and the standard factorization is

$$X \longrightarrow X \amalg Y \xrightarrow{[f,1_Y]} Y.$$

Take $I = BG$ for a nontrivial group G, say $G = C_2$. The diagram category consists of right G-sets. The class $\Phi_0(I)$ contains only the map from the empty G-set to the one-point trivial G-set. A G-map $p : X \to Y$ has its right lifting property if and only if $X^G \to Y^G$ is surjective: a map from the trivial point chooses a fixed point.

Now consider $p : \varnothing \to G$, where G acts on itself freely. Both fixed-point sets are empty, so p passes the proposed test. But the objectwise monomorphism $\varnothing \to G$ does not lift against p: in the square whose lower horizontal map is 1_G, a filler would be a map $G \to \varnothing$. Thus $\Phi_0(I)$ does not Q-generate $\Phi(I)$.

The correct generating family in this example is

$$\{\varnothing \to G/H \mid H \leq G\},$$

with right-coset or left-coset notation adjusted to the chosen action convention. An equivariant injection is obtained by attaching the orbits of its invariant complement; conversely, such attachments are injections, and injections are preserved under retracts. The right class consists of maps surjective on H-fixed points for every subgroup H. To see this directly, a map from a transitive orbit to Y is a point fixed by the stabilizer of that orbit, and a lift is a fixed preimage. Choosing such lifts orbit by orbit solves an arbitrary equivariant lifting problem against an injection. The single proposed test sees only $H = G$ and misses the free orbit $H = \{1\}$. This fully accounts for the failure; it does not contradict existence of the injective pair.

Commentary · Development (commentators') [ms. 12]

Exactly when the original singleton still generates

The preceding example suggests a sharper answer to Grothendieck's last sentence: one can characterize all diagram shapes for which his proposed singleton works. The following elementary result is our development of that sentence. We checked the generator constructions of Lurie (2009, Lemma A.2.8.3) and Makkai and Rosický (2014b, Corollary 3.4); we did not locate this precise characterization there. It is a calculation with constant presheaves, not a claim of priority.

Proposition (the constant-generator test). [ours] Let I be a small category, let Δ denote the constant-presheaf functor, and let $\Phi_0 = \{\varnothing \to 1\}$ in Set. Then $\Phi_0(I)$ Q-generates all monomorphisms in $\mathrm{Set}^{I^{\mathrm{op}}}$ if and only if I is empty or equivalent to the terminal category.

Proof. The class $\Phi_0(I)$ consists of the single map $\varnothing \to \Delta 1$: all its component domains and codomains are prescribed, and their transition maps are forced. A pushout of a coproduct of copies of this map adds a constant summand. Consequently every relative cell complex starting from the initial presheaf is $\varnothing \to \Delta S$ for some set S. This includes transfinite cell complexes, since colimits of the successive constant summands are computed pointwise. The small object argument applies, since the initial presheaf is small. Therefore every object P for which $\varnothing \to P$ belongs to the generated left class is a retract of some ΔS.

Suppose now that this left class contains every monomorphism and that I is nonempty. For every $i \in I$, the representable $h_i = I(-, i)$ is then a retract of a constant presheaf. Choose natural transformations

$$h_i \xrightarrow{a} \Delta S_i \xrightarrow{b} h_i, \qquad ba = 1_{h_i}.$$

For any arrow $\alpha : j \to k$ of I, naturality gives

$$a_j h_i(\alpha) = a_k, \qquad h_i(\alpha) b_k = b_j.$$

It follows that $h_i(\alpha)$ has inverse $b_k a_j$: composing in either order and using the two displayed equations yields the appropriate identity. Since this holds for every i, every map

$$I(k, i) \longrightarrow I(j, i), \qquad t \longmapsto t\alpha$$

is bijective. This forces α to be invertible. Explicitly, surjectivity with $i = j$ gives $\beta : k \to j$ with $\beta\alpha = 1_j$; injectivity with $i = k$ then gives $\alpha\beta = 1_k$, since $(\alpha\beta)\alpha = \alpha = 1_k\alpha$. Thus I is a groupoid.

Moreover, S_i is nonempty because $h_i(i)$ contains 1_i and maps into S_i. For every j, the map $b_j : S_i \to I(j, i)$ therefore shows that $I(j, i)$ is nonempty. The groupoid is connected. Finally, an endomorphism $\gamma : i \to i$ acts trivially on $h_i(i)$: naturality gives $a_i h_i(\gamma) = a_i$, and a_i is injective because it has a left inverse. Applying this identity to 1_i gives $\gamma = 1_i$. Every isotropy group is therefore trivial. A connected groupoid with trivial isotropy has exactly one arrow between any two objects, so it is equivalent to the terminal category.

Conversely, if I is equivalent to the terminal category, evaluation at any object is an equivalence $\mathrm{Set}^{I^{\mathrm{op}}} \simeq \mathrm{Set}$ and takes $\varnothing \to \Delta 1$ to $\varnothing \to 1$. Equivalences preserve and reflect lifting properties and monomorphisms, so the stated generation follows from the set calculation. If I is empty, the presheaf category has one object and one arrow; both the generated left class and its class of monomorphisms consist of that arrow. This proves all cases. □

The statement concerns the proposed *unchanged* generator. Even a discrete category with two objects fails the test: it asks one attachment to add a point simultaneously in both coordinates. The affirmative injective-generation theorem supplies a different set, large enough to express the independent and compatible attachments required by the chosen shape.

Proposition 1.12 [5]. *Soit* $\Phi \longleftrightarrow \Psi$ *dans* $\mathcal{M}$, *soit* $u : I \longrightarrow I'$ *une flèche dans* Cat, *d'où*

Commentary · Exposition [ms. 12]

The comma-category test for preserving projective arrows

Proposition 1.12 identifies shapes for which restriction preserves the projective left class. This is a useful exception to the usual asymmetry: restriction always preserves objectwise right arrows, but it need not preserve the left arrows defined by a lifting property against them.

The printed formula (1.13.2) contains two slips that have to be corrected in interpreting the statement. Its left side should read

$$(*) \qquad u^*\big(\Phi\langle I'\rangle\big) \subseteq \Phi\langle I\rangle,$$

not $u^*(\Phi(I')) \subseteq \Phi\langle I'\rangle$. The latter has the wrong ambient category on the right and the wrong, objectwise, class on the left. The intended equivalence follows by applying the lifting correspondence to the adjunction $u^* \dashv u_*$:

$$\begin{aligned} u^*\Phi\langle I'\rangle \subseteq {}^{\square}\Psi(I) &\iff \Phi\langle I'\rangle \perp u_*\Psi(I) \\ &\iff u_*\Psi(I) \subseteq \Psi(I'). \end{aligned}$$

The source's established mutual-orthogonality identities are exactly what the last step needs.

To prove the sufficient condition, let $K_{i'} = (u \downarrow i')$: its objects are pairs $(i, u(i) \to i')$. For presheaves, the pointwise right Kan extension is

$$(u_*X)(i') = \lim_{K_{i'}^{\mathrm{op}}} X(i).$$

Suppose each connected component c of $K_{i'}$ has a terminal object $t_c = (i_c, u(i_c) \to i')$. Then t_c is initial in the opposite category, and a limit over that component is evaluation at i_c. Therefore

$$(u_*X)(i') \cong \prod_c X(i_c).$$

For an objectwise arrow in $\Psi(I)$, the induced arrow is a product of arrows in Ψ. Any right lifting class is closed under products: project a lifting square to each factor, choose its fillers, and combine them by the product property. The empty product gives an identity of a terminal object. Thus u_* preserves $\Psi(I)$ and (*) follows. This supplies the proof left implicit in the statement.

If I is discrete, every $K_{i'}$ is discrete and each nonempty component is a singleton. For a coétale functor in the source's convention, lifting a map into i' identifies a terminal lift in each component of $K_{i'}$. These are the two advertised special cases of the third condition. All formulas use the relevant products or right Kan extensions where they exist. No factorization theorem and no accessibility hypothesis are needed for this argument; those enter only when one wants the orthogonal pairs themselves to give replacement factorizations.

2 Rappels sur les triples de Quillen clos et les triples de Quillen spéciaux

Soit $(\mathcal{M}, W)$ une *catégorie de modèles,* i.e. $\mathcal{M}$ munie d'un localiseur $W \subset \mathrm{Fl}(\mathcal{M})$, i.e. une partie satisfaisant

(2.1) W contient les isomorphismes, et si f, g sont des flèches composables, si deux parmi f, g, gf sont dans W, la troisième aussi *(saturation faible).*

Je rappelle que la donnée d'un *triple de Quillen clos* (W, C, F), ou d'une structure de Quillen close, sur $\mathcal{M}$, ayant W comme ensemble de quasi-isomorphismes, revient à la donnée de deux couples de Quillen

$$C \longleftarrow\!\!\!\shortmid\!\!\!\longrightarrow TF\ , \qquad TC \longleftarrow\!\!\!\shortmid\!\!\!\longrightarrow F\ , \tag{2.2}$$

satisfaisant

$$TC \subset C \cap W\ , \qquad TF \subset F \cap W\ , \tag{2.3}$$

plus une des trois conditions équivalentes :

$$\begin{cases} \text{a)} & TC = C \cap W & \text{(i.e. } C \cap W \subset TC\text{)} \\ \text{b)} & TF = F \cap W & \text{(i.e. } F \cap W \subset TF\text{)} \\ \text{c)} & W = TF \circ TC\ . & \end{cases} \tag{2.4}$$

Rappelons aussi que ceci implique que W *est fortement saturée,* et a fortiori que $W = W^{\natural}$, i.e. W stable par facteurs directs.

Rappelons aussi qu'en vertu de (1.4), on a :

Commentary · Exposition [ms. 13]

How the two factorizations recognize weak equivalences

The purpose of the second section is to add compatibility with a localizer to the machinery already established for one weak factorization system. Grothendieck's "category of models" at (2.1) means a category with a specified two-out-of-three class. It should not be silently identified with a modern model category. The model structure enters through the two factorizing pairs

$$(C, TF), \qquad (TC, F),$$

with $TC \subseteq C$ and $TF \subseteq F$. The letters T stand for the arrows intended to be trivial, and that intention has to be checked against W. For the equivalence in (2.4), the source explicitly assumes $TC \subseteq C \cap W$ and $TF \subseteq F \cap W$ before asking whether these inclusions are equalities.

The equivalence of the three conditions (2.4) is a short but instructive use of both factorizations. Suppose first that $TC = C \cap W$. If $f \in W$, factor $f = pi$ using (C, TF). Since $p \in W$, two-out-of-three gives $i \in C \cap W = TC$, hence $W \subseteq TF \circ TC$. The reverse inclusion follows because both factors belong to W. Conversely, if $W = TF \circ TC$ and $f \in C \cap W$, choose such a factorization. Since $f \perp p$, the retract argument makes f a retract of $i \in TC$, so $f \in TC$. This proves equivalence of (a) and (c). Using the other factorization and the dual retract argument proves equivalence with (b).

Formula (2.5) is another application of the same idea. To test $TC \subseteq W$ when W is retract-closed, it suffices to factor each arrow of TC as a W-arrow followed by an F-arrow; the left lifting property makes the original arrow a retract of the first factor. If $TC \subseteq W$ already holds, the (TC, F)-factorization supplies this for all arrows. The dual test is a factorization $f = pi$ with $i \in C$ and $p \in W$. The printed last clause "$i \in W$, $f \in C$" is incorrect and is retained as an edition slip, with its intended dual stated here.

The "special" condition adds small generators for both left classes, together with the ambient smallness hypotheses that make their small object arguments work. It is closely related to cofibrant generation in contemporary terminology, but stronger ambient hypotheses are explicitly included here. It is not synonymous with "combinatorial": local presentability is not part of (2.6). The recalled strong saturation of W uses the ambient model-category convention: Grothendieck (1990–1991e, Chapter XIII, §3, manuscript pp. 27–29) explicitly assumes M0, existence of finite limits and finite colimits, and invokes Quillen's saturation result. Strong saturation means that precisely the arrows of W become invertible in $\mathcal{M}[W^{-1}]$; retract-closedness follows since a retract of an isomorphism is an isomorphism. A modern reference is Hovey (1999a, Theorem 1.2.10(iv)). The audit records this as a recalled theorem with its inherited ambient hypotheses, not as a gap in the present proof.

(2.5) Étant donnés les deux couples (2.2), avec $TC \subset C$ (équivalent à $TF \subset F$), pour qu'on ait la première relation (2.3), i.e. $TC \subset W$, il faut, et il suffit si $W = W^\natural$, que toute flèche f de $\mathcal{M}$ (ou seulement toute flèche de TC) se factorise en $f = pi$, avec $i \in W$, $p \in F$. Dualement, pour qu'on ait $TF \subset W$, il faut et il suffit si $W = W^\natural$, que toute flèche f de $\mathcal{M}$ (ou seulement toute flèche de TF) se factorise en $f = pi$, avec $i \in W$, $f \in C$.

On dit que la structure de Quillen (W, C, F) est *spéciale* si les deux couples de Quillen (2.3) sont spéciaux, i.e. si les conditions suivantes sont satisfaites.

(2.6) a) $\mathcal{M}$ est stable par petites $\varinjlim$, et ses éléments sont accessibles ($\mathcal{M}$ "spéciale").

b) Il existe des *petites* parties $C_0 \subset C$, $TC_0 \subset TC$ qui soient Q-génératrices à gauche, i.e. telles que l'on ait

$$\left\{\begin{array}{lllllllll} C & \subset & C_0^\sim\,, & \text{i.e.} & C & = & C_0^\sim\,, & \text{i.e.} & TF = C_{0*}\,; \\ TC & \subset & (TC_0)^\sim\,, & \text{i.e.} & TC & = & (TC_0)^\sim\,, & \text{i.e.} & F = (TC_0)_*\,. \end{array}\right.$$

Ainsi, la donnée d'un tel triple de Quillen *spécial* dans $\mathcal{M}$, quand $\mathcal{M}$ satisfait (2.6. a), revient à la donnée des deux parties [page 15]

$$TC \subset C \tag{2.7}$$

de $\mathrm{Fl}(\mathcal{M})$, satisfaisant les conditions :

(2.8)

- C, TC "spéciales"
  - a) C, TC sont Q-closes à gauche.
  - b) C, TC sont Q-engendrées à gauche par des *petites* parties C_0, TC_0 de C, TC respectivement.
- c) $TC \subset W$, $TF \overset{\text{déf}}{=} C_* \subset W$.
- d) On a l'une des trois conditions équivalentes supplémentaires de (2.4), i.e. :

$$\left\{\begin{array}{lllllllll} \alpha) & TC & = & C \cap W\,, & \text{i.e.} & C \cap W & \subset & TC\,. \\ \beta) & TF & = & F \cap W\,, & \text{i.e.} & F \cap W & \subset & TF\,. \\ \gamma) & W & = & TF \circ TC\,. & & & & \end{array}\right.$$

Commentary · Exposition [ms. 15]

The extra condition in transferring a model structure

Before Proposition 2.1, it helps to identify what can go wrong. The adjunction transfers the two lifting relations formally, and small generation can provide both factorizations. Nevertheless, a map built from the transferred trivial generators might cease to be a weak equivalence after applying the right adjoint. The condition $TC' \subseteq W'$ rules out exactly that possibility.

Write $L = v_!$ and $R = v^*$. With

$$W' = R^{-1}W, \quad F' = R^{-1}F, \quad TF' = R^{-1}TF,$$

the adjunction identifies

$$C' = {}^{\square}TF', \qquad TC' = {}^{\square}F'.$$

Thus both pairs are already mutually orthogonal, although not yet known to factorize. Since $TC \subseteq C$, monotonicity gives $TC' \subseteq C'$, and inverse image gives $TF' \subseteq F'$. The class W' satisfies two-out-of-three because R is a functor. Once the two factorizations exist, the equation $TF' = F' \cap W'$ is built into the definitions; the previous block therefore reduces the entire model-structure question to $TC' \subseteq W'$.

The equivalent condition (2.1.5) has a useful practical interpretation: factor every target arrow into a weak equivalence followed by a member of F', without insisting in advance that the first arrow is in TC'. If the arrow being factored already belongs to TC', its left lifting property makes it a retract of that weak equivalence. Since W' is retract-closed, it belongs to W'. Conversely, a (TC', F')-factorization works once $TC' \subseteq W'$ is known.

The convenient stronger condition is $RL(TC) \subseteq TC$. It tests the images of the original trivial left arrows before taking their left closure. Cases A and B show two mechanisms by which that condition passes to the closure. Case C, completed on manuscript page 19, instead transports a factorization of Rf' through a fully faithful adjunction. This is why the three cases have different hypotheses. A right adjoint generally does not preserve pushouts, so the hypothesis of Case B must not be suppressed in a purported general transfer theorem.

Proposition 2.1. *Soit*

$$\mathcal{M}' \underset{v^*}{\overset{v_!}{\leftrightarrows}} \mathcal{M} \tag{2.11}$$

un couple de foncteurs adjoints, $\mathcal{M}$ étant muni d'une structure de Quillen close (W, C, F). Posons

$$\left\{\begin{array}{rcl} W' & = & (v^*)^{-1}(W) \\ F' & = & (v^*)^{-1}(F) \\ TF' & = & F' \cap W' \;=\; (v^*)^{-1}(TF) \\ C' & = & v_!(C)^\sim \\ TC' & = & v_!(TC)^\sim \ . \end{array}\right. \tag{2.1.2}$$

1°) *On a alors*

$$\left\{\begin{array}{ccccccc} C' & \longleftrightarrow & TF' \ , & & TC' & \longleftrightarrow & F' \ , \\ TC' & \subset & C' \ , & & TF' & \subset & F' \ . \end{array}\right. \tag{2.1.3}$$

Pour que les données (2.1.2) *dans $\mathcal{M}'$ y correspondent à un triple de Quillen (W', C', F'), il faut et il suffit que les conditions suivantes soient satisfaites :* [page 16]

$$\left\{\begin{array}{ll} \text{a)} & \textit{Factorisation pour } C' \longleftrightarrow TF' \textit{ et } TC' \longleftrightarrow F', \textit{ i.e. les relations} \\ & C' \longleftarrow\!\!\!\shortmid\!\!\!\longrightarrow TF' \textit{ et } TC' \longleftarrow\!\!\!\shortmid\!\!\!\longrightarrow F', \\ \text{b)} & TC' \subset W', \end{array}\right. \tag{2.1.4}$$

ou encore, au lieu de b), *la condition équivalente* (en présence de a)) :

$$\left\{\begin{array}{ll} \text{b}') & \textit{Toute flèche } f' \textit{ dans } \mathcal{M}' \textit{ (non seulement } f' \in TC') \textit{ se factorise en} \\ & f' = p'i', \textit{ avec } i' \in W', \ p' \in F'. \end{array}\right. \tag{2.1.5}$$

2°) *Supposons* (2.1.4. a) *satisfaite (factorisation). Alors, pour que (W', C', F') soit un triple de Quillen clos, il* suffit *que l'on ait*

$$\text{b}'') \qquad \boxed{v^* v_!(TC) \ \subset \ TC} \ , \tag{2.1.6}$$

et que de plus on soit dans l'un des trois cas suivants :

A) *v^* admet un adjoint à droite v_*.*

B) *v^* commute aux petites $\varinjlim$, (W, C, F) est spécial, et $\mathcal{M}'$ est spéciale, i.e. satisfait à la condition* (2.6. a).

C) *v^* est pleinement fidèle, et $v^* v_!(F) \subset F$.* p. 11 [page 17]

Notons tout de suite le

Corollaire 2.2. *Supposons que (W, C, F) soit un triple de Quillen spécial, que $\mathcal{M}'$ soit spéciale, que v^* commute aux petites $\varinjlim$, enfin que l'on ait* (2.1.6)*, i.e. $v^* v_!(TC) \subset TC$. Alors (W', C', F') est un triple de Quillen spécial.*

En effet, en vertu du 2.1. 2°, cas B, pour voir que (W', C', F') soit un triple de Quillen clos, il est à vérifier (2.1.6. b″). Mais cela résulte de 1.8, appliqué aux deux couples de Quillen spéciaux (C, TF), (TC, F) dans $\mathcal{M}$: les couples (C', TC') et (TC', F') sont des couples de Quillen spéciaux, ce qui prouve en même temps que le triple (W', C', F') est spécial, q.e.d.

Démontrons 2.1. Les premières deux relations (2.1.3) sont contenues dans 1.6, les relations $TC' \subset C'$, $TF' \subset F'$ sont tautologiques. Le critère (2.1.4) pour que (W', C', F') soit un triple de Quillen clos, est contenu dans le rappel de la page 13, compte tenu que l'on sait déjà que $TF' = F' \cap W'$ (relation (2.4. b)). Que la condition (2.1.4. b), en présence de (2.1.4. a), soit équivalente à la condition (2.1.5. b′), est contenu dans la première assertion (2.5), en notant que l'on a $W' = W^{\pitchfork}$ (ce qui résulte de la définition de W' et de $W = W^{\pitchfork}$).

Il reste à prouver 2°), i.e. que la condition b) est satisfaite moyennant a) et b″) (2.1.6) dans chacun des trois cas A), B), C).

Cas A. Par définition de $W' = (v^*)^{-1}(W)$, pour prouver que $TC' \subset W'$, il suffit de prouver

$$v^*(TC') \ \subset \ W' \ ,$$

et a fortiori, il suffit de prouver

$$v^*(TC') \ \subset \ TC \ , \qquad \text{i.e. } v^*(TC') \rightarrowtail F \ . \tag{2.1.7}$$

Or par 1.5, appliqué au couple de foncteurs adjoints (v^*, v_*), cette relation équivaut à [page 18]

$$TC' \rightarrowtail v_*(F) \ .$$

Comme $TC' \overset{\text{déf}}{=} v_!(TC)^{\sim}$, ceci équivaut à

$$v_!(TC) \rightarrowtail v_*(F) \ ,$$

ou encore (en réappliquant 1.5 à $(v_!(TC), F)$ au lieu de (TC', F)), à

$$v^* v_!(TC) \rightarrowtail F \ , \qquad \text{i.e. } v^* v_!(TC) \subset \underbrace{TC}_{= F^*} \ ,$$

or c'est là l'hypothèse b″).

Cas B. Il suffit encore de prouver 2.1.7. Or, du fait que $v_!(TC)$ admet un petit ensemble Q-générateur à gauche, $v_!(TC)^{\sim}$ est la clôture de $v_!(TC)$ pour les opérations de cochangement de base, de composition transfinie, de facteurs directs. Comme v^* commute à toutes ces opérations (comme il commute aux petites $\varinjlim$), et comme TC dans $\mathrm{Fl}(\mathcal{M})$ est stable par ces opérations, on voit donc que pour montrer que v^* applique $v_!(TC)^{\sim}$ dans TC, il suffit de voir qu'il applique $v_!(TC)$ dans TC, ce qui est encore l'hypothèse b″).

Commentary · Exposition [ms. 18]

Two ways of passing from generators to their closure

The proofs of Cases A and B establish the stronger conclusion $R(TC') \subseteq TC$. They are worth comparing because one uses only lifting properties, whereas the other uses the cellular description supplied by small generation.

In Case A, R has a right adjoint $V = v_*$. For each $p \in F$, the condition $RL(TC) \perp p$ is equivalent to $L(TC) \perp Vp$. Taking the left double-orthogonal closure of $L(TC)$ does not change which arrows have the right lifting property against it; hence $TC' \perp Vp$. Applying the adjunction once more gives $R(TC') \perp p$. Since $TC = {}^{\square}F$, this proves the desired containment. This argument does not require R to preserve any colimit and does not require the ambient categories to be locally presentable.

In Case B, the small object argument identifies TC' with the retracts of cellular composites of a small family inside $L(TC)$. The functor R preserves pushouts and transfinite composites by the stated colimit hypothesis; every functor preserves retract diagrams. Since TC is closed under these operations and $RL(TC) \subseteq TC$, it follows that $R(TC') \subseteq TC$. One may equally use the full weakly saturated closure of $L(TC)$: Corollaries 1.8–1.9 show that its small generating family has the same left closure.

Corollary 2.2 combines this argument with Corollary 1.8, which gives both target factorizations and their small generators. Its printed proof contains two local slips. The first transferred pair is (C', TF'), not (C', TC'). Moreover, the remaining condition supplied by Corollary 1.8 is factorization (2.1.4.a), not (2.1.6.b″), which is already an explicit hypothesis of Corollary 2.2. In the subsequent Case A proof, $R(TC')$ is a class in $\mathcal{M}$, so the intermediate target must be W, not W'. With these corrections of interpretation, the proof establishes the corollary exactly as stated.

Cas C. On va vérifier b) sous la forme équivalente b′). Soit donc $f' \in \mathrm{Fl}(\mathcal{M}')$, $f' : X' \longrightarrow Y'$, posons p. 12

$$f \;=\; v^*(f'), \qquad \text{[page 19]}$$

et factorisons f en pi, avec $i \in TC$, $p \in F$, d'où

$$v_!v^*(f') = v_!(f) = v_!(p)v_!(i)\ .$$

Mais v^* étant pleinement fidèle, $v_!v^* \xrightarrow{\sim}$ id, donc on trouve une factorisation de f' en $v_!(p)v_!(i)$. Il suffit donc de voir que

$$v_!(p) \;\in\; F'\ , \qquad\qquad v_!(i) \;\in\; W'\ ,$$

ce qui équivaut à

$$v^*v_!(p) \in F\ , \qquad\qquad v^*v_!(i) \in W\ ,$$

et résulte des hypothèses que $v^*v_!(F) \subset F$ et $v^*v_!(TC) \subset TC \subset W$, q.e.d.

N.B. J'ai noté les cas A) et C) par acquis de conscience, sans application précise en vue. Le cas le plus utile sera justiciable du cas B), et mérite d'être réexplicité en un

Commentary · Exposition [ms. 19]

Free diagrams and the projective model structure

The concluding Case C can first be made completely explicit. Write $L = v_!$, $R = v^*$ and $\varepsilon : LR \to 1$ for the counit. Since R is fully faithful, ε is an isomorphism. For $f' : X' \to Y'$, choose in $\mathcal{M}$ a factorization

$$RX' \xrightarrow{i} Z \xrightarrow{p} RY', \qquad i \in TC, \quad p \in F.$$

Define

$$i' = L(i)\varepsilon_{X'}^{-1} : X' \longrightarrow LZ, \qquad p' = \varepsilon_{Y'}L(p) : LZ \longrightarrow Y'.$$

Naturality of the counit gives $p'i' = f'$. Moreover $R(i') = RL(i)R(\varepsilon_{X'}^{-1})$ lies in TC, since $RL(TC) \subseteq TC$ and TC is stable under composition with isomorphisms. Likewise $R(p') = R(\varepsilon_{Y'})RL(p)$ lies in F, using the other hypothesis $RL(F) \subseteq F$. Thus $i' \in W' = R^{-1}W$ and $p' \in F' = R^{-1}F$, proving the factorization condition (2.1.5). The two factorizing pairs required separately in Proposition 2.1 remain part of its hypotheses; this argument supplies their compatibility with weak equivalences.

Grothendieck now puts the transfer argument to its principal use: a homotopy theory of coefficients should supply a homotopy theory of diagrams of every small shape. The weak equivalences must be tested at the objects of the indexing category, since this is what allows a diagram to retain its homotopy coherence while its individual values are replaced. The freedom lies in choosing the auxiliary cofibrations and fibrations. For homotopy left Kan extensions, the useful choice fixes the fibrations componentwise and lets lifting determine the cofibrations.

Write $\mathcal{M}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})$, as in the source, and use $L^{\square}$ and ${}^{\square}R$ for right and left lifting classes. The intended formulas are

$$C_{\mathrm{proj}}(I) = {}^{\square}(F(I) \cap W(I)), \qquad TC_{\mathrm{proj}}(I) = {}^{\square}F(I).$$

The first equality in Theorem 2.3 as printed has $F(I)$ where $TF(I)$ is required. This is visible in the edition and is therefore retained in the transcription. Its correction follows already from (1.16), applied to (C, TF). With the printed reading, the alleged cofibrations would be precisely the trivial cofibrations, and even the case $I = e$ would give the wrong class.

The free-diagram adjunction makes the construction concrete. For $i \in I$, evaluation at i has a left adjoint

$$(i_!A)(k) = \coprod_{I(k,i)} A.$$

A lifting problem against $i_!a$ is exactly a lifting problem against a at i. If S and T generate the two lifting pairs in $\mathcal{M}$, the small families

$$\{i_!s \mid i \in \operatorname{Ob} I,\ s \in S\}, \qquad \{i_!t \mid i \in \operatorname{Ob} I,\ t \in T\}$$

therefore detect the componentwise trivial fibrations and fibrations. The required smallness is inherited because evaluation preserves the colimits used in the small object argument. Thus a domain small for a sufficiently long cellular construction in $\mathcal{M}$ remains small after applying $i_!$. The common bound may depend on I and on the generating families; no bound independent of every small category is needed.

To see why the second family produces weak equivalences, evaluate a cell attachment at k. It becomes a coproduct of pushouts of maps in T, indexed by the sets $I(k, i)$. Trivial cofibrations in $\mathcal{M}$ are closed under coproducts, pushouts, transfinite composites and retracts. The evaluated relative cell map is consequently a trivial cofibration. The transfer criterion applies. This is the projective model structure of present terminology; the modern combinatorial statement appears in Groth (2013, Theorem 1.28). The word "special" in this chapter includes small generating families and the stated accessibility of objects, but it does not by itself assert that the underlying category is locally presentable.

The rest of Theorem 2.3 is formal once these factorizations exist, but one step deserves to be made explicit. Suppose L preserves cofibrations and trivial cofibrations and that $f : X \to Y$ is a weak equivalence between cofibrant objects. Factor

$$(f, 1_Y) : X \amalg Y \xrightarrow{k} Z \xrightarrow{p} Y$$

with k a cofibration and p a trivial fibration. Let $i = k|_X$ and $j = k|_Y$. Both are cofibrations because X and Y are cofibrant. Since $pi = f$ and $pj = 1_Y$, two-out-of-three makes i and j trivial cofibrations. Now $L(p)L(j) = 1$, while $L(j)$ is weak; hence $L(p)$ is weak, and so is $L(f) = L(p)L(i)$. This proves exactly the homotopy invariance needed to define $u_!^W$ on cofibrant diagrams. It also explains why taking the ordinary Kan extension of an arbitrary representative is insufficient.

Théorème 2.3[7]. *Soit (W, C, F) un triple de Quillen spécial dans $\mathcal{M}$. Pour toute I dans* Cat*, considérons le triple $(W(I), C\langle I\rangle, F(I))$ dans $\mathcal{M}(I) = \underline{\mathrm{Hom}}(I^\circ, \mathcal{M})$, où les notations sont celles de page 10, donc $W(I)$, $F(I)$ et $TF(I)$ se définissent fibre par fibre, et $C\langle I\rangle = (F(I))^* = (v_{I\,!}(C(I_0)))^\sim$*[8].

1°) *Pour toute I dans* Cat*, $(W(I), C\langle I\rangle, F(I))$ est un triple de Quillen spécial dans $\mathcal{M}(I)$.* [page 20]

2°) *Si $u : I \longrightarrow I'$ est une flèche dans* Cat*, d'où*

$$\mathcal{M}(I) \underset{u^*}{\overset{u_!}{\rightleftarrows}} \mathcal{M}(I'), \tag{2.3.1}$$

alors

$$\left\{\begin{array}{rcl} u^*(W(I')) & \subset & W(I) \\ u^*(F(I')) & \subset & F(I) \\ u^*(TF(I')) & \subset & TF(I) \end{array}\right\} \textit{tautologie}$$
$$\left\{\begin{array}{rcl} u_!(C\langle I\rangle) & \subset & C\langle I'\rangle \\ u_!(TC\langle I\rangle) & \subset & TC\langle I'\rangle\ , \end{array}\right. \tag{2.3.2}$$

7. cf. scholie 2.10, qui devrait précéder le théorème 2.3.

8. où $v_I : I_0 \longrightarrow I$ (I_0 catégorie discrète ayant mêmes objets que I).

enfin, $u_!$ induit un foncteur

$$\mathcal{M}(I)_c \longrightarrow \mathcal{M}(I')_c \qquad (2.3.3)$$

[9]

compatible aux localiseurs $W(I)_c = W(I)|\mathcal{M}(I)_c$ *et* $W(I')_c = W(I')|\mathcal{M}(I')_c$, *donc induit un foncteur*

$$u_!^W \ : \ \mathrm{Ho}_W(I) \longrightarrow \mathrm{Ho}_W(I') \ . \qquad (2.3.4)$$

Ce foncteur est un adjoint à gauche du foncteur u_W^*, p. 13

$$u_W^* \ : \ \mathrm{Ho}_W(I') \longrightarrow \mathrm{Ho}_W(I) \ , \qquad (2.3.5)$$

induit par u^* (3.3.1).

Démonstration de 2.3.

Prouvons 1°). On considère comme dans 1.10 le foncteur

$$v = v_I \ : \ I_0 \longrightarrow I$$

et le couple de foncteurs adjoints

$$\mathcal{M}(I) \underset{v^*}{\overset{v_!}{\leftrightarrows}} \mathcal{M}(I_0) \ , \qquad (2.3.6)$$

auquel on peut appliquer 2.2. Il reste à vérifier seulement [page 21]

$$v^* v_!(TC) \ \subset \ TC \ , \qquad (2.3.7)$$

or on a, pour $X = (X_i)_{i\in I_0} \in \mathcal{M}(I_0)$,

$$\begin{aligned} v_!(X)(i) \ &\simeq \ \coprod_{j\in I_0} v_{j\,!}(X_j)(i) \\ &\simeq \ \coprod_{j\in I_0} \ \underbrace{X_j^{\mathrm{Hom}(i,j)}}_{\substack{\text{somme directe} \\ \text{de } \mathrm{Hom}(i,j) \text{ copies}}} \ , \end{aligned}$$

et la relation (2.3.7) résulte du fait que TC, étant Q-clos à gauche, est stable par petites sommes directes.

Commentary · Examples [ms. 21]

A constant diagram whose homotopy colimit is a classifying space

The free objects in the preceding proof have a geometric meaning: they introduce the room needed to carry the relations in a diagram through a replacement. A diagram may have cofibrant values and still fail to be cofibrant as a diagram. Group actions give a complete calculation of the difference.

Let G be a nontrivial group and let $I = BG$ be the category with one object and automorphism group G. A contravariant diagram of simplicial sets on BG is a simplicial set with a right G-action. Give simplicial sets their usual Kan model structure and give these action diagrams the projective structure. The ordinary colimit is the orbit simplicial set. In particular the colimit of the point with trivial action is a point. We calculate its derived colimit directly.

Let $\mathcal{E}_G$ be the category whose objects are the elements of G and which has exactly one morphism between any ordered pair of objects. Right translation gives a free action on this category. Its nerve EG has

$$(EG)_n = G^{n+1},$$

with faces deleting an entry and degeneracies repeating an entry; G acts diagonally on the right. The category $\mathcal{E}_G$ has an initial object, indeed every object is initial, so its nerve is contractible. An

9. Sous-catégories des objets cofibrants.

explicit contraction is obtained by choosing the identity element and inserting it as an extra first vertex. The augmentation $EG \to *$ is therefore a weak equivalence of the underlying simplicial sets. Since $\mathcal{E}_G$ is a groupoid, its nerve is Kan: a missing face in a horn is supplied by composition and inversion. Thus the augmentation is also a fibration.

It is also a projective cofibrant replacement. To verify cofibrancy without assuming an equivariant model theorem, filter EG by its skeleta. The action on its nondegenerate simplices is free: an element fixing the tuple $(g_0, \dots, g_n)$ must fix g_0, hence is the identity. After choosing one representative in every orbit of nondegenerate n-simplices, the n-skeleton is obtained from the preceding skeleton by attaching copies of

$$G \times \partial\Delta^n \longrightarrow G \times \Delta^n.$$

These are the free diagrams on the generating cofibrations of simplicial sets. Starting from the empty diagram proves that EG is projectively cofibrant.

Its orbit simplicial set is the ordinary bar construction BG. There is one vertex, an edge for every group element, and a two-simplex for every composable pair. Its fundamental group has generators $[g]$, $g \in G$, with relations

$$[1] = 1, \qquad [g][h] = [gh],$$

so the evident map identifies it with G. Thus the derived colimit of the constant point is

$$\operatorname{hocolim}_{BG^{\mathrm{op}}} * \simeq EG/G \simeq BG,$$

which cannot be contractible for nontrivial G. For $G = C_2$ the first homology group is $\mathbb{Z}/2$, whereas the first homology of the ordinary orbit point vanishes. The calculation also proves that the trivial-action point was not projectively cofibrant: otherwise the weak equivalence $EG \to *$ between cofibrant diagrams would remain a weak equivalence after taking orbits, contrary to the calculation.

Every individual simplicial set in this example is cofibrant. What the replacement corrects is therefore the action, including its coherent relations, rather than the values of the diagram. This is the concrete content of the angle brackets in $C\langle I\rangle$. The same distinction will reappear with arrows reversed when injectively fibrant diagrams are used to compute right Kan extensions. The general diagram conventions and their Kan adjunctions are recorded in Lurie (2009, Definitions A.2.8.1 and Proposition A.2.8.7); the calculation above gives the elementary free resolution behind this instance.

Prouvons 2°). Les formules (2.3.2) sont essentiellement tautologiques, les deux dernières résultent de la troisième et de la deuxième, en vertu de 1.5 appliqué au couple de foncteurs adjoints $(u_!, u^*)$. La relation $u_!(C\langle I\rangle) \subset C\langle I'\rangle$, et le fait que $u_!$ transforme objet initial en objet initial, impliquent (2.3.3). Que $u_!$ restreint à $\mathcal{M}(I)_c$ soit compatible aux localiseurs provient de $u_!(TC\langle I\rangle) \subset TC\langle I'\rangle$, et du fait que toute flèche f dans $\mathcal{M}(I)_c$ qui est dans $W(I)$, se décompose en $f = pi$, avec $i \in TC$ et p inverse à gauche d'une $j \in TC\langle I\rangle$. Ceci vu, joint aux deux premières formules (2.3.2) montre qu'on est sous les conditions du théorème d'adjonction de Quillen, d'où l'adjonction de $u_!^W$ et de u_W^*, q.e.d. [page 22]

Corollaire 2.4. *Soit W un localiseur dans $\mathcal{M}$, tel qu'il existe un triple de Quillen spécial (W, C, F) incluant W. Alors le prédérivateur* Ho_W *sur* Cat *satisfait aux axiomes Dér 1 (décomposition), Dér 2 (localisation), Dér 3 (objet final), Der 4 bis (existence des $u_!^W$), Dér 5 bis (calcul des fibres des $u_!^W$), Dér 6 bis (exactitude à gauche, i.e. exactitude à gauche des carrés W-cocartésiens dans les* $\mathrm{Ho}_W(I)$*), Dér 6 (exactitude à droite des carrés W-cartésiens).*

On vient de prouver Dér 4 bis, et Dér 5 bis est pratiquement contenu dans le mode d'obtenir de $u_!$, compte tenu de proposition 1.12, qui implique que pour X dans $\mathcal{M}(I)_c$, et i' dans I', l'image inverse de X dans $\mathcal{M}(i'\backslash I)$ est dans $\mathcal{M}(i'\backslash I)_c$ …

L'axiome de décomposition est satisfait pour tout prédérivateur de la forme $\mathbf{D}_{\mathcal{M},W}$. p. 14
L'axiome d'exactitude à gauche Dér 5 bis est valable, pourvu que les $(\mathcal{M}(I), W(I))$ s'insèrent [page 23]
dans une structure à cofibrations, ce qui est le cas. De même pour l'axiome Dér 2 de localisation, pourvu que de plus W soit fortement saturé, ce qui est également le cas. Enfin, l'axiome de l'objet final dit que si I admet un objet final, alors

$$\mathrm{Ho}_W(e) \longrightarrow \mathrm{Ho}_W(I)$$

est pleinement fidèle, ou encore que le morphisme d'adjonction

$$u_! u^*(\xi) \longrightarrow \xi$$

est un isomorphisme. Mais en vertu de 1.12, cas 3°, dans ce cas u^* applique $\mathcal{M}(e)_c = \mathcal{M}_c$ dans $\mathcal{M}(I)_c$, donc le calcul du couple de foncteurs adjoints $u_!^W$, u_W^* peut se faire en utilisant les restrictions de $u_!$, u^* à $\mathcal{M}(I)_c$ et $\mathcal{M}_c$ respectivement. Comme le morphisme d'adjonction $u_!^c u_c^* \longrightarrow \mathrm{id}$ est un isomorphisme, il en est donc de même de $u_!^W u_W^* \longrightarrow \mathrm{id}$, qui s'en déduit en localisant, q.e.d.

Commentary · Exposition [ms. 23]

The comma formula and the first derivator axioms

Grothendieck wants more than an adjoint on each localized diagram category. He wants its values to be calculable from the part of the diagram lying over a chosen object. This local calculation is what makes the construction a derivator and permits the subsequent base-change arguments. The opposites in his convention must be retained throughout the calculation.

Let $u : I \to J$, $j \in J$, and let $q : j \downarrow u \to I$ forget the arrow $j \to u(i)$. For a contravariant diagram X, the ordinary formula is

$$(u_! X)(j) = \mathrm{colim}_{(j\downarrow u)^{\mathrm{op}}} q^* X.$$

To derive this equality, one must know that the same representatives compute both sides. Put $E = j \downarrow u$. The functor $q : E \to I$ is a discrete opfibration: an arrow $i \to i'$ carries $(i, a : j \to u(i))$ to $(i', u(i \to i')a)$, uniquely. For every $i \in I$ and object $A \in \mathcal{M}$, this unique-lifting property gives

$$q^*(i_! A) \cong \coprod_{e \in q^{-1}(i)} e_! A.$$

Indeed, at $e' \in E$, the indexing sets on the two sides are identified by the bijection

$$\coprod_{e \in q^{-1}(i)} E(e', e) \xrightarrow{\sim} I(q(e'), i).$$

Each arrow on the right has exactly one lift with source e', whose target is in the indicated fibre. Uniqueness also makes the bijection compatible with precomposition, so it defines an isomorphism of diagrams, natural in A. The same formula holds for arrows a in place of objects A.

Apply it to the two generating families in the preceding block. Restriction sends each generating projective cofibration to a coproduct of generating projective cofibrations in $\mathcal{M}(E)$, and likewise for trivial cofibrations. It preserves colimits, computed pointwise, and every functor preserves retract diagrams. It consequently preserves the cellular and retract closures of both families, hence all projective cofibrations and trivial cofibrations. It also preserves the initial object, so q^*QX is projectively cofibrant whenever QX is. This proof uses precisely the cocompleteness and generation hypotheses already available here.

Apply the ordinary formula to a projectively cofibrant replacement $QX \to X$. On the left it computes $u_!^W X$; on the right it computes the homotopy colimit of q^*X. Hence

$$(u_!^W X)_j \cong \mathrm{hocolim}_{(j\downarrow u)^{\mathrm{op}}} q^* X.$$

The isomorphism is the canonical comparison obtained from the comma square, since the ordinary comparison was used before localization. This last point matters: an abstract isomorphism between the two objects would not establish the base-change axiom.

The argument for a terminal object in I is similarly precise. If t is terminal, then $I(i, t)$ is a singleton for each i, so $t_! A$ is the constant diagram on A. Thus the constant-diagram functor takes cofibrant objects to projectively cofibrant diagrams. Since I is nonempty and connected, the colimit of a constant diagram is A, and the counit is an isomorphism already before localization. Its derived counit is consequently an isomorphism. This establishes full faithfulness of constant coefficients in the form claimed by Dér 3.

There is one overstatement in the paragraph being commented on. Decomposition for arbitrary small disjoint unions does not follow for an entirely arbitrary relative category merely from the

formula $\mathbf{D}_{\mathcal{M},W}(I) = \mathcal{M}(I)[W(I)^{-1}]$. Localization need not commute with infinite products: a single morphism in a product localization has a finite zigzag presentation whose length is uniform over all components. The commentary on Chapter VI, manuscript p. 131, addresses that obstruction, and should be consulted here. In the present model-category situation the conclusion is valid. Componentwise replacements and the description of maps between cofibrant-fibrant objects by homotopy classes supply uniform representatives and uniform homotopies. The same description proves that evaluation detects isomorphisms: a representative with weak-equivalence components is a weak equivalence in the diagram model structure.

Finally, the two exactness axioms concern finite homotopy pushouts and pullbacks. They do not require that arbitrary right Kan extensions have already been constructed. The cofibration and fibration structures provide the required finite calculus. The reference to "Dér 5 bis" for left exactness on manuscript page 23 should read "Dér 6 bis"; the statement on page 22 has the right numbering. The author supplies the omitted right-exactness argument himself on page 24. These are local repairs in the exposition, not failures of Corollary 2.4.

2.5. Pour achever de construire Ho_W comme un dérivateur sur Cat tout entier, il faut donc établir Dér 4, Dér 5 : existence des u_*^W, et calcul des fibres de u_*^W. Quant à Dér 6, il est acquis automatiquement, du fait que chaque $(\mathcal{M}(I), W(I))$ s'insère dans une structure de fibration $(W(I), F(I))$. (Oubli dans la démonstration de 2.4.) L'idée naturelle est d'utiliser à présent la structure de triple [page 24]

$$(2.5.1) \qquad (W(I), C(I), \quad \underbrace{F[I]}_{\overset{\text{déf}}{=} TC(I)_*} \quad) \ ,$$

mais la difficulté est de prouver la factorisation pour un couple

$$(2.5.2) \qquad C(I) \longleftrightarrow TF[I] \ , \qquad \underbrace{TC(I)}_{\overset{\text{déf}}{=} C(I)\cap W(I)} \qquad \longleftrightarrow F[I] \ ,$$

faute de pouvoir montrer, dans les conditions générales de 2.3 seulement (triple de Quillen spécial) que $C(I)$ et $TC(I)$ sont également spéciaux. (Cf. question 1.11.) Mais moyennant des conditions convenables sur $\mathcal{M}$, on arrivera à s'en tirer si $C = mono$. L'énoncé pertinent, un peu technique, se trouve dans XV cor. 7.4 (p. 98-99), que je vais rappeler ici.

Commentary · Context [ms. 24]

Why monomorphisms enter the construction

The obstruction to right Kan extensions is now a problem about generating cofibrations. The source already knows how to generate the projective classes by free diagrams. The injective classes are prescribed componentwise, and a small generating family for them is not produced by simply taking the old generators componentwise. Grothendieck returns to monomorphisms because subobjects provide a way to control the size of successive attachments. This is the same geometry of unions and injective objects that underlies the older theory of sheaves and abelian categories.

The six conditions in Theorem 2.6 separate this size control from the exactness needed to glue subobjects. Cocompleteness and accessibility of individual objects supply the small object argument. The cardinal filtration adds a supply of objects bounded in size; it must not be silently absorbed into the word "special." Left exactness of filtered colimits allows intersections to pass through increasing unions. Condition (e) says that the union of two subobjects can be formed by their pushout over the intersection. Condition (f) ensures that attaching such a piece preserves monicity even when the attaching map is not itself monic. These hypotheses explain why the subsequent proof can remain inside the category of subobjects of a fixed target.

The direction of the limit in (2.6.1d) requires an editorial correction. The edition prints a projective-limit arrow. The cited antecedent, XV, Theorem 6.1(d), manuscript page 76, has inductive limits, and XVIII, Proposition 4.6.7, manuscript page 157, likewise gives closure of the cardinal stages under inductive limits of bounded size (Grothendieck, 1990–1991k,-). This is also what the intended examples require. For the ordinary filtration of sets by cardinality at most π,

a coproduct of at most π sets of that size still has size at most π. By contrast, the product of π copies of a two-element set has size $2^\pi > \pi$. We preserve the printed sign and use the intended inductive-limit condition when explaining the theorem.

The examples in the footnotes give a useful test of the exactness assumptions. In an abelian category the pushout of subobjects $A_1, A_2 \subset B$ over their intersection is their sum $A_1 + A_2$, which embeds in B. If $i : A_0 \hookrightarrow A_1$ is monic and $f : A_0 \to A_2$ is arbitrary, the pushout is

$$(A_1 \oplus A_2)/\operatorname{im}(i, -f).$$

The map from A_2 into this quotient is monic: an element of the intersection of $0 \oplus A_2$ with $\operatorname{im}(i, -f)$ must come from an element killed by i, hence from zero. The same proof can be phrased with kernels and images in any abelian category. Thus these conditions extend beyond topoi.

For groups the effective-union condition fails visibly. Inside $C_2 \times C_2$, take the two coordinate subgroups. Their intersection is trivial, while their pushout in groups is $C_2 * C_2$. The canonical map to $C_2 \times C_2$ kills the commutator of the two nonidentity generators. That commutator is a nonempty reduced word in the free product, so the map is not injective. The appeal to the absence of enough injectives in groups is therefore not an arbitrary warning: the precise gluing mechanism used by the theorem has already broken. The cited SGA passage establishes that there are groups which embed in no injective group (Artin et al., 1972, Exposé I, Example 8.12.9).

The tentative footnote about removing condition (d) should be read alongside Grothendieck's own refinement in XVIII, 4.6.7. There he replaces the excessive demand on all quotients by factorization into an effective epimorphism followed by a monomorphism, recovering the weaker quotient condition actually used in XV. This is a specified replacement of hypotheses; it does not justify the projective-limit sign printed here, nor does it establish a small generating set for every accessible class of monomorphisms.

p. 15
[page 25]

Théorème 2.6. *Soit $\mathcal{M}$ une catégorie satisfaisant les conditions suivantes.*

(2.6.1)

a) *$\mathcal{M}$ est "spéciale", i.e. stable par petites $\varinjlim$, et ses éléments sont accessibles.*

b) *Les limites inductives filtrantes dans $\mathcal{M}$ sont exactes à gauche (et dans $\mathcal{M}$ les $\varprojlim$ finies sont représentables – résulte de* a *et* c*).*

c) *$\mathcal{M}$ admet une filtration cardinale $(\mathrm{Filt}^\pi)_{\pi \geq \pi_0}$.*

d) *Les Filt^π sont stables par $\varprojlim$ indexées par des catégories I telles que $\operatorname{card} \mathrm{Fl}(I) \leq \pi$, et par quotients ($Z \in \mathrm{Filt}^\pi$ et $Z \longrightarrow Z'$ épimorphisme implique $Z' \in \mathrm{Filt}^\pi$).*

e) *Si A_1, A_2 sont deux sous-objets d'un objet B de $\mathcal{M}$, et $A_0 = A_1 \cap A_2$, alors $A_1 \amalg_{A_0} A_2 \longrightarrow B$ est un monomorphisme.*

f) *Si on a un carré cocartésien*

$$\begin{array}{ccc} A_0 & \xrightarrow{i} & A_1 \\ \downarrow & & \downarrow \\ A_2 & \xrightarrow{i'} & A_3 \end{array}$$

avec i monomorphisme, alors i' est un monomorphisme.

[10,11,12,13]. *(On dira alors que $\mathcal{M}$ est* "très spéciale"*). Soit de plus*

$$W \subset \mathrm{Fl}(\mathcal{M}) \tag{2.6.2}$$

un localiseur dans $\mathcal{M}$, qui satisfait les conditions

(2.6.3)
- a) *W est stable par $\varinjlim$ filtrantes* [14].
- b) *W est de plus L_1-accessible, i.e. il existe une* petite *partie $W_0 \subset W$ telle que W soit la L_1-enveloppe de W, i.e. que W soit la plus petite partie de $\mathrm{Fl}(\mathcal{M})$ contenant W_0, et stable par $\varinjlim$ filtrantes.*

Posons alors

p. 16

$$C = \mathrm{Mono}(\mathcal{M}), \qquad TC = C \cap W\ , \qquad TF = C_*\ , \qquad F = (TC)_*\ . \tag{2.6.4}$$

[page 26]

Sous ces conditions :

1°) *$C \leftarrow\!\!\!\!\!\!\rightarrow TF$, plus précisément $C \rightarrowtail TF$ est un couple de Quillen spécial.*

2°) *Pour que $TC \rightarrowtail F$ soit un couple de Quillen, il faut et il suffit que TC soit stable par cochangement de base, et alors c'est un couple de Quillen spécial.*

3°) *Pour que (W, C, F) soit un triple de Quillen (lequel sera nécessairement spécial par* 1°, 2°*, et en particulier clos), il faut et il suffit que les conditions suivantes soient satisfaites.*

(2.6.5) [15]
- a) TC ($\overset{\text{déf}}{=} W \cap \mathrm{Mono}$) *est stable par cochangement de base.*
- b) TF ($\overset{\text{déf}}{=} (\mathrm{Mono})_*$) = *"applications de type injectif"* $\subset W$.

Et la condition b) *équivaut encore à :*

(2.6.6)
- b′) *Toute flèche f de $\mathcal{M}$ (ou seulement de TF) se factorise en $f = pi$, avec i monomorphisme, $p \in W$.*

Corollaire 2.7. *$\mathcal{M}$ et W étant comme dans* (2.6.1), (2.6.3)*, pour que (W, C, F) soit un triple de Quillen* propre à gauche *(i.e. $C \subset \mathrm{Cof}_W$), il faut et il suffit que W satisfasse la condition* (2.6.5. b) *(i.e. W contient les flèches de type injectif), et de plus*

$C \subset \mathrm{Cof}_W$, *i.e. la condition :*

a′) *Pour tout diagramme cocartésien*

[page 27]

$$\begin{array}{ccc} A_0 & \xrightarrow{i} & A_1 \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f'} \\ A_2 & \xrightarrow{i'} & A_3 \end{array} \tag{2.7.7}$$

avec i monomorphisme, si $f \in W$, alors $f' \in W$. (Stabilité de W par cochangement de base par monomorphismes.)

10. **N.B.** a + c signifie aussi que $\mathcal{M}$ est une "catégorie $\mathfrak{U}$-paratopos", et implique l'existence d'une filtration cardinale satisfaisant d) (sauf l'assertion concernant les quotients Z' de Z). Donc il s'agit d'un $\mathfrak{U}$-paratopos satisfaisant de plus b) e) f). (Est-ce alors un topos ? *Non,* car e), f) sont O.K. dans les *catégories abéliennes !*)

11. **N.B.** La condition d) est sans doute inutile, du moins si les épimorphismes sont effectifs, car d) sera satisfaite en tous cas pour $\pi = 2^c$, avec $c \geq \pi_0$.

12. **N.B.** La condition e) n'est *pas* satisfaite pour la catégorie (Gr), et le théorème est en défaut pour cette catégorie, laquelle n'admet *pas* "assez d'injectifs", cf. SGA 4 I 8.12.9. Par contre, e) et f) sont satisfaites par les catégories *abéliennes.*

13. Cf. XVIII 4.6.7 (p. 157) pour une formulation plus sympathique de l'ensemble des conditions a) à f) pour $\mathcal{M}$.

14. **N.B.** a) implique déjà que $W = W^{\natural}$.

15. **N.B.** Ces conditions (2.6.5) équivalent à dire que (W, C) est une structure de catégorie à cofibrations sur $\mathcal{M}$.

Sous ces conditions, ce triple de Quillen est spécial, et a fortiori clos.

Ce corollaire résulte de 2.6. 3°), puisque $C \subset \mathrm{Cof}_W$ implique $TC \overset{\text{déf}}{=} C \cap W = C \cap W^{\mathrm{univ}}$ (car $\mathrm{Cof}_W \cap W = W^{\mathrm{univ}}$), donc que TC est stable par cochangement de base, d'où la condition (2.6.5. a).

Commentary · Exposition [ms. 27]

The recognition argument and its essential cancellation

Grothendieck's criterion is designed so that the difficult set-theoretic work produces two factorizations, after which the model axioms follow from a short argument. Keeping these stages distinct also prevents the recalled theorem from being confused with a broader assertion about arbitrary accessible classes of monomorphisms. The latter is not what Theorem 2.6 needs.

Set $C = \mathrm{Mono}$, $TC = C \cap W$, $TF = C^{\square}$ and $F = (TC)^{\square}$. Suppose that the two asserted weak factorization systems have been obtained and that $TF \subset W$. Then $TF \subset F$ because $TC \subset C$. We verify the remaining equality $F \cap W = TF$. Given $f \in F \cap W$, use the first factorization system to write

$$f = pi, \qquad i \in C, \quad p \in TF.$$

Since $p, f \in W$, two-out-of-three puts i in TC. Since f has the right lifting property against i, the usual diagonal makes f a retract of p in the arrow category. Right lifting classes are retract-closed, so $f \in TF$. The reverse inclusion has already been observed. Hence the two weak factorization systems have exactly the intersections required for a closed Quillen triple.

The alternative condition (2.6.6) is the same retract argument in a different position. If $TF \subset W$, factorization with respect to (C, TF) supplies a monomorphism followed by a weak equivalence. Conversely suppose each $f \in TF$ factors as $f = pi$ with i monic and $p \in W$. The right lifting property of f against i makes f a retract of p, so $f \in W$, provided W is retract-closed. That last property is already forced by (2.6.3a): if f is a retract of $g \in W$, split the associated idempotent $e : g \to g$ by the chain

$$g \xrightarrow{e} g \xrightarrow{e} g \xrightarrow{e} \cdots .$$

Its colimit in the arrow category is f. Filtered-colimit closure therefore gives $f \in W$.

The historical proof of the generating-set assertion should be located accurately. XV, Theorem 6.1 carries the author's warning that its proof is invalid. The surviving argument is the separate Lemma 7.3 and its application in 7.1–7.4. Starting with $A \hookrightarrow B$ in TC, one chooses a bounded subobject $B_0 \subset B$ for which $A \cap B_0 \hookrightarrow B_0$ lies in TC and adds it to A. The density argument permits B_0 to contain a prescribed bounded piece of B; when $A \neq B$, choose that piece not contained in A. Thus the union strictly enlarges A. Effective unions keep $A \cup B_0 \to B$ monic; pushout stability makes $A \to A \cup B_0$ weak. Since $A \to B$ is weak, cancellation makes $A \cup B_0 \to B$ weak. Repeat this construction, taking unions at limit stages. Filtered-colimit closure keeps the resulting map to B in TC at such stages. Since B has only a set of subobjects, strict enlargement cannot continue indefinitely: the process reaches B. The cancellation step is the extra ingredient missing for an arbitrary accessible mono class (Grothendieck, 1990–1991k, §7, especially Lemma 7.3 and Corollary 7.4).

A later independent formulation is Smith's recognition theorem, proved in Beke (2000, Theorem 1.7): with a locally presentable underlying category and a chosen set generating the cofibrations, accessibility supplies the solution-set condition for weak equivalences, and pushout/transfinite closure of the trivial cofibrations completes the construction. Beke's Proposition 1.12 identifies hypotheses ensuring that all monomorphisms admit such generators. This provides a modern route to the intended very-special case without appealing to the withdrawn general claim.

Corollary 2.7 records an additional condition, left properness. Its pushout square tests whether a weak equivalence remains weak after attachment along a monomorphism. When the attached map itself is both a monomorphism and a weak equivalence, the two-out-of-three argument in the source identifies it with a universally weak map, whose every cobase change is weak. Hence left properness supplies the pushout stability of TC required by Theorem 2.6. The recognition theorem needs that stability; the stronger properness property is singled out for applications rather than inserted into the definition of a model structure.

2.8. On dit qu'une *structure de Quillen* (W, C, F) sur $\mathcal{M}$ est *très spéciale,* si elle est p. 17

obtenue comme au théorème 2.1., i.e. si on a les conditions :

(2.8.1)
$$\begin{cases} \text{a) } \mathcal{M} \text{ est très spéciale, i.e. satisfait aux conditions (2.6.1).} \\ \text{b) } W \text{ est stable par petites } \varinjlim \text{ filtrantes, et est accessible (conditions (2.6.3)).} \\ \text{c) } C = \text{Mono.} \end{cases}$$

Donc pour qu'un localiseur W dans $\mathcal{M}$ corresponde à une structure de Quillen très spéciale dans $\mathcal{M}$ (laquelle sera forcément unique), il faut et il suffit que $\mathcal{M}$ et W satisfassent les conditions (2.8.1. a) b)), et que de plus on ait : [page 28]

(2.8.2)
$$\begin{cases} \text{a) } TC \overset{\text{déf}}{=} \text{Mono} \cap W \text{ est stable par cochangement de base.} \\ \text{b) } TF \overset{\text{déf}}{=} (\text{Mono})_* \subset W, \text{ i.e. } W \text{ contient les flèches de type injectif dans } \mathcal{M}. \end{cases}$$

[16].

Commentary · Later developments [ms. 28]

Injective structures and the role of accessibility

Grothendieck has reached a class of coefficient categories for which the second half of the diagram theory can be constructed. Theorem 2.9 uses componentwise cofibrations, so restriction along every functor preserves both cofibrations and trivial cofibrations. The right Kan adjoint is then a right Quillen functor. This is the injective model structure; the square brackets in $F[I]$ indicate that its fibrations have been determined by a lifting property on whole diagrams.

There are two sorts of permanence hidden in the phrase "par AQT." The exactness conditions are evaluated at objects of I: limits, colimits, intersections, pushouts and the maps from unions to ambient objects are computed there. Monicity is also componentwise. For the converse direction of that assertion, apply the defining monomorphism test to free diagrams $i_!A$: monicity of $X \to Y$ in the diagram category says that $\mathcal{M}(A, X_i) \to \mathcal{M}(A, Y_i)$ is injective for every A, hence $X_i \to Y_i$ is monic. The existence of the free adjoint is what makes this argument valid in the stated generality.

The size statements require a common bound. One chooses a cardinal larger than the arrow set of I and enlarges the bounds used for the coefficients and for W. A small diagram then involves only a bounded family of objects, structure maps and equations. A sufficiently large accessible presentation can carry all these data at one stage. Equalities of composites are imposed at a later common stage, and the filtered system of such choices recovers the original diagram. Thus the bounds are allowed to grow with the shape. The source's cardinal-filtration hypothesis is doing real work here; accessibility of each individual object alone would not justify this conclusion. A precise antecedent for the diagram-filtration step is Artin et al. (1972, Exposé I, Corollary 9.24), with the indexing category held fixed and the cardinal enlarged as prescribed there.

In the later combinatorial formulation, Lurie (2009, Lemma A.2.8.3) proves that the componentwise class associated to a set-generated weakly saturated class is again set-generated in a small diagram category. Proposition A.2.8.2 then gives both projective and injective model structures. This settles the obstacle of page 24 when local presentability is imposed; it should not be quoted as a theorem about every historical "special" category with that hypothesis omitted. For presheaves with an accessible localizer and monomorphism cofibrations, the corresponding statement is Cisinski (2006a, Corollary 1.4.22). These references supply exact later versions of the passage from coefficients to diagrams.

The derived right adjunction itself can be checked without new size arguments. Since u^* preserves the componentwise trivial cofibrations, adjunction shows that u_* preserves injective fibrations. Applying the same reasoning to all componentwise cofibrations gives preservation of trivial fibrations. It preserves the terminal object, hence fibrant objects. The dual of the Brown argument above shows that it preserves weak equivalences between those objects. Localizing its restriction to fibrant objects defines u_*^W, and the derived unit and counit give

$$u_W^* \dashv u_*^W.$$

16. On dit aussi que le localiseur W est très spécial, s'il définit une structure de Quillen très spéciale.

The replacement needed for the pointwise formula can also be specified. Let $q : E = (u \downarrow j) \to I$ forget the arrow $u(i) \to j$. This projection is a discrete fibration: an arrow $i' \to i$ uniquely lifts into an object $(i, u(i) \to j)$ by precomposition. Consequently its left Kan extension on contravariant diagrams is

$$(q_! Y)(i) \cong \coprod_{e \in q^{-1}(i)} Y(e).$$

Coproducts preserve cofibrations and trivial cofibrations, so $q_!$ preserves both componentwise left classes. The adjunction $q_! \dashv q^*$ therefore makes q^* a right Quillen functor for the injective structures. In particular, if $X \to RX$ is an injective fibrant replacement, then q^*RX is injectively fibrant and $q^*X \to q^*RX$ is a weak equivalence. Applying the ordinary right Kan formula to RX now gives

$$(u_*^W X)_j \cong \mathrm{holim}_{(u\downarrow j)^{\mathrm{op}}} q^* X.$$

Here the comma category has objects $u(i) \to j$, opposite to the comma category used for the left extension. This accounts for the two different fibre formulas in the derivator axioms.

The two model structures have the same weak equivalences and therefore produce the same localized diagram category. Their purpose is computational: one makes the left adjoints homotopical on cofibrant objects, the other makes the right adjoints homotopical on fibrant objects. The special monomorphism hypotheses guarantee these choices in the source's proof. They are not an invariant property that every presentation of the resulting derivator must share.

17. sous-catégories pleines des objets fibrants.

Démonstration de 2.9. Pour prouver 1°), il faut vérifier d'abord que les conditions préliminaires (2.8.1. a) b)) sur $\mathcal{M}$, W sont stables par passage de $\mathcal{M}$, W à $\mathcal{M}(I)$, $W(I)$, ce qui se fait par AQT `[âne qui trotte]`. D'ailleurs on vérifie tout de suite que

$$C(I) \;=\; \mathrm{Mono}(\mathcal{M}(I))\ ,$$

et le théorème 2.6 (1°, 2°) implique alors que

$$\begin{array}{ccccc} C(I) & \longmapsto & C(I)_* & \overset{\text{déf}}{=} & TF[I] \\ \underbrace{TC(I)}_{\overset{\text{déf}}{=}C(I)\cap W(I)} & \longmapsto & (TC(I))_* & \overset{\text{déf}}{=} & F[I] \end{array}$$

sont des couples de Quillen spéciaux. (En notant pour le deuxième, que $TC(I)$ est bien stable par cochangement de base, TC l'étant.) Pour vérifier que l'on a un triple de Quillen très spécial, il reste en vertu de 2.8 à vérifier que [page 30]

$$TF[I] \;\subset\; W(I)\ ,$$

ce qui s'écrit

$$v^*(TF[I]) \;\subset\; W(I_0)\ ,$$

où

$$v \;:\; I_0 \longrightarrow I$$

est défini comme dans (1.12) (p. 10). En fait, on aura même

$$v^*(TF[I]) \;=\; v^*v_*(TF(I_0)) \;\subset\; \underbrace{TF(I_0)}_{=F(I_0)\cap W(I_0)}\ ,$$

et la démonstration est duale de celle de

$$v^*v_!(TC(I_0)) \;\subset\; TC(I_0)$$

(cf. (2.3.7), p. 21), elle ne dépend pas des questions de factorisation dans $\mathcal{M}(I)$, et provient ici de la stabilité de TF par petits produits. Cela prouve 1°.

Commentary · Development (commentators') [ms. 30]

The cofree image is smaller than the lifting class

Grothendieck needs the inclusion $TF[I] \subset W(I)$ to finish the injective model structure. The intended conclusion is correct, but the equality involving cofree diagrams on this page is stronger than the adjunction permits. We spell out both the direct repair and a finite example distinguishing the two classes.

First there is a short proof of the necessary inclusion. For $v : I_0 \to I$, the free-diagram functor $v_!$ takes componentwise monomorphisms to monomorphisms. Indeed, at i it is a coproduct of the given component maps, and these coproducts are monic under the hypotheses in use. One can also see the coproduct assertion by expressing a coproduct of monomorphisms as a transfinite succession of pushouts, using closure of monomorphisms under filtered colimits at limit stages. If $p \in TF[I] = \mathrm{Mono}(\mathcal{M}(I))^{\square}$, adjunction now gives

$$v^*p \in \mathrm{Mono}(\mathcal{M}(I_0))^{\square} = TF(I_0).$$

Since $TF \subset W$, this proves the required inclusion. No factorization of p and no assertion that it is cofree have been used.

Finite separation of the two image classes. [ours] In Set, with weak equivalences all maps and cofibrations the injections, take $I = (0 \to 1)$. Then

$$v^*(TF[I]) \neq v^*v_*(TF(I_0)).$$

Here the model structure is generated by the usual injection–surjection weak factorization system; it satisfies the intended, inductive-limit version of the very-special hypotheses.

Proof. A contravariant I-diagram is a map $X_1 \to X_0$. Let X_0 have two elements and X_1 three, and choose a surjection $r : X_1 \twoheadrightarrow X_0$. Let $p : X \to 1$ be the map to the terminal diagram. We show directly that it has the right lifting property against every componentwise injection $A \hookrightarrow B$. Regard A_i as a subset of B_i. Given a map $A \to X$, first extend $A_0 \to X_0$ to $h_0 : B_0 \to X_0$ by sending all new elements to one fixed element of X_0. Choose a section $s : X_0 \to X_1$ of r. On $B_1 \setminus A_1$, define

$$h_1(b) = s\big(h_0(r_B(b))\big),$$

and on A_1 retain the specified map. The two definitions have disjoint domains and agree with the required compatibility on A_1. Thus $rh_1 = h_0 r_B$, giving a lift of diagrams. Hence $p \in TF[I]$.

For a family (E_0, E_1), the cofree diagram is

$$(v_*E)_0 = E_0, \qquad (v_*E)_1 = E_0 \times E_1,$$

with the projection as its structure map. Consequently the restriction of a cofree arrow has component source sizes $|E_0|$ and $|E_0||E_1|$. If it were isomorphic, after restriction, to p, these sizes would be 2 and 3. The equation $2|E_1| = 3$ has no solution. Therefore v^*p is not in the cofree image class, even up to isomorphism. This proves the assertion. □

The product argument in the source does establish

$$v^*v_*(TF(I_0)) \subset TF(I_0),$$

because right lifting classes are closed under products. It does not replace the direct lifting proof for the larger class $TF[I]$. In a closure formulation one must retain the appropriate right-orthogonal saturation; deleting it creates exactly the mistaken equality.

We checked the diagram-model discussions of Lurie (2009, §A.2.8) and Cisinski (2006a, Corollary 1.4.22); both use lifting to establish the relevant preservation statements. We did not find this particular finite illustration there. The example is recorded as a local development of the printed argument, with no claim of priority for the general distinction between cofree objects and a right lifting class.

La démonstration de 2° est maintenant la duale de celle de (2.3. 2°). Comme cela nous fait répéter deux fois la même démonstration, cela montre qu'on n'a pas "monté le sorite" tout à fait avec assez de soin. Donc à titre de rattrapage, j'ajoute un

p. 19 [page 31]

Scholie 2.10. *Soit (W, C, F) un triple de Quillen clos dans $\mathcal{M}$. Pour I dans* Cat*, pour que $(W(I), C\langle I\rangle, F(I))$ soit un triple de Quillen clos pour $\mathcal{M}(I)$, il faut et il suffit que les couples $C\langle I\rangle \longleftrightarrow TF(I)$ et $TC\langle I\rangle \longleftrightarrow F(I)$ soient factorisants. Supposons que cette condition soit satisfaite pour I et pour I', et soit $u : I \longrightarrow I'$ une flèche de I dans I'. Alors les assertions de* 2.3. 2° *sont valables, en particulier on trouve un foncteur $u_!^W : \mathrm{Ho}_W(I) \longrightarrow \mathrm{Ho}_W(I')$, adjoint à gauche de u_W^** [18]*. Ces résultats se dualisent aussitôt (par $\mathcal{M} \longmapsto \mathcal{M}^\circ$, $I \longmapsto I^\circ$) pour les triples $(W(I), C(I), F[I])$, et pour la construction de u_*^W, adjoint à droite de u_W^*. En particulier, pour que le triple précédent soit un triple de Quillen (forcément clos), il faut et il suffit que les deux couples $C(I) \longleftrightarrow TF[I]$ et $TC(I) \longleftrightarrow F[I]$ soient factorisants ; et quand cette condition est satisfaite pour I et pour I' (pour une flèche $u : I \longrightarrow I'$ dans* Cat *donnée), alors u_*^W existe et se construit dualement de la construction de $u_!^W$ explicitée dans* 2.3. 2°.

Corollaire 2.11. *Le prédérivateur $\mathbf{D}_{\mathcal{M},W}$ défini pour un localiseur* très spécial *W dans $\mathcal{M}$ est un dérivateur en plein sens du terme, i.e. il satisfait à tous les axiomes Dér 1 à Dér 6 (y inclus Dér 4 bis et Dér 5 bis et Dér 6 bis) des dérivateurs.*

N.B. À ma propre surprise, je n'ai pas été capable de trouver un cas d'un localiseur W qui définisse un dérivateur sur Cat tout entier (avec existence de $u_!^W$, u_*^W), *que* pour W un localiseur très spécial, donc s'insérant dans un triple de Quillen très spécial – ou quand on peut s'y ramener de la façon standard. (Par exemple dans le cas où $\mathcal{M} = \mathrm{Cat}$, W un

18. Dire aussi que le calcul des fibres de $u_!^W(X)$, prévu dans Dér 5 bis, est OK.

localiseur fondamental satisfaisant Loc 6 a) et Loc 8, 8 bis) [19] – les monomorphismes dans W se refusent formellement à être stable par cochangement de base !) J'ignore totalement si le résultat mirobolant "prouvé" par Anderson est vrai ou faux. Ça a l'air presque trop beau pour être vrai …D'ailleurs, je ne connais pas de structure de Quillen spéciale qui ne soit très spéciale – désolé !

Commentary · Present state [ms. 32]

The existence question after Chapter XIX

The final note measures the distance between the construction just completed and the general statement Grothendieck hoped for. Theorem 2.11 provides both Kan extensions by imposing enough smallness and exactness to construct two model structures on every diagram category. The subsequent uncertainty concerns how much of this apparatus is necessary. That existence question now has a definitive answer for ordinary complete and cocomplete Quillen model categories.

Cisinski (2003, Theorem 6.11) proves the existence and pointwise calculation of homotopy right Kan extensions for a Quillen model category admitting all small limits; applying the dual result supplies the left extensions when all small colimits exist. This gives the associated derivator on all small categories, without requiring the original category to be combinatorial or the diagram categories to possess the two projective and injective model structures used here. The same general statement is recorded in Groth (2013, Theorem 1.32). Groth's Proposition 1.30 gives a shorter proof for combinatorial models and establishes the usual strength axiom in that setting. These later results settle the mathematical question; they do not certify the details of the historical proof attributed to Anderson.

There is already a very small distinction between "special" and "very special." On Set take

$$W = \mathrm{Iso}, \qquad C = F = \mathrm{Fl}(\mathrm{Set}).$$

The two weak factorization systems are $(\mathrm{Fl}, \mathrm{Iso})$ and $(\mathrm{Iso}, \mathrm{Fl})$. The first is generated by $\varnothing \to 1$ and $2 \to 1$: right lifting against the first means surjectivity, and right lifting against the second means injectivity. The empty generating family gives the second system. All sets are accessible at a suitable cardinal and all small colimits exist, so this is special in the chapter's sense. It is not very special because $2 \to 1$ is a cofibration but not a monomorphism. Its associated derivator is the represented diagram theory of sets. This elementary example separates a chosen model presentation from the special construction with all monomorphisms as cofibrations.

The warning about Cat points to a different, genuine obstruction. Here is a complete finite construction for the ordinary weak-homotopy localizer. Let P be the poset of nonempty proper faces of a tetrahedron. Its nerve is the barycentric subdivision of the boundary sphere, so $|NP|$ is homeomorphic to S^2. For each nonidentity arrow a of P, take a copy of the walking arrow $[1]$ and its inclusion in the groupoid J with two objects and one isomorphism between them. Form the disjoint unions

$$A = \coprod_a [1], \qquad B = \coprod_a J,$$

and map $A \to P$ by the chosen arrows. The map $A \to B$ is a monomorphism of categories: it is injective on objects and faithful. It is also a weak homotopy equivalence, since it is a disjoint union of maps between contractible nerves.

The pushout $P \amalg_A B$ is the ordinary groupoid completion of P, by the universal property of freely adjoining inverses to all arrows. The fundamental groupoid of the nerve of a category is its groupoid completion: its generators are the one-simplices, and its two-simplex relations are exactly composition. Since S^2 is connected and simply connected, this groupoid is equivalent to the terminal groupoid. Thus the pushout map

$$P \longrightarrow P \amalg_A B$$

induces $S^2 \to *$ on homotopy types and is not a weak equivalence, as its effect on $H_2(-;\mathbb{Z})$ already shows. All categories used to specify the pushout are finite. The claim on page 32 that weak monomorphisms in Cat need not survive pushout therefore has a concrete content; one cannot obtain the usual homotopy theory of categories by simply declaring every monomorphism to be a cofibration.

19. axiome des carrés cocartésiens (version directe), axiome des limites inductives, accessibilité.

Scholie 2.10 isolates what the direct proof actually requires: the two lifting pairs must factor at the diagram shapes being used. For its pointwise assertion one must also justify the corresponding comma-shape calculation, as done above when all the projective structures are available. Cisinski's theorem supplies the general alternative when that direct model-structure construction is unavailable. The categorical limits and colimits remain essential hypotheses; this is the distinction the examples in the following section must continue to respect.

[page 33]

3 Cas des catégories à cofibrations, des catégories à fibrations

Je rappelle les axiomes d'une *structure à cofibrations* (W, C) sur une catégorie $\mathcal{M}$.

Cof_0 : W est un localiseur.

Cof_1 : C contient les isomorphismes, est stable par cochangement de base, par composition.

Cof_2 : $C \cap W$ est stable par cochangement de base (et aussi par composition, et contient les isomorphismes, en vertu de Cof_0, Cof_1).

Cof_3 : Toute flèche f dans $\mathcal{M}$ se factorise en $f = pi$, avec $i \in C$, $p \in W$.

(Axiomes de K. S. Brown, légèrement généralisés par Anderson). Il y a un "axiome de continuité" ou *"axiome transfini"* facultatif, qui est le suivant : p. 20

Cof_4 : $\mathcal{M}$ stable par petites $\varinjlim$ filtrantes, et C et $TC = C \cap W$ sont stables par composition transfinie.

Ainsi, Cof_1, Cof_2, Cof_4 peuvent se résumer en disant que C et TC sont Q-saturés transfiniment à gauche.

La structure de cofibration est dite *spéciale* si elle satisfait Cof_4, si $\mathcal{M}$ est spéciale, et si C admet une *petite* partie C_0 qui soit Q-génératrice à gauche, i.e. telle que

$$C \ \subset \ C_0{}^{\sim}, \qquad \text{i.e.} \quad \tilde{C} = C_0{}^{\sim}. \tag{3.1}$$

Alors, par le théorème de factorisation 1.1, on a [page 34]

$$C \ \leftarrow\!\!\!\!\!\rightarrow \ TF \ \overset{\text{déf}}{=} \ C_* \ ,$$

et l'axiome de factorisation Cof_3 implique (cf. 1.4) $TF \subset W^{\natural}$. Plus généralement, on a :

Proposition 3.1. *Supposons que $\mathcal{M}$ soit spéciale (stable par petites $\varinjlim$, et éléments accessibles), que (W, C) satisfasse à Cof_0, Cof_1, et que C soit stable par composition transfinie (ce qui, joint à Cof_1, s'énonce en disant que C est Q-saturé transfini à gauche), enfin que C admette une petite partie C_0 Q-génératrice à gauche, de sorte que $C \leftarrow\!\!\!\!\!\rightarrow TF \overset{déf}{=} C_*$. Alors pour que l'axiome de factorisation Cof_3 soit satisfait, il suffit qu'on ait*

$$TF \ \subset \ W \ , \tag{3.1.1}$$

et il faut qu'on ait $TF \subset W^{\natural}$, donc si $W = W^{\natural}$, l'axiome Cof_3 équivaut à (3.1.1).

Commentary · Exposition [ms. 34]

What one factorization can accomplish

Grothendieck now removes the fibrations from the starting data. His purpose is to isolate what is actually needed to construct homotopy colimits: the ability to replace a map by a cofibration, together with the invariance of gluing along an acyclic cofibration. The resulting structure is deliberately asymmetric. It controls homotopy cofibres without committing to a second factorization, and therefore without assuming that every lifting class already belongs to a model structure.

Write $TC = C \cap W$ and, in modern notation, write $S^{\perp}$ for the maps having the right lifting property against S. The symbol $TF = C_* = C^{\perp}$ initially names a lifting class; its membership in W

is a separate assertion. Proposition 3.1 keeps this distinction correctly. If the small object argument gives a factorization $f = pi$ with $i \in C$ and $p \in C^{\perp}$, then $C^{\perp} \subset W$ immediately supplies Cof_3. Conversely, apply Cof_3 to a map $f \in C^{\perp}$, obtaining $f = pi$, $i \in C$, $p \in W$. The square with left side i, right side f, and identity on the common source has a diagonal s satisfying $si = 1$ and $fs = p$. In the arrow category, $(i, 1)$ and $(s, 1)$ exhibit f as a retract of p. This proves exactly $C^{\perp} \subset W^{\pitchfork}$; replacing the latter class by W requires retract closure. No additional lifting axiom has entered the argument.

The two closure requirements on C and TC have different tasks. Closure under cobase change gives the elementary gluing operation. Closure under transfinite composition permits a diagram to be assembled through its successive stages. Closure under retracts then turns a factorization into a characterization by lifting. In the terminology of these pages, Q-closed means equality with ${}^{\perp}(S^{\perp})$, whereas Q-saturated describes specified operations on arrows. Theorem 1.1 identifies them under a small generation hypothesis; section 3 ends by asking how far that hypothesis can be removed.

The historical starting point is Brown's theory of categories of fibrant objects, used here in its dual form (Brown, 1973). Theorem-Scholie 2 of Chapter VI, manuscript p. 108, already places this asymmetry in the development of the manuscript. What is new here is its systematic application to categories of diagrams. Grothendieck's assertion that a special cofibration structure has functorial factorizations uses the functorial version of the small object construction from section 1. It is a conclusion of that construction, not part of the definition of an arbitrary cofibration category.

La structure de cofibration est dite *semi-close* si C est Q-clos à gauche, i.e. si on a $C = C^{\sim}$ (ce qui implique que C est stable par composition transfinie), *close* si de plus $TC = (TC)^{\sim}$ (ce qui implique l'axiome transfini Cof_4).

Je ne reviens pas ici sur la théorie de K. S. Brown des catégories à cofibrations. C'est [page 35]
à ma connaissance l'ensemble d'axiomes le plus économique connu, pour assurer d'une part une bonne prise sur Ho_W (par une notion correspondante d'homotopie d'applications, et un calcul de fractions dans $\Pi\mathcal{M}_c$), et d'autre part l'existence de la suite *exacte* de cofibrations, donc une théorie de cofibres W-homotopiques. (**N.B.** Quand la structure est *propre,* i.e. $C \subset \mathrm{Cof}_W$, alors l'existence de cette structure revient à dire simplement que "W admet assez de W-cofibrations", i.e. que toute $f \in \mathrm{Fl}(\mathcal{M})$ se factorise en pi, avec $i \in \mathrm{Cof}_W$, $p \in W$; et on peut donc prendre $C = \mathrm{Cof}_W$. Dans le cas où W est stable par petites $\varinjlim$ filtrantes, $C = \mathrm{Cof}_W$ et $TC = W^{\mathrm{univ}}$ satisfont de plus l'axiome transfini Cof_4.) Enfin, K. S. Brown montre que toute flèche $i : X \longrightarrow Y$ dans C, *avec X, Y cofibrants* (i.e. $\emptyset_{\mathcal{M}} \longrightarrow X$, $\emptyset_{\mathcal{M}} \longrightarrow Y$ dans C) est dans Cof_W ("Lemme de Brown").

Commentary · Examples [ms. 35]

Brown excision and the scope of properness

Grothendieck wants gluing to depend only on the weak equivalences, which explains the intrinsic class Cof_W. One qualification is necessary in the final sentence on this page. Brown excision gives homotopy invariance of a pushout along a cofibration when the weak-equivalence comparison is between cofibrant objects. It does not say that a cofibration with cofibrant endpoints belongs to the ambient, universally defined class Cof_W.

This is a distinction in the manuscript's own terminology. Chapter XIII, ms. p. 8, defines Cof_W by two consecutive pushout squares: after any initial cobase change, pushing out a weak equivalence must again give a weak equivalence (Grothendieck, 1990–1991e, Ch. XIII, ms. p. 8). Thus it requires invariance on the entire undercategory. The safe form of Brown's assertion is obtained by restricting the coefficient category and the comparison maps to cofibrant objects. Alternatively, one may assume $C \subset \mathrm{Cof}_W$, the properness hypothesis already distinguished in the preceding parenthesis.

A concrete obstruction makes the difference visible. In simplicial associative unital $\mathbb{Z}$-algebras, let $A = \mathbb{Z}/p$ be constant and choose a simplicial free algebra resolution $B \longrightarrow A$. Adjoining a free noncommuting generator has underlying simplicial abelian group

$$B\langle x\rangle \cong \bigoplus_{n\geq 1} B^{\otimes_{\mathbb{Z}} n}.$$

The summand for $n = 2$ has first homotopy group $\mathrm{Tor}_1^{\mathbb{Z}}(A, A) \cong \mathbb{Z}/p$, whereas $A\langle x\rangle$ is constant. Hence $B\langle x\rangle \longrightarrow A\langle x\rangle$ is not a weak equivalence. But $\mathbb{Z} \longrightarrow \mathbb{Z}\langle x\rangle$ is a free cofibration with cofibrant

source and target. Its pushout functor is precisely adjoining x, so it is not a W-cofibration. This is the mechanism of Rezk (2002, Example 2.11, arXiv version). The error concerns the unrestricted formulation of the sentence, not Brown's excision theorem and not the finite-diagram constructions that follow.

Je m'intéresse ici à la question d'étendre la structure à cofibrations à une catégorie de la forme $\mathcal{M}(I)$, et d'utiliser cette extension pour construire les foncteurs $u_!^W$. Notons déjà que la théorie de K. S. Brown, avec les compléments d'Anderson [20], donne essentiellement ceci : [page 36] p. 21

Proposition 3.2. *Soit $W \subset \mathrm{Fl}(\mathcal{M})$ un localiseur associé à une structure à cofibrations (C, W) dans $\mathcal{M}$.*

1°) *Sur la catégorie* Diag_0 *des ensembles ordonnés* finis*, ce prédérivateur satisfait aux axiomes Dér 1 (décomposition), Dér 2 (localisation), Dér 3 (objet final), Dér 4 bis (existence de $u_!^W$), Dér 5 bis (calcul des fibres de $u_!^W$), Dér 6 bis (exactitude à gauche).*

2°) *C'est encore vrai sur la sous-catégorie* Diag_1 *dans* Cat *plus grande, formée des ensembles ordonnés I* noethériens *tels que l'espace topologique associé à I° soit noethérien (toute suite croissante d'objets de I, ou d'ouverts de I°, est stationnaire).*

3°) *Enfin, si l'axiome transfini Cof_4 est satisfait, i.e. si C et TC sont stables par composition transfinie, alors la conclusion de* 1° *reste valable sur la sous-catégorie pleine* Diag_2 *de* Cat *formée des ensembles ordonnés qui sont noethériens sans plus.*

Corollaire 3.3. *Supposons que l'on ait Cof_3 sous la forme plus forte d'une factorisation $f = pi$* fonctorielle *en f, ce qui est le cas en particulier si la structure à cofibrations est spéciale.* [page 37] *Alors pour toute I dans* Cat*, $\mathcal{M}(I)$ muni de $(W(I), C(I))$ est une catégorie à cofibrations, laquelle satisfait l'axiome transfini Cof_4 si (W, C) y satisfait. Donc on peut lui appliquer les résultats de* 3.2*, qui impliquent notamment que les axiomes Dér 1, 2, 3 (?) sont valables sur* Cat *tout entier, et que $u_!^W$ existe quand u est de la forme $\mathrm{id}_I \times v$, avec $v : J \longrightarrow K$ une flèche dans* Diag_1 *(resp. dans* Diag_2*, si l'axiome transfini est satisfait).*

3.4. La clef de la théorie est dans l'extension de la structure à cofibrations (W, C) de $\mathcal{M}$ à une catégorie $\mathcal{M}(I)$, où I est un ensemble ordonné, en $(W(I), C_I)$. Les faits principaux sont énoncés dans XVII, dans les théorèmes p. 26-27, p. 50, p. 60. C'est quand I est *noethérien,* et qu'on suppose soit que $\mathrm{Esp}(I^\circ)$ est également noethérien (p.ex. I fini), soit que (W, C) satisfait l'axiome transfini Cof_4, qu'on prouve que $(W(I), C_I)$ est également une structure à cofibrations sur $\mathcal{M}(I)$.

Commentary · Exposition [ms. 37]

Attaching a diagram in the order of its dependencies

Grothendieck's noetherian hypothesis makes an inductive construction possible: the value at an object can be attached after the values on which it depends have been constructed. With his convention $\mathcal{M}(I) = \mathrm{Fun}(I^\circ, \mathcal{M})$, it is I° that serves as a direct indexing category. In a finite example this is the familiar Reedy construction, although the manuscript allows transfinite well-founded orders as well.

For a direct category J and a diagram $X : J \longrightarrow \mathcal{M}$, let

$$L_j X = \operatorname*{colim}_{(k \to j),\ k \neq j} X_k$$

be the latching object, when the indicated colimit exists. A map $f : X \longrightarrow Y$ is a Reedy cofibration when

$$X_j \amalg_{L_j X} L_j Y \longrightarrow Y_j$$

belongs to C for every j. The relative latching object incorporates all the compatibility already imposed at preceding objects. Merely requiring $X_j \longrightarrow Y_j$ to be a cofibration would omit those compatibility conditions.

20. revus et arrangés par mes soins.

For the arrow $0 \to 1$, the two tests are $X_0 \to Y_0 \in C$ and $X_1 \amalg_{X_0} Y_0 \to Y_1 \in C$. Given a map of arrows $X \to Y$, first factor its component at 0 as $X_0 \to Z_0 \to Y_0$. Next factor the induced map $X_1 \amalg_{X_0} Z_0 \to Y_1$ as a cofibration followed by a weak equivalence. Its intermediate object defines Z_1, and the pushout supplies $Z_0 \to Z_1$. The resulting $X \to Z$ is a Reedy cofibration and $Z \to Y$ is objectwise a weak equivalence. The same construction applies successively at every vertex of a finite direct category. Transfinite stages require colimits and the continuity condition Cof_4.

The identity $C_I \cap W(I) = (TC)_I$ records a second induction. In the arrow example, if the component at 0 is acyclic, its pushout $X_1 \to X_1 \amalg_{X_0} Y_0$ is acyclic. Consequently the relative latching map is a weak equivalence exactly when $X_1 \to Y_1$ is one, by two-out-of-three. This proves both directions of the identity at the second vertex. The general induction repeats this argument with the latching diagram; at a limit stage Cof_4 supplies the required continuity. This is why the equality, rather than the bare definition of C_I, is central to homotopy left Kan extension.

Corollary 3.3 uses a different construction. A functorial factorization in $\mathcal{M}$ can be applied to all components and all transition maps of an arbitrary diagram at once. Cof_0, Cof_1, and Cof_2 then hold objectwise, and functoriality supplies Cof_3 in $\mathcal{M}(I)$. This gives finite homotopy-colimit operations inside every shifted diagram category. It does not itself make the ordinary colimit functor preserve objectwise acyclic cofibrations. That additional issue is exactly what the projective classes $C\langle I\rangle$ are meant to address.

Un fait important pour la construction des foncteurs $u_!^W$, pour $u : I \longrightarrow I'$ une flèche [page 38]
entre catégories ordonnées noethériennes, est la relation

$$C_I \cap W(I) \;=\; (TC)_I \;, \tag{3.4.1}$$

d'où résulte que l'on a, pour u comme dessus,

$$u_!(C_I \cap W(I)) \;\subset\; C_{I'} \cap W(I') \;, \tag{3.4.2}$$

ingrédient essentiel de la construction du foncteur $u_!^W$. Pour étendre cette construction au cas d'une flèche $\pm$ quelconque dans Cat, il se pose donc le problème d'étendre la définition de C_I, et les formules (3.4.1) et (3.4.2), au cas de catégories $\pm$ quelconques dans Cat. Or on a prouvé :

Proposition 3.5. *Si $\Phi = \Psi^*$ est une partie* Q-close *à gauche de* $\mathrm{Fl}(\mathcal{M})$*, et I un ensemble ordonné noethérien, Φ_I l'extension de Φ en une partie de* $\mathrm{Fl}(\mathcal{M}(I))$ *définie par* Anderson*, alors on a*

$$\Phi_I \;=\; \Psi(I)^* \;=\; v_!(\Phi(I_0))^\sim \;, \tag{3.5.1}$$

où $v : I_0 \longrightarrow I$ est le foncteur canonique de la catégorie discrète définie par $\mathrm{Ob}\, I$*.*

C'est (avec des notations différentes) le lemme 6.2.5 (p. 107) de XVII, dont je ne reprends pas ici la démonstration. p. 22

Ceci donne la clef d'une définition de Φ_I comme $\Phi\langle I\rangle$ (avec les notations des paragraphes 1, 2), pour I quelconque dans Cat,

$$\Phi_I \;\overset{\text{déf}}{=}\; \Phi\langle I\rangle \;\overset{\text{déf}}{=}\; \Psi(I)^* \;=\; v_!(\Phi(I_0))^\sim \;, \tag{3.5.2}$$ [page 39]

où $\Psi = \Phi_*$, et où on suppose Φ Q-clos à gauche, i.e. $\Phi = \Psi^*$. Dans le cas où on suppose seulement Φ Q-saturé transfini sans plus, on aurait envie de poser

$$\Phi_I \;\overset{\text{déf}}{=}\; \text{Q-saturé transfini de } v_!(\Phi(I_0)) \;, \tag{3.5.3}$$

et je présume que pour I ordonné noethérien, cela coïncide avec la définition d'Anderson. Mais je vais me borner pour la suite au cas où $C = \Phi$ est Q-clos à gauche.

Revenons alors au cas d'une structure à cofibrations (W, C) dans $\mathcal{M}$, en supposant C et $TC = C \cap W$ Q-clos à gauche. Définissons pour toute I dans Cat $C_I = C\langle I\rangle$ comme dans (3.5.2). On a alors, pour $u : I \longrightarrow I'$ une flèche dans Cat,

$$u_!(C\langle I\rangle) \;\subset\; C\langle I'\rangle \;, \tag{3.5.4}$$

mais on n'y a guère de raison d'espérer avoir aussi (3.4.2), sans disposer de la formule

$$C\langle I\rangle \cap W(I) \overset{?}{=} (TC)\langle I\rangle \qquad [21]. \tag{3.5.5}$$

On a prouvé que cette formule est valable si I est ordonné noethérien (XVII th. 2.1, p. 26-27). Cela nous amène à la [page 40]

Question 3.6. *Soit $\mathcal{M}$ une catégorie stable par petites limites, et soit (W, C) une structure à cofibrations dans $\mathcal{M}$ telle que C et $TC = C \cap W$ soient Q-clos à gauche. Soit I un objet de* Cat*, a-t-on alors*

$$C\langle I\rangle \cap W(I) \;=\; (TC)\langle I\rangle\,? \tag{3.6.1}$$

Commentary · Exposition [ms. 40]

Lifting properties retain the coherence

Grothendieck replaces a geometric attachment rule by a characterization that makes sense for every small category. Put $TF = C^{\perp}$, $F = (TC)^{\perp}$, and

$$C\langle I\rangle = {}^{\perp}TF(I), \qquad (TC)\langle I\rangle = {}^{\perp}F(I).$$

The lifting problem here is a problem in the category of diagrams. A diagonal must commute with every arrow of I; a collection of independently chosen componentwise diagonals is insufficient. This is the coherence retained by the projective lifting class.

Let $v : I_0 \to I$ include the discrete category of objects. The adjunction $v_! \dashv v^*$ gives

$$(v_!\Phi(I_0))^{\perp} = \{p : v^*p \in \Phi(I_0)^{\perp}\} = \Psi(I),$$

where $\Psi = \Phi^{\perp}$ and Φ is Q-closed. The last equality follows because a lifting problem in a discrete family is solved component by component; equivalently, one tests a single component and puts identity maps in the others. Taking left orthogonals proves (3.5.2). The same adjunction calculation for $u_! \dashv u^*$ gives (3.5.4), since restriction preserves the objectwise right class. These arguments require existence of the ordinary left Kan extension, not a factorization system on diagrams.

The specification of Ψ matters, just as in the arbitrary-test-class defect in (1.14) discussed earlier. If Proposition 3.5 is read as allowing an arbitrary presentation $\Phi = {}^{\perp}\Psi$, its first equality needs qualification. In sets, take $\Psi = \{\emptyset \to 1\}$. Then Φ consists of the maps with nonempty source together with $1_{\emptyset}$. On the direct arrow category $J = [1]$, the diagram map

$$f : (\emptyset \longrightarrow 1) \longrightarrow (1 \xrightarrow{1} 1)$$

fails the relative latching condition at 0. Yet it lifts vacuously against $\Psi(J)$: that class contains only the map from the constant empty diagram to the constant singleton diagram, and the source of f has no map to the former. Thus ${}^{\perp}\Psi(J)$ is too large for this nonclosed Ψ. The canonical choice $\Psi = \Phi^{\perp}$, explicitly imposed in (3.5.2), removes this issue. It leaves the intended construction and the subsequent propositions intact.

For a well-founded direct indexing order, the latching description and this lifting description agree by induction on objects: at stage j, the already constructed diagonals determine a map out of the relative latching object, and its lifting property supplies the next component. The converse can be checked explicitly for the posets in Proposition 3.5. Given a lifting problem from the relative latching map at j to $p : A \to B$, use the diagram map which is 1_A at strict predecessors of j, is p at j, and is the identity of the terminal object elsewhere. The map $L_jY \to A$ supplies its predecessors. A coherent diagonal then gives exactly the requested relative lift. The canonical right class $\Phi^{\perp}$ contains all identities, as this test requires. This proves the comparison under the stated existence assumptions.

There is also a direct cellular verification of the conjecture (3.5.3) whenever the small colimits needed for its transfinite construction exist. Assume that Φ contains isomorphisms and is closed under pushouts and small transfinite composition. The following is the direct-poset version of the standard Reedy cellular construction; compare Riehl and Verity (2014, Proposition 6.3 and Corollary 6.7). Let $J = I^{\circ}$ be the well-founded poset and well order its objects so that every strict

predecessor is earlier. Write $j_!$ for the left adjoint of evaluation, so $(j_!A)_k = A$ if $j \leq k$ and is initial otherwise. A map $j_!a$, $a \in \Phi$, has relative latching map a at j and an identity elsewhere.

The class of maps whose relative latching maps lie in Φ is closed under pushouts, since forming a relative latching map takes a pushout of diagram maps to a pushout of that relative map. For transfinite closure, let $(X^\alpha)_{\alpha\leq\lambda}$ be a continuous chain of such maps. For fixed j put

$$Q_\alpha = X^\alpha_j \amalg_{L_jX^\alpha} L_jX^\lambda.$$

Each $Q_\alpha \to Q_{\alpha+1}$ is a pushout of the relative latching map of $X^\alpha \to X^{\alpha+1}$. The Q-chain is continuous because latching objects are colimits. Its starting object is the relative-latching domain of $X^0 \to X^\lambda$, and $Q_\lambda = X^\lambda_j$. Transfinite closure of Φ therefore proves the assertion. Consequently this relative-latching class contains the transfinite saturation of all the maps $j_!a$.

For the reverse inclusion, take $f : X \to Y$ with all relative latching maps in Φ. Starting from X, successively attach the value Y_j at each object j. When j is reached, all strict predecessors already equal their values in Y, and the current value at j is

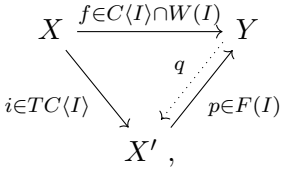
$$X_j \amalg_{L_jX} L_jY.$$

Push out the free diagram map $j_!(X_j \amalg_{L_jX} L_jY \to Y_j)$ along its evaluation-adjoint map to the current diagram. This replaces the value at j by Y_j and leaves every earlier value fixed. At limit ordinals take colimits. The resulting composite ends at Y, since every component is eventually fixed to Y_j. Each step is a pushout of $j_!a$ for some $a \in \Phi$. Finally these one-object free maps belong to $v_!\Phi(I_0)$ by putting identity maps of the initial object in the other components; conversely a whole family is a coproduct of such one-object maps, formed by successive pushouts. This proves precisely the proposed transfinite-saturation description, without adding retract closure. It is a presentation by a class of cells, not an assertion that a small set of them suffices. If the required colimits have not been assumed, that existence qualification must remain explicit.

The easy inclusion in (3.5.5) is structural. Under the small-completeness hypothesis of 3.6, evaluation at an object j has a right adjoint whose values are products indexed by the arrows into j in I°. Right lifting classes are closed under products, so this right adjoint sends a map of F to an objectwise F-map. If $f \in {}^\perp F(I)$, adjunction therefore implies $f_j \in {}^\perp F = TC$. Hence projective TC-cofibrations are objectwise in TC, and therefore in $W(I)$; also $TC \subset C$ gives $(TC)\langle I\rangle \subset C\langle I\rangle$. The difficult inclusion says that an objectwise weak equivalence which already satisfies one coherent lifting condition satisfies the stronger one. Existence of abstract homotopy Kan extensions, established later, does not by itself identify these two specifically prescribed classes of strict diagrams.

On a vu au paragraphe précédent qu'il en est ainsi si (W, C) s'insère dans un triple de Quillen clos $(W, C, F = (TC)_*)$, et quand on suppose de plus que les couples

$$C\langle I\rangle \longleftrightarrow TF(I)\ , \qquad TC\langle I\rangle \longleftrightarrow F(I)$$



sont factorisant, auquel cas $(W(I), C\langle I\rangle, F(I))$ est une structure de Quillen close dans $\mathcal{M}(I)$. D'ailleurs, (W, C, F) est une structure de Quillen (nécessairement close) si et seulement si les couples $C \longleftrightarrow \underbrace{TF}_{\overset{\text{déf}}{=}C_*}$, $TC \longleftrightarrow \underbrace{F}_{\overset{\text{déf}}{=}(TC)_*}$ eux-mêmes sont factorisants, et si de plus $TF \subset W$ (ce qui est automatique si $W = W^\natural$, car on aura en tous cas, par Cof_4, $TF \subset W^\natural$). p. 23

Mais peut-on s'en tirer avec moins, pour pouvoir conclure à (3.6.1) ? Ne suffirait-il pas de savoir que $TC\langle I\rangle \longleftrightarrow F(I)$ est factorisant (ce qui n'a guère de chances d'être vrai pour une I ± générale, si on n'a déjà $TC \leftrightarrows F$, factorisation dans $\mathcal{M}$ lui-même). C'est bien le cas :

Proposition 3.7. *Sous les conditions générales de* (3.6) *sur $\mathcal{M}$, W, C, I, supposons que le couple $TC\langle I\rangle \longleftrightarrow F(I)$ (où $F \overset{déf}{=} (TC)_*$) soit factorisant, i.e. $TC\langle I\rangle \leftrightarrow\!\!\!\!\rightarrow F(I)$. Alors la formule* (3.6.1) *est vraie.* [page 41]

En effet, si $f \in C\langle I\rangle \cap W(I)$, on factorise f en pi, avec $i \in TC\langle I\rangle$, $p \in F(I)$. Comme $f, i \in W(I)$, on aura $p \in W(I)$, i.e. $p \in TF(I)$, et à cause de $\underbrace{C\langle I\rangle}_{\ni f} \longleftrightarrow \underbrace{TF(I)}_{\ni p}$, il existe

$p : Y \longrightarrow X'$ telle que $pq = \mathrm{id}_Y$, $qf = i$,

donc f est facteur direct de $i \in TC\langle I\rangle$. Comme $TC\langle I\rangle$ est stable par facteurs directs, on gagne.

Corollaire 3.8. *Soit (W, C, F) une structure de Quillen close dans $\mathcal{M}$, et supposons que $TC = C \cap W$ soit une partie Q-spéciale de $\mathcal{M}$, i.e. le couple $TC \leftarrow\!\!\!\!\!\rightarrow F$ un couple spécial (i.e. $\mathcal{M}$ est* spéciale*, et il existe une petite partie TC_0 Q-génératrice à gauche pour TC). Alors pour toute I dans* Cat*, on a*

$$C\langle I\rangle \cap W(I) \;=\; TC\langle I\rangle \;. \tag{3.8.1}$$

Commentary · Exposition [ms. 41]

The lifting lemma inside the retract argument

Grothendieck has found that only one diagram factorization is needed for (3.6.1). The proof is sound, but the line identifying a weak equivalence in F with a map lifting against C uses a short lemma that is useful beyond the present proposition.

Suppose (W, C) satisfies Cof_0–Cof_3, and set $F = (C \cap W)^{\perp}$. Then

$$F \cap W \subset C^{\perp}.$$

To prove this, consider a square from $a : A \to B$ in C to $p : X \to Y$ in $F \cap W$, with top map $h : A \to X$ and bottom map $k : B \to Y$. Form $Z = X \amalg_A B$, write $j : X \to Z$, and let $g : Z \to Y$ be induced by p and k. Factor $g = q\ell$ by Cof_3, where $\ell : Z \to T$ is in C and $q : T \to Y$ is in W. The composite ℓj belongs to C, and $q\ell j = p$ shows by two-out-of-three that $\ell j \in TC$. Since $p \in F$, the square with left side ℓj, right side p, top 1_X, and bottom q admits $s : T \to X$ satisfying $s\ell j = 1_X$ and $ps = q$. If $b : B \to Z$ is the other pushout map, then $s\ell b$ is the desired lift. This proves the inclusion without a second factorization in $\mathcal{M}$, and without retract closure of W.

Now take $f : X \to Y$ in $C\langle I\rangle \cap W(I)$ and factor it as $f = pi$ with $i \in (TC)\langle I\rangle$ and $p \in F(I)$. The already established easy inclusion makes i an objectwise weak equivalence, hence $p \in F(I) \cap W(I)$. Applying the preceding lemma at every object gives $p \in TF(I) = C^{\perp}(I)$. The defining coherent lifting property of f produces a natural map $q : Y \to X'$ with $qf = i$ and $pq = 1_Y$. The arrow-category maps $(1_X, q)$ and $(1_X, p)$ exhibit f as a retract of i. Left lifting classes are retract closed, so $f \in (TC)\langle I\rangle$.

The printed prose writes $p : Y \to X'$ for the new diagonal; the diagram and both identities show that q is intended. The earlier reference on ms. p. 40 to Cof_4 in the assertion $TF \subset W^{\natural}$ is likewise a reference slip: the relevant axiom is Cof_3, as in Proposition 3.1. Neither slip changes the argument. Corollary 3.8 is then exactly the small object theorem applied to TC in diagram categories. It proves the equality without assuming that C has a small generating set; the separate difficulty is obtaining the other factorization needed for a complete diagram model structure.

[page 42]

En apparence, on n'a pas eu à supposer que C soit elle aussi une partie Q-spéciale de $\mathrm{Fl}(\mathcal{M})$. Mais comme on a besoin de la factorisation pour $C \longleftrightarrow TF$ (pour avoir au moins une structure de cofibrations sur $\mathcal{M}$), on n'a guère le moyen de l'établir sans supposer C spéciale. Sans compter que pour pouvoir expliciter (3.8.1) pour la construction de $u_!^W$, on a besoin de savoir que $(W(I), C\langle I\rangle)$ définit bien une structure à cofibrations sur $\mathcal{M}(I)$, ce qui ne peut guère se faire (il me semble) sans avoir la factorisation pour $C\langle I\rangle \longleftrightarrow TF(I)$ également ; chose que je n'arrive à établir pour un I général dans Cat, que moyennant l'hypothèse de spécialité sur C également.

3.9. Pour en avoir le cœur net, il faudrait quelques exemples concrets et illuminants, du type suivant :

a) `[Il n'y a pas de b).]` Structure de Quillen close (W, C, F) sur $\mathcal{M}$, telle que pour le prédérivateur associé, $u_!^W$ n'existe pas toujours, ou u_*^W n'existe par toujours. Je pense notamment au cas d'une flèche $u : I \longrightarrow I'$ avec $I' = e$ (présumant que si dans ce cas, $u_!^W$ resp. u_*^W existe, alors il existe dans tous les cas). Un tel exemple serait encore plus

instructif, bien sûr, si $\mathcal{M}$ est stable par petites $\varinjlim$, que ses objets soient accessibles etc. et que W soit L-accessible (i.e. stable par petites $\varinjlim$ filtrantes, et de plus accessible …). Le premier candidat pour I auquel je pense serait un $\overrightarrow{B}_G$ (G un groupe, p.ex. $G = \pm 1$), c'est en effet l'exemple aux antipodes des ensembles ordonnés, lesquels, eux, ne semblent pas faire trop de problème (moyennant l'hypothèse noethérienne tout au moins). p. 24 [page 43]

Les exemples suivants ne sont pas aussi convaincants que ça, hélas!

Exemple 3.10. Soit $\mathcal{M}$ une catégorie quelconque, alors les couples $(\mathrm{Fl}(\mathcal{M}), \mathrm{Is}(\mathcal{M}))$ et $(\mathrm{Is}(\mathcal{M}), \mathrm{Fl}(\mathcal{M}))$ sont tous deux des couples de Quillen,

$$\mathrm{Fl}(\mathcal{M}) \longleftarrow\!\!\!\!\!\!\longrightarrow \mathrm{Is}(\mathcal{M}) \ , \qquad \mathrm{Is}(\mathcal{M}) \longleftarrow\!\!\!\!\!\!\longrightarrow \mathrm{Fl}(\mathcal{M}) \ . \tag{3.10.1}$$

Il s'ensuit que si on pose

$$W \ = \ \mathrm{Is}(\mathcal{M}) \ , \qquad C \ = \ F \ = \ \mathrm{Fl}(\mathcal{M}) \ , \tag{3.10.2}$$

(W, C, F) est un triple de Quillen clos [22]. D'ailleurs pour toute I dans Cat, on a $W(I) = \mathrm{Is}(\mathcal{M}(I))$, donc

$$\mathrm{Ho}_W(I) \ = \ \mathcal{M}(I) \ . \tag{3.10.3}$$

Donc la question de l'existence des foncteurs $u_!^W$, u_*^W se réduit à celle des foncteurs $u_!$, u_* habituels, adjoints à gauche et à droite de $u^* : \mathcal{M}(I') \longrightarrow \mathcal{M}(I)$.

Commentary · Present state [ms. 43]

Finite completeness and the modern model category theorem

Example 3.10 isolates the completeness issue. Every map factors as itself followed by an identity, or as an identity followed by itself. A map with the lifting property against every map lifts against itself, and that diagonal is its inverse. Consequently the two displayed pairs really are closed factorization pairs in any category. With finite limits and colimits they give the historical, finitely complete version of Quillen's axioms. Their localization does nothing, so existence of homotopy Kan extensions is precisely existence of ordinary Kan extensions. For a functor between finite categories, the relevant comma categories are finite and the assumed finite limits and colimits suffice. For arbitrary indexing categories those assumptions say nothing about the required infinite constructions. The small-generation calculation for the corresponding example in sets is already given in the commentary to ms. p. 32.

The terminology now usually includes *all* small limits and colimits in the definition of a model category. Under that convention the requested example in 3.9 does not exist. Cisinski (2003, Theorem 6.11) proves the derivator assertion for an arbitrary Quillen model category with the required small limits; duality gives the assertion about colimits. Neither cofibrant generation nor local presentability is required. The distinction matters: this theorem supplies homotopy Kan extensions without asserting that the specific projective Quillen structure written in Question 3.6 exists on every diagram category. The bounded-complex example below therefore addresses the older finite-completeness convention, while Question 3.6 retains its more specific lifting-class content.

Grothendieck's suggestion that terminal projections should suffice anticipates the pointwise Kan-extension formulas. In the established derivator framework the value of a Kan extension is a homotopy limit or colimit over a comma category. For an arbitrary prederivator, however, adjoints to terminal projections alone do not supply the coherent pointwise construction or its base-change isomorphisms. Those are additional assertions proved by the model-category theorem, rather than a formal consequence of representability at the terminal category.

[page 44]

On sait bien que l'existence de ces foncteurs pour u donné, fait appel à l'existence de certaines $\varinjlim$ resp. $\varprojlim$ dans $\mathcal{M}$; p.ex. si $I' = e$, il est nécessaire et suffisant que les $\varinjlim$ (resp. $\varprojlim$) de type I° soient représentables dans $\mathcal{M}$. Mais avec les hypothèses faites sur $\mathcal{M}$, il n'y a pas de problème si $u : I \longrightarrow I'$ est un foncteur entre catégories *finies.* On va donner un exemple où il n'en est plus ainsi.

Exemple 3.11. Soit k un anneau commutatif, et $\mathcal{M} = K^{\mathrm{b}}(k\text{-Ab})$ la catégorie des complexes de cochaînes bornés de k-modules, W l'ensemble des quasi-isomorphismes, donc

$$\mathrm{Ho}_W \;=\; D^{\mathrm{b}}(k\text{-Ab})\ ,$$

catégorie dérivée bornée de la catégorie abélienne des k-modules. On sait, en utilisant l'existence d'assez de projectifs dans k-Ab, que cette structure est associée à une structure de Quillen close (W, C, F), décrite par Quillen dans Homotopical Algebra – à cela près qu'il prend [page 45]
$D^-(k)$ au lieu de $D^{\mathrm{b}}(k)$. Peut-être, pour vérifier les axiomes, doit-on supposer que k est de dimension cohomologique finie.

Prenons $I = B_G$, où G est un groupe (p.ex. $G = \{\pm 1\}$), et $u : I \longrightarrow e$. Alors $\mathcal{M}(I)$ est la catégorie des complexes bornés de $k[G]$-modules. On voit que $u_!^W$ resp. u_*^W existe si et seulement si pour tout tel complexe borné, ou simplement pour un $k[G]$-module sans plus M, le complexe $L\Gamma^G(M)$ resp. $R\Gamma_G(M)$ appartient à $D^{\mathrm{b}}(k)$, ou ce qui revient au même, si et p. 25
seulement si on a

$$H_i(G, M) \;=\; 0 \quad \text{pour } i \gg 0\ ,$$
$$\text{resp.} \quad H^i(G, M) \;=\; 0 \quad \text{pour } i \gg 0\ ,$$

pour tout $k[G]$-module M. Ce n'est pratiquement jamais le cas; quand on prend p.ex. $k = \mathbf{Z}$ et G groupe fini, cela n'est le cas que si $G = e$. L'exemple le plus économique me paraît $G = \pm 1$, $k = \mathbf{F}_2$.

Commentary · Examples [ms. 45]

A finite group can force an unbounded resolution

The notation $K^{\mathrm{b}}(k\text{-Ab})$ is explicitly defined here as the category of bounded complexes and chain maps. It is what is now usually denoted $C^{\mathrm{b}}(k\text{-Mod})$, before quotienting by chain homotopy. The sentence about enough projectives needs the qualification which Grothendieck immediately adds: an unbounded projective resolution does not provide a bounded cofibrant replacement. It is enough for his example to take the proposed field $k = \mathbf{F}_2$, where every bounded acyclic complex is contractible.

Here is a complete verification of the finite Quillen structure in that case. Put W = quasi-isomorphisms, C = degreewise injections, and F = degreewise surjections. A bounded contractible complex of vector spaces is a finite direct sum of disk complexes and is both projective and injective in the category of complexes. Thus a surjective quasi-isomorphism, whose kernel is contractible, has the right lifting property against every injection; dually an injective quasi-isomorphism has the left lifting property against every surjection. For a bounded complex X, the cone $I(X) = \mathrm{Cone}(1_X)$ is contractible and has a natural degreewise injection $X \to I(X)$. Dually $P(Y) = \mathrm{Cone}(1_Y)[-1]$ has a natural degreewise surjection $P(Y) \to Y$. For $f : X \to Y$ the factorizations

$$X \xrightarrow{(f, i_X)} Y \oplus I(X) \longrightarrow Y, \qquad X \longrightarrow X \oplus P(Y) \xrightarrow{(f, p_Y)} Y$$

have types $(C, F \cap W)$ and $(C \cap W, F)$ respectively. Retract closure and two-out-of-three are immediate from degreewise linear algebra and cohomology. All objects and constructions remain bounded. Finite limits and colimits exist, whereas, for example, a coproduct of $k[n]$ over all integers cannot be bounded: its universal injections and retractions would force nonzero cohomology in every degree.

For $G = C_2$ write $A = k[G] = k[\epsilon]/(\epsilon^2)$, with $\epsilon = g - 1$. Since BG has one object, a diagram of bounded complexes is exactly a bounded complex of A-modules. There is no uniform-boundedness

22. au moins si on admet que $\mathcal{M}$ est stable par $\varinjlim$ et $\varprojlim$ *finies.*

issue here; for a general category with infinitely many objects, an objectwise bounded diagram need not be bounded uniformly. Thus the relevant restriction functor is

$$p^* : D^{\mathrm{b}}(k) \longrightarrow D^{\mathrm{b}}(A), \qquad V \longmapsto V \text{ with trivial } G\text{-action.}$$

The exact projective resolution

$$\cdots \xrightarrow{\epsilon} A \xrightarrow{\epsilon} A \xrightarrow{\epsilon} A \longrightarrow k \longrightarrow 0$$

is exact because $\ker(\epsilon) = \epsilon A$. Tensoring it with k, or applying $\mathrm{Hom}_A(-, k)$, kills every differential. Consequently

$$\mathrm{Tor}^A_n(k,k) = k \quad \text{and} \quad \mathrm{Ext}^n_A(k,k) = k \qquad (n \geq 0).$$

This proves nonexistence of the adjoints themselves, not merely failure of one proposed construction. If R were right adjoint to p^*, then

$$H^n(Rk) = \mathrm{Hom}_{D(k)}(k[-n], Rk) \cong \mathrm{Hom}_{D(A)}(k[-n], k) = k$$

for every $n \geq 0$, contradicting boundedness. If L were left adjoint, then

$$\mathrm{Hom}_{D(k)}(Lk, k[n]) \cong \mathrm{Hom}_{D(A)}(k, k[n]) = k$$

for every $n \geq 0$. Over a field, the left side vanishes outside a finite range for every bounded Lk, another contradiction.

The source's general boundedness criterion can also be justified. The unbounded derived adjunctions are tensoring with the trivial module and derived invariants. If they take every module to a bounded complex, finite truncation triangles show that they do so for every bounded complex. Their restrictions are then the required adjoints. Conversely, the shifts of k detect all cohomology of the proposed right adjoint. For the left adjoint, test maps into shifts of an injective cogenerator of k-modules: these detect the homology of the derived tensor product and force its boundedness. For $k = \mathbf{Z}$ and a nontrivial finite group, choose a subgroup C_p of prime order and induce its trivial $\mathbf{F}_p$-module to G. The cyclic periodic resolution and the induction/coinduction identities give nonzero homology and cohomology in arbitrarily large degrees; see Brown (n.d., Lecture 3). Thus the stated finite-group obstruction is valid. Its mechanism is the arbitrarily long composable strings in BG, despite the finiteness of its object and arrow sets.

Donc ici $u^W_!$ et u^W_* n'existent pas, pour $I \longrightarrow e$ avec I catégorie finie. Mais aussi $\mathcal{M}$ n'est pas stable par petites $\varinjlim$. [page 46]

Exemple 3.12. Soit $\mathcal{M}$ une catégorie muni d'un localiseur W fortement saturé, tel que $\mathcal{M} \longrightarrow \underbrace{\mathcal{M}W^{-1}}_{=\mathcal{H}}$ admette un adjoint – à gauche disons. On a donc une situation de deux foncteurs adjoints

$$\mathcal{H} \underset{v^* \text{ localisation}}{\overset{v_! \text{ pleinement fidèle}}{\rightleftarrows}} \mathcal{M} \quad , \tag{3.12.1}$$

et $W = (v^*)^{-1}(\mathrm{Iso}(\mathcal{H}))$. On trouve que pour toute I dans Cat, on a

$$\mathrm{HO}_W(I) \;\simeq\; \mathcal{H}(I) \overset{\text{déf}}{=} \mathrm{Hom}(I^\circ, \mathcal{H}). \tag{3.12.2}$$

On peut donc songer à faire un exemple où dans $\mathcal{M}$ les petites $\varinjlim$ et $\varprojlim$ existent, mais non dans $\mathcal{H}$, de sorte que les $u^W_!$ ou u^W_* n'existent pas toujours. Mais ce semble difficile à construire, vu que dans la situation envisagé, on voit facilement que les petites $\varprojlim$ existent dans $\mathcal{H}$. Donc si dans $\mathcal{H}$ il existe une petite famille cogénératrice (et pour ceci, il suffit qu'une telle famille existe dans $\mathcal{M}$), il y aura également des petites $\varinjlim$, en vertu de SGA 4 I 8.12.7. De même, elles existent si $\mathcal{H}$ est une sous-catégorie pleine de $\mathcal{M}$ *stable par petites* $\varinjlim$, et il paraît pratiquement impossible de faire un exemple (3.12.1) sans que $\mathcal{H}$ ait cette propriété de stabilité. Sans compter qu'il y a même la perplexité suivante : [page 47]

! |

Question 3.13. *Existe-t-il une $\mathfrak{U}$-catégorie ($\mathfrak{U}$ un univers donné) où les petites $\varinjlim$ soient représentables, sans qu'il en soit de même des petites $\varprojlim$?* **N.B.** Une telle catégorie n'admet pas de petite famille génératrice, a fortiori elle n'est pas équivalente à une petite catégorie.

Commentary · Exposition [ms. 47]

A coreflective localization inherits both kinds of limits

The proposed difficulty in Example 3.12 is removed by a formal adjunction argument. Write $L : \mathcal{H} \to \mathcal{M}$ for the fully faithful left adjoint and $R : \mathcal{M} \to \mathcal{H}$ for the localization. The unit is an isomorphism. The counit $\varepsilon_X : LRX \to X$ belongs to W, since $R\varepsilon_X$ is an isomorphism by the triangle identity. These facts hold objectwise in every diagram category. Therefore L^I and R^I descend to inverse equivalences

$$\mathcal{M}(I)[W(I)^{-1}] \simeq \mathcal{H}(I),$$

which proves (3.12.2) directly and explains why the example becomes a question about ordinary completeness.

If $\mathcal{M}$ is complete and $D : J \to \mathcal{H}$ is small, then

$$R\big(\varprojlim_J LD\big)$$

is its limit in $\mathcal{H}$: applying $\mathrm{Hom}_{\mathcal{H}}(H, -)$ and the adjunction identifies the required universal property with the limit universal property in $\mathcal{M}$. If $\mathcal{M}$ is cocomplete, let $X = \mathrm{colim}_J LD$. Every cocone map $LD(j) \to X$ has a unique factorization through $\varepsilon_X : LRX \to X$, because its source lies in the image of L. These factorizations form a cocone, hence induce $g : X \to LRX$ with $\varepsilon_X g = 1_X$. Postcomposition with ε_X is a bijection on maps from any object in the image of L. Applying this with source LRX gives $g\varepsilon_X = 1_{LRX}$. Thus ε_X is an isomorphism and X belongs to the essential image of L. In particular that image is automatically closed under all small colimits, and $R\,\mathrm{colim}\, LD$ is the colimit in $\mathcal{H}$.

Consequently a full coreflective subcategory of a bicomplete category is bicomplete. No cogenerating family is needed, and the envisaged counterexample cannot have the adjunction (3.12.1). The source's auxiliary observation about cogenerators is nevertheless correct: if $\{C_s\}$ conservatively detects arrows in $\mathcal{M}$ by $\mathrm{Hom}_{\mathcal{M}}(-, C_s)$, then $\{RC_s\}$ does so in $\mathcal{H}$, by adjunction and full faithfulness of L. The cited representability criterion, Artin et al. (1972, Exposé I, 8.12.7), supplies another sufficient argument when that hypothesis is available; the colimit argument above shows why it is unnecessary here.

Commentary · Examples [ms. 47]

All small suprema without a largest ordinal

Question 3.13 has a direct affirmative answer, with its universe distinction essential. Let $\mathrm{Ord}_{\mathfrak{U}}$ have the ordinals belonging to $\mathfrak{U}$ as objects, with one arrow $\alpha \to \beta$ when $\alpha \le \beta$. It is locally $\mathfrak{U}$-small: every Hom-set is empty or a singleton. For a $\mathfrak{U}$-small diagram its colimit is the supremum of the ordinals occurring in the diagram. This supremum belongs to $\mathfrak{U}$ by the universe axioms; for the empty diagram it is 0. There is no terminal object, since $\alpha + 1$ is again an object and is larger than α. Thus all small colimits exist but even the empty limit does not. The category is necessarily large relative to $\mathfrak{U}$.

The note about generators is correct with the convention used in SGA 4. In Artin et al. (1972, Exposé I, 7.1), a generating family means that the associated represented functors jointly *reflect isomorphisms*. Given any small family of ordinals $\{\alpha_s\}$, put $\beta = \sup_s \alpha_s$. Every map

$$\mathrm{Hom}(\alpha_s, \beta) \longrightarrow \mathrm{Hom}(\alpha_s, \beta + 1)$$

is a bijection between singletons, but $\beta \to \beta + 1$ is not an isomorphism. Hence there is no small generating family in this conservative sense. A merely faithful family of Hom-functors would be a different convention: every poset has at most one arrow with given endpoints, so faithfulness alone says almost nothing here. It would be incorrect either to reject Grothendieck's note using that weaker convention or to conclude from this example that a small cocomplete category need not be complete.

[page 48]

Question 3.14. Anderson prétend que pour le prédérivateur défini par une catégorie à cofibrations satisfaisant l'axiome Cof_4 transfini, les foncteurs $u_!^W$ existent. Sa démonstration est totalement canulée, néanmoins je n'arrive pas à faire de contre-exemple. Le résultat qu'il annonce serait-il vrai? Je ne connais pas même d'exemple d'un localiseur W, dans une catégorie $\mathcal{M}$ *avec petites* $\varinjlim$ *et petites* $\varprojlim$ *,* tel que $u_!^W$ ou u_*^W n'existent pas toujours – mais je suis persuadé qu'il y a des exemples (même avec $\mathcal{M}$ une petite catégorie?). J'en suis moins convaincu si on suppose W stable par $\varinjlim$ filtrantes, et au besoin, de plus, que les éléments de $\mathcal{M}$ sont accessibles (plus éventuellement d'autres propriétés catégoriques anodines sur $\mathcal{M}$, telles l'existence d'une filtration cardinale etc.) p. 26 [page 49]

Commentary · Later developments [ms. 48]

The cofibration assertion is true under the stated continuity hypothesis

The first question in 3.14 now has a positive answer. Modern cofibration-category theory separates this assertion from the existence of projective Quillen structures. In the presence of the initial object and pushouts in the standing framework, Cof_4 implies the coproduct and sequential-colimit axioms of an Anderson–Brown–Cisinski cofibration category. To see the coproduct assertion, well order a small family of cofibrant objects, attach its members one at a time by pushout from the initial object, and take colimits at limit stages. The resulting transfinite composite is the coproduct. Applied to a family of cofibrations, the same construction proves closure of cofibrations under coproducts; for acyclic cofibrations use the asserted transfinite closure of TC. Countable sequential composites are already a special case of Cof_4.

Rădulescu-Banu (2009, Lemma 1.6.2 and Theorem 10.3.2) gives the corresponding axioms and proves that every such cofibration category defines a strong derivator with all homotopy left Kan extensions. His Theorem 10.3.3 includes arbitrary Quillen model categories. A complementary formulation uses derivable categories: the dual of Cisinski (2010, Corollary 6.21) supplies the colimit theorem, while that corollary itself treats the limit direction in Cisinski's conventions. These results require neither a small set of generating cofibrations nor functorial factorization. They settle the existence question raised here, without retroactively validating the proof which Grothendieck criticizes.

The broader request in the same paragraph drops the cofibration structure entirely. It has a different answer, even when the underlying category and localizer have every finiteness and accessibility property explicitly mentioned here. The following finite example makes that distinction precise.

Commentary · Development (commentators') [ms. 48]

A finite complete lattice whose localization loses binary limits

An eight-object counterexample to the broader request in 3.14. [ours] There is a finite complete and cocomplete category P, with a strongly saturated localizer W stable under filtered colimits and accessible as a full subcategory of the arrow category, for which neither homotopy Kan extension along the discrete two-object category $D \to e$ exists. This elementary construction was prepared for this commentary. A targeted search for localizations of finite and Boolean lattices and failures of products or coproducts did not establish an attribution for this exact presentation. No priority claim is made. This is not a counterexample to the cofibration-category theorem just cited.

Let P be the Boolean lattice of subsets of $\{1,2,3\}$, ordered by inclusion, and abbreviate subsets by their strings of elements. Put $a = 1$, $b = 12$, and let W consist of the identities and $s : a \to b$. The two-out-of-three property holds: $a < b$ is a cover, so a factorization of its only nonidentity weak equivalence has an identity factor. The underlying category has all small limits and colimits, computed by intersections and unions.

We first compute the localization as a category, not just its object classes. Adjoin $s^{-1} : b \to a$. Any composable word containing two such inverses has the intervening forward path $a \to b$, which is s; it therefore reduces to a word with at most one inverse. Thus a morphism $x \to y$ is represented either by an inclusion or by

$$x \longrightarrow b \xrightarrow{s^{-1}} a \longrightarrow y.$$

If both forms occur, then $x \subseteq b$, $a \subseteq y$, and $x \subseteq y$. Either $x \subseteq a$, or x contains 2 and therefore $b \subseteq y$. In the first case the inverse cancels on the source side; in the second it cancels on the target side. The two forms consequently represent the same arrow. The localization is thin, with relation

$$x \preceq y \quad \Longleftrightarrow \quad x \subseteq y \ \text{ or } \ (x \subseteq 12 \text{ and } 1 \subseteq y).$$

This also verifies its universal property: for any functor F inverting s, the new arrow must be sent to $F(a \to y)F(s)^{-1}F(x \to b)$; the reductions just proved verify compositions and uniqueness. Only a and b become isomorphic. A skeleton Q therefore has seven objects, and W is exactly the inverse image of its isomorphisms, hence is strongly saturated.

In Q the common upper bounds of 2 and 3 are 13, 23, and 123. The first two are incomparable, so no least upper bound exists. Dually the common lower bounds of 13 and 23 are $\emptyset$, 2, and 3, and there is no greatest one. Thus Q lacks both a binary coproduct and a binary product. Localization of the product relative category $(P \times P, W \times W)$ gives $Q \times Q$: one may first invert $(w, 1)$ and then $(1, w)$, and these arrows generate the same inversions as $W \times W$. The restriction along $D \to e$ consequently identifies with the diagonal $Q \to Q \times Q$. Its left and right adjoints would give exactly the missing binary coproducts and products. Both therefore fail to exist.

Finally, all the accessibility qualifications can be checked directly. A filtered diagram in a finite poset has a finite directed image, hence a largest value which occurs at some stage and is its colimit. Every object of P is therefore finitely presentable. The same observation applies to the finite arrow category $P^{[1]}$. A filtered diagram all of whose objects lie in W has its colimit equal to one of those objects, hence in W. The full subcategory on W is itself finitely accessible: it has filtered colimits, every object is finitely presentable, and its finite set of objects supplies a generating set. The inclusion preserves filtered colimits. A cardinal filtration is trivial for this finite category. Thus the counterexample persists under the explicit additional hypotheses in the final sentences of 3.14. What fails is the extra homotopical structure supplied by the cofibration axioms, not any smallness or ordinary completeness condition.

Question 3.15. Cela me ramène à la question particulièrement élusive et irritante, de l'existence des petits ensembles Q-générateurs, dans une partie Φ de $\mathrm{Fl}(\mathcal{M})$, quand on suppose (disons) que $\mathcal{M}$ est stable par petites $\varprojlim$, que ses éléments sont accessibles et qu'il admet une filtration cardinale. Ainsi on a la question : une partie L-accessible de $\mathrm{Fl}(\mathcal{M})$, qu'on suppose au besoin Q-saturé à gauche (ou ce qui revient au même, contenant les isomorphismes, et stable par cochangement de base, par composition et par facteurs directs) admet-elle une *petite partie* Φ_0 Q-génératrice à gauche?

Commentary · Development (commentators') [ms. 49]

An accessible class with no small Q-generating subset

A negative answer to the Q-saturated form of Question 3.15. [ours] Let $\mathcal{K}$ be the category of directed multigraphs, with sets of edges and vertices and two functions $s, t : E \to V$, and let Φ be its class of pure monomorphisms. Then $\mathcal{K}$ is bicomplete, every object is accessible, and cardinality supplies a cardinal filtration. The full subcategory of $\mathcal{K}^{[1]}$ on Φ is accessible and is closed under all filtered colimits. The class Φ contains the isomorphisms and is closed under pushouts, transfinite compositions, and retracts, yet it has no small Q-generating subset. The non-generation theorem is due to Cox et al. (2026a, Theorem 5.1); the detailed translation to the hypotheses of this manuscript is the development supplied here. We make no priority claim for that translation.

Write $\mathcal{K} = \mathbf{Set}^{\mathcal{E}}$, where $\mathcal{E}$ has objects e, v, the distinct arrows $s, t : e \to v$, and identities. Limits and colimits are computed on the two sets, and finite graphs are finitely presentable. More generally a graph of cardinality less than a regular infinite cardinal λ is λ-presentable: maps out of it and equalities between such maps involve fewer than λ elements and equations, all of which occur at a common stage of a λ-filtered diagram. Thus every graph is presentable at some rank, and the subcategories with bounded cardinality are essentially small.

For an inclusion $A \subseteq B$, purity means that every finite system of equations in vertices and edges, with parameters from A, which has a solution in B, has a solution in A. Equivalently, in a commutative square from an arrow $P \to Q$ of finitely presentable graphs to $A \to B$, the top map $P \to A$ extends to $Q \to A$; equality with the given bottom map into B is not required. These are the equivalent descriptions in Cox et al. (2026a, Definition 2.7 and Remark 2.8).

We verify accessibility of the *full arrow subcategory*, whose maps are arbitrary commuting squares. This is distinct from the category with graphs as objects and only pure maps as morphisms. Given a pure inclusion $A \subseteq B$ and countable subsets in its domain and codomain, first close them under s, t and ensure that the chosen part of A is included in the chosen part of B. Suppose countable subgraphs $A_n \subseteq A$ and $B_n \subseteq B$, with $A_n \subseteq B_n$, have been chosen. There are only countably many finite equation systems with parameters in A_n. For each such system that has a solution in B_n, choose a solution in A, using purity of $A \subseteq B$. Adjoin all these witnesses to A_n, close under s, t, and adjoin their images to B_n. Repeat for $n < \omega$. The unions $A' \subseteq B'$ are countable. Any finite system over A' with a solution in B' has all its parameters and witnesses in a common stage, and was therefore given a solution in A' at the next stage. Hence $A' \to B'$ is pure.

The poset of countable pure subarrows of $A \to B$ is $\aleph_1$-directed: for a countable collection take the unions of their domains and codomains as seeds and apply the preceding closure construction. Its union is the whole arrow, since any chosen vertex or edge can be included in the seeds. There is a set of isomorphism types of countable graph arrows. Each is $\aleph_1$-presentable in $\mathcal{K}^{[1]}$, by the same element-and-equation argument already used for graphs, with the two components of the arrow included as additional functions. In particular every pure arrow is a filtered colimit of a fixed small family of bounded-size pure arrows, exactly the filtered-colimit-envelope condition used by the manuscript's earlier accessibility language.

We must also check preservation of the relevant colimits. Let $f_i : A_i \to B_i$ be a filtered diagram of pure arrows with arbitrary commuting-square transition maps. A square from finite $P \to Q$ into its colimit factors through a common stage, and its required equality holds at some later stage, because P, Q are finitely presentable. Purity at that stage gives $Q \to A_i$ extending the top map; composing into the colimit proves purity of the colimit arrow. Filtered colimits of sets preserve injections, so it is again a monomorphism. Thus the full subcategory on Φ has filtered colimits created in $\mathcal{K}^{[1]}$. Its countable arrows remain $\aleph_1$-presentable in that full subcategory, and the preceding directed presentation proves that it is $\aleph_1$-accessible. This verifies both parts of the manuscript's L-accessibility requirement, rather than inferring them from accessibility of a different category of pure maps.

For completeness, the closure conditions on Φ are also those required in the question. Composition follows by solving the same finite system first in the intermediate graph and then in the source. A retract of a pure arrow is pure: carry a parameter system and its solution along the section of the retract diagram, solve it in the larger source, and carry the solution back along the retraction. Arbitrary pushouts of pure monomorphisms are pure, as recorded in Cox et al. (2026a, Fact 2.9(iii)). Finally transfinite closure follows from composition at successor stages and the filtered-colimit argument at limit stages, applied to the arrows from the fixed starting object. Thus Φ is Q-saturated in the sense of the question, and in fact has the additional transfinite stability used elsewhere in the chapter.

The cited classification says that pure monomorphisms in $\mathbf{Set}^{\mathcal{E}}$ are cofibrantly generated precisely when, for every span $y \leftarrow x \to z$ in $\mathcal{E}$, one leg factors through the other. The span $v \xleftarrow{s} e \xrightarrow{t} v$ fails this test: the only endomorphism of v is its identity, and $s \neq t$. Hence Φ is not cofibrantly generated.

To connect that conclusion exactly to Grothendieck's terminology, suppose a small subset $S \subseteq \Phi$ were Q-generating. Its defining property is

$$\Phi \subseteq {}^{\perp}(S^{\perp}).$$

The small object argument applies in the locally presentable category $\mathcal{K}$. It identifies ${}^{\perp}(S^{\perp})$ with $\mathrm{cof}(S)$, the class of retracts of transfinite composites of pushouts of maps in S. The closure properties just proved give $\mathrm{cof}(S) \subseteq \Phi$. Both inclusions force equality, contradicting the classification theorem. This proves the asserted negative answer with no additional set-theoretic principle. The example concerns Q-*saturation*; it does not silently strengthen the question to the different hypothesis that Φ is already Q-*closed*. Nor does the argument identify accessibility of an arrow class with combinatoriality of a model structure, since no model structure has been supplied.

D'autre part, je n'ai pas à présent construit un seul exemple d'un couple $\Phi \longleftrightarrow \Psi$, dans une catégorie $\mathcal{M}$, qui ne soit factorisant! Le cas où $\mathcal{M}$ est spéciale, était bien sûr le plus intéressant. Visiblement, dans tout ça ce sont les exemples qui manquent. Le clef d'une compréhension semble bien être dans les questions de factorisation entre ensembles $\Phi \longleftrightarrow \Psi$. Il faudrait en faire une étude systématique, mais je recule devant la perspective d'une digression qui me ! | [page 50]

prendrait peut-être encore des semaines!

Commentary · Examples [ms. 50]

Mutual lifting classes need not factor every arrow

The failure of a mutually orthogonal pair to admit factorizations is already illustrated by Taylor (1999, Example 5.7.10). The following rational-cut presentation gives a small elementary instance, with no priority claim; it does not meet the stronger condition that the ambient category be special. Regard $\mathbf{Q}$ as a category under its usual order, and fix an irrational real number r, for example $\sqrt{2}$. Define $\mathcal{L}$ to contain the identities and the nonidentity arrows $a \to b$ with $b < r$. Define $\mathcal{R}$ to contain the identities and the nonidentity arrows $x \to y$ with $r < x$.

In a poset a lifting problem from $a \to b$ to $x \to y$ has a solution exactly when $b \leq x$, provided the square exists. Nonidentity arrows in the displayed classes have $b < r < x$, so $\mathcal{L} \perp \mathcal{R}$. Conversely, if a nonidentity $a \to b$ is not in $\mathcal{L}$, then $b > r$. Choose a rational x with $\max(a, r) < x < b$. The square from $a \to b$ to $x \to b \in \mathcal{R}$, with bottom identity, has no lift. Hence ${}^{\perp}\mathcal{R} = \mathcal{L}$. If a nonidentity $x \to y$ is not in $\mathcal{R}$, then $x < r$. Choose rational b with $x < b < \min(y, r)$. The square from $x \to b \in \mathcal{L}$ to $x \to y$, with top identity, has no lift. Thus $\mathcal{L}^{\perp} = \mathcal{R}$.

Nevertheless, an arrow $a \to b$ with $a < r < b$ has no factorization of the indicated type. An intermediate object z with both factors nonidentity would have to satisfy simultaneously $z < r$ and $r < z$; choosing either factor to be an identity also fails. This is a pair of mutually closed lifting classes, but not a weak factorization system. The rational poset is not cocomplete, so the example answers the unrestricted request only. It leaves the final, more demanding special-ambient question logically separate from the counterexample.

Overview · XIX

Chapter XIX: factorization, diagram categories, and the existence of derived Kan extensions.

Grothendieck has reached the point at which his formalism must acquire its examples. Given a category $\mathcal{M}$ and a class W of weak equivalences, the intended coefficient system is

$$\mathbb{D}_{\mathcal{M},W}(I) = \mathrm{Fun}(I^{\mathrm{op}}, \mathcal{M})[W(I)^{-1}], \qquad u^* : \mathbb{D}(J) \longrightarrow \mathbb{D}(I).$$

The problem is to construct both adjoints to restriction, prove their pointwise formulas, and explain which hypotheses on the models are doing the work. The chapter's fifty manuscript pages therefore move from lifting and factorization to model structures on diagrams, and then return to the places where that method appears to stop. In the edition the chapter occupies printed pages 1–26, after two preliminary leaves.

The historical motivation precedes the terminology of this chapter. In *Pursuing Stacks*, §69, Grothendieck relates the passage from a single derived category to a system of derived diagram categories to the inadequacy of the former for the variance and trace constructions arising in SGA 5. His letter to Thomason of 2 April 1991 connects the long investigation of accessible categories in Chapter XVIII with the foundations needed for this coefficient formalism (Grothendieck, 1983, 1991a). Thus accessibility enters here for a concrete reason: the homotopical operations must be constructed using sets of generators and controlled colimits before they can be recognized intrinsically after localization.

The two levels of closure. The opening pages isolate the relation $i \perp p$ of admitting a diagonal in every lifting square. It gives an antitone correspondence between classes of arrows, hence the closures ${}^{\perp}(S^{\perp})$ and $({}^{\perp}T)^{\perp}$. Pushouts, transfinite compositions, and retracts describe a second closure process. The small object argument identifies the two when a set of arrows generates the lifting condition and their domains have the required smallness. The retract argument is the decisive step: factor an arrow already having the left lifting property, then use its lift against the right factor to express it as a retract of the constructed cellular arrow. This is why the distinction between an orthogonal pair and a factorizing pair must remain visible. The source's initial identification of separate closedness of two orthogonal classes with mutual determination of the classes is too strong; the factorization hypothesis supplies the missing implication later.

Grothendieck's word "special" must also retain its stated meaning. His ambient category has small colimits and each object is presentable at some cardinal; his special left classes have a small set of lifting generators. This does not itself supply the small generating subcategory required for local presentability. Modern statements about combinatorial model categories may consequently be used only after the additional ambient hypothesis has been made explicit.

The asymmetry of projective and injective diagrams. For contravariant diagrams, evaluation at i has a left adjoint $i_!A(j) = \coprod_{\mathrm{Hom}_I(j,i)} A$. Applying these adjoints to generating cofibrations and generating trivial cofibrations constructs the projective structure. Its fibrations and weak equivalences are pointwise; its cofibrations encode compatibility with the arrows of the indexing category. Theorem 2.3 then derives $u_!$, and Proposition 1.12 supplies the restriction property needed to compute its values on comma categories. In the variance used here the formulas are

$$(\mathbf{L}u_!X)_j \simeq \operatorname*{hocolim}_{(j\downarrow u)^{\mathrm{op}}} X, \qquad (\mathbf{R}u_*X)_j \simeq \operatorname*{holim}_{(u\downarrow j)^{\mathrm{op}}} X.$$

Writing the opposite categories is necessary: the manuscript's diagrams are presheaves, whereas much modern derivator notation uses covariant diagrams.

For the injective structure the cofibrations are pointwise, and it is the right class whose compatibility is no longer pointwise. One cannot obtain small generators merely by placing the

old generators at every component. Question 1.11 has a positive answer for locally presentable ambient categories, by the generation theorem of Lurie (2009, Lemma A.2.8.3), but its final suggested choice of generators already fails for sets with a nontrivial group action. The commentary gives the sharper elementary criterion for when the sole generator $\varnothing \to 1$ can be used unchanged on a diagram category, with a complete proof and an explicit statement of the literature checked.

Theorems 2.6 and 2.9 secure the injective construction in Grothendieck's "very special" situation, in which the cofibrations are all monomorphisms. The geometric conditions on unions and pushouts, together with accessibility of W, are the mechanism behind the recognition theorem. Here two-out-of-three does essential work: after building a bounded trivial subextension, it keeps the remaining extension in W. This is a substantially stronger situation than an arbitrary accessible class of monomorphisms. The proof recalled from Chapter XV must be read through its corrected argument in §7, not through the explicitly abandoned general claim in §6. The cardinal-stage condition printed with a projective-limit arrow in XIX is identified in the apparatus as a source slip: the cited formulations require closure under the corresponding small inductive limits.

The latching interpretation in section 3 returns to the same care about testing classes. Proposition 3.5 needs the canonical right class, which the source explicitly chooses in (3.5.2); an arbitrary presentation by right tests can give a false equality. The commentary supplies the counterexample and the valid comparison. It also proves the classwise cellular description conjectured in (3.5.3) for noetherian posets, with the required colimits stated, and supplies the short lifting lemma implicit in Proposition 3.7.

What later existence theorems change. The existence of a convenient diagram model structure and the existence of derived Kan extensions are different assertions. Cisinski proves the latter for an arbitrary Quillen model category with small limits; duality supplies the colimit statement when small colimits exist (Cisinski, 2003, Theorem 6.11). Consequently the bicomplete Quillen case of Question 3.9 admits no counterexample of the requested kind. For combinatorial models, both diagram model structures give a direct and symmetric proof; Groth (2013, Theorem 1.28 and Proposition 1.30) presents this route. The later existence theorem does not retroactively prove every factorization assertion contemplated in the manuscript, and it does not make the adjective "very special" necessary.

The final section shows why the size of the permitted diagrams matters. Its bounded-complex example is effective precisely because bounded derived categories need not contain the result of a homotopy limit indexed by a finite category with arbitrarily long composable strings. For $k = \mathbf{F}_2$ and $G = C_2$, the resolution of the trivial $k[G]$-module is periodic and gives nonzero group homology and cohomology in every nonnegative degree. Testing a hypothetical adjoint to the trivial-action functor against shifts proves its nonexistence within the bounded category. This supplies the required obstruction without identifying a bounded category with a bicomplete modern model category. The distinction between cofibration-category excision on cofibrant objects and the manuscript's absolute W-cofibrations is equally necessary in reading the Brown lemma invoked on manuscript page 35.

Some of the closing searches have elementary answers. A fully faithful coreflective image in a bicomplete category is itself bicomplete: the coreflector constructs limits, and the image is closed under colimits. Thus the proposed adjoint-localization construction in Example 3.12 cannot produce its hoped-for failure. The category of ordinals small relative to the fixed universe has all small suprema and no terminal object, answering Question 3.13 with the universe convention made explicit. Its lack of a small conservative generating family is consistent with the convention of SGA 4. A rationally ordered category cut at an irrational number supplies a mutually lifting-closed pair which does not factor arrows across the cut; it does not have the cocompleteness required of a special ambient category.

The broader localizer question in 3.14 admits a small counterexample. Localize the

Boolean lattice of subsets of $\{1,2,3\}$ at the single cover $\{1\} \subset \{1,2\}$. The resulting seven-object skeleton has neither a least upper bound for $\{2\},\{3\}$ nor a greatest lower bound for $\{1,3\},\{2,3\}$. The localizer is strongly saturated, accessible, and stable under filtered colimits, and the original lattice is complete and cocomplete. The commentary computes the localization and proves each assertion. This answers the broad question even with the additional smallness hypotheses. The cofibration-category question in the same paragraph has the opposite answer: the transfinite continuity axiom supplies the coproduct and sequential-colimit hypotheses of modern cofibration-category theory, which yields all homotopy left Kan extensions (Rădulescu-Banu, 2009, Theorem 10.3.2).

Question 3.15 also benefits from separating the closures introduced at the start. The class of pure monomorphisms in directed multigraphs is accessible, closed under filtered colimits, pushouts, transfinite composition, and retracts. It nevertheless has no small set of Quillen generators. The non-generation theorem is due to Cox, Feigert, Kamsma, Mazari-Armida, and Rosický, in their 2026 classification for presheaf categories (Cox et al., 2026a, Theorem 5.1); the commentary verifies the translation into the hypotheses stated here and supplies the small-subdiagram argument for accessibility. This answers the question for a Q-saturated class. It does not identify that class with its double lifting orthogonal, and the stronger question obtained by imposing that additional condition is not silently substituted for the question Grothendieck actually wrote.

The commentary retains the edition's slips as source evidence, distinguishes them from errors of transcription, and states repairs at the point where they are needed. The claim register records the source's proof status separately from later theorems or counterexamples. Mathematical dependencies on Chapters XIII, XV, XVII, and XVIII are checked against the relevant original passages or explicitly identified as recalled results.

Register of claims

The audit of each part records the definitions, axioms, propositions, claims, conjectures and questions of the text, each with the status the text gives it: proved, sketched, stated, assumed, conjectured, false (the assertion, or the inference as written, is false) or open. The table counts the entries of each part by status; the list after it gives every entry whose status is false, open or conjectured, with its manuscript page and its identifier in the audit.

I-a · Chapter I, part 1 of 2, manuscript pages 1–66

ms. 3 CONJECTURED I-a-E020 – For a monotone map of finite ordinals, restriction on A-valued presheaves has a second adjoint on each side when A is pointed and has finite

limits and colimits.

ms. 3 FALSE I-a-E021 – All restriction functors associated with all maps between two fixed finite ordinals occur in the same successive adjunction chain.

ms. 3 CONJECTURED I-a-E022 – For [n] and [n+1], the face and degeneracy restrictions form a chain of 2n+3 terms, extendible by two terms at each end to 2n+7.

ms. 4 FALSE I-a-E024 – A category in which every arrow is monic and every isomorphism is an identity is a poset.

ms. 15 FALSE I-a-E066 – The abelianization morphism preserves all right Kan extensions.

ms. 15 FALSE I-a-E067 – A homotopy pullback of spaces along a fibration is sent by abelianization to a homotopy pullback.

ms. 25 FALSE I-a-M007 – The mixed interchange map might be invertible in additive derivators.

ms. 29 CONJECTURED I-a-M021 – There should be a stable or triangulated derivator theory in which left and right exact morphisms coincide.

ms. 32 FALSE I-a-M030 – The withdrawn Der5 asserts that a strict hot-equivalence has fully faithful restriction, equivalently $1 \to f_* f^*$ is invertible.

ms. 32 FALSE I-a-M032 – The dual withdrawn Der5 asserts $f_! f^* \to 1$ invertible for every costrict hot-equivalence.

ms. 32 FALSE I-a-M033 – The withdrawn argument would make f_*, respectively $f_!$, localization functors.

ms. 47 FALSE I-a-M060 – The same cohomology invariance would follow if instead all (α/x) were contractible.

ms. 47 FALSE I-a-M062 – The terminal-object condition above would substantially strengthen cohomological cofinality.

ms. 47 FALSE I-a-M064 – The condition $\alpha_! \varepsilon_{X'} \simeq \varepsilon_X$ follows from either orientation of cofinality.

ms. 47–48 FALSE I-a-M067 – Corollary2 repeats the claim that strict hot-equivalence implies $F \to f_* f^* F$ invertible for arbitrary F.

ms. 48 FALSE I-a-M071 – The preceding slice calculation proves the withdrawn full-faithfulness corollary by opposite cofinality.

ms. 49 FALSE I-a-L003 – The same sufficient base-change criterion holds with $h_{y'}$ homotopy aspherical (all $h_{y'}/(x,u)$ contractible).

ms. 58 CONJECTURED I-a-L035 – If right base change for a fixed f holds for every base change and every derivator, then f is proper.

ms. 58 CONJECTURED I-a-L036 – If base change along a fixed p commutes with right direct images for every f and every coefficient theory, then p is smooth.

ms. 58 CONJECTURED I-a-L037 – Testing HOTAB and HOT should suffice to detect the universal proper/smooth base-change properties.

ms. 59 CONJECTURED I-a-L039 – For f, the four conditions universal right base change, universal left-mate base change, coasphericity of X_y->X/y, and contractibility of every fibre of x\X->f(x)\Y are equivalent.

I-b · Chapter I, part 2 of 2, manuscript pages 67–126

ms. 78 CONJECTURED I-b-A069 – The doubled-arrow construction probably does not give the desired counterexample to base-change stability.

ms. 79 FALSE I-b-B079-03 – Every universally cohomological D-fibration preserves all constant-coefficient D-equivalences under pullback.

ms. 79 FALSE I-b-B079-04 – Every universally homological D-fibration preserves all constant-coefficient D-equivalences under pullback.

ms. 79 FALSE I-b-B079-07 – The implication (b)⇒(a) nevertheless holds for all derivators D_i of i-truncated homotopy types.

ms. 81 FALSE I-b-B081-04 – Universal cohomological/homological D-fibrations as subsequently redefined are closed under composition.

ms. 84 CONJECTURED I-b-B084-01 – For a universal D-equivalence f:X→Y, restriction f^*:D(Y)→D(X) is fully faithful.

ms. 84 FALSE I-b-B084-06 – For D-fibrations over S, a D-equivalence of total categories must be a D-equivalence on each fibre.

ms. 84 FALSE I-b-B084-07 – The converse of Proposition6(a) holds whenever S is D-contractible.

ms. 87 FALSE I-b-B087-05 – A bundle over the circle is determined up to unique isomorphism by a specified monodromy automorphism of its fibre.

ms. 93 FALSE I-b-B093-04 – Conditions(a)–(c) alone imply that the inclusion of a fibre of(E×Z)/G→E/G is not a D-equivalence.

ms. 93 FALSE I-b-B093-05 – If additionally H*(Z;k)^G=k, then X=(E×Z)/G is D(k)-aspherical.

ms. 95 FALSE I-b-B095-01 – The orbit of the six-object poset has the displayed globular relations p1^-p0^-=p1^-p0^+ and p1^+p0^-=p1^+p0^+.

ms. 96 CONJECTURED I-b-B096-04 – Under Der3a′, the revised weakly-contractible-base test condition is equivalent to each of the universal one-sided fibration conditions.

ms. 102 FALSE Ib-C003 – If f is Hot-proper then both X_y→X/y and X/y→X/y′ are Hot-equivalences, universally.

ms. 107 CONJECTURED Ib-C021 – Footnote55: for HOT, cohomological equivalence, homological equivalence, and constant-coefficient equivalence coincide.

ms. 109–110 CONJECTURED Ib-C026 – Every Hot-equivalence induces an equivalence on locally constant HOT coefficients and hence preserves their cohomology and homology.

ms. 115 CONJECTURED Ib-C048 – For HOT all five equivalence notions coincide with nerve weak equivalence.

ms. 119 CONJECTURED Ib-C069 – For HOT, D-fibrations do preserve D-equivalences by pullback.

ms. 122–123 FALSE Ib-C082 – With compatible internal Homs, every unqualified D-equivalence is 1-complete.

ms. 125–126 CONJECTURED Ib-C092 – HOT satisfies c″ and its equivalences are precisely nerve weak equivalences.

ms. 126 CONJECTURED Ib-C096 – There should be a single intrinsic HOT-fibration notion on all small categories; the homotopy derivator must be constructed to justify the coefficient route.

II-a · Chapter II, part 1 of 2, manuscript pages 1–53

ms. 3–4 CONJECTURED II-A-013 – For homotopical cofinality, replace the connectedness criterion on comma categories by weak contractibility of their nerves.

ms. 5 FALSE II-A-017 – The manuscript invokes Der5 to infer $F \to u_* u^* F$ invertible for all F from homotopy strictness, i.e. contractibility of each u/c.

ms. 5 FALSE II-A-018 – The dual asserted consequence is $u_! u^* F \to F$ invertible for all F when all c/u are contractible.

ms. 5 OPEN II-A-019 – If each c/u is weakly contractible, is $H^i(C, F) \to H^i(C\prime, u^* F)$ an isomorphism for every abelian presheaf F and every i?

ms. 7 CONJECTURED II-A-025 – For $K_u(c) = \pi_0(c/u)$ there is a natural isomorphism $\lim u^* F \cong \mathrm{Nat}(K_u, F)$.

ms. 7–8 CONJECTURED II-A-026 – $\mathbf{R}\Gamma(C\prime, u^* F) \simeq \mathbf{R}\,\mathrm{Hom}_{C;k}(\mathbf{L}u_! k_{C\prime}, F)$ in D(k).

ms. 8 CONJECTURED II-A-028 – For space-valued presheaves, $\mathbf{R}\Gamma(C\prime, u^* F) \simeq \mathbf{R}\Gamma(C, \underline{\mathrm{Hom}}(u_! 1, F))$.

ms. 9 FALSE II-A-032 – The proposed unsectioned identity is $u_* u^* F \simeq \underline{\mathrm{Hom}}(u_! 1, F)$.

ms. 10 FALSE II-A-034 – The proposed general formula is $u_* \underline{\mathrm{Hom}}(G\prime, u^* F) \simeq \underline{\mathrm{Hom}}(u_! G\prime, F)$.

ms. 10 OPEN II-A-036 – There is a canonical projection comparison from adjunction, whose invertibility is in question.

ms. 12–13 FALSE II-A-049 – The first list claims equivalence between local irreducibility of Top(X), local irreducibility of Esp(X), irreducibility of components, and irreducibility of all slices X/x.

ms. 12–13 FALSE II-A-051 – The second list a–e again includes weak cofiltering of connected components among conditions equivalent to local irreducibility of Top(X).

ms. 13 FALSE II-A-054 – The prose identifies local irreducibility of the presheaf topos with PS1 plus PS2, or componentwise cofiltering.

ms. 15 OPEN II-A-060 – Find a topos-theoretic condition equivalent to PS1+PS2 and ensuring every connected étale category has weakly contractible nerve.

ms. 16 FALSE II-A-066 – The NB claims PS1 is equivalent to componentwise weak cofiltering.

ms. 18 FALSE II-B-006 – Total 0-connectedness alone implies W_infty-asphericity.

ms. 19 FALSE II-B-019 – The representable-base conditions (c,c-prime) imply the strong equivalent conditions (a,a-prime,b,d).

ms. 21 FALSE II-B-024 – For every pair of connected U,V over an arbitrary object W, U times_W V is nonempty.

ms. 24 FALSE II-B-033 – Condition 2.6(c-prime) implies PS2.

ms. 28 FALSE II-B-045 – If all slices X/x are cofiltered, then X must be locally cofiltered.

ms. 36;36ter CONJECTURED II-C-003 – Does T(A) imply that A is filtered?

ms. 36 FALSE II-C-006 – Proposition2.19: a nonempty category with cofinal diagonal satisfies T(A).

ms. 36 FALSE II-C-008 – A totally0-connected category has weakly contractible nerve.

ms. 36 FALSE II-C-009 – Corollary to2.19: Delta^op satisfies T despite not being filtered.

ms. 36bis–36ter FALSE II-C-015 – In the proposed proof of2.20, a weak equivalence i:X→ E is used to infer that X/H is weakly contractible by a reference to ChapterXII.

ms. 51 FALSE II-C-074 – The source asserts that M-connectedness is equivalent to the slice-limit comparison for coefficients on I/i restricted from I.

ms. 51 FALSE II-C-076 – The converse to4.8 holds for ordered I without restrictions on M.

ms. 52 FALSE II-C-078 – Proposition4.1(d prime) as printed: all coslice functors i\I prime→i\I are cofinal is equivalent to full faithful restriction.

II-b · Chapter II, part 2 of 2, manuscript pages 54–99

ms. 45 OPEN IIb-A004 – Find a common cofinality statement encompassing 3.4 and XVIII Proposition 4.9.6.3.

ms. 51 OPEN IIb-A026 – Does M-connectedness imply M-cofinality of all slice maps, when slice diagrams need not extend globally?

ms. 52 FALSE IIb-A031 – The printed condition that every i\ I′→ i\ I is cofinal is equivalent to full faithfulness of restriction.

ms. 54-56 OPEN IIb-A038 – Does invertibility of y_i→ u_*u^*y_i for all representables imply W_0-connectedness?

ms. 59 FALSE IIb-A052 – Are W_0-connected functors precisely ordinary localization functors, equivalently are conservative W_0-connected functors equivalences?

ms. 63bis-64bis FALSE IIb-A069 – If binary coproduct on D(e) is faithful, left Kan extension along every discrete fibration is faithful.

ms. 64bis OPEN IIb-A073 – Can a D-connected functor fail to be D-aspherical (the literal printed question)?

ms. 64bis OPEN IIb-A074 – Can D-connectedness fail to imply D-biasphericity when both coproduct and product conservativity are absent?

ms. 65 FALSE IIb-A080 – D-connectedness is an exception to closure of the seven classes under composition.

ms. 46 FALSE IIb-A085 – Nonemptiness of every comma category i\ I′ is equivalent to F0 together with F1.

ms. 67 FALSE IIb-B013 – For every base-change- and composition-stable L, N(S(N(L)))=N(L).

ms. 67 FALSE IIb-B015 – For every A contained in W, S(N(S(A)))=S(A).

ms. 77 FALSE IIb-B050 – The printed second line (5.20) states A^natural=sup_{p in A} p^natural.

ms. 79 FALSE IIb-B057 – For a Galois extension L/K, the fixed-point polarity has intermediate fields as its closed subsets of L and all subgroups as its closed subsets of G.

ms. 81 FALSE IIb-B062 – The lifting relation on classes is not induced by a relation on individual arrows.

ms. 81-82 FALSE IIb-B064 – If phi records (left edge,right edge), the lifting condition for classes (Phi right,Psi left) is phi inverse(Phi times Psi) subset D0 as printed.

ms. 83 FALSE IIb-B071 – The condition in (6.3) is equivalent to saying A is stable under pullback along L.

ms. 84 FALSE IIb-B072 – With the initial definitions, P and Q are closed under arbitrary unions.

ms. 85 FALSE IIb-B078 – The pullback-stability of T_W(A) proves T_W(A) belongs to the Q defined in (6.2).

ms. 86 FALSE IIb-B088 – The prose before (6.8) identifies all closed pairs with pairs whose two members are composition-closed.

ms. 89 OPEN IIb-B100 – Find an effective intrinsic characterization of T_W(W_asph) and T_W(W_coas).

ms. 89 OPEN IIb-B101 – Define Net_W=Stab(W_bias) and seek a characterization using bilocal factorization categories.

ms. 89 OPEN IIb-B102 – Determine Stab(Equ), the stabilizer of categorical equivalences.

ms. 89 FALSE IIb-B103 – The printed final inclusion says Equ subset P(W) for a fundamental localizer W.

ms. 90 FALSE IIb-C009 – Remark 7.2, literally: every discrete fibration is locally filtered.

ms. 91 OPEN IIb-C019 – Remark 7.4(1): are locally cofiltered or precofiltered functors stable under arbitrary base change?

ms. 92 FALSE IIb-C022 – Remark 7.4(3), literal intermediate assertion: a cofiltered functor is W_0-aspherical.

ms. 92-95 FALSE IIb-C027 – Proposition 7.4(c), literally: for any open U⊂ X/x let V be the lower open generated by the image of all X/x; then U→ V is cofiltered (respectively weakly cofiltered).

ms. 98-99 FALSE IIb-C063 – The abbreviated total-connectedness criterion C^{op}→ C^{op}× C^{op} final, without nonemptiness.

ms. 99 FALSE IIb-C065 – The parenthetical locally cofiltered = components filtered, and the label PS*1 = the x\ C satisfy PS*1′, in the first closing diagram.

ms. V:47 FALSE V-I059 – If such an ind-map induces an isomorphism in Ind(Cathot), its union map is necessarily a weak equivalence.

ms. V:47 FALSE V-I060 – A weak equivalence between the envelope unions is an isomorphism in Cathot.

ms. V:49 CONJECTURED V-I064 – The required minimal lengths of stagewise homotopies may tend to infinity, obstructing a global categorical homotopy.

ms. V:49 FALSE V-I065 – For a Thomason fibrant K′, are categorically homotopic functors X→K′ always connected by one natural transformation?

ms. V:49-50 CONJECTURED V-I066 – Different reasonable theories of paths might yield canonically and transitively isomorphic unions in Cathot, as well as isomorphic ind-objects.

ms. V:52 FALSE V-I071 – This restricted Yoneda functor is conservative.

ms. V:52 FALSE V-I072 – Bijectivity on unbased homotopy classes from all spheres already detects weak equivalence.

ms. V:52 FALSE V-I073 – Is the restricted Yoneda functor Hot→Fun(Hot_0^op,Ens) fully faithful?

VI-a · Chapter VI, part 1 of 3, manuscript pages 1–70

ms. 4, 8 FALSE VIa-039 – The initial comparison theorem asserts that all functors of the thirteen-category diagram induce equivalences after the localizations specified on ms7, identifying strict-fibrewise diagram theory with coarse Cat/S theory.

ms. 5 CONJECTURED VIa-040 – The higher coherence discarded by ordinary localization should be recovered in relative internal Hom objects interpreted as ∞-groupoid stacks over S.

ms. 6, 33 FALSE VIa-048 – Read literally for arbitrary W⊇W∞, the source identifies transitions being Hot-equivalences with transitions belonging to W (ms6), and identifies Hot_W-valued local coefficients exactly with the index-0 split categories defined by W∞-transitions (ms33).

ms. 14 CONJECTURED VIa-067 – Replacing Φ and Ψ by $\Phi'{=}\alpha'\Phi_0$ and $\Psi'{=}\beta'\Psi_0$ is proposed as a way to make the initial localized equivalence argument work.

ms. 14 FALSE VIa-068 – For an arbitrary W satisfying the initially stated localizer assumptions, the source identifies total and strict-fibrewise W-equivalence on Parf(S), Fibhot(S), $\mathrm{Fib}_0(S)$ and $\mathrm{Cofib}_0(S)$.

ms. 21 FALSE VIa-097 – Footnote 13 literally states that if X is a homotopy fibration over S then $\Psi(X)$ belongs to $\mathrm{Fibsc}_0(S)$.

ms. 22 CONJECTURED VIa-103 – Desired numbered assertion (2): for f:X→Y over S with X,Y perfect, or merely homotopy fibrations, total f∈W should imply f_s∈W for every s.

ms. 23, 45 CONJECTURED VIa-108 – The source conjectures on ms23 that perfect-base-change stability should hold for the finite homotopy-truncation localizers W_i, and on ms45 asks whether they satisfy new L5, L6 and L6 bis.

ms. 23 FALSE VIa-111 – From a commutative square with vertical weak homotopy equivalences and lower horizontal map f′ merely in W, the source concludes that the upper fibre map f′_{s′} is also a weak homotopy equivalence.

ms. 26 FALSE VIa-123 – Every Grothendieck fibration over S is isomorphic over S to a split fibration, so Fibsc(S)→Fib(S) is essentially surjective as an ordinary functor; dually for opfibrations.

ms. 26 FALSE VIa-124 – Restricting Fib(S) to Cartesian functors makes Fibsc(S)→Fib(S) fully faithful and an equivalence of ordinary categories; the cocartesian dual assertion also holds.

ms. 26-27 CONJECTURED VIa-125 – After restricting morphisms from arbitrary functors over S to coherent splitting-preserving ones and simultaneously restricting weak equivalences from coarse to fibrewise ones, the resulting localized categories might still be equivalent.

ms. 30-31 FALSE VIa-135 – In the surrounding contravariant Φ construction, its transport square is the printed covariant square with fibres X/s and X/t and transport u_*:X_s→X_t.

ms. 32-35 CONJECTURED VIa-141 – The nine nonsplit categories of the p8 diagram, with coarse W-equivalences, should model the full subcategory of locally constant objects of HOT_W(S); passing from an arbitrary diagram to its total category and then C should give its locally constant replacement.

ms. 33 FALSE VIa-143 – The category Cofibsc(S) is the outer opposite category (Fibsc(S^op))^op.

ms. 33, 35, 37 CONJECTURED VIa-145 – The functors Fibsc_0(S)→Fib_0(S) and Cofibsc_0(S)→Cofib_0(S) should induce equivalences after localization, with quasi-inverses represented by Φ_0 and Ψ_0, under the standing fibre/coarse identification hypothesis on internal objects.

ms. 33-35, 37 CONJECTURED VIa-146 – The inclusions Fibsc_0(S)→Fibsc(S) and Cofibsc_0(S)→Cofibsc(S), localized fibrewise, should be fully faithful, with essential images precisely the locally constant objects of the respective contravariant and covariant diagram homotopy categories.

ms. 33-34 FALSE VIa-147 – The fine covariant theory and its locally constant inclusion are to be written using (HOT_W(S^op))^op, as printed in the p33–34 discussion.

ms. 34-35 CONJECTURED VIa-148 – After identifying the coarse localization with local systems, forgetting the strict diagram structure should induce retractions from HOT_W(S) and HOT_W(S^op) onto their locally constant full subcategories.

ms. 38 FALSE VIa-156 – The equation $k\psi \cong \mathrm{id}_B$ implies that k is full on Hom_A(a,a′) for arbitrary objects a,a′ of A.

ms. 38 FALSE VIa-157 – Under $k\psi \cong \mathrm{id}_B$, failure of full faithfulness of ψ is equivalent to failure of faithfulness of k.

ms. 38 conjectured VIa-160 – The essential image of $\bar{\psi}'$ is expected to consist precisely of the locally constant objects of HOT_W(S).

ms. 41 conjectured VIa-173 – Left-fine W-equivalences should be preserved by smooth base change T→S, extending their stability under discrete-fibration base change.

ms. 41 conjectured VIa-174 – Right-fine W-equivalences should be preserved by proper base change T→S.

ms. 42, 44 false VIa-180 – Proposition 1(1), which compares X/s→Y/s over an independent base S, is simply the original absolute axiom L4.

ms. 43 conjectured VIa-186 – The integral-homology localizer is suspected also to fail the total-to-fibre implication for maps between homotopy fibrations.

ms. 43, 45 false VIa-188 – L1, L3 quater, relative L4 bis, and the new L5 alone force W=W∞, with no component-preservation hypothesis.

ms. 44 conjectured VIa-191 – For the fundamental localizers under consideration, L6—or even the new L5 alone—should imply L6 bis.

ms. 45 false VIa-200 – Saturation, the terminal-object axiom, relative L4 bis, and the new L5 alone imply W⊆W∞, without any component condition.

ms. 47 false VIa-208 – On Liss(S), Fib(S), and Fibsc(S), the coarse W-class equals the right-fine W-class; dually on Prop(S), Cofib(S), and Cofibsc(S), it equals the left-fine W-class.

ms. 49, 53-57 conjectured VIa-213 – Does the coarse weak-equivalence class also give the asserted comparison for the split categories Fibsc(S) and Cofibsc(S), whose morphisms must preserve the chosen splitting?

ms. 50 false VIa-218 – The common left-fine localization of Cat/S, Prop(S), Cofib(S), and Cofibsc(S) is isomorphic to HOT_W(S^op)^op.

ms. 51 false VIa-224 – The editorial replacement HOT_W^o(S):=HOT_W(S^op)^op is the correct target convention for the covariant comparison functor j.

ms. 51-52, 64-69 conjectured VIa-226 – The canonical functors i:HOT_W^lc(S)→HOT_W(S) and j:HOT_W^lc(S)→HOT_W(S^op) should be fully faithful under the p45 package L1, L3 quater, L4 bis, L7 and the new L5.

ms. 55 false VIa-238 – A Cartesian functor between split fibrations is therefore compatible with their specified splittings.

ms. 55-57 false VIa-239 – The pullback retractions γ_X:Φ(X)→X form a strictly natural transformation on the full category Fib(S), allowing every functor over S and imposing no Cartesian condition on the morphisms.

ms. 56 false VIa-242 – For every X→S and split fibration Y→S, restriction along η_X gives a bijection Hom_cart/S(ΦX,Y)≅Hom_S(X,UY), where the left-hand side includes all Cartesian functors.

ms. 65-67 false VIa-267 – To make Cbar a right adjoint to ρ, the required adjunction arrows should have the initially drawn directions id_coarse→ρCbar and Cbarρ→id_fine.

ms. 65 false VIb-A006 – The attempted unit/counit directions before p.67 do not yet give $\rho \dashv \bar{C}$.

VI-b · Chapter VI, part 2 of 3, manuscript pages 71–145

ms. 71 false VIb-A027 – The editorial outer-opposite correction asserts $\mathrm{HOT}^{o}_{W}(S) \simeq (\mathrm{HOT}_{W}(S^{op}))^{op}$ while retaining the ordinary localization definitions.

ms. 71 FALSE VIb-A031 – Footnote46 conjectures that coarse and fibrewise localized theories differ whenever S is not equivalent to a discrete category.

ms. 74 FALSE VIb-A041 – The covariant underlying diagram for arbitrary X/S is printed as $s \mapsto \mathrm{hot}_W(s\backslash X)$.

ms. 82 OPEN VIb-A070 – Can the coarse comparison be obtained from a Quillen-type replacement without choosing a functorial factorization?

ms. 82 OPEN VIb-A071 – Can fine right and left relative equivalences in M/S be defined intrinsically from a general category of models (M,W)?

ms. 82 FALSE VIb-R001 – The prose identifies local-isomorphism tests with W_S^d and co-local-isomorphism tests with W_S^g.

ms. 83 CONJECTURED VIb-A073 – The suggested smooth and Zariski-like localizations should have the same relevant invariants, and dually proper and co-Zariski-like localizations should have the same cohomology.

ms. 84 FALSE VIb-A075 – The compatibility $i_{CX} = C(i_X)$ cannot be formal under the hypotheses already available.

ms. 84 OPEN VIb-A077 – Does $i_{CX} = C(i_X)$ hold after inverting universal weak equivalences over S?

ms. 84 OPEN VIb-A078 – Does duality reverse the order of the two adjunctions in this comparison?

ms. 85 OPEN VIb-A079 – A finer localizer on M/S contained in W_S gives a localization from the fine quotient to the coarse quotient; constructing a section and adjunction requires suitable fibrant representatives.

ms. 87 OPEN VIb-A086 – To construct a quasi-inverse one seeks a functor gamma:M/S→(Fib S)[W_S^{-1}] sending X to C(X) and W_S to isomorphisms.

ms. 94 CONJECTURED VIb-B015 – Replacing local-isomorphism tests by all smooth morphisms gives the same left relative localizer.

ms. 94 OPEN VIb-B017 – Is closure of the test class $\mathcal{L}$ under composition needed?

ms. 97–98 CONJECTURED VIb-B028 – The section i is expected to be fully faithful.

ms. 98 CONJECTURED VIb-B029 – The localization rho is expected to be left adjoint to i.

ms. 105 FALSE VIb-B049 – The source attributes $(x,c) \mapsto (x, 1_{f(x)}, c)$ to i_{CX} and $(x,c) \mapsto (x, c, 1_{\beta(c)})$ to $C(i_X)$, respectively.

ms. 108 FALSE VIb-B057 – Footnote59 asserts that the stability hypotheses on Fib are used only in II and only in case A/A-prime.

ms. 115 FALSE VIb-B085 – The editorial correction inserts an outer opposite in $\mathrm{HOT}^{o}_{W}(S) = \mathrm{HOT}_W(S^{op})^{op}$.

ms. 120 FALSE VIb-C009 – The path replacement $C_S(X)$ represents the same object of $\mathrm{HOT}_W(S)$ as arbitrary $X \to S$.

ms. 120 FALSE VIb-C011 – Corollary 2, second isomorphism: $f^* q_S(X) \cong q_{S'}(C_S(X) \times_S S')$ for arbitrary $X \to S$.

ms. 120 OPEN VIb-C012 – Which changes of base $f : S' \to S$ allow strict pullback to calculate derived restriction on every $X \to S$?

ms. 122 CONJECTURED VIb-C016 – Proper $f : S' \to S$ induces a strict pullback functor preserving W^{d}_S.

ms. 122 CONJECTURED VIb-C017 – Smooth $f : S' \to S$ induces a strict pullback functor preserving W^{g}_S.

ms. 123 OPEN VIb-C019 – Is preservation of right-fine weak equivalences by pullback equivalent to W-properness of the base functor?

ms. 124 OPEN VIb-C024 – If an arrow of a chosen category over S' becomes invertible in its coarse localization, must it belong to $W_{S'}$?

ms. 124 CONJECTURED VIb-C025 – For proper change of base, the same comparison criterion can be formulated on all of Cat/S.

ms. 126 FALSE VIb-C028 – An arrow invertible after an arbitrary localization necessarily belonged to the original class of arrows being inverted.

ms. 126 OPEN VIb-C031 – Does a Hot-fibration which is not proper furnish a pullback that fails to preserve the right-fine class on all categories over the base?

ms. 127 OPEN VIb-C032 – Are there functors other than Hot-fibrations or W-fibrations for which restriction commutes with local-constant reflection?

ms. 128 CONJECTURED VIb-C035 – The varying-base assignment $S \mapsto \mathrm{HOT}^{\mathrm{lc}}_W(S)$ is not expected to be a derivator.

ms. 128 OPEN VIb-C036 – Do restriction functors between locally constant categories have left and right adjoints?

ms. 130 OPEN VIb-C042 – For an arbitrary relative category (M,W), are isomorphisms in localized diagram categories detected by evaluation?

ms. 130–132 OPEN VIb-C043 – Does $\mathrm{HOT}_W(\coprod_i S_i) \to \prod_i \mathrm{HOT}_W(S_i)$ remain an equivalence for arbitrary small index sets?

ms. 131 OPEN VIb-C045 – For arbitrary relative categories (F_i,W_i), is $(\prod_i F_i)[(\prod_i W_i)^{-1}] \to \prod_i (F_i[W_i^{-1}])$ an equivalence?

ms. 132 CONJECTURED VIb-C048 – Uniform short presentations of morphisms could prove the infinite coproduct axiom for HOT.

ms. 137 OPEN VIb-C061 – Does a Hot-fibration f ensure that direct image preserves locally constant types?

ms. 142 FALSE VIb-C070 – Pullback of the right-fine replacement map i_X along arbitrary S-prime→S is again right-fine.

ms. 142–143 FALSE VIb-C071 – The counit may always be defined by projection composed with the inverse of the base-changed replacement map.

ms. 142 FALSE VIc-A007 – Question: does the pullback i_X times_S id_{S′}:X times_S S′ -> Phi_S(X) times_S S′ necessarily belong to W_S^d?

ms. 142 FALSE VIc-A008 – Proposed formula: beta_X=pr_1^X (i_X times_S id_{S′})^{-1} defines the counit at every representative X over S.

VI-c · Chapter VI, part 3 of 3, manuscript pages 146–204

ms. 151 FALSE VIc-A021 – Proposed product formula: f_!f^*(xi)=[S′/S] times_S xi for every base functor f and every coefficient xi.

ms. 152 FALSE VIc-A025 – False Corollary1: if only one of X,Y is smooth, then [X times_S Y] is necessarily the product [X] times_S [Y].

ms. 152 FALSE VIc-A026 – Every smooth X -> S induces by pullback a functor Cat/S -> Cat/X preserving all right-fine equivalences.

ms. 159 CONJECTURED VIc-A052 – The strengthened Der3b′_2 says that every f in W induces an equivalence f_0^*:HOT_W^lc(S)->HOT_W^lc(S′).

ms. 159 CONJECTURED VIc-A054 – Full faithfulness of f_0^* is expected to follow from the enhanced cohomological equivalence condition by applying internal Hom and cohomological direct images.

ms. 159 conjectured VIc-A055 – The construction of the right adjoints f_* and of internal Hom is expected to proceed together.

ms. 163 conjectured VIc-B011 – Properness should be equivalent to preservation of the right-fine localizers by pullback.

ms. 172–173 conjectured VIc-B034 – There may exist substantial homotopy theories HOT_W for classes W strictly smaller than W∞ while W(1,2,3) hold.

ms. 180–181 false VIc-B065 – Intermediate full subcategories between Parf_omega S and Fib_W S might yield distinct fine localizations.

ms. 184 open VIc-C010 – Does the old restricted W(4b′) alone force $\lambda : \mathrm{HOT}^{lc}_{W}(S) \to \mathrm{HOT}^{lc!}_{W}(S)$ to be an equivalence?

ms. 185 conjectured VIc-C015 – The new Cartesian fibre-detection axiom should imply the strongest W(4a) preservation condition, at least for the strong saturation of W.

ms. 186 open VIc-C019 – Do $\mathrm{Parf}_W S \hookrightarrow \mathrm{Liss}_{0,W} S$ and $\mathrm{Parf}_W S \hookrightarrow \mathrm{Prop}_{0,W} S$ induce equivalences after inverting fibrewise W-equivalences, without W(4b)?

ms. 186 open VIc-C020 – The same fine-localization comparison is asked with $\mathrm{Parf}_\omega S$ in place of $\mathrm{Parf}_W S$.

ms. 186 open VIc-C022 – Does $(\mathrm{Bifib} S)[(W_S^f)^{-1}] \to (\mathrm{Fib}_W S)[(W_S^f)^{-1}]$ become essentially surjective, or an equivalence, even assuming W(4a)?

ms. 187 open VIc-C024 – Does Phi carry W-proper objects, or proper weakly W-fibred objects, to W-proper objects?

ms. 189 conjectured VIc-C028 – If both arrows in the span are open embeddings, or both closed embeddings, is the total category W-equivalent to the ordinary amalgamated sum $X_a \amalg_{X_0} X_b$?

ms. 201 conjectured VIc-C077 – If X is weakly W-fibred, then $[X \times_S Y] \to [X] \times_S [Y]$ should be invertible for every Y, without smoothness of Y.

ms. 202 false VIc-C083 – The general product formula should fail if neither X is W-proper nor Y W-smooth, even when X is weakly W-fibred.

VII-a · Chapter VII, part 1 of 3, manuscript pages 1–57

ms. 4-5 false VIIa-A013 – As printed: composable chains correspond to full simplex subcategories, and maximal chains of length i correspond exactly to object-injective functors $\Delta_i \to I$.

ms. 5 false VIIa-A018 – Proposition 1(b), literally: every endofunctor of an interval fixing both endpoints is the identity.

ms. 10 false VIIa-A031 – Proposition 3 as printed: with $A = (I/s) \setminus \{s\}$ and $B = (s\backslash I) \setminus \{s\}$, s is critical iff $I \setminus \{s\} = A \amalg B$.

ms. 11 false VIIa-A037 – Footnote 4, literally: every subcategory of I which is an interval is necessarily full.

ms. 13 false VIIa-A046 – As printed, the length n of the path is $\mathrm{card}\, I$.

ms. 33 false VIIa.B030 – A constant functor at every non-endpoint vertex of a target interval factors through exactly two critical intervals.

ms. 34 false VIIa.B033 – For increasing f, the full subcategory on the image critical vertices equals the ambient integer interval [f(s_0),f(s_r)].

ms. 36 false VIIa.B046 – The global source critical intervals contained in f^{-1}(J') are exactly all critical intervals of the preimage.

ms. 42 FALSE VIIa-C009 – Each target transition segment [i-1,i] equals the unique image block [t_{j-1},t_j] which crosses it.

ms. 45 FALSE VIIa-C017 – The object map is constant on every integer-connected component of the set of vertices incident to a collapsed source transition.

ms. 47 FALSE VIIa-C030 – The printed object-map table sends the third fibre block to l_2 and its general block to l_i.

ms. 50 FALSE VIIa-C036 – The same object concatenation extends to a bifunctor $\underline{\mathrm{Typ}} \times \underline{\mathrm{Typ}} \to \underline{\mathrm{Typ}}$, where Typ has all functors of interval categories.

VII-b · Chapter VII, part 2 of 3, manuscript pages 58–117

ms. 60 FALSE VIIb-A032 – The parenthetical restriction of the possibility of assigning an X-morphism to a path to type Δ_+ alone is too narrow.

ms. 63 FALSE VIIb-A040 – The displayed uncorrected map from a constant a-path to $(b \leftarrow a \rightarrow b)$ is a map in $\underline{Ch}_{-+}(b,b)$.

ms. 69 FALSE VIIb-A055 – An equality established only in the groupoid completion Pi(X) implies the needed equality in the relative localization Pi_Sigma(X).

ms. 76 FALSE VIIb-B012 – For a word with r alternating runs beginning with sign epsilon, its last run has sign $(-1)^r\varepsilon$.

ms. 77 FALSE VIIb-B015 – The concatenated interval $I_{\tau\tau'}$ is the pushout of I_τ and $I_{\tau'}$ over their two-element endpoint category $\{0,1\}$.

ms. 79–80 OPEN VIIb-B019 – Does the fibrewise/cartesian construction extend to a functor on the total ordinary path categories?

ms. 85 FALSE VIIb-B034 – The collapsing remainder in the alpha-th source run has type $\Delta_{\varepsilon_\alpha}^{l_{\alpha-1}}$.

ms. 86 FALSE VIIb-B036 – The quickest map is a terminal object because it is numerically ahead of every other map.

ms. 86 CONJECTURED VIIb-B037 – The quickest map is the greatest admissible map for pointwise numerical order.

ms. 86 OPEN VIIb-B038 – Is every nonempty increasing endpoint-preserving interval mapping category contractible?

ms. 93 FALSE VIIb-B052 – Reversal gives an isomorphism $P(\tau,\tau') \to P((\tau')^o,\tau^o)$.

ms. 90 FALSE VIIb-B057 – Applying the endpoint-fixed induction to the subinterval $[1,n-1] \subseteq [0,n]$ reduces a map whose active edges have one sign and include the first and last edges to a map with only those two active edges.

ms. 90 FALSE VIIb-B058 – A first source run that is not a single edge has length2.

ms. 102 FALSE VIIb-C024 – The displayed transition $C_{t_n} \to C_{t_{n-1}}$ has the variance required by the sequential direct system.

ms. 102–103 OPEN VIIb-C026 – Compare the total category C, the various sequential colimits C_∞, and the ind-object H_C, in Cat hot and in Hot; determine dependence on the chosen cofinal chain.

ms. 103 FALSE VIIb-C028 – The thin reflection of the slice satisfies $(T/t_0)_o = P/t_0 = \{t : t \le t_0\}$.

ms. 103 FALSE VIIb-C029 – Under only the stated preorder filtration, passage from T to T/t_0 automatically gives another filtered indexing preorder and leaves the same ind-object construction available.

ms. 103–104 conjectured VIIb-C030 – If the total category were canonically recovered from the ind-object, restriction to a preorder-cofinal chain would preserve its homotopy type.

ms. 104–105 open VIIb-C031 – For a left-cofinal base change $\alpha : T' \to T$ preserving the indicated ind-diagram, is $C \times_T T' \to C$ a Cat-hot isomorphism or at least a weak equivalence of nerves?

ms. 107 open VIIb-C040 – Are the sets $\mathrm{Cat\,hot}(S, C)$ or $\mathrm{Hot}(S, C)$ naturally identified with $H(S)$ beyond S=e?

ms. 107 conjectured VIIb-C041 – An isomorphism on the preceding component sets need not extend to higher homotopy groups or to a Hot equivalence of the compared objects.

ms. 112–113 conjectured VIIb-C053 – For the motivating path fibration, Grothendieck suspects that $C_\infty \to C$ is generally not a Hot isomorphism.

ms. 113 false VIIb-C054 – A loop-space multiplication cannot in general be represented by a strictly associative simplicial monoid, so such strict multiplication would obstruct the proposed comparison.

ms. 115 false VIIb-C060 – For an arbitrary chosen cofinal sequence of types, concatenation has target stage n+m: $P_{t_n}(a, b) \times P_{t_m}(b, c) \to P_{t_{n+m}}(a, c)$.

ms. 108–109 open VIIc-A003 – For T=N^op, does the canonical localization C→colim_n C_n induce a weak equivalence?

ms. 109 open VIIc-A006 – Is the canonical morphism C_∞→C always an isomorphism in Hot?

ms. 112–113 conjectured VIIc-A015 – The comparison C_∞→Ch_Σ(X;a,b) is conjectured not to be a weak equivalence in general.

ms. 113 false VIIc-A016 – The based loop object Ω(BX,a) cannot in general be modeled by a strictly associative simplicial monoid.

ms. 114 false VIIc-A020 – The object of the finite-test presheaf category associated with C_∞ equals the filtered colimit of the stage-representable presheaves.

VII-c · Chapter VII, part 3 of 3, manuscript pages 118–171

ms. 117–118 false VIIc-A029 – Every natural transformation between cofinal sequences induces a weak equivalence C_∞(t′)→C_∞(t) under the general section10 hypotheses.

ms. 119 open VIIc-A034 – Does the induced Hot morphism depend only on the endpoints t,t′ and not on the chosen natural transformation?

ms. 119 false VIIc-A035 – On finite-test presheaves every comparison is the canonical identification with the presheaf associated to H_T.

ms. 120 false VIIc-A038 – The map colim_n Hom_Hot(ξ,C_n)→Hom_Hot(ξ,C_∞) is bijective for every ξ∈Hot.

ms. 121 false VIIc-A042 – Bijectivity on all unpointed finite homotopy test sets implies that a map is an isomorphism in Hot.

ms. 121 false VIIc-A043 – Hom_Hot(Y,−) commutes with filtered colimits whenever Y is a finite category.

ms. 121,124 open VIIc-A046 – Are all comparison functors invertible already in Cat hot?

ms. 123 false VIIc-A050 – The ind-identification implies that all induced comparison maps on C_∞ are isomorphisms in Hot.

ms. 123 false VIIc-A053 – The restriction H_0 of H to the source's finite-category test subcategory is represented by the presheaf h(C_∞).

ms. 124–125 OPEN VIIc-A056 – Does a binary path composition C_∞(a,b)×C_∞(b,c)→C_∞(a,c) exist canonically in Hot?

ms. 126 FALSE VIIc-A063 – Two unrelated interval types can be compared by their categorical product τ_0×τ'_0 as another interval type.

ms. 127 OPEN VIIc-A065 – Is the constructed binary operation associative in Hot?

ms. 127 OPEN VIIc-A066 – Is Hot→widehat(Hot_0) faithful, or even fully faithful?

ms. 127 OPEN VIIc-A069 – Are the canonical maps H→C_∞ epimorphisms in Ind Hot, and do they remain so after products?

ms. 128 CONJECTURED VIIc-A072 – For a non-Kan simplicial set K, the strict endpoint fibres of K^{Δ^1}→K×K need not be the derived path spaces.

ms. 128 CONJECTURED VIIc-A073 – A correct simple path construction for finite simplicial sets would imply a finite computation of all their homotopy groups.

ms. 128 CONJECTURED VIIc-A074 – For Σ=Fl(X), a weak equivalence X→Xbar should induce Ch_∞(X;a,b)≃Ch_∞(Xbar;a,b).

ms. 129 CONJECTURED VIIc-B002 – The external-Hom parameter functor F_{a,b}(Y)=Hom_{D(Y)}(a_Y,b_Y) should send nerve weak equivalences of Y to bijections.

ms. 129 FALSE VIIc-B005 – The source infers under its locality hypothesis that the finite-parameter evaluation of H(a,b) is [Y,Ch_{infty,Sigma}(a,b)] in Hot, using finite-category compactness.

ms. 130 CONJECTURED VIIc-B006 – A nerve weak equivalence f:X→Xprime should induce weak equivalences Ch_infty(X;a,b)→Ch_infty(Xprime;fa,fb), with all arrows allowed.

ms. 130 FALSE VIIc-B009 – For Thomason-fibrant X, fixed-endpoint paths of type Delta_+ might suffice to model Ch_infty(X;a,b).

ms. 130 OPEN VIIc-B011 – Is Hot→Hot_0^wedge faithful, so that finite tests would prove associativity?

ms. 132 CONJECTURED VIIc-B018 – Noncontractible components of Omega(X,a) would make the invariance condition almost never hold.

ms. 133 FALSE VIIc-B022 – For a fixed finite circle category Y, degrees realized by functors Y→Ch_infty(X;a,a) are bounded by the number of its arrows, hence by four in the displayed example.

ms. 133 FALSE VIIc-B023 – Footnote28 proposes the sharper bound -2≤degree≤2 for the displayed four-arrow circle.

ms. 133 CONJECTURED VIIc-B024 – By enlarging alternating circle models Y_n, one can realize degrees of arbitrarily large magnitude.

ms. 134 FALSE VIIc-B026 – The proposed bound on degrees proves that pi_0 Fun(Y_2,Omega)→pi_0 Fun(Y_n,Omega) is not bijective.

ms. 134 CONJECTURED VIIc-B027 – The same finite-size obstruction should apply whenever higher homotopy groups of X provide infinitely many classes.

ms. 134 CONJECTURED VIIc-B028 – Products of alternating intervals with their boundary identified should provide categorical models of S^i.

ms. 134 FALSE VIIc-B029 – A fixed finite categorical sphere Y_n should realize only a bounded subset of pi_i Omega(X,a).

ms. 134–135 CONJECTURED VIIc-B030 – Every homotopy class should be represented after choosing a sufficiently large categorical sphere and a degree-one map to a smaller model.

ms. 135 FALSE VIIc-B034 – The absolute comparison already fails for Y=[1].

ms. 136 FALSE VIIc-B035 – For any category Y and Thomason-fibrant C, BFun(Y,C) represents RMap(BY,BC).

ms. 136 FALSE VIIc-B036 – If C is Thomason-fibrant then Fun(Y,C) is Thomason-fibrant for arbitrary Y.

ms. 136 FALSE VIIc-B037 – Footnote29 requires Thomason cofibrations to remain cofibrations after product with arbitrary Y.

ms. 136 FALSE VIIc-B038 – For fibrant C and arbitrary Z,Y, pi_0 Fun(Z×Y,C) computes [B(Z×Y),BC].

ms. 136 CONJECTURED VIIc-B040 – Categorical path objects should have the correct homotopy type without first making X Thomason-fibrant.

ms. 139 FALSE VIIc-B050 – For every f, bar f in this factorization should be both fibrant and a weak equivalence.

ms. 139 FALSE VIIc-B051 – The map alpha should be a Thomason cofibration.

ms. 139 FALSE VIIc-B052 – The map bar f is expected to be fibrant in the model-category sense.

ms. 139 CONJECTURED VIIc-B053 – Item1: p:Ch_infty(X)→X×X should be smooth, proper and a HOT-fibration.

ms. 139 CONJECTURED VIIc-B055 – Item2 additionally asserts contractible fibres for sigma and beta, hence trivial HOT-fibrations.

ms. 139 CONJECTURED VIIc-B056 – Item3: bar f:C(f)→X should be smooth, proper and a HOT-fibration for every f.

ms. 140–141 CONJECTURED VIIc-B062 – For a path c:a→b, transport should give an isomorphism bar c:hot(C(f)_a)→hot(C(f)_b).

ms. 140–141 CONJECTURED VIIc-B063 – Transport should be compatible with concatenation of base paths.

ms. 141 CONJECTURED VIIc-B066 – Transport should depend only on the homotopy class of c in the path category.

ms. 141 CONJECTURED VIIc-B067 – The fibre homotopy types and transport should define a functor Pi(X)→Hot.

ms. 141 CONJECTURED VIIc-B068 – The monodromy construction should apply to every HOT-fibration, not just this mapping-path replacement.

ms. 141 CONJECTURED VIIc-B069 – For a D-fibration and coefficient A∈D(e), fibrewise D-homology and D-cohomology should give two Pi(X)-functors to D(e).

ms. 141–142 OPEN VIIc-B070 – Footnotes33–34 ask for the effect of transport on components of the fibres.

ms. 142 CONJECTURED VIIc-B072 – The nerve of Ch_infty(X) over NX×NX should be weakly equivalent in the slice to a simplicial path object.

ms. 142 CONJECTURED VIIc-B073 – The fixed-endpoint categorical path categories should have canonically the same homotopy types as simplicial path spaces.

ms. 142 OPEN VIIc-B074 – Does a functorial classical simplicial path object exist for every simplicial set?

ms. 145 FALSE VIIc-B084 – The significant edge indices of the t_n stage are [-2i+1,2i], with 4i edges, as printed.

ms. 146 FALSE VIIc-B088 – For even n, tau_{n,m}=(+-)^{(m-n)/2} if m is even, and the printed (+-)^{(m-n)/2-1}+ if m is odd.

ms. 147 FALSE VIIc-B089 – For odd n, tau_{n,m}=(-+)^{(m-n)/2} if m is odd, and the printed (-+)^{(m-n)/2-1}- if m is even.

ms. 147 FALSE VIIc-B090 – For n<m the initial sign is (-1)^n and the terminal sign is printed as (-1)^m.

ms. 150 OPEN VIIc-C004 – Is the restricted Yoneda functor Hot → $\mathrm{Hot}_0^{\wedge}$ faithful, so that equality of the two finite-test images implies $T^2 = 1$?

ms. 151 CONJECTURED VIIc-C016 – The finite-stage composition operations should make the comparison square commute on associated ind-objects.

ms. 152 FALSE VIIc-C017 – If the comma transport becomes an isomorphism in the unbased finite-test presheaf category, it must be an isomorphism in Hot.

ms. 153 CONJECTURED VIIc-C023 – The mapping-path projection $\bar{f} : C(f) \to X$ should be smooth, proper, and a homotopy fibration.

ms. 155 CONJECTURED VIIc-C031 – The finite-stage v_* are compatible up to categorical homotopy and induce a morphism of ind-objects in Cat hot, then a map of finite-test presheaves.

ms. 155 CONJECTURED VIIc-C033 – The stagewise v^* likewise induce an ind-morphism and hence a map on finite-test presheaves.

ms. 156 CONJECTURED VIIc-C034 – The two ind-morphisms v_*, v^* are inverse, because the stagewise backtracking operations are homotopic to the identity.

ms. 156 CONJECTURED VIIc-C035 – The ind-object comparison square with the comma transport $\bar{v}$ commutes.

ms. 156 FALSE VIIc-C037 – Invertibility of $\bar{v}$ after restriction to finite unbased tests implies its invertibility in Hot.

ms. 156 OPEN VIIc-C038 – $\bar{f}$ is a trivial homotopy fibration if and only if f is a weak equivalence; a categorical long exact sequence seems necessary to prove it.

ms. 157 CONJECTURED VIIc-C039 – The canonical maps $\underline{\mathrm{Ch}}_\infty(X) \to \underline{\mathrm{Ch}}(X)$ and $\underline{\mathrm{Ch}}_\infty(X; a, b) \to \underline{\mathrm{Ch}}(X; a, b)$ in Hot are isomorphisms.

ms. 157 CONJECTURED VIIc-C040 – The total comparison is an isomorphism in the relative homotopy category over $X \times X$, giving the fixed-endpoint comparisons.

ms. 157 FALSE VIIc-C042 – $\underline{\mathrm{Ch}}(X) \to X \times X$ is both smooth and proper.

ms. 158 FALSE VIIc-C045 – $\mathcal{C}_{\mathbf{N}^o} \to X \times X$ is smooth and proper.

ms. 161 FALSE VIIc-C058 – Smoothness of $\underline{\mathrm{Ch}}(X^o) \to X^o \times X^o$ implies properness of $\underline{\mathrm{Ch}}(X) \to X \times X$.

ms. 166 FALSE VIIc-C073 – The composite $j'i' : X \to \mathcal{C}_{\mathbf{N}^o}$ is aspherical.

ms. 168 FALSE VIIc-C078 – The padded formula $\varphi(c', w') = (\widetilde{c}', \widetilde{w}')$ defines a functor from the sequential lift category to the sequential fixed-endpoint slice.

ms. 169 FALSE VIIc-C081 – The proposed sequential endofunctor $\psi\varphi$ admits a natural transformation to the identity.

ms. 169 FALSE VIIc-C083 – Because the system of interval types is self-opposite, smoothness for X^o proves properness of $\mathcal{C}_{\mathbf{N}^o}(X) \to X \times X$.

VIII-X · Chapter VIII, manuscript pages 1–9; Chapter IX, manuscript pages 1–25; Chapter X, manuscript pages 1–5

ms. VIII:4 CONJECTURED VIII-016 – For X→S→T and every groupoid fibration Γ on X, (fp)_!Γ≃f_!p_!Γ, naturally and coherently.

ms. VIII:7 CONJECTURED VIII-024 – For a cartesian square with invertible γ, the comparison f′_!q*G→p*f_!G is an equivalence if f is 1-smooth or p is 1-proper.

ms. VIII:7 FALSE VIII-029 – For i∈{0,1,2}, i-faithfulness of f* is equivalent to i-faithfulness of Γ(T,H)→Γ(S,f*H) for every H, taking only G=e_T.

ms. VIII:8 CONJECTURED VIII-036 – If f is (-1)-proper and (-1)-aspherical, or (-1)-smooth and (-1)-coaspherical, then f* is 0-faithful.

ms. VIII:8 CONJECTURED VIII-037 – If f is 0-proper and 0-aspherical, or 0-smooth and 0-coaspherical, then f* is 1-faithful.

ms. VIII:8 CONJECTURED VIII-038 – If f is 1-proper and 1-aspherical, or 1-smooth and 1-coaspherical, then f* is 2-faithful.

ms. VIII:8–9 CONJECTURED VIII-040 – Under either hypothesis of Theorem 3 with i=2, G on S is in the essential image of f* exactly when G restricted to each strict fibre S_t is equivalent to a constant groupoid fibration.

ms. VIII:9 FALSE VIII-041 – For 1-connected Z, a groupoid fibration on Z is constant up to fibred equivalence if and only if every transport functor is an equivalence.

ms. VIII:9 FALSE VIII-043 – Under Theorem 3 with i=2, G descends along f if and only if every f-vertical arrow induces an equivalence on its fibres.

ms. IX:4 FALSE IX-011 – Arbitrary arrows u:a-prime->a and v:b->b-prime induce an isomorphism of Hom objects.

ms. IX:4 FALSE IX-013 – The displayed Ind Cat hot bifunctor has domain M_Pi x M_Pi.

ms. IX:9-10 OPEN IX-R01 – For the full subcategory Hot_0 of types of finite categories, is the restricted Yoneda functor psi:Hot -> PSh(Hot_0) fully faithful (and likewise Ind psi)?

ms. IX:13 OPEN IX-037 – Ch composition is associative in Hot.

ms. IX:14 CONJECTURED IX-040 – Quillen pi_1(f,g) agrees with arrows between f and g in the fundamental groupoid of Ch_infty(a,b).

ms. IX:15 CONJECTURED IX-041 – The homotopy groupoid construction extends naturally from actual arrows to all stabilized zigzags.

ms. IX:15 OPEN IX-044 – The path compositions should lift to pointed Hom objects with associative composition and units.

ms. IX:16 FALSE IX-046 – There are canonical arrows in both directions between these zero representatives, identity at every vertex except degree zero.

ms. IX:17 CONJECTURED IX-049 – The resulting exact path pairings are associative in the pointed homotopy category and perhaps in pointed Cat hot.

ms. IX:17 FALSE IX-050 – Cartesian pointed spaces instantiate the earlier monoidal axiom with pi_0=Hom(unit,-).

ms. IX:17 FALSE IX-051 – Forgetting basepoints preserves the corrected monoidal product.

ms. IX:17 CONJECTURED IX-052 – Pointed CH should exist in Ind Hot_bullet and Ind Cat hot_bullet.

ms. IX:18 FALSE IX-054 – The displayed truncated path a->0<-b represents the desired distinguished element.

ms. IX:18 OPEN IX-055 – The zero object should remain a zero object in M[W^{-1}].

ms. IX:18 OPEN IX-056 – Find conditions under which localization preserves finite coproducts and finite products.

ms. IX:18 CONJECTURED IX-059 – An additional five-lemma-type condition may be needed for the additive localization.

ms. IX:19 CONJECTURED IX-061 – The external Hom of an additive relative category should lift to D^{<=0}(k-Mod).

ms. IX:19 conjectured IX-065 – Derived Hom objects should admit associative composition over derived tensor and units.

ms. IX:21 conjectured IX-070 – A full theory of strong derived k-bilinear Hom composition is expected.

ms. IX:21 false IX-071 – pi_1(a,b) is written pi_1(a,b;0_a,0_b).

ms. IX:21 conjectured IX-072 – Quillen pi_1(a,b) is canonically pi_1 of the pointed Ch_infty(a,b).

ms. IX:22 conjectured IX-080 – The two formulations of test (b) are equivalent up to minor qualifications.

ms. IX:22 conjectured IX-081 – Tests (a) and (b) are a decisive criterion for a homotopy theory in M.

ms. IX:23 false IX-082 – The stated tests cannot hold for a finite M except in the trivial cases.

ms. IX:23 false IX-083 – If M is empty, its localization is equivalent to the point.

ms. IX:23 conjectured IX-084 – Test (c) asks for Homext(Sigma a,b)=Homext(a,Omega b)=Omega Homext(a,b) as pointed homotopy types.

ms. IX:23 conjectured IX-086 – External Hom preserves finite products in the second variable and sends finite coproducts in the first variable to products.

ms. IX:23 conjectured IX-087 – Omega should extend to a left exact endomorphism of the derivator, and Sigma dually.

ms. IX:23 conjectured IX-088 – Test (b) is necessary for the loop-space equivalences in test (c).

ms. IX:24 conjectured IX-090 – The essential condition on the path factorization is that p be a fibration in a suitable sense.

ms. IX:25 open IX-091 – A cofibration condition on i may be useful; fibrancy of S is queried.

ms. IX:25 open IX-093 – The constructed object should represent pi_1 Ch_infty(T,S) naturally in T after localization.

ms. X:3 conjectured X022 – The categorical assertions of Chapter I that use only weak equivalences and their formal properties should extend from W_D to abstract localizers W.

ms. X:3 open X023 – Under suitable conditions on W, the pointwise localization A |-> Cat^{A^op}[(W^{A^op})^{-1}] should be a derivator.

ms. X:3 open X024 – One should be able to realize a given localizer W as W_D for a derivator constructed from (Cat,W).

ms. X:5 conjectured X038 – The derivators useful in practice seem to satisfy La.

ms. X:5 open X042 – Do Lb and Lc hold for every W_D under consideration, and what are their concrete conditions on W?

XI-XIIa · Chapter XI, manuscript pages 127–136; Chapter XII, sections 1–4, manuscript pages 1–58

ms. XI:129 false XI-017 – For an arbitrary locally constant nonabelian F, lifting $\eta \in$H0(Y,R^1f_*F) is governed by a fixed-band obstruction in H2(Y,f_*F), as written.

ms. XII:1 open XII-I-001 – Find intrinsic conditions on W implying W$\subseteq$ W_∞, without defining those conditions through W_∞.

ms. XII:5 OPEN XII-I-028 – Are Ch(X)→ X× X and Ch_∞(X)→ X× X W-fibrations for a general W?

ms. XII:5 OPEN XII-I-032 – Does the left test alone imply preservation over W-aspherical bases without additional axioms?

ms. XII:13 OPEN XII-I-057 – Do W(1)-W(5) already imply W=W_∞, or is an additional descent/limit axiom necessary?

ms. XII:14 CONJECTURED XII-I-071 – Even the strongest W(4), with W(1)-W(3) and W(5), probably does not force W=W_infty.

ms. XII:15 CONJECTURED XII-I-076 – W(1)-W(6), using the weakest fibre axiom, imply W=W_infty.

ms. XII:16 OPEN XII-I-077 – Perhaps closure under retracts must be added to W(1) for the equality conjecture.

ms. XII:17 FALSE XII-I-084 – The formula pi_n(F)=coker(pi_{n+1}(E)→ pi_{n+1}(B)) is asserted without excluding n=0.

ms. XII:18,20 FALSE XII-II-002 – W_D⊇W_infty and W(4b") imply W_D=W_infty without another stated qualification; the analogous inference is repeated for W in the HOT_W discussion.

ms. XII:19 FALSE XII-II-005 – The left/right conditions are the same as the earlier D-cohomological/D-homological fibrations.

ms. XII:19 CONJECTURED XII-II-007 – Every genuinely useful derivator/localizer should satisfy the indicated constancy condition.

ms. XII:20 OPEN XII-II-023 – Did the preceding construction and properties of f_! for HOT_W actually use the working assumption W_infty⊆W?

ms. XII:26 CONJECTURED XII-III-A-024 – Aspherical functors should be preserved by smooth base change, and coaspherical functors by proper base change.

ms. XII:36 FALSE XII-III-A-057 – It suffices, to define functorial covariant transport universally, to require only that the terminal-fibre inclusion in every pullback over [1] belongs to W.

ms. XII:36 FALSE XII-III-A-058 – The analogous initial-fibre edge-only condition suffices to define universal contravariant transport.

ms. XII:40 CONJECTURED XII-III-B-003 – Among the provisional fibration notions, only ultrafibrations appear likely to be stable under composition.

ms. XII:40 OPEN XII-III-B-005 – Find minimal hypotheses on W making the stronger fibration variants equivalent.

ms. XII:40 OPEN XII-III-B-006 – Does the interval endpoint condition a0 alone imply the remaining conditions for W∞?

ms. XII:40 CONJECTURED XII-III-B-008 – W-perfect⇒hot-strong W-fibration (circled implication).

ms. XII:40 CONJECTURED XII-III-B-009 – Footnote 48: the hot-strong condition should be equivalent to both the left and right fibration conditions.

ms. XII:42 OPEN XII-III-B-017 – If f is W-perfect and S categorically contractible, is X_s→X in W?

ms. XII:44 FALSE XII-III-B-025 – The first displayed transport is F∘f→F∘g for α:f→g.

ms. XII:45 FALSE XII-III-B-026 – The classifying functor F itself is 'in W fibre by fibre'.

ms. XII:46 CONJECTURED XII-III-B-032 – These results should use at most full W(2) rather than W(2 bis).

ms. XII:48 CONJECTURED XII-III-B-040 – The stronger complement: pullback of an arbitrary categorical homotopy equivalence along the family is a W-map.

ms. XII:54 OPEN XII-IV-011 – Does W(4c′) imply W(4c)?

ms. XII:54 OPEN XII-IV-012 – Does W(4c) imply W(4b)?

ms. XII:54 CONJECTURED XII-IV-014 – The weaker split test W(4b′) should suffice for the same conclusion.

ms. XII:54 CONJECTURED XII-IV-015 – W(4b″), perhaps with W(6 bis), should likewise suffice.

ms. XII:54 CONJECTURED XII-IV-017 – The equivalence should also include W(4b′) and W(4b″).

ms. XII:58 FALSE XII-IV-030 – Proposition 3: under W(4a), a strict Cartesian map of split fibrations with W-fibrant fibre maps is W-fibrant.

XIIb-a · Chapter XII, section 5, part 1 of 2, manuscript pages 59–122

ms. 59 FALSE XIIba-A-003 – With x<=y iff Hom_X(x,y) is nonempty and opens the lower sets, the source asserts x<=y iff x belongs to the closure of {y}.

ms. 61 FALSE XIIba-A-012 – The induced triple represents on all triples Y=(Y,V,S) the functor Hom(V,U) x Hom(S,T), as asserted in displayed (*).

ms. 61 FALSE XIIba-A-013 – The displayed unqualified functor-category version (**) of the same representability is an isomorphism.

ms. 76 OPEN XIIba-A-053 – Does W(7bis) alone imply that W-asphericity of the intersection and union forces W-asphericity of both pieces?

ms. 78 FALSE XIIba-A-058 – The ordinary weak homotopy equivalences W_infty satisfy the full axiom W(7).

ms. 79-80 FALSE XIIba-A-062 – Reverse excision is asserted to be a special property of HOT, while the dual derivator fails it.

ms. 94–97 OPEN XIIb-a-B035 – Does total W-asphericity of H imply total W-asphericity of U/H?

ms. 97–100 FALSE XIIb-a-B045 – Assuming W(7 bis), a union V=V′∪V″ of two sieves is claimed to be totally W-aspherical whenever V′,V″,V′∩V″ are totally W-aspherical, by preservation of the subobject square under f!.

ms. 98–100 FALSE XIIb-a-B047 – Under the standing W(7 bis) hypothesis, the assertion of Proposition 9(b) is repaired by categorical retractions V′→V′∩V″ and V″→V′∩V″.

ms. 98 FALSE XIIb-a-B048 – Under the same gluing hypothesis, the analogous union assertion is true for a pushout square of subpresheaves in an arbitrary presheaf category merely because the three smaller objects are totally W-aspherical.

ms. 98 FALSE XIIb-a-B049 – Under the same hypotheses, one of the two categorical retractions already suffices to imply the asserted total-asphericity conclusion.

ms. 99 FALSE XIIb-a-B051 – The existence of those categorical retractions implies that f! sends the square of the associated subterminal presheaves to a square of monomorphisms.

ms. 99 FALSE XIIb-a-B052 – The same retractions imply f!(V′∩V″)=f!V′∩f!V″.

ms. 99–100 FALSE XIIb-a-B053 – Consequently the four categories of elements of these Kan extensions form a Cartesian and cocartesian square of sieve inclusions.

ms. 100 FALSE XIIb-a-B054 – Assuming W(7 bis), the outgoing fork Ψ=(0→a,0→b) is totally W-aspherical.

ms. 100 FALSE XIIb-a-B055 – Assuming W(7 bis), every finite ordered category with an initial object is totally W-aspherical.

ms. 100 FALSE XIIb-a-B056 – A category is totally W-aspherical only if it has a final object.

ms. 103 OPEN XIIba-C005 – If Y is W_∞-aspherical, must $\underline{\mathrm{Ch}}(Y; y_0, -)$ be totally W_∞-aspherical?

ms. 104 OPEN XIIba-C009 – Can one similarly find a sieve pushout with $p \in W$ but $q \notin W$?

ms. 111 OPEN XIIba-C035 – Must a sieve that is a W-cofibration, or even a couniversal W-equivalence, be W-dwyerienne?

ms. 111 OPEN XIIba-C036 – Must such a sieve even satisfy the original Dwyer right-adjoint condition?

ms. 111 FALSE XIIba-C037 – The source asserts the converse to the W-dwyerienne criterion when the complementary category T is terminal.

ms. 111 FALSE XIIba-C038 – Under the cited gluing framework, i and all its changes of complementary category $T_1 \to T$ are W-cofibrations iff i is W-dwyerienne.

ms. 111–112 OPEN XIIba-C039 – Is there a useful Dwyer notion for arbitrary full inclusions which includes both the sieve and cosieve cases?

ms. 112 FALSE XIIba-C040 – The proof says that W-dwyerienne stability makes i' W-aspherical and in W.

ms. 113 OPEN XIIba-C045 – Are W-dwyerienne and totally W-dwyerienne inclusions stable under composition?

ms. 114 OPEN XIIba-C047 – Are strictly W-aspherical functors and totally W-aspherical functors stable under composition?

ms. 114 OPEN XIIba-C048 – Seek a class of sieve W-cofibrations stable under the endpoint pushout product with $\{0, 2n\} \to \Phi_n$, n>=2.

ms. 119 OPEN XIIba-C064 – Request: make the map $(\lambda_\alpha)_!$ in the preceding transition formula explicit.

ms. 114 (continued before 115) OPEN XIIbb-A001 – Find a class of sieve inclusions that are W-cofibrations and is closed under the endpoint pushout-product U×Phi_n union X×{0,2n} -> X×Phi_n for every n>=2.

XIIb-b · Chapter XII, section 5, part 2 of 2, manuscript pages 123–169

ms. 139 FALSE XIIb-b-B014 – The indexing category Gamma is the ordered square [1]x[1] with an initial object adjoined.

ms. 143 CONJECTURED XIIb-b-B025 – The canonical isomorphisms among the four expanded diagrams should form a transitive system.

ms. 144 CONJECTURED XIIb-b-B029 – For arbitrary diagram shapes the four expanded comparisons have the same canonical-isomorphism relations as in Proposition 14.

ms. 145–146 CONJECTURED XIIb-b-B033 – Can phi_{Q_0}:int_lis F->P fail to belong to W while there exists a strict cocone P->Y with composite phi_Q in W?

ms. 155 FALSE XIIbb-C009 – The arrows x_0→α_i(x_0) displayed in the source are the cartesian arrows in the smooth integral.

ms. 156 FALSE XIIbb-C013 – The displayed diamond A_0(u)→A_1(u),A_2(u)→(E/x_0)_u is a commutative W-cocartesian square to which W(7 bis) can be applied directly.

ms. 157 FALSE XIIbb-C021 – For x in any of the three strata, local W-smoothness of φ_Q is equivalent to local W-smoothness of f_i without any additional hypotheses on the other strata.

XIIc-a · Chapter XII, section 6, part 1 of 2, manuscript pages 171–234

ms. 172 OPEN A011 – Compare the homotopy-group theories defined using $\underline{\mathrm{Ch}}$ and $\underline{\mathrm{Ch}}_\infty$.

ms. 172 FALSE A012 – Theorem1: isomorphisms of homotopy groups through n, either at all basepoints or at one per component, are equivalent to isomorphisms of local-coefficient cohomology through n, with nonabelian H1.

ms. 172 FALSE A013 – Footnote112 suggests that the preceding converse already fails for n=2 unless source and target are simply connected.

ms. 174 OPEN A019 – Does a W-fibration E->X with a section canonically determine a functor X->Hot_{bullet,W} sending all arrows to isomorphisms?

ms. 176-177 FALSE A022 – Under the lower-degree homotopy and cohomology comparison hypotheses, pi_n(f) is an isomorphism iff H^n(f;F) is an isomorphism for all abelian local systems F.

ms. 177-178 OPEN A024 – For a homomorphism of the categorical loop monoids, a homotopy-group comparison at the units extends to every component.

ms. 179 FALSE A029 – Each arrow in the corrected implication chain is conjectured strict.

ms. 183 OPEN A042 – Does the comparison of the universal-cover E2 rows for q<=n suffice for the desired total-cohomology comparison through n?

ms. 187 FALSE A050 – The good fundamental localizer W_n for n-types is defined by a_n.

ms. 179 OPEN A062 – Footnote117 asks whether c_n implies b_n even for simply connected X,Y and conjectures counterexamples because only the Hurewicz composite from pi_nZ is seen.

ms. 194 OPEN B006 – In what sense are fixed-base or varying-base functorial factorizations unique?

ms. 196-197 OPEN B011 – Is there a construction-independent canonical comparison φ_C≅φ_C′, independent of using CC′ or C′C?

ms. 201 FALSE B022 – The existence of these common targets, or of the natural binary comparison maps, proves C_S is filtered.

ms. 202 CONJECTURED B024 – The three binary-to-ternary and three unary-to-ternary comparisons obtained by inserting coaugmentations agree.

ms. 202-203 CONJECTURED B025 – For any ordered partial product of a finite list of replacements there is a unique comparison to the full ordered product obtained by the permitted unit insertions and associativity maps.

ms. 203 OPEN B026 – Do these coherences imply that C_S is 1-connected?

ms. 204 FALSE B028 – The one-object category B_G of an arbitrary group G is a strict monoidal category of the indicated kind.

ms. 205 FALSE B032 – The functor labelled (*) is an equivalence.

ms. 208 FALSE B039 – Under only the assumptions of footnote 119, Fib_W is stable under retracts in the arrow category.

ms. 209 OPEN B042 – Construct inverse images on Ho_W^(S) for arbitrary base maps, coherently in S.

ms. 216 CONJECTURED B056 – Axioms a and b will usually be satisfied and proved together.

ms. 216 CONJECTURED B058 – For Cat, W(4a) supplies the fibre-localization comparison; footnote 122 suggests W(4b) should suffice.

ms. 217-218 OPEN B062 – Do axioms a and b alone imply the intermediate-full-subcategory assertion c?

ms. 218 CONJECTURED B065 – In practical cases verification of a should also establish c.

ms. 219 CONJECTURED C004 – For the main models of ordinary homotopy types one expects a natural notion of local isomorphism.

ms. 221 CONJECTURED C012 – A satisfactory theory for varying S should have $f^* : \mathrm{Ho}^{\mathcal{L}}_W(S) \to \mathrm{Ho}^{\mathcal{L}}_W(S')$ for every $f : S' \to S$.

ms. 221 CONJECTURED C013 – The localization of $\mathrm{Fib}_W(S)$ should identify the locally constant full subcategory of the finer relative theory, and usually not all of it.

ms. 222 OPEN C017 – The provisional definition does not visibly imply stability under all pullbacks.

ms. 222 OPEN C023 – Is $\widehat{\mathcal{L}} = \mathrm{Liss}_W$?

ms. 224-225 OPEN C030 – Does a smooth/proper complementarity occur in general models of homotopy types?

ms. 225 CONJECTURED C032 – The smooth/proper duality may extend to all presheaf models and to topological spaces.

ms. 225-226 CONJECTURED C033 – Proposed data: classes Liss and Prop containing isomorphisms and stable under composition and pullback, perhaps with $\mathrm{Liss} \cap \mathrm{Prop} \subseteq \mathrm{Fib}_W$.

ms. 226 CONJECTURED C038 – Proposed axiom (c): the two dual adjunction properties from ChapterVI theorem-scholie2 should be added.

ms. 226 OPEN C039 – Can the hypotheses for those adjunction formulas be simplified?

ms. 226-227 OPEN C040 – Construct $f_!$ and f_* for the locally constant, proper and smooth relative theories; $f_! \dashv f^*$ is expected to be comparatively direct.

ms. 227 OPEN C041 – Seek a cofiber theory dual to the homotopy-fibre theory for (Cat,W).

ms. 232-233 OPEN C057 – Does every ordinary pushout along a W-cofibration give a W-cocartesian square, in the earlier integration-based definition?

ms. 228 OPEN XIIcb-A001 – Every functor $f : X \to Y$ admits a factorization $X \xrightarrow{i_f} \widetilde{Y} \xrightarrow{p_f} Y$ with $i_f \in \mathrm{Cof}_W$ and $p_f \in W$.

ms. 232–233 OPEN XIIcb-A019 – Is every strict pushout along a W-cofibration W-cocartesian in the categorical-integral sense of XII, definition 3, ms.131?

XIIc-b · Chapter XII, section 6, part 2 of 2, manuscript pages 235–275

ms. 236 footnote 127 CONJECTURED XIIcb-A029 – The composition-and-cancellation statement should hold in every model setting with sufficient cofibrations.

ms. 238 FALSE XIIcb-A038 – For $\{1, 2, 1'\} \hookrightarrow V$, the slices at $0, 0'$ are annotated as Δ^1 and Φ.

ms. 240 conjectured XIIcb-B004 – For the proposed fibre theory, it should suffice that every W-fibration admit arbitrary pullbacks, rather than that every pair of maps admit a pullback.

ms. 240 conjectured XIIcb-B006 – The author suspects that the left factorization axiom gives the entire good relative fibre theory only if every X→ e is a W-fibration.

ms. 269–270 false XIIcb-C020 – The reduction of all three cube implications to the case where Y is the terminal square uses only the direct, pushout-stability half of W(7 bis).

ms. 272 open XIIcb-C028 – Does the factorization hypothesis alone suffice to construct the required theory when not every object is fibrant over the terminal object?

ms. 273 false XIIcb-C035 – The conservative-pushout axiom is equivalent to the conjunction of Cons1 and literal cartesian Cons2.

ms. 274 false XIIcb-C037 – Under only the theorem's general cofiber/factorization hypotheses, a terminal object and closure of aspherical objects under retracts, f_0,f_3∈ W imply f_1,f_2∈ W for every map of W-cocartesian squares.

ms. 274 false XIIcb-C038 – Corollary1: the universal map-of-squares implication f_0,f_3∈ W⇒f_1,f_2∈ W is equivalent to the object condition Z_0,Z_3 aspherical⇒Z_1,Z_2 aspherical, and to its special case Z_0=e.

XIIapp · Chapter XII, appendix, manuscript pages 1–18

ms. 1 false XIIapp-O002 – If b and c are weakly terminal and their categorical product b×c exists, BX is weakly contractible.

ms. 3 false XIIapp-O015 – H^p(T,F)=0 for every abelian presheaf F and every p≥2.

ms. 3 false XIIapp-O017 – H^2(T,F)=coker(F(i_1)-F(i_2)), with H^1 evidently intended in the displayed two-term formula.

ms. 4 false XIIapp-O021 – H^n(X_G;M)≃H^1(T,R^{n-1}f_*M)≃coker(H^{n-1}(G;M)→H^{n-1}(G²;M)).

ms. 4 false XIIapp-O025 – H²(BX_G;M)≃Hom_mon(G,M).

ms. 4 false XIIapp-O026 – X_G is 2-connected if and only if the universal abelian group of G is zero.

ms. 4 false XIIapp-O027 – If G is a nonzero abelian group, then X_G is not 2-connected.

ms. 4 open XIIapp-O029 – If y_b⊔_{y_a}y_c=1_X, must X at least be simply connected?

ms. 5 open XIIapp-O030 – Are totally W∞-aspherical categories precisely categories with a terminal object?

ms. 6 false XIIapp-O035 – X_G is simply connected, but not 2-connected whenever its universal abelian group is nontrivial.

ms. 5 false XIIapp-R001 – Every totally W∞-aspherical category, in the universal left-Kan-extension sense used here, has a terminal object.

ms. 5 conjectured XIIapp-R002 – The suspected terminal-object characterization would mean that the existing notion of open Dwyer immersion cannot be substantially improved.

ms. 9 false XIIapp-C007 – There is a retraction r:V→ D fixing D and sending b,c to a.

ms. 9 false XIIapp-C008 – The alleged retraction gives a natural transformation ir⇒ id_V and a categorical homotopy equivalence D→ V.

ms. 9 false XIIapp-C010 – BV has the homotopy type of S^1 and is not simply connected.

ms. 10 false XIIapp-C018 – The singleton-pushout condition can hold while Z is not simply connected.

ms. 11 FALSE XIIapp-C029 – The inclusion Z_0=(0_0⇉ a_0)→ Z is a homotopy equivalence by an evident retraction.

ms. 15 FALSE XIIapp-C062 – pi_1(V_0 prime) is isomorphic to Z.

ms. 15 FALSE XIIapp-C063 – V_0 prime is non-W-aspherical whenever W is contained in W_1, by its alleged nontrivial fundamental group.

ms. 17 OPEN XIIapp-G05 – The crossing arrows define a natural transformation $ip \Rightarrow jq$ and hence a homotopy-commutative square with vertices E, A, B, X; is it W-cocartesian?

ms. 17 OPEN XIIapp-G11 – Under $i \in W$ or $j \in W$ and W-asphericity of X, is the same square still W-cocartesian, in particular for $W = \mathbf{W}_\infty$?

ms. 17 FALSE XIIapp-G12 – For $W = \mathbf{W}_\infty$, under $i \in W$ (respectively $j \in W$) and W-asphericity of X, W-cocartesianness is equivalent to $q \in W$ (respectively $p \in W$).

ms. 17 OPEN XIIapp-G14 – If $A \simeq e$ and X, B are W-aspherical, must the attaching comma category $a\backslash B$ be W-aspherical, equivalently must j be W-coaspherical?

ms. 18 CONJECTURED XIIapp-G23 – The covering-descent argument should extend to higher homotopy degrees through n-gerbes.

ms. 18 CONJECTURED XIIapp-G26 – For every open–closed decomposition, $\varphi \in \mathbf{W}_\infty$.

ms. 18 CONJECTURED XIIapp-G27 – If $W \supseteq \mathbf{W}_\infty$ satisfies Loc (6a′), then the open–closed square is W-cocartesian.

XIII-a · Chapter XIII, part 1 of 2, manuscript pages 1–60

ms. 6 CONJECTURED XIIIa-A025 – The small object construction should require only pushouts and filtered, or ordinal, colimits instead of full cocompleteness.

ms. 6–7 CONJECTURED XIIIa-A026 – There should be a notion of accessible arrow class Φ implying existence of a set I⊆Φ with Φ⊆{}^□(I^□).

ms. 7 CONJECTURED XIIIa-A027 – The proposed accessible classes should be preserved by Φ↦Φ_* and Ψ↦Ψ^*.

ms. 7 CONJECTURED XIIIa-A028 – If a left/right lifting closed pair is accessible in a sense supplying a set of left generators, it has Quillen factorization.

ms. 12 CONJECTURED XIIIa-A052 – The weak axioms M0–M4,M′,M″ may be insufficient to obtain exact suspension and cosuspension sequences.

ms. 13 CONJECTURED XIIIa-A058 – The equality TC=C∩ W should imply the required exactness of W-cartesian squares and cosuspension sequences.

ms. 13 CONJECTURED XIIIa-A059 – The equality TF=F∩ W should imply the required exactness of W-cocartesian squares and suspension sequences.

ms. 14 CONJECTURED XIIIa-A061 – A relative category may admit distinct left and right pre-Q structures even when no full Quillen structure with those weak equivalences is available.

ms. 15 CONJECTURED XIIIa-A069 – Under accessibility of M, conditions (a),(a′),(a″),(b),(b′) are proposed to be equivalent.

ms. 15 CONJECTURED XIIIa-A071 – Theorem-scholie(3): a closed right pre-Q structure exists iff (b′) holds and A_W=(W^univ)^□∩ W_univ is right lifting closed.

ms. 16 CONJECTURED XIIIa-A072 – The preliminary hypotheses, accessibility of M, and the proposed equivalent recognition conditions are stable under (M,W)↦(M^I,W^I) for every small diagram category I.

ms. 16 OPEN XIIIa-A073 – Is the extra right-closedness condition in item 3 stable under passage to diagram categories?

ms. 16 OPEN XIIIa-A074 – Do the conditions in item 2 imply the extra condition in item 3, making the two criteria equivalent?

ms. 16 CONJECTURED XIIIa-A078 – (a′) should imply (a), after requiring lifting closedness of the quadruple.

ms. 17 FALSE XIIIa-A080 – The closure properties proved in item 1 imply that Cof_W and W^univ are left lifting closed.

ms. 19 CONJECTURED XIIIa-A085 – Filtered-colimit stability of W should make W accessible in a suitable sense, and then imply small generation of C∩ W when C is small-generated.

ms. 20 CONJECTURED XIIIa-A089 – Conjectural lemma(1), fibration version: if Φ is left lifting closed and Φ^□⊆ Fib_W, there exists a set Φ0⊆Φ such that Φ0^□⊆ Fib_W.

ms. 20 CONJECTURED XIIIa-A090 – Conjectural lemma(1), weak-equivalence version intended: if Φ is left lifting closed and Φ^□⊆ W, there exists a set Φ0⊆Φ such that Φ0^□⊆ W.

ms. 20 CONJECTURED XIIIa-A091 – Conjectural lemma(2): the intersection of two set-generated left lifting closed classes in a locally presentable category is again set-generated.

ms. 20 CONJECTURED XIIIa-A092 – An intrinsic class such as Fib_W, defined from an accessible W, should itself be accessible and yield the compactness lemma.

ms. 22 FALSE XIIIa-B003 – Part 1 of the conjectural theorem implies that Cof_W and W^univ are left lifting classes.

ms. 25 OPEN XIIIa-B016 – Does existence of some closed Quillen triple imply either the stronger closure conditions or the maximal compatibility A_W=(Cof_W)_*?

ms. 26 CONJECTURED XIIIa-B019 – Group I identifies weak Quillen existence, left exact weak Quillen existence, and the two orthogonality inclusions (*).

ms. 26 CONJECTURED XIIIa-B020 – Group II identifies right exact weak Quillen existence, condition (*) plus right closure of A_W, closed Quillen existence, and the displayed maximal-TC construction.

ms. 26 FALSE XIIIa-B021 – With TC=W^univ, F=TC_*, TF=F∩ W_univ, define C=(TF)_*.

ms. 26 CONJECTURED XIIIa-B022 – Group III identifies the maximal closed model candidate with (*) plus A_W=(Cof_W)_*.

ms. 26 OPEN XIIIa-B027 – Could the identity $\overline{W_{\mathrm{univ}}}$∩Fib_W=W_univ imply III⇔IV?

ms. 26 FALSE XIIIa-B029 – The displayed intersection (W^univ)_*∩$\overline{W_{\mathrm{univ}}}$ contains D→ e for discrete D without qualification.

ms. 27 FALSE XIIIa-B041 – If C,F,W are retract closed, left exactness is equivalent to right exactness for the original designated classes and forces all four classes closed.

ms. 28 FALSE XIIIa-B044 – The preceding saturation produces a structure de Quillen in the biexact sense introduced immediately afterwards.

ms. 30 CONJECTURED XIIIa-B060 – For arbitrary weak structures, right Q-homotopy is an equivalence relation whenever the target is fibrant, without exactness.

ms. 30 CONJECTURED XIIIa-B061 – On fibrant-cofibrant objects, the right and left homotopies coincide and are independent of the chosen cylinder, as suggested by Baues.

ms. 30–31 CONJECTURED XIIIa-B062 – Under left exactness, the fibrant-cofibrant quotient equivalent to Ho_W embeds as a fully faithful right adjoint to localization of the right-homotopy quotient of cofibrant objects.

ms. 32 OPEN XIIIa-B067 – Does left exactness also suffice for exactness of W-homotopy-cocartesian squares?

ms. 32 FALSE XIIIa-B068 – Exactness alone may fail to imply either cartesian or cocartesian homotopy exactness.

ms. 33–34 CONJECTURED XIIIa-B069 – If exact weak structures exist on (M,W) and on (M(Ψ),W(Ψ)) for the cospan indexing category, W-homotopy-cartesian squares are W-exact and give loop exact sequences.

ms. 33 CONJECTURED XIIIa-B071 – The dual exact-structure hypothesis for M(Φ) gives cocartesian exactness and pointed suspension exact sequences.

ms. 34 CONJECTURED XIIIa-B072 – For simultaneous homotopical algebra in all M(I), it suffices to have an exact weak Quillen structure on each relative diagram category.

ms. 37 OPEN XIIIa-B086 – For any arbitrary arrow class Φ, evaluation might send Φ(I)_* into Φ_*.

ms. 40 CONJECTURED XIIIa-B097 – The author expects filtered-colimit stability of W to be practically necessary for this strategy.

ms. 41 CONJECTURED XIIIa-C003 – Closure of W under all filtered colimits is proposed as the practical way to establish the required diagram factorizations.

ms. 42–43 CONJECTURED XIIIa-C011 – Condition a implies existence, for every small I, of a closed left-exact weak Quillen structure on Fun(I^op,M) with objectwise cofibrations.

ms. 42–43 CONJECTURED XIIIa-C012 – Condition a-prime implies existence of the prescribed injective structures for all small I.

ms. 42–43 CONJECTURED XIIIa-C013 – Condition a-double-prime implies existence of the prescribed closed left-exact weak structures for all small I.

ms. 42–43 CONJECTURED XIIIa-C014 – Condition b implies existence of the prescribed closed left-exact weak structures for all small I.

ms. 44 CONJECTURED XIIIa-C020 – The author expects a-double-prime to imply all other conditions of Theorem 2.

ms. 44 CONJECTURED XIIIa-C021 – The author expects the small-set condition a-double-prime to be the practical verification method, notably for M=Cat.

ms. 48 CONJECTURED XIIIa-C041 – The converse componentwise condition for injective fibrations need not hold.

ms. 48–49 CONJECTURED XIIIa-C044 – Restriction also preserves homotopy cartesian squares and cosuspension exact sequences.

ms. 49 FALSE XIIIa-C045 – The ordinary functor u_* preserves arbitrary homotopy cartesian squares merely because it preserves F and TF.

ms. 49 CONJECTURED XIIIa-C046 – A right homotopy Kan extension generally does not preserve homotopy cocartesian squares.

ms. 49 FALSE XIIIa-C047 – The ordinary u_! should preserve arbitrary homotopy cocartesian squares.

ms. 50 OPEN XIIIa-C049 – Do the preceding assumptions ensure the existence of homotopy adjoints u_!^W and u_*^W, even for finite posets?

ms. 52 OPEN XIIIa-C068 – What quillenization or derived-functor theory is available for unbounded complexes in a general abelian category?

ms. 53 FALSE XIIIa-C071 – The same filtered-colimit closure holds for Ch^+(A), Ch^-(A), and Ch^b(A).

ms. 53 OPEN XIIIa-C075 – Does the right derived Kan extension exist on the whole unbounded derived category?

ms. 53 CONJECTURED XIIIa-C076 – A left homotopy Kan extension need not preserve D^+ without a homological-dimension restriction.

ms. 53–54 conjectured XIIIa-C077 – For Grothendieck A, a left derived Kan extension is expected on D^-(A(I-prime)) with values in D^-(A(I)).

ms. 54 open XIIIa-C078 – Does left derived Kan extension exist on all of D(A(I-prime)) without finite cohomological dimension?

ms. 55 open XIIIa-C083 – Which derivator axioms follow from quillenizability alone?

ms. 55–56 conjectured XIIIa-C087 – The strong local-system axiom asks that u in the chosen fundamental localizer induce an equivalence on homotopy categories of locally constant diagrams.

ms. 56 conjectured XIIIa-C092 – Quillenizability alone seems too weak to ensure interesting homotopy Kan extensions.

ms. 59 false XIIIa-C101 – The parenthesis invokes finite colimits to justify the finite limits required by finite-index u_*.

ms. 60 conjectured XIIIa-C109 – A poset whose associated opposite Alexandrov space is noetherian and sober is admissible.

ms. 52 open XIIIb-Q013 – What hypotheses suffice for quillenisability of unbounded complexes, and what can be done without enough injectives or projectives?

ms. 53 false XIIIb-Q015 – If A is accessible and has filtered colimits, all the listed complex categories have the same closure properties.

ms. 53–54 open XIIIb-Q019 – Does u_* extend to a right adjoint on unbounded derived categories of diagrams?

ms. 53–54 conjectured XIIIb-Q020 – For globally bounded-above diagrams of Grothendieck coefficients, one expects a left adjoint Lu_! to restriction preserving upper bounds.

ms. 54 open XIIIb-Q021 – Does a left adjoint to restriction exist on the entire unbounded derived diagram category without a finite cohomological-dimension hypothesis?

ms. 54 footnote32 open XIIIb-Q024 – Can the square-based structure of an unpointed homotopy theory be axiomatized?

ms. 55 open XIIIb-Q026 – Which derivator axioms follow from quillenisability alone?

ms. 55–56 conjectured XIIIb-Q030 – A strongest proposed local-constancy axiom says that u in a chosen fundamental localizer induces HO_W^lc(I)≃HO_W^lc(I′).

ms. 56 open XIIIb-Q032 – How can the local-constancy equivalence be verified directly from (M,W), before a theory of u_! or u_* has been built?

XIII-b · Chapter XIII, part 2 of 2, manuscript pages 61–98

ms. 69 footnote37 open XIIIb-Q066 – Can the representing object of the preceding pointwise quotient be chosen functorially in localized G′ without admissibility?

ms. 71 false XIIIb-Q070 – Representability of F↦Hom(HO(I′))(u*F,G′) gives a left adjoint of u*.

ms. 71 false XIIIb-Q071 – The left adjoint just obtained is computed by u_* on fibrant G′.

ms. 72 open XIIIb-Q073 – Do all functors u admit homotopy right images under the earlier large-category hypotheses; can a counterexample be found?

ms. 72–73 open XIIIb-Q074 – Is a small product of W-maps between fibrant objects again a W-map?

ms. 73 open XIIIb-Q076 – Does inverse limit preserve levelwise W-maps between such fibrant towers?

ms. 73–74 OPEN XIIIb-Q078 – Can the product assertion fail even for a closed model category with the additional accessibility and filtered-colimit exactness hypotheses listed?

ms. 74 OPEN XIIIb-Q079 – Is the one-object category BG admissible for a group G?

ms. 74 OPEN XIIIb-Q080 – Is the full subcategory of Δ on [0] and [1] admissible?

ms. 74–75 FALSE XIIIb-Q081 – For the dual construction assume a closed right-exact structure with TF=F∩C.

ms. 75 CONJECTURED XIIIb-Q084 – These classes should define a uniform right quillenisability on all small categories.

ms. 76 CONJECTURED XIIIb-Q087 – If the projective construction succeeds, left homotopy Kan extensions exist for maps of finite posets and the indicated noetherian sober extensions.

ms. 76 CONJECTURED XIIIb-Q088 – Closure of W under filtered colimits should make discrete and left-filtered categories such as N^op admissible for left images.

ms. 76 CONJECTURED XIIIb-Q089 – A poset which is a filtered union of closed noetherian sober subposets should be right-admissible under the projected dual hypotheses.

ms. 76 OPEN XIIIb-Q090 – What happens to left admissibility for BG?

ms. 77 FALSE XIIIb-C07-007 – Under GCH, (pi')^pi=pi' for every pair of infinite cardinals pi'>pi.

ms. 85 FALSE XIIIb-C07-027 – The printed formula asserts Z_sup A ≅ lim_A Z_T for the covariant partial-colimit diagram.

ms. 89 FALSE XIIIb-C07-037 – The three conditions a_pi, b_pi, c_pi are equivalent.

ms. 90 FALSE XIIIb-C07-040 – To deduce membership of an arbitrary pi^+-directed colimit of M^pi-objects, it is enough to apply b_pi directly because I_M=I.

ms. 94 FALSE XIIIb-C07-054 – For every C_i' admitted by the printed image-size definition, Z_{C_i'}=colim_{C_i'} Z belongs to Filt^pi(E).

ms. 94 FALSE XIIIb-C07-055 – With the printed tilde C_i, the diagram (Z_{C_i'}) is perfectly adapted at pi.

ms. 97 OPEN XIIIb-C07-068 – If X has both a perfectly adapted Filt^pi presentation and a pi^+-directed presentation by M^pi-objects, can one show its adapted M-stages cofinal?

ms. 97 CONJECTURED XIIIb-C07-069 – After replacing pi by a larger cardinal pi' (suggested pi'=pi^+), a_pi should imply b_{pi'}.

ms. 86 (glossary discrepancy) FALSE XIIIb-G036 – The glossary states that a strict cardinal filtration has every stage Filt^π(E) closed under all filtered colimits.

ms. 86 (glossary discrepancy) FALSE XIIIb-G037 – The final glossary paragraph calls a perfectly adapted representation the colimit of a 'well adapted' system.

XIV · Chapter XIV, manuscript pages 1–8

ms. 4 CONJECTURED XIV.016 – The preceding stability axioms appear to exhaust the useful stability properties, so further such properties should be consequences.

ms. 7 FALSE XIV.030 – If the underlying category is additive, the h-cartesian and h-cocartesian classes should coincide.

ms. 8 CONJECTURED XIV.035 – In some sense the general case ought to reduce to the elementary ordinary-pullback case.

ms. 8 FALSE XIV.036 – The proposed second family of left quadrangulated examples is the localized category with the homotopy-image class of squares, for localizers admitting homotopy fibres.

ms. 8 FALSE XIV.037 – Proposition 1 is expected to hold under further hypotheses to be identified, including every presentation quillenizable on finite poset diagram shapes.

ms. 8 FALSE XIV.039 – Proposition 1, necessary direction: if $\mathrm{ho}_W(X)$ belongs to the designated h-cartesian class, the chosen strict square X is W-cartesian.

XV-a · Chapter XV, part 1 of 2, manuscript pages 1–66

ms. 7–8 FALSE XV-A-012 – If every domain of a generator is π-accessible and $I_\alpha = \{\beta < \alpha\}$ is grand devant π, the source asserts $p_\alpha(f) \in I^{\perp}$.

ms. 9–10 FALSE XV-A-024 – The proposed first stage should satisfy $i_1(f) \in C_0''$ for every arrow f, and the construction is asserted to do so.

ms. 11 FALSE XV-A-033 – If the domains of I are accessible, choose a common π; the source claims $p_\alpha(f) \in I^{\perp}$ for every ordinal grand devant π.

ms. 17 FALSE XV3-006 – GCH implies pi^pi_0=pi for every pi>pi_0.

ms. 17 CONJECTURED XV3-008 – The endpoint filtration Fl^pi(M) should itself be a cardinal filtration of the arrow category.

ms. 19 FALSE XV3-015 – Proposition 3.1(2), (3.8): for r,s>=max(pi_1,C_1), A in Filt^r and X in Filt^s imply |Hom(A,X)|<=s^(r^pi_0).

ms. 19 FALSE XV3-018 – GCH implies pi^pi_prime=pi for infinite pi>pi_prime>=1 and hence gives (3.7 bis)-(3.9 bis) for every r>pi_0.

ms. 20 FALSE XV3-020 – The category of pairs (A,B subset A) gives equality in the arrow-isomorphism bound (3.7 bis) for the indicated filtration.

ms. 20 FALSE XV3-022 – |Hom(A_i,X_j)|<=C_1 because C_1 counts arrow-isomorphism classes at level pi_1.

ms. 21 FALSE XV3-024 – For a fixed poset I of size at most mu=r^pi_0, the choices of all objects A_i up to isomorphism can be bounded by |I| times C_0<=mu.

ms. 21 FALSE XV3-025 – For fixed objects A_i, choices of all transition maps can be bounded by |I times I| times C_0<=mu.

ms. 21 FALSE XV3-026 – A cocone from a fixed I-diagram to X has at most |I| times s^mu choices.

ms. 23 FALSE XV3-031 – Lemma 3.2 literally states r^rprime=2^rprime whenever rprime>=r, without an infinitude or lower-bound qualification.

ms. 23 FALSE XV3-032 – Corollary 1 claims |Hom(A,X)|<=2^(r^pi_0) for A,X in Filt^pi and r>=max(pi_1,C_1).

ms. 27 FALSE XV3-048 – Theorem 2(1): p_alpha(f) lies in Psi when alpha is large relative to r^pi_0.

ms. 27 FALSE XV3-049 – The initial ordinal of any cardinal rprime>r^pi_0 may be chosen to satisfy the large-cofinality condition.

ms. 35 FALSE XV4-025 – In the proof of Corollary2, $C \cap W \longleftrightarrow TC$.

ms. 36 FALSE XV4-030 – For two precouples with $TC \subset C \cap W$ and $TF \subset F \cap W$, the equalities $TC = C \cap W$, $TF = F \cap W$, $W = TF \circ TC$ and the assertion that (W, C, F) is closed are all equivalent.

ms. 40 FALSE XV4-039 – Under only the hypotheses of Proposition4.4.2, Cof_W cap W equals W^univ, the maps all of whose cobase changes belong to W.

ms. 40 FALSE XV4-041 – Under only the Proposition4.4.2 hypotheses, Cof_W cap W is Q-stable on the left.

ms. 40–41 FALSE XV4-042 – Under the hypotheses of Corollary4.4.4, C=tilde(C0) equals Cof_W.

ms. 40–41 FALSE XV4-043 – Under only the hypotheses of Corollary4.4.4, TC=C cap W equals C cap W^univ and is contained in W^univ.

ms. 41 FALSE XV4-045 – TC is Q-stable on the left under only Corollary4.4.4 hypotheses.

ms. 43 OPEN XV4-054 – Given suitable small C0 and accessible W, does there exist a small TC0⊂C cap W generating C cap W under left lifting closure?

ms. 46 FALSE XV5-015 – Footnote 17: (d_2) should imply (d_1).

ms. 52 FALSE XV5-033 – Proposition 5.6 as first stated: at a rank where bounded objects are π-accessible, condition (5.3) alone is equivalent to b_π.

ms. 53 FALSE XV5-036 – The proof applies (5.3) directly to the image J of the monomorphic stage indices in $\mathrm{Sub}_\pi(X)$.

ms. 58 FALSE XV5-042 – Printed condition (cprime): M is the smallest class closed under filtered colimits, with no stated requirement to contain M_0.

ms. 58–59 OPEN XV5-045 – Footnote 22 asks whether (cprime) implies (c) without the special object-accessibility assumption on pi.

ms. 62–63 FALSE XV5-053 – The printed lemma and display assert that the unrestricted $\mathrm{Sub}_\pi(Y)$ maps canonically and cofinally into M^π/Y.

ms. 64 FALSE XV5-057 – The projection in Corollary 5.11 is described parenthetically as fibrant.

XV-b · Chapter XV, part 2 of 2, manuscript pages 57–137

ms. 58–59 OPEN XVb-A009 – Without requiring every Filt^pi object to be pi-accessible, footnote22 asserts (a)⇔(b), (a)⇒(c′), (b)⇒(c), and tentatively (c′)⇒(c).

ms. 62–63 FALSE XVb-A021 – As printed, all of Ss_pi(Y) is a cofinal subcategory of M^pi/Y.

ms. 72 FALSE XVb-A041 – The individual good-index sets I_{M_alpha} are parenthetically asserted to be filtered without a cofinality hypothesis.

ms. 75 OPEN XVb-A049 – The exactness assumption(e) might be eliminated from the general machinery.

ms. 76 FALSE XVb-A056 – If C is an L-accessible class of monomorphisms containing all isomorphisms under(a)–(e), there is a small C_0⊂C with C⊂tilde(C_0).

ms. 76–77 FALSE XVb-A057 – For any pi witnessing C accessibility,6.1 further asserts C⊂tilde(C^pi), with C^pi=C∩Fl^pi(M).

ms. 77 FALSE XVb-A059 – Under the proposed unconditional hypotheses of6.1,6.2 asserts C_*=C_{0*} and tilde(C)=tilde(C_0) for a small generating C_0.

ms. 79 FALSE XVb-A066 – For every nonisomorphism f:A→B in C, there exists A⊊A_1⊂B with A→A_1∈tilde(C^pi) and A_1→B∈C.

ms. 83 OPEN XVb-A078 – The proof needs the comparison j:C′=A amalg_{A′}B′→B to lie in C, and does not even know that it is monic.

ms. 83–84 FALSE XVb-A080 – The diagram of C_i and gamma_i is called pi-adapted after checking continuity, without establishing that its objects lie in the bounded filtration stage.

ms. 84 FALSE XVb-A081 – Since colim gamma_i is an isomorphism in C and C is pi-accessible, the indices with gamma_i∈C are claimed cofinal.

ms. 84 FALSE XVb-A082 – The attempted proof concludes Lemma6.4 and Theorem6.1 by choosing an index with both alpha_i∈C^pi and gamma_i∈C.

ms. 84–85 OPEN XVb-B001 – The generation assertion of §6 may be false: an accessible or L-accessible class need not be the left Q-closure of a set.

ms. 85 CONJECTURED XVb-B002 – For a fundamental localizer W, the classes Cof_W and W^{univ} in Cat should be accessible, in particular for W=W_infty.

ms. 85 OPEN XVb-B003 – If C=tilde(C) is closed under filtered colimits and generated on the left by a set, and W is L-accessible, is C intersect W generated on the left by a set, even when C consists of monomorphisms?

ms. 90 FALSE XVb-B026 – For every monomorphism i:A->B, there is a generator i_prime mapping to it whose pushout strictly enlarges A inside B.

ms. 99 FALSE XVb-B046 – In the cartesian square (7.4.3), if the left vertical f belongs to F and the bottom p belongs to W, then the top q belongs to W.

ms. 102 OPEN XVb-B056 – Effective unions of subobjects may fail in Cat.

ms. 104 OPEN XVb-B066 – Is the presheaf model structure necessarily also right proper?

ms. 106 FALSE XVb-B073 – Footnote38(d_prime): j_A sends every W-equivalence of categories to a universally W_A-equivalent map of presheaves, and this is equivalent to the local test condition.

ms. 112–114 FALSE XVb-B089 – Lemma8.7: finite cocompleteness, two-out-of-three for W, composition/pushout stability of C, a fold factorization with left factor in C and right factor in W, and the stated coproduct inclusions suffice for mapping-cylinder factorizations C then W.

ms. 115 CONJECTURED XVb-B096 – If the connected-component axiom fails in the presence of the other listed axioms, perhaps W is the class of all functors.

ms. 116 CONJECTURED XVb-C010 – Loc(3bis) should suffice when tested only on split fibred categories and split cartesian morphisms, assuming Loc(1,2).

ms. 121 OPEN XVb-C033 – Can coproduct reflection f1⊔f2∈W⇒f1,f2∈W be proved with only the preceding basic assumptions?

ms. 122 OPEN XVb-C037 – Footnote 47: the converse, arbitrary coproduct preservation under only Loc(1,2,3,6c′), is not known to the author.

ms. 125 CONJECTURED XVb-C051 – Loc(8) and Loc(5bis) are conjectured independent under the basic localizer axioms.

ms. 125 CONJECTURED XVb-C052 – The author expects every localizer useful in practice to satisfy connectivity and decomposition, while these are not needed in preceding general developments.

ms. 125 CONJECTURED XVb-C053 – Connectivity may matter when recovering contractibility and asphericity structures from one another.

ms. 130 CONJECTURED XVb-C068 – The author expects connectivity to hold automatically for localizers that will be introduced.

ms. 133 bis FALSE XVb-C084 – The editorial bracket says (c′)⇒(c) is the trivial implication and the quotient argument below proves (c)⇒(c′).

ms. 136 FALSE XVb-C104 – 10.1(3b) with current Loc(1ter,2,3,5b) read literally: every f∈W induces an equivalence on locally constant objects.

XVI · Chapter XVI, manuscript pages 1–124

ms. 9 FALSE XVI-A038 – With filtered-colimit stability, finite Loc (4a) is equivalent to full Loc (4).

ms. 10-11 FALSE XVI-A045 – Lemma2.5: product closure for an arbitrary subset W implies preservation of binary, finite, or arbitrary products by localization.

ms. 17' CONJECTURED XVI-A089 – The same forward/reverse distinction holds for all finite n-equivalence classes W_n.

ms. 17',22-23,25 OPEN XVI-A092 – Does (6-prime a) imply (6a), hence provide the desired intrinsic cofibration theory?

ms. 23 OPEN XVI-A112 – Does (6-prime a) alone make trivial Dwyer inclusions stable under every pushout?

ms. 23-24 OPEN XVI-A114 – Is a square W-homotopy cocartesian exactly when the integral of its span maps to its corner by a W-map?

ms. 24 OPEN XVI-A116 – Every presheaf monomorphism is in Cof_WA under the stated excision hypotheses.

ms. 27 CONJECTURED XVI-A130 – Loc (6c) is probably satisfied only when W is retract closed.

ms. 29 CONJECTURED XVI-B013 – W-smooth maps and W-proper maps, hence W-perfect maps, should be closed under retracts.

ms. 29 OPEN XVI-B014 – Fibf_W and F_W need not be closed under composition; examples should be supplied.

ms. 37 CONJECTURED XVI-B026 – Loc(7), or even Loc(7b), probably does not imply Loc(6a) or Loc(6′a); possible left Kan extensions without left exactness are suggested.

ms. 40 FALSE XVI-B039 – B(F)⇒C(F) for arbitrary F⊂Fl(Cat).

ms. 50 FALSE XVI-B059 – A(Parf_{W0}) is the assertion Parf_{W0}⊂W.

ms. 52–53 OPEN XVI-B063 – Objectwise universally equivalent replacements alone may not suffice to transfer B from G to F.

ms. 57 FALSE XVI-B072 – For arbitrary weakly W-fibrant input, the infinite-path unit is universally a W0-equivalence whenever W0 satisfies Loc8bis.

ms. 64–65 OPEN XVI-B084 – Does D imply A without sequential-colimit stability, perhaps with the extra condition printed Loc3ter?

ms. 65 OPEN XVI-B085 – Does D_W0 imply A under the printed assumption that W and W0 satisfy Loc8bis?

ms. 65 CONJECTURED XVI-B086 – The minimum weak fundamental localizer Wω almost certainly fails Loc8 and even Loc8bis.

ms. 65 OPEN XVI-B087 – It is not clear whether Wω satisfies F; if it fails F then it also fails D and D⇒A is vacuous there.

ms. 66 CONJECTURED XVI-B088 – Does F imply A under Loc1ter,3bis,8bis?

ms. 66–67 OPEN XVI-B089 – Does enough intrinsic W-cofibrations imply Loc6a?

ms. 70 OPEN XVI-B098 – Without Loc8bis it remains unclear whether the arrows in the eight-condition diagram are strict.

ms. 70 OPEN XVI-B099 – The truncation localizers bold W_n should be tested for Loc7F.

ms. 28–29 CONJECTURED XVI-B100 – The Wω-perfect maps and the locally constant Wω-Grothendieck fibrations should play a role dual to Dwyer maps.

ms. 73 FALSE XVI-C005 – Neither W_ω nor Parf_{W_ω} is closed under filtered colimits.

ms. 79 conjectured XVI-C019 – All fundamental localizers used in contemporary examples appear to satisfy Loc(8) and Loc(9).

ms. 79 false XVI-C021 – W_∞ satisfies Loc(1 ter,2,3 bis,4,5,6,7,8,9).

ms. 85–86 conjectured XVI-C034 – A future descent axiom Loc10 should characterize W∞ uniquely together with Loc5 and D_{W_ω}.

ms. 86–87 conjectured XVI-C036 – There exists a fundamental localizer strictly contained in W∞; in particular Wω≠W∞.

ms. 87 open XVI-C037 – The smallest fundamental localizer satisfying D_{W_ω} might be strictly smaller than W∞.

ms. 87–88 false XVI-C039 – The listed axioms define a localizer tilde W∞⊂W∞, which consequently satisfies Loc5.

ms. 87–88 conjectured XVI-C040 – The proposed tilde W∞ is strictly smaller than W∞.

ms. 88 conjectured XVI-C042 – Hot_{tilde W∞} might model Whitehead simple homotopy types.

ms. 88 open XVI-C043 – A Whitehead invariant might be defined on pointed Hot_{tilde W∞}, provisionally as an element of K(Z[π1]).

ms. 88–89 conjectured XVI-C044 – Elementary Whitehead expansion/collapse of a finite simplicial complex should induce an isomorphism of its face-poset model in Hot_{tilde W∞}.

ms. 88; fn43 false XVI-C045 – Barycentric subdivision leaves the strict categorical homotopy type of a finite face poset unchanged.

ms. 91;124 open XVI-C048 – Whether n-equivalence localizers W_n have enough intrinsic W_n-fibrations is asked; knowing Loc7F alone supplies no canonical perfect-path calculation.

ms. 92–93 conjectured XVI-C050 – Simplicial approximation suggests that homotopy-equivalent polyhedra have suitably subdivided models that are categorically homotopy equivalent.

ms. 93–95 open XVI-C052 – Is the maximum map sd(I)→I always a categorical homotopy equivalence?

ms. 96 conjectured XVI-C055 – A fundamental localizer strictly below W∞ might retain simple homotopy types and support Whitehead and higher Whitehead invariants.

ms. 96 open XVI-C056 – Before a finer localizer is constructed, determine whether the intended Whitehead invariant is invariant under categorical homotopy equivalence of finite poset models.

ms. 97–98 open XVI-C057 – For which W are (Cat,W,Cof_W) and (Cat,W,Fib_W) Brown cofibration/fibration categories?

ms. 97–98 open XVI-C058 – For which W and u do derived direct images u_!,u_* exist, with exact homotopy pushout/pullback squares?

ms. 98 open XVI-C059 – Which derivator axioms does HOT_W satisfy, on which diagram domain, and when is it a full derivator on all small categories?

ms. 98 open XVI-C060 – When can W be the weak-equivalence class of a closed Quillen model structure on Cat, preferably a proper one?

ms. 99–100 open XVI-C063 – The explicit integrated-span construction models W-homotopy pushouts; the author asks whether its identification needs Loc3bis.

ms. 100 conjectured XVI-C065 – Loc3bis alone probably does not imply the source's homotopy-pushout exactness axiom Der6*.

ms. 102 false XVI-C068 – D_{W_ω} implies W⊂W∞.

ms. 105–106 OPEN XVI-C073 – Do Loc6a,Loc8,Loc9 imply enough intrinsic fibrations, Loc7F?

ms. 106–107 OPEN XVI-C074 – Can infinite paths in simplicial presheaves make localized right homotopy operations concrete without Loc7?

ms. 121 OPEN XVI-C097 – Does Loc6a,Loc8,Loc9 imply the coproduct decomposition axiom Loc4?

ms. 122–123 OPEN XVI-C100 – Let V be the least fundamental localizer satisfying6′a,8, with or without3bis. Is V accessible, and is V strictly contained in W∞?

ms. 123–124 OPEN XVI-C102 – Does Thomason's model structure extend to special localizers or to other broader fundamental localizers?

ms. 124 CONJECTURED XVI-C104 – For special localizers, Loc6a may admit a direct elementary proof without the full Thomason construction.

ms. 124 OPEN XVI-C105 – Do the suggested homological or cohomological equivalence localizers satisfy Loc7F?

XVII-a · Chapter XVII, part 1 of 2, manuscript pages 1–70

ms. 3 FALSE XVIIa-A011 – The printed reduction says alpha_i∈TC is equivalent to alpha_i∈C in the proof of the reverse implication.

ms. 7 FALSE XVIIa-A022 – Footnote 5 claims that cofibrancy of X and Y is unnecessary in Proposition 2 and both its corollaries, including all conclusions of Corollary 2.

ms. 19 FALSE XVIIa-A047 – The proof says that the case I'_0≠I is covered by induction on the size of I, with the alternative giving a terminal object i0.

ms. 23 OPEN XVIIa-A053 – Does u∈C_I together with local finiteness imply u_{K,I/i}∈C for every i and every lower ideal K⊂I/i?

ms. 24 FALSE XVIIa-A057 – The printed condition (I/i⊂P⇒i∈P) forces P=I for artinian I.

ms. 27,38 OPEN XVIIa-B008 – Question: can the artinian hypothesis be removed from Theorem 2.1(3), with C_I understood in the strong sense?

ms. 32 FALSE XVIIa-B021 – The intermediate cube in the proof of Lemma 2.6 is totally cocartesian, if this is read as saying all six faces are pushouts.

ms. 33–34 FALSE XVIIa-B022 – Lemma 2.7 as printed: every increasing ordinal sequence of opens yields the relative map as a transfinite composite of successor relative maps, including an extra initial factor.

ms. 55 FALSE XVIIa-C021 – Footnote 17 asserts that the candidate in (3.3.1) exists even when I prime is an arbitrary small category, without distinguishing the finite and cocomplete branches.

ms. 56–57 OPEN XVIIa-C025 – Is the constructed candidate u_!^W left adjoint to the localized restriction u_W^*?

ms. 58–59 FALSE XVIIa-C028 – The preceding density and homotopicality hypotheses alone imply that the transported candidate L is left adjoint to the localized G.

ms. 66 FALSE XVIIa-C052 – The cofibrant-replacement Kan-extension candidate extends to arbitrary small targets under only the finite-colimit assumptions of the finite-source branch.

ms. 67 OPEN XVIIa-C054 – Does this candidate for arbitrary target admit the desired adjunction, given that C(u) may no longer be a poset and the established diagram cofibration structure is unavailable there?

XVII-b · Chapter XVII, part 2 of 2, manuscript pages 58–118

ms. 64,69 FALSE XVIIb-A065 – Theorem 3.7, formulated for covariant diagrams on artinian posets, immediately proves the corresponding restriction of the presheaf prederivator on the same artinian posets.

ms. 66 FALSE XVIIb-A017 – For arbitrary target category I' and artinian-poset source I, the displayed formula $(u_!X)(j) = \operatorname{colim}_{(u\downarrow j)} X$ still constructs a weak-equivalence-preserving functor on cofibrant diagrams without further hypotheses.

ms. 67 OPEN XVIIb-A019 – Without a suitable cofibration structure on diagrams over non-posets, the mapping-cylinder proof of Theorem 3.7 has not yet established the adjunction for arbitrary target shapes.

ms. 68 FALSE XVIIb-A021 – The inference attributed here to Anderson, from ordinary full faithfulness of restriction to full faithfulness of localized restriction without further control of derived unit/counit, is not a valid formal implication.

ms. 70–71 OPEN XVIIb-A026 – Find hypotheses on a strict cofibration category guaranteeing all small left homotopy Kan extensions and their pointwise formula.

ms. 79 OPEN XVIIb-A056 – Under suitable additional assumptions, seek $L(TC) \subset TC' \subset \widetilde{L(TC)}$, or the stronger $\widetilde{C'} \cap W' \subset \widetilde{L(TC)}$.

ms. 81 OPEN XVIIb-B002 – Under what additional assumptions does $F' = (v^*)^{-1}(F)$ hold for the transferred cofibration structure?

ms. 82 FALSE XVIIb-B013 – Footnote 23 proposes the literal equality $v_!(TC(I_0)) = TC(I)$ under stronger special-model hypotheses.

ms. 82 CONJECTURED XVIIb-B014 – Footnote 23 proposes $F(I) = (v^*)^{-1}F(I_0)$ under stronger special-model hypotheses.

ms. 97 CONJECTURED XVIIb-B055 – The informal expectation that special Quillen triples probably occur only when W is stable under all small filtered colimits.

ms. 101 FALSE XVIIb-C013 – As printed, $C(I) = C_I$ and $TC(I) = TC_I$ whenever I is artinian, with $\mathcal{M}(I) = \mathrm{Fun}(I^{op}, \mathcal{M})$.

ms. 116 FALSE XVIIb-C044 – The proof of6.3 completes the equality assertion of6.1(d).

XVIII-a · Chapter XVIII, part 1 of 5, manuscript pages 50–138

ms. 53 FALSE XVIII-A50-014 – The operation subsequently denoted $X \boxtimes Y$ was initially proposed as a bicategorical product of pseudo-topoi.

ms. 60–61 FALSE XVIII-A50-033 – Equation4.2.8 claims restriction $\mathrm{Cont}(S\text{-hat}^{op}, N) \to [S^{op}, N]$ is an equivalence for arbitrary N.

ms. 61 FALSE XVIII-A50-034 – The unrestricted functor category $[S\text{-hat}^{op}, N]$ appearing twice on p61 is identified with the continuous-functor category.

ms. 63 OPEN XVIII-A50-037 – The remaining tensor problem is to construct a left adjoint to its fully faithful restricted-nerve embedding.

ms. 63 CONJECTURED XVIII-A50-038 – Lemma4.2.3: for arbitrary pseudo-topos M,N and s∈M,t∈N, evaluation F↦F(s,t) on M⊠N is representable by s⊠t.

ms. 64 FALSE XVIII-A50-040 – Elementary tensors should decompose as products of two objects depending separately and cocontinuously on the factors.

ms. 66 OPEN XVIII-A66-003 – Does the tensor of arbitrary pseudo-topoi remain a pseudo-topos?

ms. 66 FALSE XVIII-A66-004 – Lemma 4.3.2: for complete $\mathcal{E}$, pointwise corepresentability of $\alpha : \mathcal{E} \to X^\wedge$ is sufficient for a left adjoint.

ms. 66 FALSE XVIII-A66-006 – The displayed evaluation $\xi \mapsto \mathrm{Hom}_{X^\wedge}(x, \alpha\xi)$ has domain $\mathcal{E}^\circ$.

ms. 67 FALSE XVIII-A67-004 – Lemma 4.3.3(b): the images under the reflector of a small dense family in $\mathcal{F}$ form a small dense family in $\mathcal{F}$.

ms. 76 FALSE XVIII-A76-003 – This proposed I is grand devant π.

ms. 76 FALSE XVIII-A76-006 – "On a donc prouvé PTA⇒c."

ms. 78 FALSE XVIII-A78-004 – It remains to prove that $\mathrm{Ind}_\pi C$ is closed under colimits in ordinary $\mathrm{Ind}\, C$.

ms. 82 FALSE XVIII-A82-001 – Proposition4.4.4: condition(b) implies condition(c).

ms. 82 FALSE XVIII-A82-008 – Alternative(e′): finality of one diagonal $J \to J^{A_0}$ with $|A_0| = \pi$ is sufficient without further hypotheses.

ms. 82 FALSE XVIII-A82-009 – The attempted F2 argument using three terminal subcategories proves finality without the added hypothesis.

ms. 82 FALSE XVIII-A82-010 – Corollary4.4.5: $F \in \mathrm{Ind}'_\pi C$ if and only if C/F satisfies all four conditions of4.4.4.

ms. 85 FALSE XVIII-A85-002 – The index $I = \mathrm{Fun}(J, C)/\varphi$ is an ordered filtered set.

ms. 88 FALSE XVIII-A88-004 – The preceding lemma is equivalent to closure of the restricted ind-category under all pi^+-filtered colimits of its objects.

ms. 94 CONJECTURED XVIII-A91-011 – Question/negative expectation: even if C has colimits of cardinal at most π, evaluation $C^J/\varphi \to C/\varphi(j)$ need not be final for $\varphi : J \to \mathrm{Ind}(C)$.

ms. 102 FALSE XVIII-A91-029 – Claim as written: unrestricted restriction $\mathrm{Fun}(M, E) \to \mathrm{Fun}(C, E)$ is fully faithful because C strictly generates M.

ms. 106 FALSE XVIII-A91-037 – Claim encoded in the diagram: restriction sends every filtered-colimit-preserving functor Ind(C)→E to a functor Ind_pi(C)→E preserving all size≤pi colimits.

ms. 107 FALSE XVIII-A91-042 – Proposition4.5.2 as first stated: conditions a,a′,a″,b,c,c′ are equivalent for every pi≥pi1.

ms. 108 FALSE XVIII-A91-046 – Claim implicit in(4.5.2.2): presheaves F∈M that are pi-accessible in the ambient presheaf category are closed under all ambient colimits of size≤pi.

ms. 109 FALSE XVIII-A91-049 – The proposed proof of c⇒a invokes SGA4 I9.16 after constructing the claimed cardinal filtration.

ms. 109 FALSE XVIII-A91-051 – Corollary4.5.3 as first stated: (Filt^pi)_{pi≥pi1} is a cardinal filtration of M.

ms. 110 FALSE XVIII-A91-054 – Corollary4.5.4 as first stated: Filt^pi is closed under every colimit in M indexed by a category with at most pi arrows.

ms. 111 FALSE XVIII-A91-057 – The earlier proof of4.3.6(b⇒c) is asserted to have already established this same pointwise filtration with the desired cardinal bounds.

ms. 113 FALSE XVIII-A91-062 – Lemma4.5.5 as first stated: whenever pi>pi0 and J is pi0^+-filtered, every set of at most pi arrows of J lies in a pi0^+-filtered subcategory with at most pi arrows.

ms. 114 FALSE XVIII-A91-064 – Claim as printed: closing a set Φ of at most pi arrows under identities and finite compositions produces a subcategory with at most pi0 arrows, although pi>pi0.

ms. 114 FALSE XVIII-A91-066 – Claim as written: [S]^{≤pi0} is the smallest pi0^+-directed subposet of P(S) containing all singleton subsets.

ms. 115 FALSE XVIII-A91-069 – The cardinality calculation for [S]^{≤pi0} is taken to prove that a directed hull in P(S) must have size pi^{pi0}.

ms. 115 FALSE XVIII-A91-070 – The source concludes that its original equivalences can hold only for cardinals with pi^{pi0}=pi.

ms. 117–118 FALSE XVIII-A116-009 – The proof claims that a fixed Filt^pi is closed under all colimits large relative to pi0.

ms. 120 FALSE XVIII-A116-014 – The right adjoint to evaluation at c on covariant functors C→E is claimed to have value E^{Hom(c,d)} at d.

ms. 126–129 FALSE XVIII-A116-031 – Proposition4.5.13(1): the six conditions a,a-prime,a-double-prime,b,b-prime,b-double-prime are equivalent.

ms. 126 FALSE XVIII-A116-036 – The definition of Filt-prime^pi via the supposed common condition P(pi) in4.5.13 is unambiguous.

ms. 127 CONJECTURED XVIII-A116-047 – Footnote50 suggests that condition C on M is equivalent to the analogous condition on C for filtered diagrams of at most pi arrows.

ms. 127–128 CONJECTURED XVIII-A116-049 – Outside A,B,C, the one-step colimit classes D_pi may fail to form a cardinal filtration.

ms. 133 FALSE XVIII-A116-042 – The proof infers D_pi=M_pi from generation under pi^+-filtered colimits, solely by inclusion D_pi⊂M_pi and Lemma4.5.14.

ms. 134 FALSE XVIII-A116-058 – Lemma4.5.14,b⇒c: pi^+-filtered generation by a strictly full M0 implies M_pi⊂M0.

ms. 134 FALSE XVIII-A116-059 – Lemma4.5.14 final assertion: under M0⊂M_pi and strict generation by M_pi, conditions a,b,b-prime,c are equivalent to M0=M_pi.

ms. 134 CONJECTURED XVIII-A116-060 – Condition B implies condition C for the paratoposes under discussion.

ms. 134–135 CONJECTURED XVIII-A116-061 – Condition C does not imply condition B.

ms. 135 FALSE XVIII-A116-064 – If G0*G1→G is surjective then (G0→G,G1→G) is a strict epimorphic family in groups and Cat.

ms. 135 FALSE XVIII-A116-065 – Footnote53 retains strict epimorphy for the special axes H→H×H with H nontrivial.

ms. 137 FALSE XVIII-A116-069 – Corollary4.5.16: under C, an object covered by a universally epimorphic family of<=pi objects in D_pi belongs to D_pi.

ms. 137 FALSE XVIII-A116-070 – A universally epimorphic outer family composed with universal strict epimorphic inner families is universally strict epimorphic.

ms. 138 FALSE XVIII-A116-074 – The one-step class of arbitrary colimits of<=pi-arrow diagrams in C need not equal M_pi.

XVIII-b · Chapter XVIII, part 2 of 5, manuscript pages 127–228

ms. 127 CONJECTURED XVIIIb-A010 – The pullback-commutation hypothesis on M should be equivalent to its analogue on C for filtered colimits of cardinal at most pi.

ms. 127–128 CONJECTURED XVIIIb-A011 – Outside the three sufficient hypotheses the Filt-prime filtration may fail to be a cardinal filtration.

ms. 133–134 FALSE XVIIIb-A025 – Lemma4.5.14(b-prime) implies M_pi is contained in M0.

ms. 133–134 FALSE XVIIIb-A026 – If M0 is contained in M_pi and M_pi is dense, all four conditions of4.5.14 are equivalent to M0=M_pi.

ms. 134–135 conjectured XVIIIb-A028 – Universal strict-epimorphism hypotheses B should imply filtered pullback exactness C, whereas C need not imply B.

ms. 135 false XVIIIb-A031 – A surjection G0*G1→G makes the two corresponding group maps a strict epimorphic family in Gr and Cat.

ms. 135 false XVIIIb-A032 – The two coordinate inclusions H→H×H form a strict epimorphic family, as claimed by the special-case exemption in footnote53.

ms. 142 false XVIIIb-A051 – If card-red(C0)<=pi1, then that closure has skeletal morphism cardinal <=pi1^(pi0).

ms. 143 false XVIIIb-A053 – That iterated closure has skeletal morphism cardinal <=pi1^(pi0).

ms. 145–146 false XVIIIb-A058 – With pi1=card-red(S), one has card-red(M_pi)<=pi1^pi for pi>=pi0.

ms. 145 false XVIIIb-A059 – The equality pi1^pi=2^pi holds whenever pi>=pi0, as printed in the parenthesis of4.6.2.1.

ms. 147 false XVIIIb-A063 – Full faithfulness of Ind_pi0(C)→M alone implies that every object of C is pi0-accessible in M.

ms. 149–150 open XVIIIb-A076 – Do e_pi0, or merely alpha(pi0) and beta(pi0), plus cocompleteness and a small strict generator imply a pi0-paratopos at the same cardinal?

ms. 150 false XVIIIb-A079 – Being a paratopos is equivalent to being Ind-prime_pi0(S) for some arbitrary small S, as written without a completeness condition.

ms. 154 conjectured XVIIIb-A088 – Conjecture4.6.6(a): condition L plus a small strictly generating subcategory of accessible objects should imply a suitable Ind presentation/cardinal filtration.

ms. 155–156 conjectured XVIIIb-A093 – If these closures form a cardinal filtration, they should equal M_pi; their existence does not by itself make M_pi/X filtered.

ms. 159–160 open XVIIIb-A106 – Are there useful examples of(a)–(f) beyond topoi and abelian categories and their elementary combinations?

ms. 160 open XVIIIb-A108 – Internal groups in groups are abelian groups; could analogous constructions M boxtimes M provide further paratopos examples?

ms. 162–164 false XVIIIb-B014 – (a″) implies (c′), without a size hypothesis on C.

ms. 167 false XVIIIb-B029 – If $\pi = \pi_1 = \pi_0$, then $\mathrm{Filt}^{\pi} = \mathrm{Filt}'^{\pi}$ is the subcategory of representables and agrees with $C^{\natural}$ only when C is Karoubian.

ms. 175 open XVIIIb-B048 – Is Filt^{π} closed under retracts at $\pi^{\pi_0} = \pi$, equivalently can the missing (c)=> (b) be proved?

ms. 177 false XVIIIb-B055 – The initial level need not be retract-closed; specifically $\mathrm{Filt}'^{\pi_0} = \mathrm{Filt}^{\pi_0} \simeq e$ for non-Karoubian C because every small highly filtered category is cofinal to e.

ms. 178–179 false XVIIIb-B059 – If every slice $\mathcal{F}^{\pi}/F$ is π^{+}-filtered, the realization $\mathrm{Ind}_{\pi}(\mathcal{F}^{\pi}) \to \mathcal{M}$ is an equivalence.

ms. 181–182 conjectured XVIIIb-B070 – Canonical generalized filtrations of Ind categories need not have every larger cardinal useful; some may be superfluous.

ms. 184 open XVIIIb-B079 – Can both exponents π^{π_0} in Lemma 4.7.19 be replaced by π_0?

ms. 185 open XVIIIb-B082 – Are the sharper bounds 2^{π} and $(\pi')^{\pi}$ valid for the general intrinsic filtration of Lemma 4.7.19?

ms. 180 false XVIIIb-B098 – The initial level $\mathcal{F}^{\pi_0}$ of any accessible generalized filtration is a generating subcategory of M.

ms. 189 OPEN XVIIIb-C008 – The condition that some family of arrows from C to every X is strict epimorphic may differ from the all-arrows density criterion.

ms. 190-191 FALSE XVIIIb-C010 – The feared failure of density under passage from C to a containing full subcategory C-prime would invalidate earlier arguments.

ms. 199-200 OPEN XVIIIb-C018 – Essential surjectivity of Ind_{pi0}(S)->M does not follow merely by the asserted construction; saturating S under existing bounded colimits is proposed but not shown sufficient.

ms. 202 OPEN XVIIIb-C024 – 4.8.6(1): find a category satisfying4.8.1(a) at pi0 but not the Ind-presentation condition at pi0.

ms. 202 OPEN XVIIIb-C026 – 4.8.6(2): find serviceable additional assumptions making the dense-presentable-generator condition imply an Ind-presentation at the same rank.

ms. 203 OPEN XVIIIb-C027 – 4.8.6(3): is Filt^pi in Ind_{pi0}(C) closed under retracts for pi>pi0, at least when pi^pi0=pi?

ms. 205 OPEN XVIIIb-C032 – 4.8.6(4): find nonuseful cardinals, preferably arbitrarily large ones, for one accessible category.

ms. 205 OPEN XVIIIb-C033 – 4.8.6(4): find useful cardinals that fail quantitative regularity, preferably arbitrarily large ones.

ms. 209 FALSE XVIIIb-C046 – The displayed formula X=colim_J x_j=product_{Ob J}x_j computes the projective limit.

ms. 210-211 FALSE XVIIIb-C049 – 4.8.11 first sentence: on an accessible finitely complete M, every accessible finite-limit-preserving functor M->Set is representable.

ms. 213 CONJECTURED XVIIIb-C056 – Footnote91 conjecture: if M and M-op are both accessible, then M is essentially small.

ms. 220 CONJECTURED XVIIIb-C071 – 4.9.4(b): without the closure hypotheses the comparison can fail essential surjectivity even for J=B(Z/2).

ms. 224 FALSE XVIIIb-C082 – 4.9.6.3(b-prime) as printed: connectedness and equalization of parallel pairs in I-prime alone imply condition(a).

XVIII-c · Chapter XVIII, part 3 of 5, manuscript pages 220–328

ms. 220 CONJECTURED XVIIIc-A006 – Without an additional closure hypothesis on C, the comparison Ind_pi([J,C])->[J,Ind_pi C] need not be essentially surjective even for J=B(Z/2).

ms. 224 FALSE XVIIIc-A024 – The printed condition b-prime (I-prime connected and satisfying PF2, with no comma condition) is equivalent to a and b.

ms. 244 FALSE XVIIIc-B005 – Every section with values in D_j is κ-presentable in Γ(N/J).

ms. 248 FALSE XVIIIc-B014 – Existence and preservation of colimits large before π_0 of size$\leq\pi_0'$, with $\pi_0\leq\pi<\kappa$ and $\pi_0'>\pi_0$, imply the stated ordinal hypothesis $|\delta|\leq\pi$.

ms. 262 FALSE XVIIIc-B030 – The local consecutive-stage condition (ii) implies the t_β(a) define a morphism of ind-objects for arbitrary limit δ.

ms. 266-267 CONJECTURED XVIIIc-B041 – Question 4.10.11(a): for a small-base fibration with accessible fibres and accessible inverse images, Γ(N/J) is accessible.

ms. 267 CONJECTURED XVIIIc-B042 – Question 4.10.11(b): the category of cartesian sections under the same hypotheses is accessible.

ms. 267 OPEN XVIIIc-B043 – Find a common formulation covering fibred and opfibred sections, and possibly more general functors to the base.

ms. 272 OPEN XVIIIc-B060 – Does 4.11.6 remain true without rigidity?

ms. 280 conjectured XVIIIc-C008 – For M=N=Set, accessible functors have no common preservation cardinal.

ms. 285 false XVIIIc-C015 – 4.13.2(c): one may take pi0' minimal useful for S and for preservation by its inclusion, and pi1'=max(pi0',card_red S_{pi0'}), without bounding ambient ranks.

ms. 288 false XVIIIc-C019 – 4.13.4: the canonical functor Ind_pi(A)→M used in the classification is non-fully-faithful.

ms. 291 false XVIIIc-C028 – Footnote123: the fixed-point formulation4.13.8 additionally requires pi to be a non-limit cardinal.

ms. 292 false XVIIIc-C029 – The fixed-point equation pi^{pi0'}=pi entails pi≥2^{pi0}>pi0'.

ms. 293 false XVIIIc-C033 – The hypotheses of4.13.9 imply pi^{pi0'}=pi and hence global usefulness of pi for M.

ms. 298 false XVIIIc-C039 – The initial ordinal of cardinal pi is rho^+-filtered for every rho<pi.

ms. 300 false XVIIIc-C043 – The construction may satisfy both i0=i for arbitrary i and i_alpha∈J_{phi(alpha)} for every alpha without adjustment.

ms. 308-309 false XVIIIc-C062 – 4.13.15: under pi>pi0'≥pi0 and pi^{pi0}=pi, conditions a,a',b,c,c' are equivalent.

ms. 308 false XVIIIc-C068 – Footnote135: merely requiring usefulness of pi keeps a,a',b,c equivalent, without necessarily c'.

ms. 314 false XVIIIc-C076 – The initial ordinal pi is sufficiently filtered for taking the final alternating-chain colimits under pi>pi0' alone.

ms. 322-323 false XVIIIc-C079 – After the two successor factorization identities are imposed, naturality of u with the immediately preceding stage may still fail.

XVIII-d · Chapter XVIII, part 4 of 5, manuscript pages 316–429

ms. 336 false XVIII-d-A021 – The initial ordinal of cardinality π is large before every cardinal $\pi' < \pi$.

ms. 345 false XVIII-d-A041 – In Proposition 4.13.24, the condition that Φ contain a nonzero limit ordinal can simply be omitted with no replacement.

ms. 347–348 false XVIII-d-B006 – GCH makes $(\pi')^{\pi_0} = \pi'$ automatic for every infinite $\pi' > \pi_0$.

ms. 353–354 conjectured XVIII-d-B020 – Question 4.13.33 conjectures that the replete full essential image of every accessible functor between accessible categories is accessible and accessibly embedded; equivalently the functor factors through such a full image.

ms. 354 conjectured XVIII-d-B022 – If $\mathcal{M}$ is accessible with π_0^+-filtered colimits and A is a small full subcategory, the smallest replete full subcategory containing A and closed under those colimits is conjectured accessible and accessibly embedded.

ms. 355 conjectured XVIII-d-B023 – The same small-envelope conjecture is made after additionally closing under a small family Φ of small colimit shapes which exist in $\mathcal{M}$.

ms. 370 conjectured XVIII-d-B052 – Footnote 163 conjectures that the target completeness assumptions in Theorem 4.14.1 can be dropped; it points forward to 4.14.16 for removal of the limit-shape assumption.

ms. 373 FALSE XVIII-d-B057 – The ordinal of cardinal pi is pi0-plus-filtered merely because pi>pi0.

ms. 379 FALSE XVIII-d-C009 – Corollary 4.14.9 as printed: every small-limit-preserving functor between locally presentable categories has a left adjoint, and taking left adjoints gives an equivalence to the opposite category of cocontinuous functors.

ms. 379 FALSE XVIII-d-C011 – Lemma 4.14.10, left-adjoint half: a functor from a pseudo-topos (a cocomplete locally small category with a small family generating by strict epimorphisms) to a locally small category has a left adjoint if and only if it preserves all small limits.

ms. 380 FALSE XVIII-d-C013 – Corollary 4.14.11, covariant half: every small-limit-preserving $F : \mathcal{M} \to \mathbf{Set}$ on a locally presentable category is representable.

ms. 387 OPEN XVIII-d-C031 – Question 4.14.15: for every accessible $\mathcal{N}$, is the full category of epimorphisms accessible in $\mathcal{N}^{[1]}$?

ms. 388–390 CONJECTURED XVIII-d-C037 – Conjecture 4.14.16: one may remove the target existence assumptions in 4.14.1 and still obtain accessibility of the subcategory of diagrams that satisfy the prescribed universal cone conditions.

ms. 391 FALSE XVIII-d-C044 – Corollary 4.14.18(b), opfibration case: if pi≥max(pi_0,cardred C), a section whose values are pi^+-presentable is itself pi^+-presentable.

ms. 392 FALSE XVIII-d-C046 – Corollary 4.14.18(c): after choosing pi_0 useful for the fibres and the section category, pi_1=max(pi_0,cardred C,cardred M_pi_0), and pi≥pi_1 with pi^{pi_0}=pi, the pi-presentable sections are exactly the pointwise pi-presentable sections.

ms. 395–396 FALSE XVIII-d-C057 – Corollary 4.14.20(c): under the printed threshold and pi^{pi_0}=pi, intrinsic presentables of the cartesian/cocartesian section category are exactly the ambient presentables in it, and exactly its pointwise presentable sections.

ms. 411 FALSE XVIII-d-D017 – As printed, the inclusion E_1→E in the opfibration has a right adjoint, and the inclusion E_0→E in the fibration has a left adjoint.

ms. 420 FALSE XVIII-d-D031 – Corollary 4.14.25(1), literally: E and E_0 have π-large filtered colimits and E_0→E preserves them iff E_0 has them and all H(−,x_1) preserve them contravariantly; it then asserts existence of the same colimits in E_1.

ms. 426–429 FALSE XVIII-d-D049 – Under these bounds, if $\pi^{\pi_0}=\pi\geq\pi_1$, each π-presentable object of a fibre is π-presentable in E.

ms. 426 FALSE XVIII-d-D050 – As printed in 4.15.2(c), the subcategory E_π itself satisfies L_{π_1}, hence L_π.

ms. 426 FALSE XVIII-d-D051 – As printed in 4.15.2(c), Ind_π(E_{s,π})→E is an equivalence for a single fixed fibre s.

ms. 426 FALSE XVIII-d-D052 – Corollary 4.15.2(d): under the same hypotheses E(π)=E_π, not just E(π)⊂E_π.

XVIII-e · Chapter XVIII, part 5 of 5, manuscript pages 419–19

ms. 420–421 FALSE XVIIIe-A005 – 4.14.25(1), literally: $\mathcal{E}$ and $\mathcal{E}_0$ admit L_π-colimits and $\mathcal{E}_0 \to \mathcal{E}$ preserves them iff $\mathcal{E}_0$ admits them and each $H(-, x_1)$ takes them to limits.

ms. 426,429–431 FALSE XVIIIe-A023 – 4.15.2(c), rank conclusion: under its printed hypotheses every fibrewise pi-presentable object is pi-presentable in the total category.

ms. 426 FALSE XVIIIe-A024 – The displayed functor Ind_pi(E_{s,pi})->E is an equivalence.

ms. 426,431–432 FALSE XVIIIe-A025 – 4.15.2(d): E(pi)=E_pi at the stated numerical rank.

ms. 430 FALSE XVIIIe-A032 – The inequalities pi>=pi1>=pi_lambda imply that H_lambda(-,y) is pi0-accessible.

ms. 434 OPEN XVIIIe-A042 – Find usable necessary and sufficient local conditions on f ensuring accessibility of every pullback over a small Karoubian category.

ms. 434 OPEN XVIIIe-A043 – It might suffice to test only Delta1 and the walking retract P; the author expresses doubt.

ms. 434 CONJECTURED XVIIIe-A044 – Testing Delta1 and the two three-object categories Q=(2->1->0 with the retract0<->1) and Q-prime=(2<-1<->0) should suffice.

ms. 438 OPEN XVIIIe-A054 – The analogous construction for a fibration is not supplied; the author suggests testing the walking retract P.

ms. 456–457 CONJECTURED XVIIIe-B029 – Key lemma4.15.8.1: for a left-cancellative monoid M with $|M| \le \pi_0$, every ${\pi_0}^+$-directed diagram in BM has a tail whose transition elements are units.

ms. 461–462 FALSE XVIIIe-B040 – Condition(b) asserts literal identity of every sufficiently late transition in every diagram valued in a left-cancellative quotient of End_C(x).

ms. 462 CONJECTURED XVIIIe-B042 – Condition(b′) excludes π^+-long diagrams in the relevant left-cancellative monoids with all strict transitions noninvertible.

ms. 461–462 FALSE XVIIIe-B043 – Theorem4.15.9 declares all of(a),(a′),(a″),(b),(b′) equivalent as printed.

ms. 461 CONJECTURED XVIIIe-B044 – Grothendieck conjectures that Ind_π C is the idempotent completion whenever $|C| \le \pi$.

ms. 462–463 FALSE XVIIIe-B045 – Corollary4.15.10 says all printed equivalent conditions hold when $\pi > |C|$.

ms. 465-466 OPEN XVIIIe-R005 – For every universe U there might be an infinite cardinal pi in U such that every ultrafilter on a U-small set selecting a cell of every partition into at most pi pieces is principal.

ms. 466 FALSE XVIIIe-R006 – Every suitably definable replete full subcategory of an accessible category closed under sufficiently filtered colimits is accessible and accessibly embedded.

ms. 467-468 FALSE XVIIIe-R008 – For fixed z, failure of Hom(x,z) to be nonempty should be witnessed by a uniformly bounded member of a suitable presentable-object presentation of x.

ms. 467-468 OPEN XVIIIe-R009 – For every infinite field k, one may take pi=|k| in the small-subalgebra obstruction criterion for absence of k-points.

ms. 468-469 OPEN XVIIIe-R010 – If f:M->N^op preserves sufficiently filtered colimits and T is accessible in N and stable under the corresponding cofiltered limits in N, is f^{-1}(T) accessible in M?

ms. 470 CONJECTURED XVIIIe-R014 – The full L_pi-colimit closure S(pi) of the image of an accessible functor is accessible in M.

ms. 470 FALSE XVIIIe-R015 – The decreasing family S(pi) stabilizes for all sufficiently large pi.

ms. 470 FALSE XVIIIe-R017 – The same accessibility and eventual-stationarity claims should hold for the image of g^op:N^op->M when g:N->M^op preserves sufficiently filtered colimits.

ms. 471 FALSE XVIIIe-R019 – A full subcategory of a presheaf category closed under sufficiently filtered colimits automatically inherits a small dense subcategory of accessible objects.

ms. 471 OPEN XVIIIe-R020 – A category with a small dense family of presentable objects and sufficiently filtered colimits is accessible.

ms. 472 FALSE XVIIIe-R021 – If M and M^op are accessible, then M is essentially small.

ms. 472 OPEN XVIIIe-R022 – An accessible category with a small codense subcategory is essentially small.

ms. 472 OPEN XVIIIe-R023 – A locally small category with small dense and codense subcategories is essentially small.

ms. 473 FALSE XVIIIe-R025 – The subcategory of existing I-colimit cocones in an accessible M is accessible and accessibly embedded even if some I-diagrams have no colimit.

ms. 475 FALSE XVIIIe-R032 – Corollary4.16.6.2(b'): if C has no nonidentity idempotents, the Delta1-tests alone imply (a).

ms. 476 OPEN XVIIIe-R035 – Question4.16.6.4: do accessible fibres and transition functors of a fibration or opfibration imply accessibility after Q and Q' base change?

ms. 476-476bis OPEN XVIIIe-R037 – If E is accessible over small Karoubian C, then for every accessible M and accessible M->C, the strict pullback E x_C M and both projections are accessible.

ms. 484-485 OPEN XVIIIe-R047 – It is asked whether there is a U-ordinal-length family of fields with no morphisms from an earlier field to a later one.

ms. 4 FALSE XVIIIe-C011 – The printed identity in the inverse proof is ff′=f′=f=1.

ms. 4 FALSE XVIIIe-C013 – The last sentence asserts that k_Φ is a field quotient for every $\Phi\in\mathcal{F}$.

ms. 11 CONJECTURED XVIIIe-C030 – If π is the least cardinal in U belonging to no strictly smaller infinite universe, every π-ultrafilter on a U-small set is principal.

ms. 14 FALSE XVIIIe-C038 – The source defines both complementary classes S and S′ by Hom(A,k)=∅.

ms. 15 FALSE XVIIIe-C044 – Under the principal-ultrafilter hypothesis the source identifies k-points with coordinates satisfying {xi}=intersection(Φ).

ms. 19 OPEN XVIIIe-C053 – Does the preceding small-subalgebra witness property hold simply at $\pi\geq|\mathrm{k}|$? Does any such U-small bound exist?

XIX · Chapter XIX, manuscript pages 1–50

ms. 1 FALSE XIX-A007 – The strengthened equalities of (1.3) are claimed to be equivalent to adding separate double-orthogonal closedness of the corresponding classes to $\Phi \perp \Psi$.

ms. 4–5 OPEN XIX-A026 – Is Retr(Φ'') stable under pushout and transfinite composition, and therefore equal to Φ''', without small generation?

ms. 10 FALSE XIX-A052 – If $\Psi = \Phi^{\square}$, then $\Psi(I_0) = \Phi(I_0)^{\square}$.

ms. 12 CONJECTURED XIX-A060 – Question-conjecture 1.11: if (Φ, Ψ) is special, is the injective pair $(\Phi(I), \Psi[I])$ special for every small I, perhaps after an additional cardinal-filtration hypothesis?

ms. 12 OPEN XIX-A061 – In 1.11, if Φ_0 is a small generating family for Φ, does the particular class $\Phi_0(I)$ generate $\Phi(I)$?

ms. 12 FALSE XIX-A062 – Proposition 1.12, formula (1.13.2), prints $u^*(\Phi(I')) \subseteq \Phi\langle I'\rangle \iff u_*\Psi(I) \subseteq \Psi(I')$.

ms. 14 FALSE XIX-A074 – The printed dual criterion in (2.5) uses a factorization $f = pi$ with $i \in W$ and $f \in C$.

ms. 17 FALSE XIX-A087 – The Case A proof says that $TC' \subseteq W'$ is equivalent to $R(TC') \subseteq W'$.

ms. 10 FALSE XIX-A090 – The equalities (1.15)–(1.16) identify $(v_!\Phi(I_0))^{\square}$ with $\Psi(I)$ and its left orthogonal with $\Phi\langle I\rangle$ under the sole displayed assumption $\Psi = \Phi^{\square}$.

ms. 19 FALSE XIX-B003 – The displayed equality in Theorem 2.3 identifies $C\langle I\rangle$ with ${}^{\square}F(I)$.

ms. 23 FALSE XIX-B021 – Decomposition holds for every prederivator of the form $\mathbf{D}_{\mathcal{M},W}$, without hypotheses on the relative category.

ms. 24 OPEN XIX-B024 – For a merely special triple, the source has not established small generating sets or factorizations for the componentwise classes $C(I)$ and $TC(I)$.

ms. 25 CONJECTURED XIX-B035 – Condition (d) should be redundant, at least when epimorphisms are effective, after choosing suitable cardinals of the form 2^c.

ms. 30 FALSE XIX-B062 – $v^*(TF[I]) = v^*v_*(TF(I_0))$ as image classes of arrows.

ms. 32 OPEN XIX-B070 – Can special model structures outside the very special class define derivators on all small shapes?

ms. 32 OPEN XIX-B072 – The author expresses uncertainty about the all-shapes homotopy-Kan-extension theorem attributed to Anderson.

ms. 35 FALSE XIX-C023 – Every cofibration between cofibrant objects belongs to ambient Cof_W by Brown's lemma.

ms. 38 FALSE XIX-C038 – Proposition3.5: if Φ=^perpΨ is Q-closed, then for noetherian I the Anderson class Φ_I equals ^perp(Ψ(I)).

ms. 39 CONJECTURED XIX-C043 – For only transfinitely Q-saturated Φ, conjecturally the transfinite Q-saturation of v!Φ(I_0) agrees with Anderson's noetherian extension.

ms. 39 OPEN XIX-C045 – The desired identity is C<I>∩W(I)=(TC)<I>.

ms. 40 OPEN XIX-C048 – Question3.6 asks the identity for every small I, under small completeness of M and Q-closedness of C and TC.

ms. 40 OPEN XIX-C053 – It may suffice for Question3.6 that only (TC)<I>–F(I) factor.

ms. 42 OPEN XIX-C062 – Question3.9 requests a closed Quillen structure whose prederivator lacks some u!^W.

ms. 42 OPEN XIX-C063 – Question3.9 also requests such a structure lacking some u*^W.

ms. 42 CONJECTURED XIX-C064 – The author presumes testing u:I→e should suffice for general Kan extensions.

ms. 43 OPEN XIX-C065 – The requested counterexample would be stronger with cocomplete accessible ambient M and L-accessible W.

ms. 46–47 OPEN XIX-C092 – A counterexample might have bicomplete M but H lack some small colimits.

ms. 47 OPEN XIX-C096 – Question3.13: can a locally U-small category have all U-small colimits but lack some U-small limits?

ms. 48 OPEN XIX-C099 – Question3.14: a cofibration category satisfying Cof_4 should have u!^W for all small u.

ms. 48 OPEN XIX-C100 – The author requests a localizer on bicomplete M whose prederivator lacks some left or right Kan extension, perhaps with M small.

ms. 48–49 OPEN XIX-C101 – The author is less convinced such a counterexample exists when W is filtered-colimit stable and M has accessible objects and a cardinal filtration.

ms. 49 OPEN XIX-C102 – Question3.15 asks whether an L-accessible arrow class in the stated accessible complete ambient category has a small left Q-generating subset.

ms. 49 OPEN XIX-C103 – Question3.15 allows the extra assumption that Φ is left Q-saturated: isomorphisms, cobase change, composition, and retracts.

ms. 49–50 open XIX-C105 – The author requests any mutually Q-orthogonal closed pair that does not factor all arrows.

ms. 49–50 open XIX-C106 – The same nonfactorization request with special ambient M is of particular interest.

Transcription corrections

The corrections to the transcription, counted by kind for each part: readings of the transcription corrected against the edition (transcription), slips of the edition kept in the text with their intended reading recorded (edition slip kept), and doubtful readings settled against the edition (doubt resolved).

Results proved along the way that we did not find in the literature

Some statements had to be proved along the way, while checking Grothendieck's text and the returns of the research prompts, because we could not find them in the sources we searched. They are collected here so that a reader can check them, find the literature we missed, and see where they bear on the manuscript. Our search was limited, so some of them may well be known; whoever knows a reference is asked to tell us, and the entry will cite it. No priority is claimed. Each entry gives the statement, where the proof is, who proved it (model and effort setting), whether anyone has checked it yet, and the pages of the manuscript it bears on. Statements that turned out to be known are listed at the end with the reference.
Editorial scope. The inventory was started on 12 November 2026 by Claude Opus 5.5 (effort max). This appendix was assembled by GPT-6 Astra (OpenAI, ChatGPT Pro mode). Each numbered section preserves the inventory statement and the available cited proof, with mathematical glyphs and scripts typeset for reading. Proofs and source comments remain attributed to their source authors. The paragraph headed "GPT-6 Astra's reading" is an editorial reading of the supplied argument; it is not the separate peer review requested for later work. Missing cited evidence is stated explicitly. Original source identifiers are preserved. The source extracts and the exact glyph mapping are included among the build records. No material from STRATA, PATHS, BISITE or RESIDUE is added beyond the inventory's own references.

Notation from the cited sources. A universe U is fixed; categories are small in that universe. $BX = |NX|$ denotes the classifying space, W_∞ the functors inducing weak homotopy equivalences, and **Hot** the homotopy category. In $\mathrm{Cat}_{\mathrm{hot}}$, morphisms are $\pi_0 \operatorname{Fun}(X, K)$. The functor Π_1 inverts every arrow, with unit $\eta_X : X \to \Pi_1 X$. For a monoid M, $U(M)$ is its universal group. Brackets $[A, Y]$ denote free homotopy classes. Original labels such as Theorem 2.1 and G.4 refer to the cited source, not to the numbering of this appendix.

1. Finite monoids, finite dimension, and bounded homology

Statement recorded in the inventory.

Finite monoids: finite type, finite dimension and bounded homology coincide. For a finite monoid M: BM has the homotopy type of a finite complex ⇔ of a finite-dimensional complex ⇔ $\mathrm{H_k}$(M; Z) = 0 for all large k; then the universal group U(M) is trivial. Corollaries: a "Swan theorem" for finite monoids (U(M) ≠ 1 forces homology in infinitely many degrees; p-locally too); finite cohomological dimension forces U(M) = 1; with Theorem C of Ben-Bassat (arXiv:2610.38760v1) the homotopy types of finite monoids with bounded homology are exactly the finite simply connected complexes.
Bearing on the manuscript. V ms. 51–52 (Hot_0, "types d'homotopie de type fini"); sharpens G.4 of the CATHOT return, the counterexample to Ben-Bassat's Conjecture 7.1

Statement and proof in the supplied source

Let M be a finite monoid. Facts used, all proved in `G6_VERDICT.md`: $\pi_1(\mathrm{BM}) = \mathrm{U}(\mathrm{M})$; η: $\mathrm{M} \to \mathrm{U}(\mathrm{M})$ is onto; for an idempotent e of the minimal ideal, $\mathrm{H} = \mathrm{eMe}$ is a finite group and there is a map $\mathrm{j_e}$: $\mathrm{BH} \to \mathrm{BM}$ (through the Karoubi envelope) inducing the surjection $\eta|\mathrm{H}$ on π_1. Also $\mathrm{H_k}(\mathrm{BM}; \mathrm{Z}) = \mathrm{Tor_k}^{\mathrm{ZM}}(\mathrm{Z}, \mathrm{Z})$ is finitely generated for every k (the bar complex is finitely generated in each degree).

Theorem 2.1. If $\mathrm{H_k}(\mathrm{M}; \mathrm{Z}) = 0$ for all large k, then $\mathrm{U}(\mathrm{M}) = 1$. More precisely, if a prime p divides $|\mathrm{U}(\mathrm{M})|$, then $\mathrm{H_k}(\mathrm{M}; \mathrm{F_p}) \neq 0$ for infinitely many k.

Proof. If $\mathrm{H_k}(\mathrm{M}; \mathrm{Z}) = 0$ for $\mathrm{k} \geq \mathrm{n}$, then $\mathrm{H^q}(\mathrm{BM}; \mathrm{Z}) = \mathrm{Hom}(\mathrm{H_q}, \mathrm{Z}) \oplus \mathrm{Ext}(\mathrm{H_{q-1}}, \mathrm{Z}) = 0$ for $\mathrm{q} > \mathrm{n}$. $\pi_1(\mathrm{BM}) = \mathrm{U}(\mathrm{M})$ is finite. Theorem 1.1 applied to $\mathrm{j_e}$: $\mathrm{BH} \to \mathrm{BM}$ says $\eta|\mathrm{H}$ is trivial; it is onto; so $\mathrm{U}(\mathrm{M}) = 1$. For the second statement: if $\mathrm{H_k}(\mathrm{M}; \mathrm{F_p}) = 0$ for all $\mathrm{k} \geq \mathrm{k_0}$, then $\mathrm{H_k}(\mathrm{M}; \mathrm{Z}) \otimes \mathrm{F_p} = 0$ and $\mathrm{Tor}(\mathrm{H_{k-1}}(\mathrm{M}; \mathrm{Z}), \mathrm{F_p}) = 0$ for $\mathrm{k} \geq \mathrm{k_0}$, so the finitely generated groups $\mathrm{H_k}(\mathrm{M}; \mathrm{Z})$ have zero localization at p for $\mathrm{k} \geq \mathrm{k_0}$, and $\mathrm{H^q}(\mathrm{BM}; \mathrm{Z_{(p)}}) = 0$ for $\mathrm{q} > \mathrm{k_0}$. Theorem 1.2 applied to $\mathrm{j_e}$ gives $\mathrm{p} \nmid |\eta(\mathrm{H})| = |\mathrm{U}(\mathrm{M})|$. ■

Theorem 2.2. For a finite monoid M the following are equivalent: (i) BM has the homotopy type of a finite CW complex; (ii) BM has the homotopy type of a finite-dimensional CW complex; (iii) $\mathrm{H_k}(\mathrm{M}; \mathrm{Z}) = 0$ for all large k. If they hold, $\mathrm{U}(\mathrm{M}) = 1$ and BM is simply connected.

Proof. (i) ⇒ (ii) ⇒ (iii) are clear. (iii) ⇒ (i): by 2.1, BM is simply connected; its homology groups are finitely generated and vanish above some degree n; by Hatcher, *Algebraic Topology*, Proposition 4C.1, a simply connected CW complex with finitely generated homology is homotopy equivalent to a CW complex with one k-cell for each Z summand of $\mathrm{H_k}$ and one k-cell and one (k+1)-cell for each finite cyclic summand of $\mathrm{H_k}$: a finite complex of dimension $\leq \mathrm{n} + 1$. ■

Corollary 2.3 (Swan's theorem for finite monoids). A finite monoid with $\mathrm{U}(\mathrm{M}) \neq 1$ has $\mathrm{H_k}(\mathrm{M}; \mathrm{Z}) \neq 0$ for infinitely many k; if p divides $|\mathrm{U}(\mathrm{M})|$, then $\mathrm{H_k}(\mathrm{M}; \mathrm{F_p}) \neq 0$ for infinitely many k. (For a finite group this is Swan's theorem.)

Corollary 2.4. If the trivial left (or right) ZM-module Z has a projective resolution of finite length (M has finite left or right cohomological dimension), then $\mathrm{U}(\mathrm{M}) = 1$ and BM has the homotopy type of a finite simply connected CW complex.

Corollary 2.5 (with Theorem C of arXiv:2610.38760v1; recent, unrefereed). The homotopy types of the classifying spaces of finite monoids with bounded integral homology are exactly the homotopy types of finite simply connected CW complexes.

GPT-6 Astra's reading

The argument explicitly connects the surjective group map $eMe \to U(M)$ to a map of classifying spaces through the Karoubi envelope; section 12 below reproduces that construction. The bounded-homology implication then uses the cohomological result reproduced in section 2, and the finite-generation input is supplied by the degreewise finite bar complex. The finite-complex conclusion invokes Hatcher's Proposition 4C.1; the positive realization assertion in Corollary 2.5 invokes Theorem C of the stated, unrefereed preprint. The proof records these dependencies rather than proving them here. I found no additional missing inference in the displayed chain. In the universal-coefficient line the direct-sum decomposition is noncanonical, which does not affect the vanishing implication used. The computational observation following the source corollaries is not needed for the proof and is not reproduced here.

2. Maps from finite-group classifying spaces under a cohomological bound

Statement recorded in the inventory.

Miller's Theorem B under a cohomological bound. A map $BG \to X$, G finite, X connected with finite (or residually finite, or linear) π_1 and $H^q(X; Z) = 0$ for $q > n$, is trivial on π_1; p-local form with $Z_{(p)}$ coefficients.

Statement and proof in the supplied source

Theorem 1.1. Let X be a connected CW complex with finite fundamental group π, and suppose $H^q(X; Z) = 0$ for all $q > n$. Let G be a finite group and $f: BG \to X$ a map. Then $f_*: G \to \pi$ is trivial.

Theorem 1.2 (p-local form). Let X be a connected CW complex with finite fundamental group π, p a prime, and suppose $H^q(X; Z_{(p)}) = 0$ for all $q > n$. Then for every finite group G and every map $f: BG \to X$, the order of the image of $f_*: G \to \pi$ is prime to p.

Miller's Theorem B (Ann. of Math. 120 (1984), p. 40) has "X finite-dimensional" as hypothesis and no condition on $\pi_1(X)$. Here the dimension hypothesis is weakened to a bound on ordinary cohomology with constant coefficients, at the price of assuming $\pi_1(X)$ finite (residually finite, or linear over C, is enough for 1.1; see the remark at the end). The proof is Miller's and Atiyah's, with the covering-space step replaced by the regular representation.

K-theory used. $K^0(Y) = [Y, Z \times BU]$ for CW complexes Y; it is a ring, contravariant in Y. For a CW complex Y put $F^q(Y) = \ker(K^0(Y) \to K^0(Y^{(q-1)}))$. (K1) $F^a \cdot F^b \subset F^{a+b}$. Proof: if $x \in F^a$, $y \in F^b$, lift them to $\widetilde{x} \in K^0(Y, Y^{(a-1)})$, $\widetilde{y} \in K^0(Y, Y^{(b-1)})$; the external product $\widetilde{x} \boxtimes \widetilde{y}$ lies in $K^0(Y \times Y, Y^{(a-1)} \times Y \cup Y \times Y^{(b-1)})$, and the (a+b−1)-skeleton of $Y \times Y$ is contained in $Y^{(a-1)} \times Y \cup Y \times Y^{(b-1)}$; a cellular approximation $\Delta\prime$ of the diagonal maps $Y^{(a+b-1)}$ into it, so $(xy)|Y^{(a+b-1)} = \Delta\prime^*(x \boxtimes y)|\ldots = 0$. (K2) If $H^q(Y; Z) = 0$ for all $q > n$, then $F^q(Y) = F^{q+1}(Y)$ for all $q > n$; hence $F^{n+1}(Y) = \bigcap_q F^q(Y)$. Proof: let $x \in F^q$, $q > n$. Then $x|Y^{(q)}$ comes from a class $c \in K^0(Y^{(q)}, Y^{(q-1)}) = C^q(Y; \widetilde{K}^0(S^q))$, the cellular cochains with coefficients Z (q even) or 0 (q odd). Since $x|Y^{(q)}$ extends over $Y^{(q+1)}$, the image of c in $K^1(Y^{(q+1)}, Y^{(q)})$ vanishes; that image is the cellular coboundary δc. So c is a cocycle, hence ($H^q = 0$) a coboundary $c = \delta b$ with $b \in K^{-1}(Y^{(q-1)}, Y^{(q-2)})$, and the image of δb in $K^0(Y^{(q)})$ is zero because $K^{-1}(Y^{(q-1)}) \to K^0(Y^{(q)}, Y^{(q-1)}) \to K^0(Y^{(q)})$ is exact. So $x|Y^{(q)} = 0$, that is $x \in F^{q+1}$. (K3) A cellular map $g: Y\prime \to Y$ satisfies $g^*F^q(Y) \subset F^q(Y\prime)$. (K1)–(K3) hold verbatim for the p-localized theory $K_{(p)}$ (represented by the p-localization of the spectrum KU, coefficients $Z_{(p)}$ in even degrees), with $H^q(-; Z_{(p)})$ in (K2); and $K^0{}_{(p)}(Y) = K^0(Y) \otimes Z_{(p)}$ for finite Y.

Atiyah's theorem used (Publ. Math. IHES 9 (1961)). For a finite group G let $\mathcal{K}^0(B_G) = \lim_m K^0(B_G{}^{(m)})$ over the finite skeleta of a model of BG with finite skeleta, and α: $R(G) \to \mathcal{K}^0(B_G)$ the map sending a representation to its associated bundle. (7.2): α induces an isomorphism of the I(G)-adic completion $R(G)\hat{}$ onto $\mathcal{K}^*(B_G)$. (6.10): the kernel of $R(G) \to R(G)\hat{}$ is the set of virtual characters vanishing on all elements of prime-power order; (6.11): it is zero for a p-group. Two models of BG with finite skeleta are related by cellular homotopy equivalences, so "$\alpha(\theta)$ restricts to zero on every finite skeleton" does not depend on the model.

Proof of 1.1. Make f cellular; $BG = |NG|$ has finite skeleta. Let ρ: $\pi \to GL_d(C)$ be the regular representation ($d = |\pi|$), $V = \widetilde{X} \times_\pi C^d$ the flat bundle on X, $v = [V] - d \in K^0(X)$. Since X is connected, $v \in F^1(X)$; by (K1), $v^{n+1} \in F^{n+1}(X) = \bigcap_q F^q(X)$ by (K2). By

(K3), $f^*(v^{n+1})$ restricts to zero on every skeleton of BG. Now f^*V is the flat bundle of the representation $\rho\circ\varphi$ of G, $\varphi = f_*$; so $\alpha((\rho\varphi - d)^{n+1}) = 0$ in $\mathcal{K}^0(B_G)$. By (7.2) and (6.10) the virtual character $(\chi_{\rho\varphi} - d)^{n+1}$ vanishes at every $g \in G$ of prime-power order: $\chi_\rho(\varphi(g)) = d$. The regular character takes the value d only at 1, so $\varphi(g) = 1$ for every g of prime-power order. Every element of a finite group is a product of elements of prime-power order (its primary components). Hence $\varphi = 1$. ■

Proof of 1.2. Suppose p divides $|\varphi(G)|$. Take $u \in \varphi(G)$ of order p and g with $\varphi(g) = u$; if g has order p^a m with $p \nmid m$ ($a \geq 1$) and $mm' \equiv 1 \bmod p^a$, then $c = g^{mm'}$ has p-power order and $\varphi(c) = u$. Put $C = \langle c\rangle$ and restrict f to BC (cellular; take for BC the infinite lens space, whose odd skeleta are lens spaces L^{2j+1}). As above, with $K_{(p)}$: the image of v^{n+1} in $K^0{}_{(p)}(X)$ lies in $\bigcap_q F^q$, so $\alpha((\rho\varphi|C - d)^{n+1})$ goes to zero in $K^0(L^{2j+1}) \otimes Z_{(p)}$ for all j. The group $\widetilde{K}^0(L^{2j+1})$ is a finite p-group (Atiyah–Hirzebruch: $\widetilde{H}^{\mathrm{even}}(L^{2j+1}; Z)$ consists of copies of $Z/|C|$), so $K^0(L^{2j+1}) \to K^0(L^{2j+1}) \otimes Z_{(p)}$ is injective. Hence $\alpha((\rho\varphi|C - d)^{n+1}) = 0$ in $\mathcal{K}^0(B_C)$, and by (7.2), (6.11) (C is a p-group; for cyclic groups Atiyah's (8.1) suffices) $(\rho\varphi|C - d)^{n+1} = 0$ in R(C). Its value at c is $(\chi_\rho(u) - d)^{n+1} = (-d)^{n+1} \neq 0$. Contradiction. ■

Remark. In 1.1 the regular representation can be replaced by any finite-dimensional complex representation ρ of $\pi_1(X)$, finite or not: the same proof gives $\rho(f_*(g)) = 1$ for all $g \in G$ (a matrix of finite order with trace equal to its size is the identity). So for arbitrary $\pi_1(X)$ the image $f_*(G)$ lies in the intersection of the kernels of all finite-dimensional complex representations, and f_* is trivial if $\pi_1(X)$ is residually finite or linear.

GPT-6 Astra's reading

The proof states the skeletal-filtration facts it needs and derives the character obstruction from the regular representation. The essential point in (K2) is the exactness of the skeletal relative-K-theory sequence: the cellular coboundary representing the relative class maps to zero in absolute K-theory. This establishes the filtration inclusion actually used without asserting convergence of an unrestricted Atiyah–Hirzebruch spectral sequence. The p-local proof reduces to finite lens-space skeleta, where the reduced K-groups are finite p-groups and localization is injective. The residual-finiteness and linearity sentence uses the stated finite-dimensional representation argument. I found no gap in these deductions from the explicitly quoted Atiyah completion and character-kernel results; those external results remain cited inputs.

3. Kan–Thurston without small quotients and the ind-category statement

Statement recorded in the inventory.

A Kan–Thurston theorem without small quotients, and E.17. Every connected CW complex W has an acyclic map $BG \to W$ such that every homomorphism from G to a group of cardinality $< \lambda$ factors through $\pi_1(W)$. Hence a U-small ind-object of $\mathrm{Cat}_{\mathrm{hot}}$ is $W\infty$-invariant iff it is ind-isomorphic to an ind-object of groupoids.

Bearing on the manuscript. V ms. 46 is a theorem for "local", false for "fibrant"; VII ms. 129–132 and IX ms. 22–23: invariant path ind-categories see only Π_1

Statement and proof in the supplied source

The return leaves open (E.17): if a sequence $K = (K_n)$ in $\mathrm{Cat}_{\mathrm{hot}}$ has a W∞-invariant presheaf $H_K = \mathrm{colim}_n\, \pi_0\mathrm{Fun}(-, K_n)$, is K isomorphic in $\mathrm{Ind}(\mathrm{Cat}_{\mathrm{hot}})$ to a sequence of groupoids? It reduces this to (E.17c): H_K inverts every $\eta_X\colon X \to \Pi_1 X$. The answer is yes.

Input from the return (verified): B.7 (for every group H and every infinite cardinal $\lambda \geq |H|$ there is a non-abelian simple, integrally acyclic group $A \supset H$ with $|A| = \lambda$); A.4 and A.7; C.1, C.4; (E.17a). Input from the literature: the Kan–Thurston theorem (D. M. Kan, W. P. Thurston, *Every connected space has the homology of a K(π,1)*, Topology 15 (1976), 253–258): for every connected CW complex E there are a group T and a map $BT \to E$ inducing isomorphisms on homology with every local coefficient system on E (an *acyclic* map); T can be taken of cardinality at most $\max(\aleph_0$, number of cells of E). I could not open the paper (the publisher's open archive refused automated access); the statement is quoted from memory and agrees with the summary in Palmer–Wu, arXiv:2510.16879v1, Introduction. It is used only in the successor step for cells of dimension ≥ 3 below. Standard facts on acyclic maps (Hausmann–Husemoller): the homotopy fibre of an acyclic map is acyclic; acyclic maps are stable under homotopy pull-back and composition; an acyclic map $f\colon A \to B$ of connected CW complexes is onto on π_1 with perfect kernel N, and for every space Y, $f^*\colon [B, Y] \to [A, Y]$ is injective with image the classes of maps g with $\pi_1(g)(N) = 1$.

Theorem 3.1. Let W be a connected CW complex with one 0-cell, $\pi = \pi_1(W)$, and λ an infinite cardinal not less than the number of cells of W. There are a group G with $|G| \leq \lambda$ and a map $t\colon BG \to W$ such that (i) t is acyclic (an isomorphism on homology with every local coefficient system on W); in particular $\tau = \pi_1(t)\colon G \to \pi$ is onto; (ii) every homomorphism from G to a group of cardinality $< \lambda$ factors through τ. Consequently, for every space Y all of whose fundamental groups have cardinality $< \lambda$, $t^*\colon [W, Y] \to [BG, Y]$ is a bijection.

Proof. Enumerate the cells of dimension ≥ 2 by an ordinal, in non-decreasing order of dimension: $W_1 = W^{(1)}$, $W_{\alpha+1} = W_\alpha \cup_{a_\alpha} e^{m_\alpha+1}$ with $a_\alpha\colon S^{m_\alpha} \to W_\alpha$, $m_\alpha \geq 1$, unions at limit ordinals. We build groups G_α, injective homomorphisms $G_\alpha \to G_\beta$ ($\alpha < \beta$) and maps $t_\alpha\colon BG_\alpha \to W_\alpha$, with $t_\beta|BG_\alpha = t_\alpha$, satisfying (i) and (ii) for (G_α, W_α), with $\tau_\alpha = \pi_1(t_\alpha)\colon G_\alpha \to \pi_\alpha = \pi_1(W_\alpha)$.

Start. G_1 is the free group on the 1-cells and $t_1\colon BG_1 \to W_1$ a homotopy equivalence; (ii) is empty.

Successor step. Let $a = a_\alpha\colon S^m \to W_\alpha$. Claim: there are a group $H\prime$, an acyclic map $q\colon BH\prime \to S^m$ and a homomorphism $u\colon H\prime \to G_\alpha$ with $t_\alpha \circ Bu \simeq a \circ q$. For $m = 1$: $H\prime = Z$, $q = \mathrm{id}$, $u(1) = g$ with $\tau_\alpha(g)$ the class of the loop a (τ_α is onto). For $m \geq 2$: let E be the homotopy pull-back of $S^m \to W_\alpha \leftarrow BG_\alpha$; $E \to S^m$ is acyclic and E is connected; by Kan–Thurston choose $H\prime$ and an acyclic map $BH\prime \to E$; q is the composite to S^m, and the composite $BH\prime \to E \to BG_\alpha$ is homotopic to Bu for a homomorphism u. In both cases $|H\prime| \leq \lambda$. By B.7 choose simple acyclic groups $A\prime$, $A\prime\prime$ of cardinality λ and embeddings $i\prime\colon H\prime \to A\prime$, $i\prime\prime\colon H\prime \to A\prime\prime$. Put $P = G_\alpha \times A\prime$ and $v = (u, i\prime)\colon H\prime \to P$, which is injective, and

$G_{\alpha+1} = P *_{H\prime} A\prime\prime$ (amalgamated along v and $i\prime\prime$).

P and $A\prime\prime$ embed in the amalgam, so $G_\alpha \to G_{\alpha+1}$, $g \mapsto (g, 1)$, is injective, and $BG_{\alpha+1}$ is the double mapping cylinder of $BP \leftarrow BH\prime \to BA\prime\prime$. Define $t_{\alpha+1}$ on it by $t_\alpha \circ \mathrm{pr}_1$ on BP, by the cone of q on the mapping cylinder of $BH\prime \to BA\prime\prime$ ($BA\prime\prime$ going to the centre of the new cell), and by the chosen homotopy $t_\alpha \circ Bu \simeq a \circ q$ on the other cylinder; then $t_{\alpha+1}|BG_\alpha = t_\alpha$. *Acyclicity:* for a local system L on $W_{\alpha+1}$ compare the Mayer–Vietoris sequences of the two double mapping cylinders. On BP: $H_*(G_\alpha \times A\prime; L) = H_*(G_\alpha; L)$ because $A\prime$ is acyclic and acts trivially on L (Lyndon–Hochschild–Serre), and t_α is acyclic. On $BH\prime$: q is acyclic. On $BA\prime\prime$: L is constant on the cell and $A\prime\prime$ is acyclic. The five lemma gives (i). *No small quotients:* let $\rho\colon G_{\alpha+1} \to \Lambda$ with $|\Lambda| < \lambda$. ρ is trivial on $A\prime\prime$ and on $1 \times A\prime$ (simple groups of cardinality λ). For $h \in H\prime$, $v(h) = (u(h), 1)(1, i\prime(h))$ is identified with $i\prime\prime(h) \in A\prime\prime$, so $\rho(u(h), 1) = 1$. By (ii) for G_α, $\rho|G_\alpha = \overline{\rho} \circ \tau_\alpha$, and $\overline{\rho}$ kills $\tau_\alpha(u(H\prime))$, which is trivial for $m \geq 2$ and is

the cyclic subgroup generated by the class of the attaching loop for m = 1. By van Kampen $\overline{\rho}$ factors through $\pi_{\alpha+1} = \pi_1(W_{\alpha+1})$. Since $G_{\alpha+1}$ is generated by G_α, A′, A″, and $\tau_{\alpha+1}$ is trivial on A′ and A″ and equals $G_\alpha \to \pi_\alpha \to \pi_{\alpha+1}$ on G_α, ρ factors through $\tau_{\alpha+1}$.

Limit step. $G_\gamma = \bigcup G_\alpha$, $t_\gamma = \bigcup t_\alpha$. Homology with local coefficients commutes with these unions, and a homomorphism from G_γ to Λ factors through colim $\pi_\alpha = \pi_\gamma$.

The consequence. Let $N = \ker \tau$. A map g: $BG \to Y$ induces $G \to \pi_1(Y, g(*))$, which factors through τ by (ii); so every class in [BG, Y] kills N, and the universal property of the acyclic map t gives the bijection. ■

Theorem 3.2 (E.17 is true). Let I be a U-small filtered category and K: $I \to \mathrm{Cat}_{\mathrm{hot}}$ a diagram of U-small categories. Suppose $H_K(X) = \mathrm{colim}_i\, \pi_0\mathrm{Fun}(X, K_i)$ sends every functor in W∞ between U-small categories to a bijection. Then H_K sends every unit η_X: $X \to \Pi_1 X$ to a bijection; equivalently (E.17a) the canonical morphism $K \to (\Pi_1 K_i)_{i\in I}$ is an isomorphism in $\mathrm{Ind}(\mathrm{Cat}_{\mathrm{hot}})$. So a U-small ind-object of $\mathrm{Cat}_{\mathrm{hot}}$ is W∞-invariant if and only if it is isomorphic to an ind-object of groupoids, and then $H_K(X) = \mathrm{colim}_i\, [BX, B\Pi_1 K_i]$ depends only on $\Pi_1 X$.

Proof. Let μ be an infinite cardinal with $|\mathrm{Mor}\, K_i| \le \mu$ for all i. Let $H'(Y) = \mathrm{colim}_i\, [Y, BK_i]$ on Hot. By A.7 the canonical map c_X: $H_K(X) \to H'(BX)$ is a bijection for every U-small X, naturally in X. Fix X. Choose a base object in each component c of X, let π_c be the fundamental group there, and let $\lambda > \mu$ be an infinite cardinal not less than the number of cells of BX. By 3.1 (applied to a model of the component BX_c with one 0-cell) choose groups G_c, surjections p_c: $G_c \to \pi_c$ and acyclic maps t_c: $BG_c \to BX_c$ inducing p_c, such that every homomorphism from G_c to a group of cardinality $< \lambda$ factors through p_c. Let $\mathcal{G} = \coprod_c BG_c$ and $\mathcal{P} = \coprod_c B\pi_c$, with p: $\mathcal{G} \to \mathcal{P}$ and the equivalence of groupoids ε: $\mathcal{P} \to \Pi_1 X$. (a) p^*: $\mathrm{Fun}(\mathcal{P}, K_i) \to \mathrm{Fun}(\mathcal{G}, K_i)$ is an isomorphism of categories for every i: a functor $\mathcal{G} \to K_i$ is a family of objects k_c with homomorphisms $G_c \to \mathrm{Aut}(k_c)$, and $|\mathrm{Aut}(k_c)| \le \mu < \lambda$, so these factor uniquely through p_c; a natural transformation is a family of arrows satisfying conditions that are the same for G_c and for its quotient π_c. Hence $H_K(p)$ is a bijection, and so is H′(Bp) (c is natural). (b) $t = \coprod t_c$: $B\mathcal{G} \to BX$ induces bijections $[BX, BK_i] \to [B\mathcal{G}, BK_i]$ for every i, by the last statement of 3.1 (the fundamental groups of BK_i have cardinality $\le \mu$). Hence H′(t) is a bijection. (c) $B\eta_X \circ t = B\varepsilon \circ Bp$ in Hot: both are maps from $B\mathcal{G}$ into the classifying space of a groupoid inducing the same functor on fundamental groupoids up to isomorphism, and C.1 applies. So $H'(t)\circ H'(B\eta_X) = H'(Bp)\circ H'(B\varepsilon)$ is a bijection and H′(t) is a bijection; therefore $H'(B\eta_X)$ is a bijection, and by naturality of c so is $H_K(\eta_X)$. The rest is (E.17a), that is, A.4 for the reflection $\Pi_1 \dashv j$ of C.4. ■

Corollary 3.3 (what this says about V ms. 44–46, VII ms. 129–132, IX ms. 22–23). (a) Grothendieck's sentence at V ms. 46, "cela équivaut à la condition qu'il puisse se représenter par un système inductif sur N formé de catégories de Thomason–Kan", is a theorem when "catégorie de Thomason–Kan" is read as "local category" (C.3): a sequence (K_n) has a W∞-invariant functor exactly when it is ind-isomorphic to the sequence of groupoids $(\Pi_1 K_n)$. With "Thomason-fibrant" it is false (C.6). (b) Consequently an invariant functor only sees fundamental groupoids: $H(X) = H(\Pi_1 X)$. For the path ind-categories $H(a, b) = (\mathrm{Ch}_{n,\Sigma}(a, b))_n$ of a U-small (M, Σ), the "condition préalable" of VII ms. 129–132 and test (b) of IX ms. 22, imposed on all of Cat_U, forces $\mathrm{Hom}_{M(Y)\Sigma_Y^{-1}}(a_Y, b_Y)$ to depend only on $\Pi_1 Y$; in particular it equals $\mathrm{Hom}_{M\Sigma^{-1}}(a, b)$ for every simply connected Y. (This uses Grothendieck's description of these Hom-sets as $\mathrm{colim}_n\, \pi_0\mathrm{Fun}(Y, \mathrm{Ch}_{n,\Sigma}(a, b))$, V ms. 45, which I did not re-derive.) So for small (M, Σ) the condition can hold only when the derived mapping spaces are, as ind-objects, 1-types: a precise form of his remark that the condition "n'est pratiquement jamais satisfaite" (VII ms. 132) and of his doubt at IX ms. 23. (c) The filtered case of D.8 of the return (the functor [B−, Y] is a U-small filtered colimit of representables only if Y is a 1-type) follows: if [B−, Y] = H_K, then by 3.2 the map $[P_1 Y', Y] \to [Y', Y]$ is bijective for all Y′; for $Y' = Y$ the identity of Y factors through $Y \to P_1 Y$, so Y is a retract in Hot of a 1-type, hence a 1-type. (d) The size restriction on I is necessary (D.7 of the return).

GPT-6 Astra's reading

The source supplies the amalgamated-product construction and the factorization of every homomorphism to a smaller group. It explicitly identifies two places needing a careful independent check: the successor-step comparison with local coefficients, and the cardinal bound in the Kan–Thurston input. The cited cardinal estimate was recalled from memory, and its proof is not present in the supplied files. The construction also treats compatible classifying-space models and limit unions without spelling out their replacement maps. Thus the written argument has a specific citation and model-compatibility gap at the claimed cardinal bound and its repeated use. The deduction of Theorem 3.2 from Theorem 3.1 is written out, including the functor-category isomorphism induced by $G_c \twoheadrightarrow \pi_c$, but it also cites the return's localization results A.4, A.7 and E.17a. Corollary 3.3(b) expressly relies on the manuscript's path-category formula without re-deriving it. These are the source's dependencies; this reading does not supply missing proofs or promote its conclusion to an independently checked theorem.

4. Uncountably many homotopy classes of maps to the two-sphere

Statement recorded in the inventory.

Uncountably many maps to S^2. If X is connected with $H^1(X; Z) = 0$ and S^n is a homotopy retract of X for infinitely many n with $\pi_n(S^3) \neq 0$, then $[X, S^2]$ is uncountable.
Bearing on the manuscript. D.6 of CATHOT; V ms. 43–46 (with hunch H3)

Proved by. Claude Fable 5.2, effort max
Checked by (inventory record). not yet

Cited source. `pro_reviews_max_20261112/1_CATHOT/OWN_RESULTS.md`, section 4

Statement and proof in the supplied source

Proposition 4.1. Let X be a connected CW complex with $H^1(X; Z) = 0$. Suppose that for infinitely many n with $\pi_n(S^3) \neq 0$ the sphere S^n is a homotopy retract of X: there are maps $s_n\colon S^n \to X$ and $f_n\colon X \to S^n$ with $f_n \circ s_n$ of degree ± 1. Then $[X, S^3]$ and $[X, S^2]$ are uncountable.

($\pi_n(S^3) \neq 0$ for $n = 2p$, p prime, by Serre: the p-primary component of $\pi_{2p}(S^3)$ is Z/p.)

Proof. Let N be the set of such n. Take f_n and s_n cellular for the cell structure of S^n with one 0-cell and one n-cell; then $f_n(X^{(n-1)})$ is the base point. Choose pointed maps $a_n\colon S^n \to S^3$ representing non-zero classes, with base point $1 \in S^3 = SU(2)$, and put $g_n = a_n \circ f_n$. For $A \subset N$ define $g_A(x) = \prod_{n \in A} g_n(x)$, the product in increasing order in the group S^3; on $X^{(k)}$ only the factors with $n \leq k$ differ from 1, so g_A is continuous. Let $A \neq A'$ and $n = \min(A \triangle A')$, say $n \in A$. On $X^{(n)}$: $g_A = h \cdot g_n$ and $g_{A'} = h$, with h the product of the common factors of index $< n$. If $g_A \simeq g_{A'}$, then $h \cdot g_n \simeq h$ on $X^{(n)}$, hence $g_n|X^{(n)}$ is null-homotopic (multiply pointwise by h^{-1}), hence $g_n \circ s_n = a_n \circ f_n \circ s_n$ is null-homotopic; but it represents $\pm$ the class of a_n (free and pointed classes agree in S^3). So $A \mapsto [g_A]$ is injective on the subsets of N. For S^2: the Hopf map $S^3 \to S^2$ is a principal S^1-bundle, so two maps $X \to S^3$ with homotopic images in S^2 differ, after a homotopy, by a map $X \to S^1$, which is null-homotopic because $H^1(X; Z) = 0$; thus $[X, S^3] \to [X, S^2]$ is injective. ■

GPT-6 Astra's reading

The infinite product is locally finite on every CW skeleton, so the weak topology of the CW complex supplies its continuity. The least differing index compares the two maps on the

corresponding skeleton; the cellular representative of s_n lands there, and multiplication by the inverse of the common initial product gives the stated contradiction. The Hopf-bundle lifting argument then identifies two lifts differing by a map to S^1, whose class vanishes by $H^1(X;\mathbb{Z}) = 0$. I found the proof complete from the stated hypotheses and standard cellular approximation and bundle homotopy lifting. It does not construct a finite category satisfying the retract hypothesis; the unlisted speculative finite-category consequence is not added to this appendix.

5. The thirty-four-arrow lower bound for the projective plane

Statement recorded in the inventory.

Posets of type RP² need at least 34 arrows (the return proved 28).
Bearing on the manuscript. CATHOT G.8

Proved by. Claude Fable 5.2, effort max
Checked by (inventory record). not yet

Cited source. `pro_reviews_max_20261112/1_CATHOT/OWN_RESULTS.md`, section 5

Statement and proof in the supplied source

The return (G.8) proves $28 \le a_{pos}(RP^2) \le 49$ for the least number of arrows (pairs $x \le y$) of a poset whose order complex has the homotopy type of RP^2.

Proposition 5.1. $a_{pos}(RP^2) \ge 34$.

Proof. Let P be such a poset with the least number of arrows; it is finite. As in G.8, its comparability graph has no vertex of degree ≤ 1 (a vertex with one neighbour is a beat point and can be removed), and P has at least 13 points (Cianci–Ottina, arXiv:1512.06088v1, Corollary 5.8). If P has exactly 13 points it has 49 arrows (their Theorem 5.10). Otherwise $f_0 \ge 14$. The order complex Δ is a flag complex with $\widetilde{H}_2(\Delta; F_2) \ne 0$. By the argument of G.7 over F_2 (take a full subcomplex L minimal with $\widetilde{H}_2(L; F_2) \ne 0$; Mayer–Vietoris gives $\widetilde{H}_1(\mathrm{lk}_L\, v; F_2) \ne 0$ for each vertex v of L, and links in flag complexes are flag), every vertex of L has at least 4 neighbours in L and L has at least 6 vertices. Summing degrees: $2f_1 \ge 4|L| + 2(f_0 - |L|)$, so $f_1 \ge f_0 + |L| \ge f_0 + 6$, and the number of arrows is $f_0 + f_1 \ge 2f_0 + 6 \ge 34$. ■

GPT-6 Astra's reading

The bound combines the cited thirteen-point classification with a degree count that is explicitly proved. Minimality in arrow count removes degree-one beat points. A vertex-minimal full subcomplex with nonzero second mod-two homology has at least six vertices and degree at least four at each of them; the remaining comparability vertices have degree at least two. The sum gives $f_0 + f_1 \ge 2f_0 + 6 \ge 34$ outside the thirteen-point case. The argument is complete once the cited Cianci–Ottina object bound and classification are supplied. It proves the lower bound recorded here and does not identify the global arrow minimum.

6. The reported census of small categories

Statement recorded in the inventory.

Census of small categories. The fewest arrows for finite categories of types S^1, S^2, S^3 are 4, 5, 7; S^1: only the parallel pair; S^2: only the monoid P_2; every smallest S^3 is a monoid. Grothendieck's own S^2 model (XII app. ms. 10–11) has 10 arrows.
Bearing on the manuscript. XII app. ms. 8–11

Proved by. Claude Fable 5.2, effort max (exhaustive enumeration)
Checked by (inventory record). not yet
Cited source. `pro_reviews_max_20261112/1_CATHOT/OWN_RESULTS.md`, section 6

Statement and proof in the supplied source

Statement 6.1. (a) The numbers of monoid structures on {0, …, n−1} with identity 0 are 1, 2, 11, 156, 4,122, 208,672 for n = 1, …, 6, in 1, 2, 6, 27, 156, 1,373 classes up to isomorphism and anti-isomorphism. (b) The triples (H_1, H_2, H_3) of BM that occur for monoids of order 6 are (0,0,0) [1,159 classes], (0,Z,0) [2], (0,Z,Z) [1], (0,Z,Z/2) [2], (0,Z/2,0) [1], (Z/2,0,Z/2) [172], (Z/3,0,Z/3) [22], (Z/4,0,Z/4) [6], (Z/5,0,Z/5) [1], (Z/6,0,Z/6) [1], (Z/2,0,Z/6) [1], ($(Z/2)^2$,Z/2,$(Z/2)^3$) [5]; for order 5: (0,0,0) [126], (0,Z,0) [1, the monoid P_2], (Z/2,0,Z/2) [22], (Z/3,0,Z/3) [4], (Z/4,0,Z/4) [1], (Z/5,0,Z/5) [1], ($(Z/2)^2$,Z/2,$(Z/2)^3$) [1]. (c) Connected categories with k ≥ 2 objects and N arrows, as labelled tables with arrows sorted by (source, target): N = 3: 2; N = 4: 11; N = 5: 76 + 6 (k = 2, 3); N = 6: 977 + 54; N = 7: 22,798 + 498 + 32 (k = 2, 3, 4). None has (H_1, H_2, H_3) = (0, 0, Z); none with N ≤ 5 has H_2 = Z; exactly the two labellings of the parallel pair have (Z, 0, 0) with N = 4; none with N ≤ 7 has (Z/2, 0, 0). (d) Hence: the categories of type S^1, S^2, S^3 with the fewest arrows have 4, 5, 7 arrows; for S^1 it is the parallel pair, for S^2 the monoid P_2 (unique up to isomorphism), and for S^3 every such category is a monoid of order 7 (P_3 is one). (e) The six classes of monoids of order 6 with $H_1 = 0$ and $H_2 \neq 0$ have mod-p Betti numbers in degrees 1–5 as listed in `work/code/higher_homology_order6.out`; none has the Betti numbers of CP^∞ (0,1,0,1,0).

Method: backtracking over composition tables with associativity checks (`catlib.py`), canonical forms under relabelling and transposition, exact Smith normal forms of the normalized nerve boundaries (python-flint). Checks of the method: the counts in (a) are the known ones; group homology of C_k, ${C_2}^2$, S_3; the nerves of the parallel pair, of Grothendieck's category Z of XII app. ms. 10–11 (homology of S^2), of R_2 (RP^2), of P_2 and P_3.

GPT-6 Astra's reading

The supplied file contains the census counts and the algorithm description, but the referenced programs, enumeration certificates and output files are absent from the archive. Consequently the exhaustive lower bounds and uniqueness claims cannot be reproduced or independently certified from these attachments. The homology tests described are sufficient to exclude the listed sphere types when the enumeration is exhaustive; homology alone would not certify the positive homotopy types. The source points to separately proved models P_2, P_3 and the parallel pair for existence, but does not include an enumeration certificate in this section. The asserted ten-arrow size of Grothendieck's model is recorded by NEW_RESULTS; this section's source statement does not give its complete composition table. This entry is therefore an exact account of a reported computational result with a missing computational proof record, not a fresh exhaustive verification.

7. The reversible localizer defined by two-local spheres

Statement recorded in the inventory.

A reversible fundamental localizer not detected by spectra. W_S (homotopy cofibre null for all 2-local spheres S^n, n ≥ 2) satisfies W(7), contains $RP^\infty \to e$ and not $RP^2 \to e$, while every reversible localizer containing $RP^\infty \to e$ has RP^2 in its stable closure.
Bearing on the manuscript. POLES F.14 (1); XII §5 and XVI §3: the reversibility axiom does not single out homology theories

Proved by. Claude Fable 5.2, effort max
Checked by (inventory record). not yet (prompt REVERSIBLE$_{\text{LOCALIZERS}}$ drafted)
Cited source. `pro_reviews_max_20261112/DERIVATEURS_EXPERT/RESULT_REVERSIBLE_NOT_STABLE.md`, sections 1–4

Statement and proof in the supplied source

1. Statement

Notation as in POLES: a fundamental localizer is a class W of functors satisfying identities, two out of three, the retraction rule, the terminal-object axiom and the relative Theorem A. W is *reversible* when it satisfies Loc (6′ b) (XVI ms. 17′; W(7 bis) "⇐" of XII ms. 76), equivalently (POLES B.5) when $g \in W \Leftrightarrow C(g)$ is W-aspherical, C(g) the unreduced homotopy cofibre of Bg, pointed at the cone point. For a localizing subcategory L of Ho(Sp), $R(L) = \{g : \Sigma^\infty C(g) \in L\}$ (POLES F.2), and $T(W) = \mathrm{loc}\{\Sigma^\infty C(g) : g \in W\}$.

Let S_n denote the 2-localization of the sphere S^n, and let

$$\mathfrak{N} = \{ \text{ pointed spaces } X : \mathrm{Map}_*(X, S_n) \text{ is weakly contractible for every } n \geq 2 \},$$
$$W_S = \{ \text{ functors } g : C(g) \in \mathfrak{N} \}.$$

Theorem. (a) W_S is a fundamental localizer, it is reversible (so it satisfies Loc (6 a, b, c), W(7), W(7 bis)), and it is not Fl(Cat). (b) $RP^\infty \to e$ is in W_S and $RP^2 \to e$ is not. (c) Every reversible fundamental localizer W that contains $RP^\infty \to e$ has $\Sigma^\infty RP^2 \in T(W)$, so $RP^2 \to e \in RT(W)$. Hence $W_S \neq RT(W_S)$: W_S is not of the form R(L), and in particular is not a homology localizer W_E. The same holds for every reversible localizer between the one generated by $RP^\infty \to e$ and W_S.

So the reversible cofibration axiom of Grothendieck does not force a localizer to be "stable" or homological.

2. The class $\mathfrak{N}$ is closed under desuspension

Lemma 1. If $\Sigma X \in \mathfrak{N}$ then $X \in \mathfrak{N}$.

Proof. James: for every $n \geq 1$ there is, after localization at 2, a fibre sequence $S^n \to \Omega S^{n+1} \to \Omega S^{2n+1}$ (E followed by the Hopf–James invariant H); so for $n \geq 2$ a fibre sequence

$$\Omega^2 S_{2n+1} \text{ –P–> } S_n \text{ –E–> } \Omega S_{n+1}.$$

Let $\varphi\colon X \to S_n$ be pointed. $E\varphi$ is adjoint to a map $\Sigma X \to S_{n+1}$, which is null because $\mathrm{Map}_*(\Sigma X, S_{n+1})$ is weakly contractible. So $\varphi \simeq P\psi$ with $\psi\colon X \to \Omega^2 S_{2n+1}$, and ψ is adjoint to an element of $\pi_1(\mathrm{Map}_*(\Sigma X, S_{2n+1}), \mathrm{const}) = 0$. So φ is null: $\pi_0 \mathrm{Map}_*(X, S_n) = *$. For $j \geq 1$, $\pi_j(\mathrm{Map}_*(X, S_n), \mathrm{const}) = \pi_{j-1}(\mathrm{Map}_*(\Sigma X, S_n), \mathrm{const}) = 0$. ■

Lemma 2. (i) $\mathfrak{N}$ is closed under pointed homotopy colimits and retracts and contains the contractible spaces. (ii) For a cofibre sequence $X \to Y \to C$ of pointed spaces, if two of X, Y, C are in $\mathfrak{N}$, so is the third. (iii) $X \in \mathfrak{N} \Leftrightarrow \Sigma X \in \mathfrak{N}$. (iv) If $X \in \mathfrak{N}$ then $X \wedge Y_+ \in \mathfrak{N}$ and, if also $Y \in \mathfrak{N}$, $X \times Y \in \mathfrak{N}$.

Proof. (i) $\mathrm{Map}_*(\mathrm{hocolim}\, X_i, Z) = \mathrm{holim}\, \mathrm{Map}_*(X_i, Z)$. (ii) Use the fibre sequences $\mathrm{Map}_*(C, Z) \to \mathrm{Map}_*(Y, Z) \to \mathrm{Map}_*(X, Z)$ and $\mathrm{Map}_*(\Sigma X, Z) \to \mathrm{Map}_*(C, Z) \to \mathrm{Map}_*(Y, Z)$, with $\mathrm{Map}_*(\Sigma X, Z) = \Omega\, \mathrm{Map}_*(X, Z)$: $X, C \in \mathfrak{N} \Rightarrow Y \in \mathfrak{N}$; $X, Y \in \mathfrak{N} \Rightarrow C \in \mathfrak{N}$; $Y, C \in \mathfrak{N} \Rightarrow \Sigma X \in \mathfrak{N}$ (from $C \to \Sigma X \to \Sigma Y$), and then $X \in \mathfrak{N}$ by Lemma 1. (iii) ΣX is the cofibre of $X \to *$; Lemma 1. (iv) $\mathrm{Map}_*(X \wedge Y_+, Z) = \mathrm{Map}(Y, \mathrm{Map}_*(X, Z))$; then $Y \to X \times Y \to X \wedge Y_+$. ■

3. W_S is a reversible fundamental localizer

For f: $X \to Y$, g: $Y \to Z$ there is a cofibre sequence $C(f) \to C(gf) \to C(g)$ whose connecting map is $C(g) \to \Sigma Y \to \Sigma C(f)$.

— Identities: C(id) is a cone. Two out of three: Lemma 2 (ii).

— Retraction rule. Let $ri = id_X$, $ir \in W_S$, $D = C(i)$. From $C(i) \to C(ri) \simeq * \to C(r)$: $C(r) \simeq \Sigma D$. In $C(r) \to C(ir) \to C(i)$ –δ–> $\Sigma C(r)$ the map δ factors through the connecting map ∂: $C(i) \to \Sigma X$ of i, and $\partial \simeq (\Sigma r)(\Sigma i)\partial \simeq *$ because $(\Sigma i)\partial \simeq *$. So $\Sigma C(ir) \simeq \Sigma^2 D \vee \Sigma D$. As $C(ir) \in \mathfrak{N}$, the retract ΣD is in $\mathfrak{N}$, so $D \in \mathfrak{N}$ (Lemma 1): $i \in W_S$, and $r \in W_S$ by two out of three.

— A category with a terminal object has contractible nerve.

— Relative Theorem A. For u: $A \to B$ over C with all $u/c \in W_S$: $BA \simeq \mathrm{hocolim}_c B(A/c)$, $BB \simeq \mathrm{hocolim}_c B(B/c)$ naturally, and C(Bu) is the pointed homotopy colimit over C of the $C(B(u/c))$ (the unpointed one, with the section BC of cone points collapsed). Lemma 2 (i).

— Reversible: $X \to e \in W_S \Leftrightarrow \Sigma X \in \mathfrak{N} \Leftrightarrow X \in \mathfrak{N}$ (Lemma 2 (iii)); so the W_S-aspherical categories are those with nerve in $\mathfrak{N}$ (for any base point), and $g \in W_S \Leftrightarrow C(g) \in \mathfrak{N} \Leftrightarrow C(g)$ is W_S-aspherical. By POLES B.5 this is Loc (6 b), and Loc (6 c), W(7) follow.

— $S^2 \to e \notin W_S$ (the identity of S_2), so $W_S \neq \mathrm{Fl}(\mathrm{Cat})$. Acyclic spaces are in $\mathfrak{N}$ (the S_n are simply connected, hence HZ-local), in accordance with $W_Z \subset W_S$ (POLES B.6).

4. RP^∞, RP^2, and the stable side

(b) Miller's theorem (the Sullivan conjecture): $\mathrm{Map}_*(BG, K)$ is weakly contractible for G finite and K a finite complex; for $K = S^n$ and the 2-localization S_n use the arithmetic square (RP^∞ is rationally acyclic and maps from $BZ/2$ into a simply connected space see only its 2-completion). So $RP^\infty \in \mathfrak{N}$. On the other hand $[RP^2, S_2] = H^2(RP^2; Z_{(2)}) = Z/2 \neq 0$, so $RP^2 \notin \mathfrak{N}$.

(c) Let W be reversible with $RP^\infty \to e \in W$, A its class of aspherical pointed spaces, $L = T(W)$. Then $\Sigma^\infty A \subset L$, L is a tensor ideal (POLES F.13), and: 1. $\Sigma^\infty K(Z/2, n) \in L$ for all n: $K(Z/2, n+1)$ is the bar construction of $K(Z/2, n)$, a pointed homotopy colimit of finite products, and $\Sigma^\infty(X \times Y) = \Sigma^\infty X \vee \Sigma^\infty Y \vee \Sigma^\infty(X \wedge Y)$. Hence $HZ/2 = \mathrm{colim}_n \Sigma^{-n} \Sigma^\infty K(Z/2, n) \in L$. 2. Snaith: $\Sigma^\infty Q(RP^\infty) \simeq \bigvee_j \Sigma^\infty D_j(RP^\infty)$, and $\Sigma^\infty D_j X = (\Sigma^\infty X)^{\wedge j}{}_{h\Sigma_j} \in L$. Kahn–Priddy: the 2-localization of $Q_0 S^0$ is a retract, as a space, of $Q(RP^\infty)$. So $\Sigma^\infty (Q_0 S^0)_{(2)} \in L$. Its iterated bar constructions are the spaces of the spectrum $\tau_{\geq 1} S_{(2)}$; as in 1, $\tau_{\geq 1} S_{(2)} \in L$. 3. Smashing $\tau_{\geq 1} S_{(2)} \to S_{(2)} \to HZ_{(2)}$ with the Moore spectrum: $(\tau_{\geq 1} S_{(2)})/2 \to S/2 \to HZ/2$. So $S/2 \in L$, i.e. $\Sigma^\infty RP^2 \in L$, and $RP^2 \to e \in R(L) = RT(W)$. Applied to $W = W_S$: $RP^2 \to e \in RT(W_S) \setminus W_S$. ■

Remark. Step (c) shows $\mathrm{loc}(\Sigma^\infty RP^\infty) = \mathrm{loc}(S/2)$, the 2-torsion spectra; so RT of the reversible localizer generated by $RP^\infty \to e$ is the localizer of $Z[1/2]$-homology equivalences.

GPT-6 Astra's reading

The note supplies the desuspension argument, the localizer-axiom verification and the stable-closure argument. Its decisive outside inputs are the two-local James EHP fibre sequence, Miller's theorem together with the arithmetic-square passage to two-local spheres, Kahn–Priddy in the stated space-retraction form, and Snaith's splitting. Those inputs are named but not proved here; in particular the arithmetic-square passage and the use of iterated bar constructions are compressed. I found no algebraic discrepancy in the displayed cofibre and stable-closure steps, but the precise localization and retraction formulations need independent source checking before this is described as a completed peer review. The source's accessibility

discussion is expressly unproved and lies outside the recorded theorem; it is omitted rather than turned into an additional assertion. The relation between W_S and $RT(W_S)$ is exhibited by the specific map $\mathbb{RP}^2 \to e$ and the source's explicit construction, not inferred from a categorical label.

8. The two-cone counterexample to the reverse axiom

Statement recorded in the inventory.

XII Théorème 2 (ms. 78) is false for W∞: X = A ⋆ {t, s}, A connected, acyclic, not aspherical. Everything in XII that uses the strong form of W(7 bis) holds for homology localizers only.

Bearing on the manuscript. XII Th. 4 Cor. 4 and 5, Cor. of ms. 85, Prop. 7, ms. 105, XIIapp ms. 7, 15

Proved by. Claude Fable 5.2, effort max (also TOTASPH A.13 of the return)

Checked by (inventory record). Pro return + expert agree

Cited source. `pro_reviews_max_20261112/DERIVATEURS_EXPERT/FINDINGS.md`, F-G1; `pro_reviews_max_20261112/2_TOTAL_ASPHERICITY/REVIEW.md`, A.12–A.13

Statement and proof in the supplied source

F-G1 (mine). **XII Théorème 2 (ms. 78), "W∞ satisfait à W(7)", is false**, and so is the reverse half of W(7 bis) for W∞: X = A ⋆ {t, s} with A connected, acyclic, not aspherical. Grothendieck did not write the verification ("je devrais sans doute réparer cette omission"). Everything in XII that uses "W(7 bis) forme forte" (his own footnotes 104, 105 mark these places: Th. 4 Cor. 4 and 5; also the Corollary of ms. 85, Prop. 7, and the uses at ms. 105, XIIapp ms. 7 and 15) holds for homology localizers and not for W∞. (Also in TOTASPH A.13; it is the starting point of POLES.)

Proof details recorded in the supplied TOTASPH review

Own check of the data: 3 + 17 + 15 simplices; arrows 35 + 34 + 45 + 45 = 159; nerve ranks (35, 124, 90). $d_2 = [[5, -2], [-3, 1]]$, determinant −1 (exponent sums of a^5b^{-3} and $b^3(ab)^{-2}$). In A_5: a = (1 4 3 2 5), b = (1 2 3), ab = (1 5)(3 4) (I composed them), so both relators die and $a \neq 1$. Hatcher's Example 2.38 is the binary icosahedral presentation.

X = A ⋆ {u, t}: U = A ∪ {u}, V = A ∪ {t} are sieves with contractible nerves, BX = ΣBA is contractible (simply connected and acyclic), U ∩ V = A is not. I had found the same counterexample independently while reading XII ms. 78. **This refutes XII Théorème 2 (ms. 78)** as stated; only the direct halves hold. Consequence I add: in II ms. 36ter (Contre-exemple 2.20) the step "i ∈ W∞ ⇒ X/H aspherical" is not available; one gets only that X/H is connected and acyclic. The counterexample 2.20 survives (take H connected with ΣB(Δ/H) not contractible).

GPT-6 Astra's reading

The source's two-cone construction makes the failure concrete: both cones and their union have contractible classifying spaces, while their intersection has the specified nontrivial fundamental group. The supplied TOTASPH review gives the relation matrix and an explicit nontrivial permutation representation for an acyclic example. The suspension is simply connected and acyclic, so its contractibility follows from Hurewicz and Whitehead. This proves the counterexample to the reverse axiom once the category model of the presentation

complex is supplied; the review reports that model's counts but the full attaching data are outside the cited FINDINGS paragraph. The list of later manuscript dependencies is a source attribution, not a separate proof of each later statement. The inventory adds the word "only" to its homology-localizer sentence; the cited FINDINGS paragraph says "for homology localizers and not for W_∞." The two-cone proof supplies the stated failure for W_∞ but gives no classification excluding every other localizer. The inventory's stronger word is preserved in its exact statement and flagged here as unsupported by that proof.

9. The reported trefoil argument for failure of Loc (7 F)

Statement recorded in the inventory.

A direct proof that $\mathbf{W_Z}$ and $\mathbf{W_k}$ fail Loc (7 F) (trefoil complement over a base of type S^1).

Bearing on the manuscript. XVI ms. 105 (Grothendieck: "Je ne hasarderais aucune conjecture")

Proved by. Claude Fable 5.2, effort max

Checked by (inventory record). not yet

Cited source. `pro_reviews_max_20261112/DERIVATEURS_EXPERT/FINDINGS.md`, F3-5; `pro_reviews_max_20261112/3_POLES/REVIEW.md`, C.5

Statement and proof in the supplied source

F3-5 (mine). Direct proof that $\mathbf{W_Z}$ and $\mathbf{W_k}$ fail (7 F) (trefoil complement over a base of type S^1; the Alexander module appears in H_1 of the base change). Independent of Cisinski's properness theory.

The available proof sketch

Independent confirmation for $\mathbf{W_Z}$ and $\mathbf{W_k}$, k a field (my argument before reading, `work/checks_3/own_thoughts_before_reading.md` item 7, not using E.2): if $e \to E \to S$ with $BS \simeq S^1$, E acyclic and $p \in \mathrm{Fib}_W$, the local system $s \mapsto H_0(E/s)$ must be $Z[t, t^{-1}]$, and base change along a functor $Y' \to S$ realizing the map from the trefoil complement to S^1 gives $H_1(E \times_S Y') \twoheadrightarrow Z[t, t^{-1}]/(t^2 - t + 1) \neq 0$, although $E \times_S Y' \to E$ should be a homology isomorphism. This answers XVI 7.5 (ms. 105): **Loc (6 a, 8, 9) does not imply Loc (7 F)**; and it answers the wish of XVI ms. 124 ("regarder quelques exemples (équivalences homologiques ou cohomologiques, W_n) … si Loc (7 F) est satisfait").

GPT-6 Astra's reading

The cited FINDINGS entry gives a claim and one-line description, not a full proof. The supplied POLES review adds the trefoil outline reproduced below, including the Alexander module $\mathbb{Z}[t, t^{-1}]/(t^2 - t + 1)$. Its derivation of the fibre local system, the comparison from strict categorical base change to the stated homology calculation, and the claimed surjection are not written out. The review refers for those steps to a working note absent from the archive. Thus the direct proof as supplied has a definite missing middle step. The field-coefficient version is also asserted without its corresponding derivation. This appendix preserves that limitation and does not replace the missing proof with an invented argument.

10. Totality and the fixed-origin path category

Statement recorded in the inventory.

For Y simply connected, Ch(Y; y_0, −) total ⇒ Y total.
Bearing on the manuscript. XII ms. 102–103, 112

Proved by. Claude Fable 5.2, effort max
Checked by (inventory record). not yet

Cited source. `pro_reviews_max_20261112/DERIVATEURS_EXPERT/FINDINGS.md`, F2-11

Statement and proof in the supplied source

F2-11 (mine). C005 (XII ms. 103) follows from Grothendieck's own remarks: the endpoint functor of Ch(Y; y_0, −) is final when Y is 1-connected (ms. 102–103), totality passes to final images (Lemma, ms. 112), and Ψ is aspherical and not total (his footnote at ms. 103). General form: for Y simply connected, Ch(Y; y_0, −) total ⇒ Y total. Open: the converse, starting with Y = e (the category of interval types).

GPT-6 Astra's reading

The proof is the composition of two identified manuscript facts: the endpoint functor is final for the specified simply connected target, and total asphericity passes to final images. The source identifies both manuscript locations, and the supplied review repeats the deduction. These two cited facts establish exactly the displayed implication. Their internal proofs are not reproduced in FINDINGS; this is a short proof by reference rather than a standalone construction of the endpoint category. The converse is not asserted here.

11. Exact colimits, total asphericity, and injective ordinals

Statement recorded in the inventory.

Grothendieck's conjecture of II ms. 36ter ("totally W∞-aspherical ⇒ filtered") is false (Δ_{inj}); with the bridge from exactness of abelian colimits to total asphericity (TOTASPH C.5–C.6). The category and the key fact are Isbell–Mitchell (Bull. AMS 79, 1973, Theorem 3); the bridge is not found there.
Bearing on the manuscript. II ms. 36–36ter

Proved by. GPT-6 Astra (effort Pro, ChatGPT Pro mode); proof of C.9 taken from our Open Maths lesson "Derived colimits over a small category" (20 Oct 2026)

Statement and proof in the supplied source

An intrinsic criterion and the failure of Lead 4

Source definition 1 (Proved: the action criterion)**.** *Let R be a nonzero commutative ring with identity. We write $\mathcal{P}_R(A)$ for the following property of a small category A: for every covariant functor $H : A \to \mathbf{Set}$, each connected component E of the category of elements $\mathrm{El}_A(H)$ is R-acyclic, meaning that $H_0(BE; R) = R$ and $H_j(BE; R) = 0$ for $j > 0$. No condition is imposed on the empty category of elements. We write $\mathcal{P}_\infty(A)$ when every such component is weakly contractible. These definitions use covariant, rather than presheaf, categories of elements: an arrow $(a, h) \to (a', h')$ is an arrow $v : a \to a'$ with $H(v)(h) = h'$.*

Source lemma 1 (Proved: homological Theorem A in the final variance)**.** *Let $f : A \to B$ be a functor. If every $b\backslash A$ is nonempty and R-acyclic, then $Bf : BA \to BB$ induces an isomorphism on homology with coefficients in R. More generally, if every $b\backslash A$ is nonempty and its reduced R-homology vanishes in degrees $0, \dots, d-1$, for an integer $d \geq 1$, then Bf induces isomorphisms in degrees less than d and an epimorphism in degree d.*

Proof. We use the bisimplicial set whose (p, q)-simplices are strings

$$b_0 \longrightarrow \cdots \longrightarrow b_p \longrightarrow f(a_0), \qquad a_0 \longrightarrow \cdots \longrightarrow a_q.$$

The forgetful map to NA is a weak equivalence after diagonal realization: for a fixed string in A, the remaining simplicial direction is the nerve of $B/f(a_0)$, which has terminal object $\mathrm{id}_{f(a_0)}$. The other projection is to NB. Taking normalized R-chains in both directions and filtering by p gives the spectral sequence of this projection. Its row in degree $q = 0$ is the chain complex of NB, because each comma category is connected; the rows in degrees $1, \dots, d-1$ vanish after taking vertical homology. The first possible additional row has degree d. Thus the projection induces isomorphisms below degree d and an epimorphism in degree d. The first-quadrant filtration is finite in each total degree, so it converges without a boundedness or finiteness assumption on the categories. If all positive rows vanish, it induces isomorphisms in every degree. The two projections commute with the canonical map Bf up to the homotopy supplied by the displayed arrow $b_p \to f(a_0)$; consequently the comparison just computed is the map induced by f. □

Source lemma 2 (Proved: inheritance by categories of elements)**.** *If A satisfies $\mathcal{P}_R$, then every connected component E of $\mathrm{El}_A(H)$, for every $H : A \to \mathbf{Set}$, also satisfies $\mathcal{P}_R$. The corresponding assertion holds for $\mathcal{P}_\infty$.*

Proof. The elements lying in E define a subfunctor $H_E \subseteq H$, because arrows preserve connected components. Let $K : E \to \mathbf{Set}$ be any covariant functor. Define

$$L(a) = \coprod_{h \in H_E(a)} K(a, h).$$

For an arrow $v : a \to a'$ in A, its restriction to the summand indexed by h is the map $K(v) : K(a, h) \to K(a', H(v)h)$, landing in the indicated summand of $L(a')$. This defines a covariant functor $L : A \to \mathbf{Set}$. The map

$$((a, h), k) \longmapsto (a, (h, k))$$

is an isomorphism of categories $\mathrm{El}_E(K) \cong \mathrm{El}_A(L)$, including their specified arrows. Its connected components therefore have the required property. □

Source lemma 3 (Proved: integral acyclicity detects every cyclic subgroup)**.** *Suppose that a connected, nonempty small category E satisfies $\mathcal{P}_\mathbb{Z}$. Then BE is weakly contractible. Consequently $\mathcal{P}_\mathbb{Z}(A)$ and $\mathcal{P}_\infty(A)$ are equivalent for every small category A.*

Proof. The constant singleton functor on E shows that BE is integrally acyclic. Fix an object e_0 and let ΠE be the groupoid obtained by inverting all arrows of E. The usual edge-path presentation of the fundamental group identifies $\mathrm{Aut}_{\Pi E}(e_0)$ with $G = \pi_1(BE, e_0)$. For any subgroup $K \leq G$, define

$$H_K(e) = \mathrm{Hom}_{\Pi E}(e_0, e)/K,$$

where K acts by precomposition, and an arrow $v : e \to e'$ acts by postcomposition with its image in ΠE. All these maps are bijections. The projection $\mathrm{El}_E(H_K) \to E$ is therefore a categorical covering: each arrow has a unique lift with either a prescribed source or a prescribed target. On nerves this gives the usual covering of BE whose monodromy is the transitive

coset action of G. It is connected, and its fundamental group, at the lift represented by id_{e_0}, is precisely K. The covering classification is also recorded in Hatcher (2002, Theorem 1.38). These assertions follow directly here by lifting the edge-path presentation; a loop lifts to a loop exactly when its class belongs to K.

Take K to be the cyclic subgroup generated by an arbitrary element of G. The hypothesis gives

$$0 = H_1(B\,\mathrm{El}_E(H_K);\mathbb{Z}) = K_{\mathrm{ab}} = K.$$

The identification of first homology with abelianization is Hatcher (2002, Theorem 2A.1). Thus G is trivial. A simply connected acyclic CW complex is weakly contractible: if a first nonzero homotopy group existed, the Hurewicz theorem would identify it with a nonzero homology group (Hatcher, 2002, Theorem 4.32). A nerve realization is a CW complex, so this applies to BE.

For general A satisfying $\mathcal{P}_{\mathbb{Z}}$, apply Lemma 2 and the preceding argument to each component E of each category of elements. The converse follows from homotopy invariance of integral homology. □

Source theorem 1 (Proved: characterization of total asphericity)**.** *For every small category A, the following conditions are equivalent:*

1. *A is totally W_∞-aspherical in the sense of XII, Definition 1.*
2. *A is totally $W_{\mathbb{Z}}$-aspherical.*
3. *A is nonempty and connected, and satisfies $\mathcal{P}_{\mathbb{Z}}$.*
4. *A is nonempty and connected, and satisfies $\mathcal{P}_\infty$.*

In particular, this is a criterion in terms of all covariant set-valued diagrams on A, involving no quantification over target categories or final functors. Moreover every connected component of every $\mathrm{El}_A(H)$ is itself totally W_∞-aspherical whenever A is totally W_∞-aspherical.

Proof. The implication (1)⇒(2) follows because a weak homotopy equivalence induces an integral homology isomorphism. Assume (2). The identity functor is final, so A is integrally acyclic and hence nonempty and connected. For any connected nonempty category of elements, the collage of Part B is a final image of A. Its homotopy-pushout description gives the homology exact sequence

$$\cdots \to \widetilde{H}_{j+1}(BA_H;\mathbb{Z}) \to \widetilde{H}_j(B\,\mathrm{El}_A\,H;\mathbb{Z}) \to \widetilde{H}_j(BA;\mathbb{Z}) \to \cdots .$$

Both outside terms vanish. For a component of an arbitrary H, first replace H by its component subfunctor. This proves (3). Lemma 3 proves (3)⇒(4).

Assume (4), and let $f : A \to B$ be any ordinary final functor. For $b \in B$, the category $b\backslash A$ is the category of elements of the covariant functor $a \mapsto \mathrm{Hom}_B(b, f(a))$. It is connected and nonempty by finality, and therefore weakly contractible by the hypothesis. Quillen's Theorem A (Quillen, 1973, Section 1, Theorem A) implies that the specified map Bf is a weak homotopy equivalence. The constant singleton functor in (4) makes BA weakly contractible. Thus BB is weakly contractible, proving (1) by the comprehensive-factorization criterion. The final assertion follows from Lemma 2 and (4). □

Source proposition 1 (Proved: exact integral colimits are sufficient)**.** *Let A be nonempty and connected. If $\mathrm{colim}_A : \mathbf{Ab}^A \to \mathbf{Ab}$ is exact, then A is totally W_∞-aspherical.*

Proof. For $H : A \to \mathbf{Set}$, define $\Sigma_H : \mathbf{Ab}^{\mathrm{El}_A(H)} \to \mathbf{Ab}^A$ by

$$(\Sigma_H F)(a) = \bigoplus_{h \in H(a)} F(a,h),$$

with the transition maps specified in the proof of Lemma 2. It is exact because direct sums of abelian groups are exact. The universal property of a cocone gives the canonical natural isomorphism

$$\operatorname*{colim}_{\mathrm{El}_A(H)} F \cong \operatorname*{colim}_{A} \Sigma_H F.$$

Thus the colimit functor on each category of elements is exact, and the same is true on any one of its components, by extending diagrams by zero on the other components. The bar resolution computing derived colimits identifies $L_j \operatorname{colim}_E \mathbb{Z}$ with $H_j(BE;\mathbb{Z})$: its term in degree j is the free abelian group on strings of j composable arrows of E, and its differential is the alternating sum of the nerve faces. Exactness therefore makes every component E integrally acyclic. Now apply Theorem 1. □

An explicit nonfiltered totally aspherical category

Source definition 2 (Proved: the category of injective ordinals)**.** *Let Δ_{inj} have objects $[n] = \{0, \dots, n\}$ for $n \geq 0$, and all strictly increasing functions as arrows, with ordinary composition of functions. This is a countable small category. In the next construction $\mathbb{Z}[S]$ denotes the free abelian group on a set S, and the augmentation of a finite linear combination of arrows is the sum of its coefficients.*

Historical source wording. The review corrects the attribution below to Isbell–Mitchell (1973), Theorem 3; the source wording is retained.

The exact-colimit example is attributed to Isbell (1974) in Husainov (2002, Section 2.3, after Theorem 2.5); its bibliographic record was verified, but the original article's body was not available in this run. We do not use that unavailable body as a proof. The following explicit verification uses polynomial interpolation. A CC0 AI-authored exposition containing the construction was found during the literature search (Claude Opus 5.5, 2026, Section 4); we independently verify its algebraic identities here and by the accompanying program `cd_affine_polynomials.py`. Its provenance is recorded in the report, and it is not used as an authority.

Source lemma 4 (Proved: interpolation on coordinate hyperplanes)**.** *Let $F_0, \dots, F_n$ be polynomials in $\mathbb{Z}[x_0, \dots, x_n, u]$ such that $F_i - F_j \in (x_i, x_j)$ for every pair i, j. There exists C in this polynomial ring with $C - F_i \in (x_i)$ for every i. If all F_i are homogeneous of the same degree, C can be chosen homogeneous of that degree.*

Proof. For a subset $S \subseteq \{0, \dots, n\}$ let ρ_S set $x_i = 0$ for $i \in S$. For $S \neq \varnothing$, the value $\Phi_S = \rho_S(F_i)$ is independent of the choice of $i \in S$: the difference of two choices belongs to (x_i, x_j) and is killed by ρ_S. Set

$$C = \sum_{\varnothing \neq S \subseteq \{0,\dots,n\}} (-1)^{|S|+1} \Phi_S.$$

Modulo (x_j) the terms indexed by S and $S \cup \{j\}$ cancel whenever $j \notin S$ and $S \neq \varnothing$. The remaining term is $\Phi_{\{j\}}$, congruent to F_j. All substitutions preserve homogeneity. □

Source lemma 5 (Proved: normalized affine cones)**.** *For every $n \geq 0$ there are an integer $M \geq n$ and*

$$t \in \mathbb{Z}[\mathrm{Hom}_{\Delta_{\mathrm{inj}}}([n], [M])]$$

of augmentation 1 such that $th = th'$ whenever $h, h' : [m] \to [n]$ are parallel arrows. Here composition is extended bilinearly in the free preadditive category. For $n \geq 1$ one can take $M = 2^{n+1} - 2$.

Proof. We prove a polynomial assertion simultaneously for all integers $k \geq 1$. For variables $z_0, \dots, z_{n+1}$, let D_i identify z_i and z_{i+1} and relabel the remaining variables in order as $y_0, \dots, y_n$. We claim that there is a homogeneous integral polynomial $C_{n,k}$ with value 1 when all variables are 1, such that $y_i^k D_i(C_{n,k})$ is independent of i.

For $n = 0$, use $C_{0,k} = 1$. Assume the assertion for $n-1$ and all k. Let $Q = C_{n-1,2k}$, expressed in the variables $y_0, \dots, y_n$, and prescribe

$$D_i(C_{n,k}) = F_i := Q \prod_{l \neq i} y_l^k.$$

These prescriptions agree on every pairwise intersection of the hyperplanes $z_i = z_{i+1}$. Indeed, for $i < j$, one must check $D_{j-1}(F_i) = D_i(F_j)$. If $j = i+1$, both omitted-variable products become $\prod_l w_l^k$ and the images of Q agree. If $j \geq i+2$, put $p = i$, $q = j-1$. The two expressions are respectively

$$w_q^{2k} D_q(Q) \prod_{l \neq p,q} w_l^k, \qquad w_p^{2k} D_p(Q) \prod_{l \neq p,q} w_l^k,$$

and are equal by induction. Choose homogeneous polynomial lifts of the F_i. The change of coordinates $x_i = z_i - z_{i+1}$, $u = z_{n+1}$ is invertible over $\mathbb{Z}$; the kernels of the D_i are the coordinate ideals (x_i). Lemma 4 therefore supplies $C_{n,k}$. It has value 1 at the all-ones point, and the required common expression is $Q \prod_l y_l^k$. Its degree satisfies

$$d(n,k) = d(n-1,2k) + nk = k(2^{n+1} - n - 2).$$

For an injection $g : [n] \to [M]$, let its gaps be

$$e_0 = g(0), \quad e_i = g(i) - g(i-1) - 1 \ (1 \leq i \leq n), \quad e_{n+1} = M - g(n).$$

This gives a bijection between injections and monomials of degree $M - n$ in $z_0, \dots, z_{n+1}$. Extend it linearly, writing P_t for the polynomial of an arrow combination t. If $\delta^i : [n-1] \to [n]$ omits i, deleting $g(i)$ merges two gaps and the deleted point; hence

$$P_{t\delta^i} = y_i D_i(P_t).$$

Take $P_t = C_{n,1}$ and $M = n + d(n,1)$. Its augmentation is 1, and all $t\delta^i$ agree.

We finally check that this equalizes every parallel pair, rather than just the cofaces. If their common value is s, the relation $\delta^{b+1}\delta^a = \delta^a\delta^b$ for $a \leq b$ gives $s\delta^a = s\delta^b$. Induction on n therefore shows that s equalizes all parallel injections into $[n-1]$. Every proper injection into $[n]$ factors through a coface; factoring two such injections proves $th = th'$. The identity is the only injection $[n] \to [n]$. The case $n = 0$ is immediate. □

Source theorem 2 (Refuted: total asphericity need not imply filteredness)**.** *The category Δ_{inj} is totally W_∞-aspherical and has exact colimits of abelian-group-valued diagrams, but is not filtered. Consequently Lead 4 for W_∞ and manuscript row II-C-003 have a negative answer for arbitrary small categories.*

Proof. The affine category $\mathrm{Aff}_{\mathbb{Z}}(\Delta_{\mathrm{inj}})$, defined and analyzed in Theorem D.4 of the source return, has the same objects and all integral arrow combinations of augmentation 1. Any two objects map to a common larger ordinal. Given two parallel affine arrows $\alpha, \beta : [m] \to [n]$, Lemma 5 provides t for which th is independent of the ordinary injection $h : [m] \to [n]$. Since the coefficients of both α and β sum to 1, we get $t\alpha = t\beta$. Thus the affine category is filtered. Theorem D.4 of the source return proves exactness of integral colimits. The original category is nonempty and connected, so Proposition 1 proves total W_∞-asphericity.

There are two distinct injections $a, b : [0] \to [1]$, taking 0 to 0 and 1 respectively. Every arrow $c : [1] \to [n]$ is injective, so $ca \neq cb$. Hence this parallel pair has no equalizer by postcomposition, and the category is not filtered. This verifies every hypothesis and the failure in a completely specified countable category; no finite-to-infinite inference is involved. □

The supplied reviewer on attribution and the exact-colimit step

I verified the return's proof line by line (gap monomials: $P_{t\delta^i} = y_i\, D_i(P_t)$; the compatibility $D_{j-1}(F_i) = D_i(F_j)$ in both cases; value 1 at the all-ones point; degree $k(2^{n+1} - n - 2)$), and the case $n = 1$ by hand: $t = (1,2) - (0,2) + (0,1)$, $t\delta^0 = t\delta^1 = [1]$. I also opened the 1973 note (free at ams.org), which the return did not: it states the theorem and sketches a different, combinatorial proof. The label "Proved" should read "Known (Isbell–Mitchell 1973, Th. 3); independent proof".

$\mathrm{Aff}_{\mathbb{Z}}(\Delta_{\mathrm{inj}})$ filtered $\Rightarrow$ colim exact: I checked this direction directly ($\mathrm{colim}_A\, F = \mathrm{colim}_{\mathrm{Aff}\, A}\, \widetilde{F}$, since $x - (\Sigma\, n_c\, c)x = \Sigma\, n_c\, (x - cx)$); it is the "if" part of Isbell–Mitchell's Theorem 1. Then C.6. Not filtered: d^0, d^1: $[0] \to [1]$ are never equalized. **So the conjecture Grothendieck states at II ms. 36ter is false, and the counterexample is the Isbell–Mitchell category of 1973**; what is new is the identification of total asphericity (C.5) that makes the old example apply. Independent evidence of mine: for several explicit H on Δ_{inj} I computed El(H) by hand before reading the proof (subfunctors and quotients of h^0, h^1; all components came out contractible).

GPT-6 Astra's reading

The supplied text writes out the covering-space argument that converts the category-of-elements acyclicity condition into weak contractibility, and it gives the exact direct-sum functor that transfers exact colimits to categories of elements. It then supplies the polynomial affine-cone construction and the two injections which no postcomposition can equalize. The source excerpt retains two dependencies outside its boundaries: the collage model from Part B and the affine-category exactness theorem from Part D. The supplied review checks both and gives the short colimit relation used in the latter; its text is reproduced as an accompanying source note. I found the bridge C.5–C.6 and the displayed polynomial identities internally consistent. The theorem that the affine category of injective ordinals is filtered is credited to Isbell–Mitchell, 1973, Theorem 3, as the review requires. This is an independent written proof with recorded dependencies, not a claim of priority for that theorem.

12. The projective-plane counterexample for finite monoids

Statement recorded in the inventory.

Counterexample to Conjecture 7.1 of arXiv:2610.38760v1: RP^2 is not BM for a finite monoid M (a finite monoid whose classifying space is finite-dimensional has trivial universal group).

Bearing on the manuscript. sent to the author on 12 Nov 2026

Statement and proof in the supplied source

Source G.4. A finite monoid cannot have a nonsimply connected finite-dimensional type *Proved*

Let M be a finite monoid. Its universal group $U(M) = \pi_1(BM)$ is finite. If BM is homotopy equivalent to a finite-dimensional CW complex, then $U(M) = 1$. In particular neither S^1 nor $\mathbb{RP}^2$ is the classifying-space type of a finite monoid.

Proof. Let $\eta : M \to U(M)$ be the universal homomorphism. For $a \in M$, finiteness gives $a^r = a^s$ for some $r < s$, so $\eta(a)^{s-r} = 1$. Every inverse of a generator is therefore a nonnegative power of that generator. It follows that every word in the generators and their inverses equals $\eta(m)$ for some $m \in M$. Thus η is surjective, and $U(M)$ is finite. The identification with $\pi_1(BM)$ follows directly from the edge-and-triangle presentation: the generators are the nonidentity elements and the relations are $[a][b] = [ab]$.

Choose an idempotent e in the minimal nonempty two-sided ideal I of M. Such an ideal exists by finiteness, and a sufficiently large power of any of its elements is idempotent. We verify that $H = eMe$, with identity e, is a group. For $x \in eMe$, minimality gives $MxM = I$, so $e = axb$ for some $a, b \in M$. Multiplying by e at both ends yields

$$e = (eae)x(ebe)$$

in the finite monoid eMe. In any finite monoid a product is invertible only if each factor is invertible: a right inverse makes right multiplication injective, hence surjective, and gives a two-sided inverse; the dual argument treats a left inverse. Thus x is invertible. The group H is finite, and the homomorphism $H \to U(M)$ is surjective since $\eta(eme) = \eta(m)$.

There is a canonical morphism $BH \to BM$ in **Hot** even though the inclusion $H \subset M$ sends 1_H to e, not necessarily to 1_M. To type this map, let $\mathrm{Kar}(M)$ be the category of idempotents of M with

$$\mathrm{Hom}_{\mathrm{Kar}(M)}(f, g) = gMf.$$

The full one-object subcategory at 1_M is M and the full one-object subcategory at e is H. Every object is a retract of 1_M. The inclusion $j : M \to \mathrm{Kar}(M)$ is a weak equivalence: for each object f, the comma category j/f is a retract of $j/1_M$, which has a terminal object. A retract of a contractible space is contractible, and Quillen's Theorem A applies. Hence the typed morphism is

$$BH \longrightarrow B\,\mathrm{Kar}(M) \xleftarrow[\simeq]{Bj} BM.$$

It induces the surjection $H \to U(M)$ on fundamental groups, after the basepoint path given by the retract arrows is chosen.

Suppose $h : BM \to Z$ is a homotopy equivalence with Z a connected finite-dimensional CW complex. Miller's theorem states that every map from the classifying space of a torsion group to Z induces the zero map on fundamental groups (Miller, 1984, Theorem B, p. 40). Apply it to the composite $BH \to BM \xrightarrow{h} Z$. Its map on fundamental groups is both zero and surjective. Consequently $\pi_1(Z) = U(M) = 1$. Notice that this step uses the precise fundamental-group theorem, with no assumption that Z was simply connected. □

Source G.6. Finite fundamental group is not sufficient for finite monoids *Refuted*

The assertion that every connected finite CW complex with finite fundamental group is the classifying space of a finite monoid is false.

Proof. Take $\mathbb{RP}^2$, whose fundamental group is $\mathbb{Z}/2$. G.4 excludes any finite monoid realization. In particular this refutes Conjecture 7.1 in the verified version of Ben-Bassat (2026); it does not refute that paper's simply connected Theorem C. The explicit finite categorical and poset models below verify that the obstruction concerns the one-object restriction. □

The supplied verdict extquotesingle s verification of the finite-group step

The proof of step 4, so that nothing is taken on authority. Let f: BG → X with G finite, X a connected CW complex of dimension d, and suppose $f_* = \varphi$ is non-trivial on π_1. Pick c ∈ G of prime-power order p^k with $\varphi(c) \neq 1$ (a primary component of an element not in the kernel), C = ⟨c⟩, N = φ(C) ≠ 1, X′ → X the covering with $\pi_1(X') = N$, f′: BC → X′ the lift, ψ a character of N of order p, L the flat line bundle of ψ on X′. Then f'^*L is the line bundle of $\chi = \psi \circ \varphi|C$ on BC, and χ has order p. In $K^0(X')$, $([L] - 1)^{d+1} = 0$, because the skeletal filtration is multiplicative and X′ has dimension d (Miller argues with Lusternik–Schnirelmann category). So $(\chi - 1)^{d+1}$ restricts to zero in K^0 of every finite skeleton of BC. By Atiyah, *Characters and cohomology of finite groups*, Publ. Math. IHES 9 (1961), Proposition (8.1) for cyclic groups (or Theorem (7.2), p. 46: $\widehat{\alpha}$: $R(G)\hat{} \to \mathcal{K}^*(B_G)$ is a topological isomorphism) and Proposition (6.11), p. 45 (for a p-group $R(G) \to R(G)\hat{}$ is a monomorphism), $(\chi - 1)^{d+1} = 0$ in R(C). But its value at c is $(\zeta - 1)^{d+1} \neq 0$ with ζ a primitive p-th root of unity. Contradiction. (Miller's own computation: $K^0(BZ_{mn}) = Z[[x]]/((1+x)^{mn} - 1)$ and the image $(1+x)^n - 1$ of x_m is not nilpotent; I verified this by mapping x to ζ − 1 in $Z_p[\zeta]$ for ζ of order p^c, p^c the exact power of a prime p | m in mn.)

GPT-6 Astra's reading

The proof specifies the exact morphism from the maximal subgroup's classifying space to that of the monoid through its Karoubi envelope, and computes the induced surjection on fundamental groups. Miller's stated theorem makes the same induced map trivial for a finite-dimensional target; the two conclusions force $U(M) = 1$. The fundamental group of $\mathbb{RP}^2$ then supplies the counterexample. I found the source proof complete from Quillen's Theorem A and Miller's stated theorem. The supplied verdict adds a K-theoretic verification of the latter finite-group case. The separately cited EMAIL_CLAIMS_CHECK file is absent, so its purported additional checks cannot be reproduced here. The refutation is tied to the conjecture as quoted in the supplied version-1 record; no assertion about a later version or publication status is added.

Statements found to be known

The inventory closes by recording the following prior references, so that these statements are not presented as priority claims.

1. The filteredness of the affine category of injective ordinals: J. R. Isbell and B. Mitchell, "Exact colimits," *Bulletin of the American Mathematical Society* **79** (1973), 994–996, Theorem 3. This is the prior theorem used in section 11; the bridge to total asphericity is the additional connection recorded there. The source review also identifies the intermediate CC0 Open Maths lesson, "Derived colimits over a small category" (20 October 2026), as the provenance of the return's polynomial proof.
2. Uniqueness in Nielsen realization: W. J. Harvey, "On branch loci in Teichmüller space," *Transactions of the American Mathematical Society* **153** (1971), 387–399. NEW_RESULTS records that the La Longue Marche expert located this reference; its proof and precise formulation are outside the supplied new-results proof files.
3. The identification recorded as "localiseur spécial" and accessible fundamental localizer: D.-C. Cisinski, *Les préfaisceaux comme modèles des types d'homotopie*, Astérisque 308 (2006), Corollary 4.2.22, as cited in NEW_RESULTS and the supplied expert FINDINGS F3-4. The exact axiom translation is not added as a new appendix theorem.

The cited numbering is the checked preprint's; the full-arrow accessibility argument and translation to Question 3.15 are supplied in this commentary.

Sean Cox, Jonathan Feigert, Mark Kamsma, Marcos Mazari-Armida, and Jiří Rosický. Cofibrant generation of pure monomorphisms in presheaf categories. *Advances in Mathematics*, 497:111010, 2026b. doi: 10.1016/j.aim.2026.111010. URL https://arxiv.org/pdf/2506.20278v3. verified: Definition 2.7, Remark 2.8, Fact 2.9, Theorem 5.1 and its reduction to the preceding results, Examples 5.3 and Corollary 5.4, in arXiv v3 (29 April 2026), 26 pages; published metadata checked on the publisher's page. The application to Grothendieck's strong L-accessibility criterion is proved in this commentary.

Daniel Dugger. A primer on homotopy colimits. verified: author's 109-page online manuscript, section 14.9, Proposition 14.10 and Corollary 14.11 on pp. 61–62; telescope construction and its proof checked. Accessed 10 November 2026, n.d. URL https://pages.uoregon.edu/ddugger/hocolim.pdf.

William G. Dwyer and Daniel M. Kan. Calculating simplicial localizations. *Journal of Pure and Applied Algebra*, 18(1):17–35, 1980a. doi: 10.1016/0022-4049(80)90113-9. URL https://www.uio.no/studier/emner/matnat/math/MAT9580/gamle-undervisningsressurser/varen-2018/documents/dwyer-kan-calculating-simplicial-localizations-jpaa-1980.pdf. verified.

William G. Dwyer and Daniel M. Kan. Function complexes in homotopical algebra. *Topology*, 19(4):427–440, 1980b. doi: 10.1016/0040-9383(80)90025-7. URL https://www.uio.no/studier/emner/matnat/math/MAT9580/gamle-undervisningsressurser/varen-2018/documents/dwyer-kan-function-complexes-in-homotopical-algebra-topology-1980.pdf. verified.

William G. Dwyer and Daniel M. Kan. Simplicial localizations of categories. *Journal of Pure and Applied Algebra*, 17(3):267–284, 1980c. doi: 10.1016/0022-4049(80)90049-3. URL https://www.uio.no/studier/emner/matnat/math/MAT9580/gamle-undervisningsressurser/varen-2018/documents/dwyer-kan-simplicial-localizations-of-categories-jpaa-1980.pdf. verified.

Samuel Eilenberg and J. A. Zilber. On products of complexes. *American Journal of Mathematics*, 75(1):200–204, 1953. URL https://webhomes.maths.ed.ac.uk/~v1ranick/papers/eilenzilb2.pdf. verified.

Jacopo Emmenegger, Luca Mesiti, Giuseppe Rosolini, and Thomas Streicher. A comonad for Grothendieck fibrations. *Theory and Applications of Categories*, 40(13):371–389, 2024. URL https://arxiv.org/abs/2305.01474. verified.

Marcel Evrard. Fibrations de petites catégories. *Bulletin de la Société Mathématique de France*, 103:241–265, 1975. doi: 10.24033/bsmf.1804. URL https://www.numdam.org/article/BSMF_1975__103__241_0.pdf. verified: Section I.1, pp.241–242, definitions of variable-length path categories; Sections II and V consulted for the categorical fibration and Quillen A/B framework.

Vítor H. Fernandes, Jörg Koppitz, and Tiwadee Musunthia. The rank of the semigroup of all order-preserving transformations on a finite fence. *Bulletin of the Malaysian Mathematical Sciences Society*, 42(5):2191–2211, 2019. doi: 10.1007/s40840-017-0598-1. URL https://novaresearch.unl.pt/en/publications/the-rank-of-the-semigroup-of-all-order-preserving-transformations/. verified: institutional author record, publication metadata and abstract only; the linked accepted manuscript was blocked by access protection, so no theorem or proof in the paper was verified.

Peter Freyd. Algebra valued functors in general and tensor products in particular. *Colloquium Mathematicum*, 14(1):89–106, 1966. doi: 10.4064/cm-14-1-89-106. URL https://www.impan.pl/en/publishing-house/journals-and-series/colloquium-mathematicum/all/14/1/96064/algebra-valued-functors-in-general-and-tensor-products-in-particular. verified: publisher metadata and the indexed primary text on page 95 concerning module theories and tensor products of rings. The publisher download returned HTTP 403; an 18-page scan was located, but its full proof was not text-extractable. The abelian-group calculation used here is proved independently in the commentary.

Peter Freyd. Homotopy is not concrete. In *The Steenrod Algebra and Its Applications*, volume 168 of *Lecture Notes in Mathematics*, pages 25–34. Springer, 1970. doi: 10.1007/BFb0058516. URL https://tac.mta.ca/tac/reprints/articles/6/tr6.pdf. verified: revised reprint, Reprints in Theory and Applications of Categories 6 (2004), pages 1–10; main theorem on page 1 and simply connected unpointed consequence on page 5; page citations refer to the reprint.

Peter Gabriel and Friedrich Ulmer. *Lokal präsentierbare Kategorien*, volume 221 of *Lecture Notes in Mathematics*. Springer, 1971. doi: 10.1007/BFb0059396. URL https://link.springer.com/book/10.1007/BFb0059396. verified: publisher metadata and contents, including the chapters on presentable objects, generators and locally presentable categories; no unseen theorem number or proof is certified.

Peter Gabriel and Michel Zisman. *Calculus of Fractions and Homotopy Theory*, volume 35 of *Ergebnisse der Mathematik und ihrer Grenzgebiete*. Springer, Berlin, Heidelberg, 1967. doi: 10.1007/978-3-642-85844-4. URL https://link.springer.com/book/10.1007/978-3-642-85844-4. verified.

Bernhard Ganter and Rudolf Wille. *Formal Concept Analysis: Mathematical Foundations*. Springer, Berlin and Heidelberg, 1999. doi: 10.1007/978-3-642-59830-2. URL https://link.springer.com/book/10.1007/978-3-642-59830-2. verified: first English edition, section 0.4, Propositions 4–8 and Theorem 2, pp. 11–14; Chapter 1, Theorem 3, pp. 20–21, and proofs, in a digitized copy; publisher metadata checked.

Richard Garner. Understanding the small object argument. *Applied Categorical Structures*, 17(3):247–285, 2009. doi: 10.1007/s10485-008-9137-4. URL https://arxiv.org/abs/0712.0724. verified: arXiv:0712.0724v2, Proposition 3.8, Proposition 3.12, hypotheses 4.2–4.3, Theorem 4.4, and Proposition 5.4; publisher metadata confirms the 2009 article is the canonical publication, distinct from the duplicate 2012 publication withdrawn by the publisher.

Richard Garner and Thomas Streicher. An essential local geometric morphism which is not locally connected though its inverse image part is an exponential ideal. *Theory and Applications of Categories*, 37(26):908–913, 2021. URL https://www2.mathematik.tu-darmstadt.de/~streicher/FIBR/GS.pdf. verified.

Jean Giraud. *Cohomologie non abélienne*, volume 179 of *Grundlehren der mathematischen Wissenschaften*. Springer, 1971. doi: 10.1007/978-3-662-62103-5. URL https://link.springer.com/book/10.1007/978-3-662-62103-5. verified: publisher metadata and table of contents only, including the section on bands and gerbes, pp. 184–301; no numbered internal theorem has been certified from the full text.

John W. Gray. Fibred and cofibred categories. In Samuel Eilenberg, David K. Harrison, Saunders Mac Lane, and Helmut Röhrl, editors, *Proceedings of the Conference on Categorical Algebra*, pages 21–83. Springer, 1966. doi: 10.1007/978-3-642-99902-4_2. URL https://link.springer.com/chapter/10.1007/978-3-642-99902-4_2. verified.

Moritz Groth. Derivators, pointed derivators and stable derivators. *Algebraic & Geometric Topology*, 13(1):313–374, 2013. doi: 10.2140/agt.2013.13.313. URL https://msp.org/agt/2013/13-1/agt-v13-n1-p10-s.pdf. verified.

Moritz Groth and Michael Shulman. Generalized stability for abstract homotopy theories. arXiv:1704.08084v1, 2017. URL https://arxiv.org/abs/1704.08084v1. verified.

Moritz Groth and Jan Šťovíček. Tilting theory for trees via stable homotopy theory. *Journal of Pure and Applied Algebra*, 220(6):2324–2363, 2016. doi: 10.1016/j.jpaa.2015.11.009. URL https://arxiv.org/abs/1402.6984. verified.

Moritz Groth, Kate Ponto, and Michael Shulman. Mayer–Vietoris sequences in stable derivators. *Homology, Homotopy and Applications*, 16(1):265–294, 2014a. doi: 10.4310/HHA.2014.v16.n1.a15. URL https://arxiv.org/abs/1306.2072. verified.

Moritz Groth, Kate Ponto, and Michael Shulman. The additivity of traces in monoidal derivators. *Journal of K-Theory*, 14(3):422–494, 2014b. doi: 10.1017/is014005011jkt262. URL https://arxiv.org/abs/1212.3277v3. verified.

Alexander Grothendieck. Sur quelques points d'algèbre homologique. *Tôhoku Mathematical Journal, Second Series*, 9(2):119–183, 1957. doi: 10.2748/tmj/1178244839. URL https://webusers.imj-prg.fr/~leila.schneps/grothendieckcircle/AG/AG-28.pdf. verified: Theorem 1.10.1 in the complete primary scan, and publisher metadata for the first installment, which contains that theorem; the full work continues in a second installment on pp. 185–221.

Alexander Grothendieck. *Revêtements étales et groupe fondamental (SGA 1)*, volume 224 of *Lecture Notes in Mathematics*. Springer, 1971a. doi: 10.1007/BFb0058656. URL https://arxiv.org/pdf/math/0206203. verified.

Alexander Grothendieck. *Revêtements étales et groupe fondamental (SGA 1)*, volume 224 of *Lecture Notes in Mathematics*. Springer, 1971b. doi: 10.1007/BFb0058656. URL https://arxiv.org/pdf/math/0206203. verified: Exposé VI, sections 8–9, pseudofunctors and split fibrations; read in the recomposed arXiv:math/0206203v2 edition, pages 139–143.

Alexander Grothendieck. Pursuing Stacks, section 69: Digression on six weeks' scratchwork: derivators, and integration of homotopy types. verified, 1983. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/ps-69.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre V: Catégories de chemins et localisation. verified: manuscript page 45 explicitly defines finite categories by finiteness of objects and arrows; manuscript pages 51–52 define Hot0 and record the editors' objections to the conservativity claim, 1990a. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChV-234.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre VI: HOT, 1990b. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChVI-345.pdf. verified.

Alexander Grothendieck. Les dérivateurs, chapitre XI: Hot-fibrations, foncteurs propres et foncteurs lisses etc. verified: all six numbered pages, manuscript pp. 127–136, against the edition; the source explicitly states that manuscript pp. 1–126 do not exist in this chapter, 1990c. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXI-890.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre v: Catégories de chemins et localisation. verified: electronic edition dated 9 September 2001, printed pages 31–32, manuscript pages 51–52, especially the definition of Hot-0 by finite categories, 1990d. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChV-234.pdf.

Alexander Grothendieck. Les dérivateurs: Chapitre I, généralités sur les (pré)dérivateurs. verified, 1990–1991a. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/Derivateurs.html.

Alexander Grothendieck. Les dérivateurs: Chapitre ii, cofinalité (à droite et à gauche). verified, 1990–1991b. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/Derivateurs.html.

Alexander Grothendieck. Les dérivateurs, chapitre VII: Catégories de chemins (2). verified, 1990–1991c. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/Derivateurs.html.

Alexander Grothendieck. Les dérivateurs: Chapitre xii, section v, sommes amalgamées et carrés w-cocartésiens dans cat. verified, 1990–1991d. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIIb-012.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XIII: Catégories de modèles (1). verified: printed pages 1–33 of the edition, manuscript pages 1–60; online complete chapter metadata checked, 1990–1991e. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIII-25-01-04.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre xii, sections i–iv: Caractérisation de w infini; foncteurs w-propres, w-lisses et fibrations. verified, 1990–1991f. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIIa-012.pdf.

Alexander Grothendieck. Les dérivateurs: Appendice au chapitre XII. verified: all 14 leaves of the edition's file, printed pages 1–13, manuscript pages 1–18; visual collation against the transcription, 1990–1991g. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIIapp-19-06-03.pdf.

Alexander Grothendieck. Les dérivateurs: Chapitre xii, section vi. verified: edition pp. 115–149, manuscript pp. 171–234; full editors' file also checked at manuscript pp. 240–241 and 269–273 for the subsequent factorization hypothesis and conservative pushout discussion. These later pages were consulted as context, 1990–1991h. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIIc-30-03-03.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XIV: Carrés h-cartésiens et h-cocartésiens. verified: against all eleven leaves of the edition dated 7 October 2010, including the preliminary editorial notice and the editors' postface. Printed pp. 1–9; manuscript markers 1–8. The editors date the complete manuscript to October 1990 through the first half of 1991; no more precise date for this chapter is asserted. The corresponding online chapter is Der-ChXIV-07-10-10.pdf., 1990–1991i. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIV-07-10-10.pdf.

Alexander Grothendieck. Les dérivateurs: Chapitre XIX, modèles (4). verified: Proposition 3.2 and the discussion in Section 3.4, which formulate the presheaf diagram domain using noetherian posets and, in the smaller domain, noetherianity of the topology on the opposite poset; these explicitly recall the construction in Chapter XVII; verified: manuscript pp. 23–24, terminal-object axiom; Proposition 3.2 and section 3.4, manuscript pp. 36–38, corrected noetherian variance; version 11 February 2019, 1990–1991j. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/der-ch19.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XV: Théorèmes de factorisation (modèles (2)). verified: Section 9, manuscript pp. 116–118, especially p. 117, where Loc (6) denotes the fibration axiom and its primed variants refer to XII pp. 53–59, 1990–1991k. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXV-05-11-10.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XVI: Les localiseurs fondamentaux. verified: title and edition metadata; Section 7.6, manuscript pp. 108–116, for the older derivator axiom discussion, and the opening distinction between weak, mild, and retract saturation, 1990–1991l. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/der-ch16.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XVII: Catégories à fibrations et à cofibrations (Modèles 3). verified: the electronic edition's two preliminary leaves and printed pp. 1–33, manuscript pp. 1–70; the complete-chapter URL identifies the edition. Commentary AI-produced by GPT-6 Astra (OpenAI, ChatGPT Pro mode), checked and integrated by Claude (Anthropic), 1990–1991m. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/der-ch17.pdf.

Alexander Grothendieck. Les dérivateurs: Chapitre xviii, catégories et ensembles accessibles. verified, 1990–1991n. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/der-ch18.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre vii: Catégories de chemins (2). verified: printed pages 34–73, manuscript pages 50'–117 with the opening continuation, visually compared with the transcription. The complete 109-page chapter PDF was also consulted for Section 13, manuscript pages 157–170, and its later comparison for unrestricted paths;

the constant-path lemma stated at manuscript page 160 is left without a written proof at page 170. The later comparison and these locators were checked, and the present commentary supplies an elementary proof of that lemma, 1990–1991o. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChVII-456.pdf.

Alexander Grothendieck. Les dérivateurs: Appendice au chapitre xii. verified: manuscript pages 10–12, especially the four-object category and footnote 7 correcting its homotopy type to the 2-sphere; electronic edition dated 20 June 2003, printed pages 6–8. Appendix manuscript pages 13–16 also checked for the subsequent pushout application, 1990–1991p. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIIapp-19-06-03.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XIII: Catégories de modèles (1). verified: electronic edition of 25 January 2004, printed pp. 29–64, manuscript pp. 50–98 and editorial appendices; official edition landing page and chapter PDF metadata. Transcribed and edited by M. Künzer, J. Malgoire and G. Maltsiniotis, 1990–1991q. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/Derivateurs.html.

Alexander Grothendieck. Les dérivateurs, chapitre XIV: Carrés h-cartésiens et h-cocartésiens. verified: manuscript p. 6, Corollary 2, printed p. 5, states Hom-set surjectivity and explicitly denies general injectivity; manuscript p. 7 states the dual cocartesian theory. The editorial postface distinguishes these consequences from stronger failed quadrangulated-category axioms. No independent numbered Der 6 definition is claimed from this chapter, 1990–1991r. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/Der-ChXIV-07-10-10.pdf.

Alexander Grothendieck. Lettre à Robert Thomason du 2 avril 1991 sur les dérivateurs. verified, 1991a. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/lettreder.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre xvi: Les localiseurs fondamentaux. verified, 1991b. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/der-ch16.pdf.

Alexander Grothendieck. Les dérivateurs, chapitre XVI: Les localiseurs fondamentaux. verified: section 3, manuscript pp. 16–27, especially the separation of Loc(6a), Loc(6b), Loc(6c), Commentary 3.4 and Proposition 3.6; no claim that this passage proves the false reverse excision for ordinary weak equivalences, 1991c. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/groth/ps/der-ch16.pdf.

Philip Hackney, Viktoriya Ozornova, Emily Riehl, and Martina Rovelli. Pushouts of Dwyer maps are $(\infty, 1)$-categorical. *Algebraic & Geometric Topology*, 24(4):2171–2183, 2024. doi: 10.2140/agt.2024.24.2171. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/HORR.pdf. verified: published version, Definition 1.2, Theorems 1.5 and 1.6, Proposition 3.3, Definition 3.4, Example 3.5 and Proposition 3.6; the general form of Theorem 1.6 is printed on p. 2179, whereas its initial statement on p. 2174 is restricted to Dwyer maps.

W. J. Harvey. On branch loci in Teichmüller space. *Transactions of the American Mathematical Society*, 153:387–399, 1971. doi: 10.1090/S0002-9947-1971-0297994-0. Prior reference recorded by NEW_RESULTS; the relevant proof is outside the supplied appendix source files.

Allen Hatcher. *Algebraic Topology*. Cambridge University Press, 2002. URL https://pi.math.cornell.edu/~hatcher/AT/AT.pdf. verified.

Allen Hatcher. Spectral sequences in algebraic topology: Chapter 1. verified: author's chapter dated January 5, 2004; Theorem 1.14, cohomological differential indexing and abutment filtration; its displayed statement assumes trivial monodromy on fibre cohomology, and is used only for those formal features, 2004. URL https://pi.math.cornell.edu/~hatcher/SSAT/SSch1.pdf.

Pavol Hell and Arash Rafiey. Monotone proper interval digraphs and min–max orderings. *SIAM Journal on Discrete Mathematics*, 26(4):1576–1596, 2012. doi: 10.1137/100783844. URL https://cs.indstate.edu/~arash/publication/MinMaxPoly.pdf. verified.

Alex Heller. *Homotopy Theories*, volume 71 of *Memoirs of the American Mathematical Society, no. 383*. American Mathematical Society, 1988. doi: 10.1090/memo/0383. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/heller.pdf. verified.

Simon Henry. Ind-completion and accessibility of functor categories. *Journal of Pure and Applied Algebra*, 229(9):108030, 2025a. doi: 10.1016/j.jpaa.2025.108030. URL https://arxiv.org/abs/2307.06664. verified: Theorems 1.2 and 1.3, Corollary 2.2 and the proof in section 2.2, read in arXiv:2307.06664v2, 9 October 2024, whose title is When does Ind-kappa of a functor category equal the functor category of Ind-kappa? The theorem numbering cited here is that version's. Published metadata checked against the journal record; the publisher PDF itself was not accessible.

Simon Henry. Ind-completion and accessibility of functor categories. *Journal of Pure and Applied Algebra*, 229(9):108030, 2025b. doi: 10.1016/j.jpaa.2025.108030. URL https://arxiv.org/html/2307.06664v2. verified: Theorem 1.3, Construction 3.1 and Section 3.2 read in arXiv:2307.06664v2 of 9 October 2024. Journal metadata, unchanged Theorem 1.3 and added Examples 1.4–1.5 checked in the publisher's indexed text; direct publisher access returned HTTP 403. The preprint title differs. Its Theorem 1.5 and Corollary 1.6 become journal Theorem 1.7 and Corollary 1.8. No claim to having read the full journal PDF is made.

Chris Heunen. On the functor ℓ^2. In Bob Coecke, Luke Ong, and Prakash Panangaden, editors, *Computation, Logic, Games, and Quantum Foundations: The Many Facets of Samson Abramsky*, volume 7860 of *Lecture Notes in Computer Science*, pages 107–121. Springer, 2013. doi: 10.1007/978-3-642-38164-5_8. URL https://arxiv.org/pdf/1012.4526. verified: arXiv:1012.4526v6, 18 September 2018, section 3.2, Proposition 3.6, Lemma 3.8 and Theorem 3.9, pp. 4–6; locators refer to this revised preprint, not the 2013 pagination.

Philip S. Hirschhorn. *Model Categories and Their Localizations*, volume 99 of *Mathematical Surveys and Monographs*. American Mathematical Society, 2003. doi: 10.1090/surv/099. URL https://webhomes.maths.ed.ac.uk/~v1ranick/papers/hirschhornloc.pdf. verified: scanned published PDF, Proposition 11.1.10 on p.211, Theorem 11.3.2 with its proof on pp.214–215, and Theorem 11.6.1 with its proof on p.224, inspected visually; bibliography uses publication numbering, not a preprint.

Mark Hovey. *Model Categories*, volume 63 of *Mathematical Surveys and Monographs*. American Mathematical Society, 1999a. doi: 10.1090/surv/063. URL https://ericmalm.net/ac/projects/symmetric-spectra/hovey--model-cats.pdf. verified: publicly available author-text PDF, Definition 1.1.1(2), Lemmas 1.1.9, 1.1.10 and 1.1.12, Corollary 1.1.11; Theorem 1.2.10 and proof; Lemmas 1.3.4 and 1.3.10 and their proofs, Definition 1.3.6; Definitions 5.1.2 and 5.2.2, Theorem 5.2.5 and its proof; Definitions 6.2.6–6.2.7, Lemma 6.3.3 and Proposition 6.3.4 with their proofs. Numbering refers to this text; these are selected passages, not verification of entire chapters.

Mark Hovey. *Model Categories*, volume 63 of *Mathematical Surveys and Monographs*. American Mathematical Society, Providence, RI, 1999b. doi: 10.1090/surv/063. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/hovey-model-cats.pdf. verified: in the online author typescript (213 PDF leaves, no explicit version date on its title pages): Theorem 1.2.10(iv), p. 13, including its proof; Theorem 2.3.11, p. 44; Theorem 5.2.5 and its Reedy-model proof, pp. 125–126; Lemma 5.2.6 and its proof, pp. 126–127. Page locators refer to this typescript, whose later pagination differs from the published volume. Publication metadata and DOI were checked against AMS records.

Mark Hovey. Model category structures on chain complexes of sheaves. *Transactions of the American Mathematical Society*, 353(6):2441–2457, 2001. doi: 10.1090/S0002-9947-01-02721-0. URL https://arxiv.org/abs/math/9909024v1. verified: theorem scope in the author's arXiv preprint math/9909024v1, dated 3 September 1999: Theorem 2.2, p. 5, and Proposition 2.12, on the injective model structure and its fibrations for unbounded complexes in a Grothendieck category. The arXiv submission stamp is 3 September 1999; the retrieved PDF also carries a typesetting date of 26 November 2024. Locators refer to this preprint, not to the published pagination. Published metadata was checked against the indexed first page of the journal article.

Ahmet A. Husainov. Homological dimension theory of small categories. *Journal of Mathematical Sciences*, 110(1):2273–2321, 2002. Bibliographic metadata checked against the author's publication list; the appendix reproduces the source return's Section 2.3 citation.

John Isbell. Exact colimits. I. *Annals of Mathematics*, 100(3):633–637, 1974. doi: 10.2307/1970960. URL https://annals.math.princeton.edu/1974/100-3/p05. The source return's original attribution; the supplied review identifies the earlier Isbell–Mitchell 1973 Theorem 3.

John R. Isbell. Small adequate subcategories. *Journal of the London Mathematical Society*, s1-43(1):242–246, 1968. doi: 10.1112/jlms/s1-43.1.242. URL https://londmathsoc.onlinelibrary.wiley.com/doi/abs/10.1112/jlms/s1-43.1.242. verified: publisher metadata; the attribution to Example 1 is verified indirectly in Avery–Leinster (2021), Example 8.7. The original article's proof was not available for direct inspection; the needed properties are proved in the commentary.

John R. Isbell and Barry Mitchell. Exact colimits. *Bulletin of the American Mathematical Society*, 79:994–996, 1973. doi: 10.1090/S0002-9904-1973-13296-3. Theorem 3, as identified and checked in the supplied TOTASPH review.

André Joyal. Lettre à Alexandre Grothendieck du 11 avril 1984. verified: discussion of Heller's diagram model structures and derived images on page 3, and statement of Theorem 2 on page 10 in the edited 16-page PDF; the introduction identifies Joyal's added footnotes as dating from 2006, 1984. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/ps/lettreJoyal.pdf.

André Joyal. The theory of quasi-categories and its applications. CRM Quaderns 45, part II, lecture notes, 2008. URL https://ncatlab.org/nlab/files/JoyalTheoryOfQuasiCategories.pdf. verified: Sections 7.1–7.2, printed pages 309–311, definitions of complementary sieves and cosieves, categorical collages, and simplicial cylinders; not the unrelated cumulative key Joyal2008.

Daniel M. Kan. A combinatorial definition of homotopy groups. *Annals of Mathematics*, 67(2):282–312, 1958. doi: 10.2307/1970006. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/Kan-Comb.pdf. verified: original journal scan,

Definition 6.3 and Theorem 7.1 on p. 291, including the principal bundle and the reference to its contractibility proof in section 13.

H. Jerome Keisler. The ultraproduct construction. In *Ultrafilters across Mathematics*, volume 530 of *Contemporary Mathematics*, pages 163–179. American Mathematical Society, 2010. doi: 10.1090/conm/530/10444. URL https://people.math.wisc.edu/~hkeisler/ultraproducts-web-final.pdf. verified: author manuscript dated 1 June 2010, Definitions 2.4–2.5, Theorem 3.1 and its proof, Corollaries 3.2–3.3 and Section 5 through Proposition 5.3; metadata checked against the author publication list and the AMS volume record. The locators in this commentary refer to the author manuscript.

Bernhard Keller. On differential graded categories. In *Proceedings of the International Congress of Mathematicians, Madrid 2006*, volume II, pages 151–190. European Mathematical Society, Zürich, 2006. doi: 10.4171/022-2/8. URL https://webusers.imj-prg.fr/~bernhard.keller/publ/dgcat.pdf. verified.

Gregory Maxwell Kelly. *Basic Concepts of Enriched Category Theory*, volume 64 of *London Mathematical Society Lecture Note Series*. Cambridge University Press, 1982. URL https://tac.mta.ca/tac/reprints/articles/10/tr10.pdf. verified: Sections 1.1–1.3 in the 2005 Theory and Applications of Categories reprint, number 10, corrected online version dated 2023; monoidal categories, enrichment, and underlying ordinary categories.

Gregory Maxwell Kelly and Ross Street. Review of the elements of 2-categories. In Gregory Maxwell Kelly, editor, *Category Seminar*, volume 420 of *Lecture Notes in Mathematics*, pages 75–103. Springer, 1974. doi: 10.1007/BFb0063101. URL https://link.springer.com/chapter/10.1007/BFb0063101. verified.

Kerodon. The category of simplices, 2026. URL https://kerodon.net/tag/01N8. verified: archived subsection 11.9.11, Construction 11.9.11.2, Theorem 11.9.11.4 and Corollary 11.9.11.5; the latter states the last-vertex weak homotopy equivalence for every simplicial set. The page notes replacement by section 6.3.6; consulted 10 November 2026.

Henning Krause. Morphisms determined by objects and flat covers. *Forum Mathematicum*, 28(3):425–435, 2016. doi: 10.1515/forum-2014-0115. URL https://www.math.uni-bielefeld.de/~hkrause/flatcover.pdf. verified: author manuscript dated 23 March 2014, p. 2 (right minimality), p. 6 (minimal weak kernels, paragraph before Proposition 1.12); publication metadata verified on the author's publications page.

Henning Krause. Homological theory of representations. Author manuscript dated 15 September 2021, 2021. URL https://www.math.uni-bielefeld.de/~hkrause/HomTheRep.pdf. verified: Lemma 1.1.6 on descent of adjunctions through localization and Lemma 2.2.1 with its proof on additive localization under finite direct-sum closure; this entry cites the dated author manuscript.

Alexander Kurz and Jiří Rosický. Weak factorizations, fractions and homotopies. *Applied Categorical Structures*, 13(2):141–160, 2005. doi: 10.1007/s10485-004-6730-z. URL https://alexhkurz.github.io/papers/WEAK/weak.pdf. verified: publication metadata in the Chapman University author repository. Definition 3.1, Observation 3.3 and Example 3.6 checked in the author preprint dated 21 October 2004, pp. 5–9; these are preprint pages, not journal pagination. The commentary uses the literal right lifting property for multigraphs, including each specified target edge, rather than the abbreviated adjacency wording in Example 3.6.

Ioannis Lagkas Nikolos. *Levelwise Modules and Localization in Derivators*. PhD thesis, University of California, Los Angeles, 2018. URL https://escholarship.org/uc/item/8

6h4g32m. verified: thesis metadata, Corollary 4.2.5, Proposition 4.2.8 and its Der2 proof on printed pages 84–86, and Remark 4.2.19 on printed page 95 in the institutional PDF.

François Lamarche. Path functors in Cat. verified, 2013. URL https://www.researchgate.net/publication/281566170_Path_Functors_in_Cat.

Tom Leinster. *Basic Category Theory*, volume 143 of *Cambridge Studies in Advanced Mathematics*. Cambridge University Press, 2014. URL https://arxiv.org/pdf/1612.09375. verified: Exercise 6.3.23(d), printed page 168 of the author PDF, asserting that a finite category with finite products is equivalent to a complete ordered set; the version read is arXiv:1612.09375v2, 26 August 2025; the commentary supplies the finite-arrow counting proof.

Tobias Lenz. Homotopy (pre)derivators of cofibration categories and quasicategories. *Algebraic & Geometric Topology*, 18(6):3601–3646, 2018. doi: 10.2140/agt.2018.18.3601. URL https://msp.org/agt/2018/18-6/agt-v18-n6-p12-s.pdf. verified: published version, Definition 1.5 and Warning 1.7 on ABC axioms; Definition 1.33; Example 1.49; Proposition 3.32 and concluding comparison argument of Theorem 3.33; Corollary 4.1 and proof. Earlier auxiliary constructions used in the comparison were checked selectively, not re-proved.

Michael Lieberman, Jiří Rosický, and Sebastien Vasey. Sizes and filtrations in accessible categories, 2019. URL https://arxiv.org/abs/1902.06777. verified: arXiv:1902.06777v3, 5 June 2019, Definitions 2.5 and 2.10, Fact 2.11; preprint numbering.

Michael Lieberman, Jiří Rosický, and Sebastien Vasey. Sizes and filtrations in accessible categories. *Israel Journal of Mathematics*, 238(1):243–278, 2020. doi: 10.1007/s11856-020-2018-8. URL https://svasey.com/academic-homepage-may-2020/papers/lrv-st-accessible/lrv-st-accessible_v3.pdf. verified: arXiv:1902.06777v3, dated 5 June 2019, Definitions 2.1 and 2.5, Section 8 through Theorem 8.8, in particular Definition 8.1, Lemma 8.4 and its following paragraph on club agreement. Numbering in the commentary refers to this author version; journal metadata checked separately.

A. J. Lindenhovius. Grothendieck topologies on posets, 2014. URL https://arxiv.org/pdf/1405.4408v2. verified: version 2, dated 3 December 2014, Definition B.1 and Proposition B.5 with its proof, pages 49–50, for the lower Alexandrov topology. The commentary reverses the order to match the manuscript.

Zhen Lin Low. The heart of a combinatorial model category. *Theory and Applications of Categories*, 31(2):31–62, 2016. URL https://arxiv.org/abs/1402.6659. verified: Theorem 4.4, Remark 4.5, Theorem 5.9 and Proposition 5.12 in arXiv:1402.6659v4, posted 6 January 2016 (PDF title page carries 6 January 2015); published metadata checked at the journal. The cited numbering is that of this preprint.

Fernando Lucatelli Nunes and Lurdes Sousa. On lax epimorphisms and the associated factorization. *Journal of Pure and Applied Algebra*, 226(12):107126, 2022. doi: 10.1016/j.jpaa.2022.107126. URL https://arxiv.org/abs/2109.09836. verified.

Jacob Lurie. *Higher Topos Theory*, volume 170 of *Annals of Mathematics Studies*. Princeton University Press, 2009. URL https://www.math.ias.edu/~lurie/papers/HTT.pdf. verified.

Jacob Lurie. Higher algebra. Author's online manuscript, 18 September 2017, 2017. URL https://www.math.ias.edu/~lurie/papers/HA.pdf. verified: Proposition 1.1.3.4 and proof, pp. 31–32; Propositions 1.3.4.24 and 1.3.4.25, p. 119.

Michael Makkai and Robert Paré. *Accessible Categories: The Foundations of Categorical Model Theory*, volume 104 of *Contemporary Mathematics*. American Mathematical Society, 1989. doi: 10.1090/conm/104. URL https://doi.org/10.1090/conm/104. verified: metadata and publisher's description only; used for historical orientation, not as the source of an unchecked numbered theorem.

Michael Makkai and Jiří Rosický. Cellular categories. *Journal of Pure and Applied Algebra*, 218(9):1652–1664, 2014a. doi: 10.1016/j.jpaa.2014.01.005. URL https://archive.math.muni.cz/project/amega/files/data/publications/Rosicky/cc4.pdf. verified: author preprint dated 21 November 2013, Definition 2.3, Theorem 3.2 and its proof, Corollary 3.4 and its proof, and Remark 3.8; numbering refers to this preprint; journal metadata checked against publisher.

Mihály Makkai and Jiří Rosický. Cellular categories. *Journal of Pure and Applied Algebra*, 218:1652–1664, 2014b. URL https://arxiv.org/abs/1304.7572. verified: journal metadata on the arXiv record; Definition 2.1, Lemma 2.2, and Corollary 3.4 and its proof in arXiv:1304.7572v1 (29 April 2013). All result numbers cited refer to that preprint; the retract-closure argument is reconstructed explicitly in the commentary.

Georges Maltsiniotis. Structures d'asphéricité, foncteurs lisses, et fibrations. *Annales mathématiques Blaise Pascal*, 12(1):1–39, 2005. doi: 10.5802/ambp.194. URL https://www.numdam.org/article/AMBP_2005__12_1_1_0.pdf. verified.

Georges Maltsiniotis. Le théorème de Quillen, d'adjonction des foncteurs dérivés, revisité. *Comptes Rendus Mathématique*, 344(9):549–552, 2007. doi: 10.1016/j.crma.2007.03.011. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/ps/adjquill.pdf. verified: author's seven-page preprint, definitions of absolute derived functors on pp. 2–3 and the main unnumbered theorem on pp. 3–4 with the construction of derived unit and counit; journal metadata checked on the author's publication list. The linked version is the longer 2006 preprint, not the four-page journal layout.

Georges Maltsiniotis. Carrés exacts homotopiques, et dérivateurs. *Cahiers de Topologie et Géométrie Différentielle Catégoriques*, 53(1):3–63, 2012. URL https://arxiv.org/abs/1101.4144. verified: arXiv:1101.4144v1, 21 January 2011, Sections 1.1 and 1.5.2–1.5.5; Propositions 2.12–2.13 and their proofs; Theorem 4.32 and its proof. The commentary uses the numbering of this 49-page preprint, not unverified pagination in the 2012 publication; publication metadata checked against the journal record.

Georges Maltsiniotis. La théorie de l'homotopie de Grothendieck. Author's expanded provisional version, March 2020, 2020. URL https://webusers.imj-prg.fr/~georges.maltsiniotis/ps/prstnewprov2020.pdf. verified.

Marco Manetti and Francesco Meazzini. Formal deformation theory in left-proper model categories. *New York Journal of Mathematics*, 25:1259–1311, 2019. URL https://nyjm.albany.edu/j/2019/25-52v.pdf. verified: published version, Definition 2.1 and Lemma 2.4 on pp. 1263–1264, and the historical attribution to Grothendieck on p. 1264; Definition 2.9 uses a different, stronger meaning of flatness.

Andrew Marks. Set theory. Author's lecture notes, updated 31 January 2026, 2026. URL https://math.berkeley.edu/~marks/notes/set_theory_notes_4.pdf. verified: Theorems 10.11–10.12, Corollary 10.13, Theorem 11.7 and Exercise 11.8, printed pages 45–49; proof of the cofinality obstruction checked.

Takao Matumoto, Norihiko Minami, and Masahiro Sugawara. On the set of free homotopy classes and Brown's construction. *Hiroshima Mathematical Journal*, 14(2):359–369, 1984. doi:

10.32917/hmj/1206133043. URL https://projecteuclid.org/euclid.hmj/1206133043. unverified.

J. Peter May, Inna Zakharevich, and Marc Stephan. The homotopy theory of equivariant posets. *Cahiers de topologie et géométrie différentielle catégoriques*, 58(2):82–114, 2017. URL https://cahierstgdc.com/wp-content/uploads/2018/01/May-al._58-2.pdf. verified: published author order and metadata; Lemma 3.6 on subdivided horn Dwyer maps, Lemma 4.7 and its full pushout proof, and Lemma 4.8 and its proof on preservation of fixed points. The author preprint has a different author order and numbers the last lemma 4.9; all citations here use the published version.

Aaron Mazel-Gee. Hammocks and fractions in relative ∞-categories. *Journal of Homotopy and Related Structures*, 13(2):321–383, 2018. doi: 10.1007/s40062-017-0184-0. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/mazel-gee18.pdf. verified.

Aaron Mazel-Gee. The universality of the Rezk nerve. *Algebraic & Geometric Topology*, 19 (7):3217–3260, 2019. doi: 10.2140/agt.2019.19.3217. URL https://msp.org/agt/2019/19-7/agt-v19-n7-p01-s.pdf. verified.

Haynes Miller. The Sullivan conjecture on maps from classifying spaces. *Annals of Mathematics*, 120(1):39–87, 1984. Theorem B, p. 40; Theorem 10.1 and proof, pp. 84–85. Reference as specified in the supplied CATHOT return and verdict.

Russell Miller, Bjorn Poonen, Hans Schoutens, and Alexandra Shlapentokh. A computable functor from graphs to fields. *The Journal of Symbolic Logic*, 83(1):326–348, 2018. doi: 10.1017/jsl.2017.50. URL https://math.mit.edu/~poonen/papers/graphs-to-fields.pdf. verified: publisher metadata; Theorem 1.1, the graph-morphism convention in Section 1.A, Section 5.A, Remark 5.1, and Section 6 in the author-hosted version received 11 June 2017. The construction uses characteristic zero and preserves infinite cardinalities; Lemma 5.3's real-field argument for arbitrary cardinalities is applied to finite subgraphs containing the finitely many parameters.

James S. Milne. Fields and galois theory. Author's course notes, version 5.10, September 2022, 2022. URL https://www.jmilne.org/math/CourseNotes/FT.pdf. verified: Proposition 7.12 and Theorem 7.13 with proofs, pp. 97–98 of version 5.10; finite and infinite Galois correspondence distinguished.

John Milnor. Whitehead torsion. *Bulletin of the American Mathematical Society*, 72(3): 358–426, 1966. doi: 10.1090/S0002-9904-1966-11484-2. URL https://webhomes.maths.ed.ac.uk/~v1ranick/papers/milnorwh.pdf. verified: scan of the published article, Section 6 definition of the group Wh, Section 7 definitions of relative torsion and torsion of a homotopy equivalence, including the mapping-cylinder formulation and zero-torsion criterion. No use is made of the algebraic claims flagged by Milnor's added-in-proof warning on p. 360.

Sidney A. Morris. *Pontryagin Duality and the Structure of Locally Compact Abelian Groups*. Cambridge University Press, 1977. doi: 10.1017/CBO9780511600722. verified: Chapter 7, Proposition 38 and its proof from character separation, in the publisher's primary-text extract; chapter pp. 90–103 and publication metadata checked.

Robert Paré and Jiří Rosický. Colimits of accessible categories. *Mathematical Proceedings of the Cambridge Philosophical Society*, 155(1):47–50, 2013. URL https://arxiv.org/abs/1110.0767. verified: arXiv:1110.0767v1, Introduction, uniform strong accessibility and statement of Makkai–Paré Theorem 5.4.7; proof of Theorem 2.1 and Corollary 3.2

for simultaneous choice of ranks. Published metadata checked against the arXiv journal reference.

Dmitri Pavlov. The enriched Thomason model structure on 2-categories. *Journal of Pure and Applied Algebra*, 228(5):107496, 2024. doi: 10.1016/j.jpaa.2023.107496. URL https://arxiv.org/abs/2208.02954. verified: Definition 2.6, Proposition 2.9, and Propositions 4.1–4.3 with proofs in arXiv:2208.02954v4, 16 November 2023; author identifies v4 as the journal version except formatting and style; journal year follows the arXiv journal-reference field.

Jorge Picado and Aleš Pultr. *Frames and Locales: Topology without Points*. Frontiers in Mathematics. Birkhäuser, 2012. doi: 10.1007/978-3-0348-0154-6. URL https://www.mat.uc.pt/~picado/publicat/bookpage.html. verified: publisher and author metadata; Chapter II, Proposition 6.4.4, on sobriety of the Alexandrov space of a poset, checked in an indexed excerpt of the digitized first-edition text; finiteness argument is supplied in the commentary.

Andrew M. Pitts. On product and change of base for toposes. *Cahiers de topologie et géométrie différentielle catégoriques*, 26(1):43–61, 1985. URL https://www.numdam.org/item/CTGDC_1985__26_1_43_0.pdf. verified: Proposition 1.5, Definition 2.2, Theorem 2.3 and its proof, printed pages 47–52; the theorem identifies the tensor of Grothendieck topoi with their product in the indexed setting. Here the base is specialized to sets.

Pietro Polesello and Ingo Waschkies. Higher monodromy. *Homology, Homotopy and Applications*, 7(1):109–150, 2005. doi: 10.4310/HHA.2005.v7.n1.a7. URL https://arxiv.org/abs/math/0407507. verified: journal metadata against the journal's EMIS archive; mathematical passages checked in arXiv:math/0407507v1, Corollary 2.2.4, Theorem 2.2.5 and section 2.3, including the description of abelian gerbes by degree-two cohomology; theorem references in the commentary use this arXiv version.

Kate Ponto and Michael Shulman. The linearity of traces in monoidal categories and bicategories. *Theory and Applications of Categories*, 31(23):594–689, 2016. URL https://tac.mta.ca/tac/volumes/31/23/31-23abs.html. verified.

Leonid Positselski. Notes on limits of accessible categories. *Cahiers de Topologie et Géométrie Différentielle Catégoriques*, 65(4):390–437, 2024. URL https://cahierstgdc.com/wp-content/uploads/2024/10/Positetski-LXV-4.pdf. verified: published PDF, Corollary 5.1 with proof, Theorem 6.1, the definitions and proofs in Section 8, Theorems 8.1–8.3 and 9.1, and Corollary 9.2. The different preservation hypotheses for chain colimits, filtered colimits and presentable objects were checked. Metadata checked against the journal volume page. Numbers refer to the published version.

Leonid Positselski. On pure monomorphisms and pure epimorphisms in accessible categories. *Theory and Applications of Categories*, 45(7):246–288, 2026. URL https://tac.mta.ca/tac/volumes/45/7/45-07abs.html. verified: publisher metadata and abstract only, including publication on 30 January 2026. Screened in the current-status search because it treats pure epimorphisms; no result about all epimorphisms in arbitrary accessible categories is attributed to it.

Daniel Quillen. Higher algebraic K-theory: I. In Hyman Bass, editor, *Algebraic K-Theory I: Higher K-Theories*, volume 341 of *Lecture Notes in Mathematics*, pages 85–147. Springer, Berlin, 1973. doi: 10.1007/BFb0067053. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/bass-seattle.pdf. verified.

Daniel G. Quillen. *Homotopical Algebra*, volume 43 of *Lecture Notes in Mathematics*. Springer, 1967. doi: 10.1007/BFb0097438. URL https://aareyanmanzoor.github.io/assets/books/homotopical-algebra.pdf. verified: original publication metadata and the 2022 TEXromancers retypesetting, Chapter I, Section 2, Proposition 1.2.1 and Theorem 1.2, especially equation (5) in its proof; Chapter II, Section 2, final paragraph identifying the fundamental groupoid of a simplicial mapping complex. Numbering cited is that retypesetting, not an asserted original pagination.

Andrei Rădulescu-Banu. Cofibrations in homotopy theory. verified: version 4, sections 1.3–1.4, including the Brown factorization and functor criteria in Lemmas 1.3.1 and 1.3.4 and the gluing/properness results in Lemmas 1.4.1–1.4.3; used as a modern one-sided formulation, not to add retract closure or functorial factorization to the manuscript hypotheses, 2009. URL https://arxiv.org/abs/math/0610009v4.

George Raptis. Homotopy theory of posets. *Homology, Homotopy and Applications*, 12(2): 211–230, 2010. doi: 10.4310/HHA.2010.v12.n2.a7. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/raptis-poset.pdf. verified: Proposition 2.4 and the following pseudo-Dwyer discussion, Theorem 2.6 and its proof, and the noncartesian example on pp. 220–221; published version.

George Raptis. Notes on combinatorial model categories, 2020. URL https://www.graptismath.net/files/notes-comb-model-cat.pdf. verified: author-hosted notes, originally lectures in July 2014 and revised in 2020; Section 2.3, Proposition 2.7 and Theorem 2.8 read. These cite the uniformization and inverse-image results rather than giving their complete proofs.

George Raptis and Jiří Rosický. The accessibility rank of weak equivalences. *Theory and Applications of Categories*, 30(19):687–703, 2015. URL https://www.tac.mta.ca/tac/volumes/30/19/30-19abs.html. verified: journal metadata, Proposition 2.2 and the preceding pseudopullback argument, the statement of Theorem 4.2, and Corollary 5.1 with proof in arXiv:1403.3042v2, dated 12 May 2015. Proposition 2.2 of that author version is Proposition 2.3 on page 690 of the journal article. The full proof of Theorem 4.2 was not rechecked.

Olivier Renaudin. Plongement de certaines théories homotopiques de Quillen dans les dérivateurs. *Journal of Pure and Applied Algebra*, 213(10):1916–1935, 2009. doi: 10.1016/j.jpaa.2009.02.014. URL https://arxiv.org/abs/math/0603339. verified.

Charles Rezk. A model category for categories. verified: primary six-page note, Section 2 and Theorem 3.1; date and September 2000 addendum checked against the author's publication list, 1996. URL https://ncatlab.org/nlab/files/Rezk_ModelCategoryForCategories.pdf.

Charles Rezk. Fibrations and homotopy colimits of simplicial sheaves. verified: Section 2 definition of sharp maps and Propositions 2.2 and 2.7, pp. 3–4 of the author's manuscript; arXiv metadata checked, 1998. URL https://rezk.web.illinois.edu/rezk-sharp-maps.pdf.

Charles Rezk. Every homotopy theory of simplicial algebras admits a proper model. *Topology and its Applications*, 119(1):65–94, 2002. doi: 10.1016/S0166-8641(01)00057-8. URL https://arxiv.org/abs/math/0003065. verified: arXiv math/0003065v1, Example 2.11 and the adjoining-a-generator calculation; example numbering cited in the commentary is that of the preprint, not the journal version.

Emily Riehl. *Categorical Homotopy Theory*, volume 24 of *New Mathematical Monographs*. Cambridge University Press, 2014. doi: 10.1017/CBO9781107261457. URL https://emilyriehl.github.io/files/cathtpy.pdf. verified.

Emily Riehl. Category theory in context. Author's online second-edition revision; first edition published by Dover in 2016, n.d. URL https://emilyriehl.github.io/files/context.pdf. verified.

Emily Riehl and Dominic Verity. The theory and practice of Reedy categories. *Theory and Applications of Categories*, 29(9):256–301, 2014. URL https://math.jhu.edu/~eriehl/reedy.pdf. verified: author-hosted 43-page version, Proposition 6.3 and its proof, Corollary 6.7, Lemma 7.1 and Observation 7.2; journal metadata checked against the journal abstract page. The cited proposition and lemma numbers are those of the author-hosted version; additionally checked: published version dated 13 June 2014, read from https://emilyriehl.github.io/files/reedy.pdf (47 PDF pages, distinct from the 43-page April preprint at math.jhu.edu); Definition 4.14, Observation 5.1, Example 5.2, Definition 5.3, and Proposition 6.3, including the relative latching formula, composition identity, continuity convention, and cellular presentation. Journal pagination, rather than the earlier April preprint pagination, is used.

Emily Riehl and Dominic Verity. Kan extensions and the calculus of modules for ∞-categories. *Algebraic & Geometric Topology*, 17(1):189–271, 2017. doi: 10.2140/agt.2017.17.189. URL https://emilyriehl.github.io/files/equipment.pdf. verified.

Emily Riehl and Dominic Verity. *Elements of ∞-Category Theory*, volume 194 of *Cambridge Studies in Advanced Mathematics*. Cambridge University Press, 2022. doi: 10.1017/9781108936880. URL https://emilyriehl.github.io/files/elements.pdf. verified: author's prepublication PDF, Lemma 1.2.19 and its proof, Appendix C.1, especially Lemmas C.1.10–C.1.11; numbering is that of this PDF; published metadata and DOI checked against the Cambridge book page and front matter.

Jiří Rosický. On combinatorial model categories. *Applied Categorical Structures*, 17:303–316, 2009. doi: 10.1007/s10485-008-9171-2. URL https://www.math.muni.cz/~rosicky/papers/comb2.pdf. verified: author manuscript, Example 3.5(1), printed manuscript page 8, on split monomorphisms of posets as a full accessible image; publisher metadata checked separately. Example numbering cited is from the author manuscript.

Jiří Rosický. Accessible model categories. *Applied Categorical Structures*, 25(2):187–196, 2017. doi: 10.1007/s10485-015-9419-6. URL https://arxiv.org/pdf/1503.05010v2. verified: Example 2.8 and its proof, Definition 4.1 and Remark 4.2 in arXiv v2 (22 July 2015), with published volume, pages and DOI checked on the publisher's page. The non-generation proof cites Christensen–Hovey; that cited theorem was not independently re-proved here.

Jiří Rosický. Remarks on combinatorial and accessible model categories. *Theory and Applications of Categories*, 37(9):266–275, 2021. URL https://tac.mta.ca/tac/volumes/37/9/37-09.pdf. verified: published revision of 18 May 2021, Introduction and Section 3, especially Remarks 3.2 and 3.5, Examples 3.7 and Theorem 3.9; the distinction between full images and accessible arrow subcategories was checked against the corrected version.

Jonathan Rubin. Elmendorf constructions for G-categories and G-posets. verified: manuscript dated December 30, 2020, Section 2.3, Theorem 2.6 and the following explicit natural comparison. The theorem is attributed there to Thomason (1979), Theorem 1.2. This entry identifies the version actually consulted, rather than assuming the numbering of the subsequent publication, 2020. URL https://par.nsf.gov/servlets/purl/10393703.

Helmut H. Schaefer and Manfred P. Wolff. *Topological Vector Spaces*, volume 3 of *Graduate Texts in Mathematics*. Springer, New York, 2 edition, 1999. doi: 10.1007/978-1-4612-1468-7. URL https://link.springer.com/book/10.1007/978-1-4612-1468-7. verified: Chapter IV, section 1, Theorem 1.5, p. 126, and its separation proof in the indexed primary text; publisher metadata checked; the full text was not consulted.

Stefan Schwede and Brooke Shipley. Equivalences of monoidal model categories. *Algebraic & Geometric Topology*, 3:287–334, 2003. doi: 10.2140/agt.2003.3.287. URL https://homepages.math.uic.edu/~bshipley/monoidalequi.final.pdf. verified: Section 2.3 of the author version dated 11 February 2003, the shuffle and Alexander–Whitney identities and homotopies, and equation (2.8) giving the monoidal comparison for denormalization; publication metadata also checked.

Christian Serpé. Resolution of unbounded complexes in Grothendieck categories. *Journal of Pure and Applied Algebra*, 177(1):103–112, 2003. doi: 10.1016/S0022-4049(02)00075-0. URL https://www.sciencedirect.com/science/article/pii/S0022404902000750. verified: publisher metadata and abstract only; the general existence theorem was independently checked in the Stacks Project, Tag 079P, and Beke's Proposition 3.13.

Jean-Pierre Serre. Homologie singulière des espaces fibrés: Applications. *Annals of Mathematics*, 54(3):425–505, 1951. doi: 10.2307/1969485. URL https://www.sas.rochester.edu/mth/sites/doug-ravenel/otherpapers/Serre-HSEF.pdf. verified: original published scan; introduction pp. 425–426, Chapter II section 8 Proposition 6 on the fibre-cohomology local system, Chapter IV sections 1 and 5, Proposition 7 on contractibility of based paths; Chapter IV section 3 Proposition 3 and its proof on H-space simplicity.

Jean-Pierre Serre. Faisceaux algébriques cohérents. *Annals of Mathematics*, 61(2):197–278, 1955. doi: 10.2307/1969915. URL https://www.college-de-france.fr/media/jean-pierre-serre/UPL5435398796951750634_Serre_FAC.pdf. verified.

Boris Shoikhet. On Evrard's homotopy fibrant replacement of a functor. *Theory and Applications of Categories*, 31:989–1015, 2016. URL https://arxiv.org/abs/1412.0317. verified: arXiv:1412.0317v4, 7 November 2016, Theorems 1.8, 1.9 and 2.8, Proposition 1.14, Sections 1.5 and 2.1; numbering cited is that of this version.

Michael Shulman. Flat functors and morphisms of sites. Author's post, The n-Category Café, June 2011, 2011. URL https://golem.ph.utexas.edu/category/2011/06/flat_functors_and_morphisms_of.html. verified: indexed text of the author's opening discussion distinguishing Set-valued flatness and representable flatness; full page retrieval timed out, so no further claims rely on its contents.

Michael Shulman. Reedy categories and their generalizations, 2015. URL https://home.sandiego.edu/~shulman/papers/reedy.pdf. verified: author-hosted version dated 29 June 2015, Definition 4.6, Theorem 4.7 and its proof, and Remark 4.8, pp. 15–16; the ordinal-valued degree convention in the introduction was also checked. No universal monomorphism-recognition theorem for posets was found in these inspected passages.

Michael Shulman. The derivator of setoids. *Cahiers de Topologie et Géométrie Différentielle Catégoriques*, 64(1):29–96, 2023. URL https://cahierstgdc.com/wp-content/uploads/2023/01/SHULMAN-LXIV-1.pdf. verified: publisher issue metadata and the discussion on printed p. 33 identifying the classical truth-value derivator with the two-element lattice and with homotopy minus-one-types; this citation is not an attribution of our free-cycle counterexample.

Nicolas Spaltenstein. Resolutions of unbounded complexes. *Compositio Mathematica*, 65(2): 121–154, 1988. URL https://www.numdam.org/article/CM_1988__65_2_121_0.pdf. verified: introduction, definitions of K-projective and K-injective complexes, Theorems C and D; these concern modules and sheaves, not arbitrary abelian categories.

Danny Stevenson. Décalage and Kan's simplicial loop group functor. *Theory and Applications of Categories*, 26(28):768–787, 2012. URL https://arxiv.org/abs/1112.0474. verified: Theorem 21 and its proof in arXiv:1112.0474v2, pages 17–18, identifying the unit from a reduced simplicial set to the classifying complex of its loop group as a weak equivalence; theorem numbering cited is the preprint numbering.

Marshall H. Stone. The theory of representations for Boolean algebras. *Transactions of the American Mathematical Society*, 40(1):37–111, 1936. doi: 10.1090/S0002-9947-1936-1501865-8. URL https://www.ams.org/journals/tran/1936-040-01/S0002-9947-1936-1501865-8/. verified: metadata only; the publisher PDF was identified but returned an access error. Cited for historical context; the particular spectrum and ultrafilter identification used in this commentary is proved in full.

Ross Street and R. F. C. Walters. The comprehensive factorization of a functor. *Bulletin of the American Mathematical Society*, 79(5):936–941, 1973. doi: 10.1090/S0002-9904-1973-13268-9. URL https://researchers.mq.edu.au/en/publications/the-comprehensive-factorization-of-a-functor/. verified: metadata in the authors' institutional publication record; original article download was inaccessible; theorem attribution and correction of its proof checked in Kelly, section 4.7.

Paul Taylor. *Practical Foundations of Mathematics*, volume 59 of *Cambridge Studies in Advanced Mathematics*. Cambridge University Press, 1999. ISBN 0-521-63107-6. URL https://paultaylor.eu/~pt/prafm/html/s57.html. verified: author-hosted metadata; Section 5.7, Definitions 5.7.1–5.7.2 and the statement and surrounding explanation of Example 5.7.10. The HTML omits its diagram, whose individual arrows were not checked. Cited for the earlier nonfactorization phenomenon, not for the rational-cut presentation.

Giacomo Tendas. On continuity of accessible functors. *Applied Categorical Structures*, 30 (5):937–946, 2022. doi: 10.1007/s10485-022-09677-x. URL https://link.springer.com/article/10.1007/s10485-022-09677-x. verified: published version, Lemmas 2.5–2.6, Corollary 2.8 and Theorem 3.7; the strict size threshold in Lemma 2.5 was checked explicitly.

Giacomo Tendas. Flatness, weakly lex colimits, and free exact completions. *Annali di Matematica Pura ed Applicata*, 203:823–856, 2024. doi: 10.1007/s10231-023-01383-2. URL https://link.springer.com/article/10.1007/s10231-023-01383-2. verified: publisher's full HTML, Section 2, especially the definition of representable flatness in Remark 2.4 and its distinction from Definition 2.1; online publication 5 October 2023, journal volume 2024.

The Stacks Project Authors. Cofinal and initial categories. The Stacks Project, Section 4.17, Tag 09WN, 2026a. URL https://stacks.math.columbia.edu/tag/09WN. verified: Definition 4.17.1 and Lemma 4.17.2, including the explicit connected-zigzag criterion for cofinality; accessed 10 November 2026.

The Stacks Project Authors. Cofinal and initial categories. The Stacks Project, Section 4.17, Tag 09WN, 2026b. URL https://stacks.math.columbia.edu/tag/09WN. verified: Definitions 4.17.1 and 4.17.3 and Lemmas 4.17.2 and 4.17.4; accessed 11 November 2026.

The Stacks Project Authors. Dold–Kan. The Stacks Project, Section 14.24, Theorem 14.24.3, Tag 019D, 2026c. URL https://stacks.math.columbia.edu/tag/019D. verified.

The Stacks Project Authors. Filtered colimits. The Stacks Project, Section 4.19, Tag 04AX, 2026d. URL https://stacks.math.columbia.edu/tag/04AX. verified: Definition 4.19.1 and the eventual-equality description of filtered colimits of sets; accessed 10 November 2026.

The Stacks Project Authors. Filtered colimits. The Stacks Project, Section 4.19, Tag 04AX, 2026e. URL https://stacks.math.columbia.edu/tag/04AX. verified: Definition 4.19.1 and Lemmas 4.19.2, 4.19.4, 4.19.6, 4.19.8 and 4.19.9, including the available proofs; accessed 11 November 2026.

The Stacks Project Authors. The stacks project: Injective modules and duality into Q/Z, 2026f. URL https://stacks.math.columbia.edu/tag/01D8. verified: Tags 01D8 and 08WE accessed November 10, 2026; Lemmas 15.56.6–15.56.8 on exact duality, detection of nonzero elements, and the coinduced injective; Lemma 35.4.10 on reflection of injections and surjections. The commentary gives the left-module formula explicitly for the possibly noncommutative ring Z[pi].

The Stacks Project Authors. K-injectives in Grothendieck categories: Theorem 19.12.6, Tag 079P, 2026g. URL https://stacks.math.columbia.edu/tag/079P. verified: Theorem 19.12.6 and its transfinite-construction proof; accessed 10 November 2026. The stable tag, rather than the changing section number, identifies the result.

The Stacks Project Authors. The Stacks Project: K-injectives in Grothendieck categories, 2026h. URL https://stacks.math.columbia.edu/tag/079P. verified: Theorem 19.12.6, tag 079P, statement and transfinite-construction proof, accessed 10 November 2026.

The Stacks Project Authors. The stacks project: Categories, section 4.19, filtered colimits, 2026i. URL https://stacks.math.columbia.edu/tag/04AX. verified: Definition 4.19.1 and Lemmas 4.19.2–4.19.4, including the parallel-arrow filtering condition, eventual equality, and commutation with finite limits; consulted 10 November 2026.

R. W. Thomason. Cat as a closed model category. *Cahiers de topologie et géométrie différentielle*, 21(3):305–324, 1980. URL https://www.numdam.org/article/CTGDC_1980__21_3_305_0.pdf. verified.

Robert W. Thomason. Homotopy colimits in the category of small categories. *Mathematical Proceedings of the Cambridge Philosophical Society*, 85(1):91–109, 1979. doi: 10.1017/S0305004100055535. verified: publisher bibliographic metadata; the statement attributed to Theorem 1.2 was checked in Cegarra (2020), section 3, equation (9); the original proof was not accessed in this audit.

Stanisław Ulam. Zur masstheorie in der allgemeinen mengenlehre. *Fundamenta Mathematicae*, 16:140–150, 1930. doi: 10.4064/fm-16-1-140-150. URL https://impan.pl/pl/wydawnictwa/czasopisma-i-serie-wydawnicze/fundamenta-mathematicae/all/16/0/92858/zur-masstheorie-in-der-allgemeinen-mengenlehre. verified: metadata only, on the publisher record; the linked article download returned an access error. The measurable-cardinal and inaccessibility arguments needed here are supplied in the commentary, with no unverified theorem number attributed to this article.

Jaap van Oosten. Topos theory. Utrecht University lecture notes, version dated 2 May 2021, 2021. URL https://webspace.science.uu.nl/~ooste110/syllabi/toposthеory20.pdf. verified: dated title page, Proposition 0.7 and its proof, and the idempotent-splitting argument leading to Theorem 0.8, pp. 10–12 of the notes.

Sebastien Vasey. Accessible categories, set theory, and model theory: an invitation, 2020. URL https://arxiv.org/abs/1904.11307. verified: arXiv:1904.11307v2, 7 January 2020,

Theorem 3.1, Remark 3.2, Lemma 3.3, Theorem 3.4 and proof, Remark 3.7 and Example 3.8; preprint numbering verified: arXiv:1904.11307v2, 7 January 2020, Remark 3.7 and Example 3.8, printed p. 19, on directed-poset categories and failures of upward accessibility. The companion supplies the elementary presentability and cofinality checks for unbounded singular cardinals of countable cofinality.

Chencheng Zhang. Gabriel–Zisman localizations, products, coproducts, and product categories, 2026. URL https://arxiv.org/abs/2609.18617. verified: primary arXiv search-record metadata and abstract only, submission 16 September 2026. Full text could not be retrieved; no numbered result or exact example is attributed on this evidence.
